Underlying each of the concerns about market-orientation is the notion that ‘an obsessive focus on customers or competitors encourages research and development (R&D) to develop more line extensions and me-too products at the expense of new-to-the-world products’ (Lukas & Ferrell, 2000, p. 241). However, regardless of the difference in views concerning the amount of emphasis that should be placed on customer and marketplace input, there is little disagreement about the need to link technology development to potential markets—and this is a critical component for successful innovations (Jolly, 1997; Leifer et al., 2000). Certainly such things as customers being bounded by the familiar, being unaware of emerging new technologies, or having difficulty comprehending or appreciating radical new products and the implications of these innovations for their businesses or their lives can severely undermine marketing research efforts (Christensen, 1997; Jolly, 1997; Ver-

zyer 1998b). Nevertheless, despite problems in procuring and applying appropriate market-based inputs for the development of highly innovative products, inherent in innovation is a fundamental need to address customer needs or to uncover latent needs (Leonard-Barton, 1995; Veryzer, 1998b). Although the innovation context presents significant challenges for incorporating customer or market information that is helpful to the radical new product development process, it does not preclude valid and meaningful customer understanding and input (Veryzer, 1998b).

As Jolly (1997, p. 42) notes, ‘deep research, without any context or problem to solve, is inevitably hostage to serendipity alone’. Thus, while he sees customers as neither the sole source of ideas nor the best arbitrators for how ideas should be pursued, they provide a necessary context. A number of researchers (Hamel & Prahalad, 1994; Jolly, 1997, Leifer et al., 2000; Leonard-Barton, 1995) suggest that the imagination underlying all successful technology-based innovations—the ‘techno-market insight’—comes from how a problem is approached technically and an ability to identify compelling benefits of that technology and characterize these in terms of a market that may not presently exist. Marketing’s role is to both aid in identifying or deriving these benefits as well as in keeping the innovation process grounded in producing a new product that truly provides benefits to the intended users.

Innovation: Context and Dimensions

How we understand innovation is dependent on the perspective from which it is viewed and applied. From the vantage point of business and marketing the primary concerns and challenges center around identifying viable new product directions and then executing the development of the projects so as to produce an offering that provides both a significant benefit for customers and is commercially feasible. This orientation shapes both how innovation is viewed as well as influencing the implications that one draws concerning the best course with respect to any particular product development project.

In the context of marketing, ‘innovation’ refers to the creation of a new product, service, or process that may be either offered to a market, customer, or group of customers. Innovations may be thought of as falling on a continuum from evolutionary or ‘continuous’ to revolutionary or ‘discontinuous’. The vast majority of new products that are launched—some 25,000 a year (Fellman, 1998)—are incremental innovations or what are referred to in the literature as continuous or dynamically continuous products (Engel, Blackwell & Miniard, 1986). These represent limited changes or improvements to existing products or product forms. The phrase ‘discontinuous innovation’ is generally used to refer to radically new products that involve dramatic leaps in terms of customer benefits relative to

previous product offerings (e.g. Chandy & Tellis, 2000; Garcia & Calantone, 2002; Meyers & Tucker, 1989). Frequently these types of products involve the development or application of significant new core technologies (Ali, 1994; Lee & Na, 1994; Tushman & Nadler, 1986).

S-curves provide a theoretical background for understanding the evolution of these types of innovations as driven by companies seeking to maximize their position in a particular market (Chandy & Tellis, 2000; Narayanan, 2001, p. 76; Utterback & Abernathy, 1975). Technologies evolve along what appears to be a series of these S-shaped curves which occur because initially the new product—based on a new technology—offers limited benefits to customers, but offers an increased number of benefits as the technology underlying the product matures and the product offering is refined (see Fig. 1). Eventually, a product class reaches a mature phase where it levels off in terms of the rate of increase in new benefits offered (Chandy & Tellis, 2000; Narayanan, 2001, p. 76; Utterback & Abernathy, 1975). This remains the case, unless and until, a new technology is applied to create a new product form that offers significantly enhanced and/or new benefits to consumers. In instances when consumers are able to appreciate the value of the new product and the new capabilities that it offers, the new form usually supplants the mature product in the marketplace. This displacement process may occur relatively quickly as in the case of calculators displacing slide rules, slowly

as in the case of steamships displacing sailing vessels, achieve co-existence as in the case of microwaves and conventional ovens, or it may not occur at all as in the case of BetaMax.

In addition to the issue concerning the degree of ‘newness’ of a technology or its application, there are also questions concerning issues such as the range and scope of innovation. For example, Lee & Na (1994) distinguish between ‘incrementally improving innovativeness’ and ‘radical innovativeness’ and explicitly exclude commercial performance as a basis for classifying innovation. However, researchers such as Meyers & Tucker (1989) hold that discontinuous innovation, in addition to being based on new technology and aimed at a market that is unfamiliar with the product class, encompasses both the development and the introduction of the product into the market.

Two critical dimensions may be used to delineate the various levels or degrees of innovation with respect to the application of technology in the form of a product offered to a market (see Fig. 2); product innovation may be viewed as lying along a ‘Technological Capability’ dimension and a ‘Product Capability’ dimension (Veryzer, 1998a). The technological capability dimension refers to the degree to which the product involves expanding capabilities—the way product functions are performed—beyond existing boundaries. Discontinuous products involve advanced capabilities that do not exist in current products and cannot be achieved through the extension of existing

Figure 1. General form of S-curves representing technological evolution.

Stages in the evolution of a performance characteristic:

- (a) Emergence phase, product offers limited benefits;
- (b) Rapid Improvement phase, product offers increased benefits and/or performance at an accelerating rate;
- (c) Plateau phase with limited continued improvement, also convergence in product standards and form;
- (d) Successive Generational Improvement phase, product refinement and additional improvement—widespread market acceptance;
- (e) Maturity and Possible Decline phase, new applications or improvements may be sought that result in extending the curve or lead to development of a new product. The new technology may begin to challenge an existing technology (already in the Maturity phase) during the Rapid Improvement phase. Efforts to make the older technology competitive with the new technology may result in improvements sufficient to maintain market viability, otherwise products based on the older technology will be replaced by those stemming from the new technology.

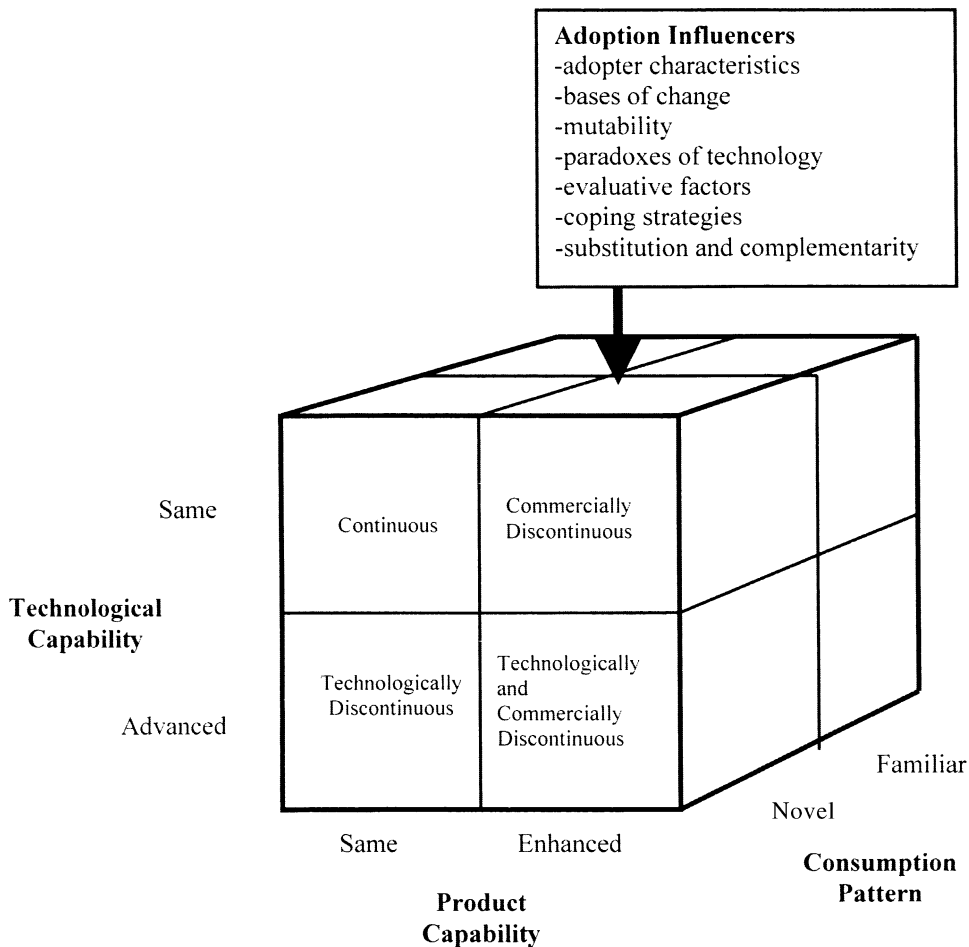

Figure 2. Dimensions of product innovation and adoption influencers.
Adapted from Veryzer (1998a).

technologies. The Product Capability dimension refers to the benefit(s) of the product as perceived and experienced by the customer or user.

In this view of innovation there are essentially four types or levels of innovation (excluding moderately innovative products). The first type encompasses products that utilize existing technology and provide the same benefits as existing products. Such products are continuous in terms of the technology employed and the way they are experienced by customers. Although they may be new, they are not very innovative. In addition to continuous new products, new products may be discontinuous with respect to technology, the benefits perceived by the customer, or both. Products that are perceived by customers as being really new regardless of whether or not they utilize new technology are commercially discontinuous. For example, the SONY Walkman offered new benefits (i.e.

functionality) utilizing available technology. In cases when the delivery of new benefits involves the application of a significant new technology, the product is technologically discontinuous in addition to being commercially discontinuous. PCs and pagers were examples of this type of innovation when they were first introduced. In some cases, products may be perceived as being essentially the same as existing products even though they utilize highly advanced technology. For example, the switch from vacuum tube televisions to televisions utilizing solid-state technology had little impact on consumers in terms of product benefits or use. Thus, even though solid-state circuitry represented a dramatic change in technology (Technologically Discontinuous), the product as perceived by consumers had changed little (Veryzer, 1998a).

To this conceptualization of innovation, a third relevant dimension involving change may be added.

'Consumption Pattern' refers to the degree of change required in the thinking and behavior of the consumer in using the product. Although the consumption pattern dimension is not often explicitly discussed by researchers, it seems to be implied in many discussions of new products (cf. Ali, 1994; Hughes & Chafin, 1996; Mahajan & Wind, 1986; Millison, Raj & Wilemon, 1992; Robertson, 1967; Rogers, 1995). A product can be familiar or novel in the way it requires users to interact with it. The nature of the change involved with respect to this aspect of a new product can play a significant role in product evaluation and adoption (Veryzer, 1998b). Products involving consumption pattern changes can require customers to alter their thinking and habits and this may affect their willingness to embrace a new product.

In considering highly innovative products it is important to take the customer's view and experience of the product into account. A technology-driven view of innovation that does not consider the customer's perspective might result in a product that is at odds with the market's perception of it (Veryzer, 1998b). Even though technology may be the means for enabling an innovation, new products are more than simply (technical) innovations—they must benefit and be used by people who can appreciate them and the impact that the innovative new products will have on their lives. The different dimensions of innovation are also useful in terms of understanding marketing's role in innovation. The role of marketing during the product development process is likely to be especially important for the success of products that fall into the commercially discontinuous portion of the grid. Certainly, marketing's role in ensuring acceptance when a product is introduced into a market could be significant for virtually any product (regardless of which part of the grid into which it fits), particularly if the benefits offered are not readily apparent.

Marketing, Innovation, and Diffusion

Marketing can play a key role both in the development of an innovative new product and in the successful diffusion of an innovative new product. In both cases it is usually the insights with respect to understanding potential customers that marketing supplies (Cooper, 1990, 2002; Kohli & Jaworski, 1990; Kotler, 1999; Trott, 2002). Such insights do not necessarily come directly from customers. In fact, quite often, deep insights relevant for the development of truly innovative products require that much of the information that may be easily ascertained from customers be ignored (Leifer et al., 2000; Veryzer, 1998a, 1998b). In this 'high' or radical innovation product development domain, one has to delve well beyond the superficial and readily apparent in order to gain an understanding of the deeper influences that drive customers' thinking and choices. This requirement to 'delve deeper' can be applicable to new product development in general, but

is particularly necessary in cases involving radical innovations where there is little, if any, precedent to follow and high uncertainty concerning market reaction.

One of the most dramatic illustrations of this need to delve deeply is the outcome of the market research conducted by the Coca-Cola Company for the development of what became known as 'New Coke'. As Pepsi Cola, with its sweeter taste and 'Pepsi Challenge' taste tests, continued to successfully chip away at Coke's market share in the 1980s, the Coca-Cola Company began the largest new product research project in the company's long history (Honomichl, 1985; Kotler & Armstrong, 2001, p. 130). In an effort that spanned over two years, the company spent in excess of \$4 million exploring new, sweeter product formulations and conducting extensive testing with customers to develop a taste that customers would prefer over both Pepsi Cola and the Coke formulation it was to replace (Honomichl, 1985; Kotler & Armstrong, 2001, p. 130). Some 200,000 taste tests were conducted, 30,000 of these on the final new Coke formula (Kotler & Armstrong, 2001, p. 130). The blind taste tests showed that 60% of consumers chose the new Coke product over the old, and 52% chose the new Coke product over Pepsi (Kotler & Armstrong, 2001, p. 130). However, in researching customers' stated preferences for the new Coke taste, important questions concerning other drivers behind Coke drinkers' consumption behavior were overlooked. Among these were factors such as brand identity, brand familiarity, 'intangibles' relating to the product's history and peoples' emotional ties to and memories of it, symbolic meaning, and so on (Honomichl, 1985; Kotler & Armstrong, 2001, p. 130). When the new Coke product was introduced into the market as a replacement for the original formula Coke (what is now known as 'Coke Classic'), customers quickly rejected the new product, clamoring for reinstatement of original or 'real' Coke. Within three months the Coca-Cola Company was forced to bring back the old formula, which quickly eclipsed the highly researched, 'sure-winner' that the company had introduced with such confidence. Thus, although marketing research with customers did reflect taste perceptions, that is customers were asked questions and provided accurate answers, the research conducted did not delve deeply enough to sufficiently uncover other important influences (e.g. brand loyalty, emotional attachment) that act to shape customer purchase and consumption behavior. Ultimately, these influences proved to be the determinants of the product's fate. This need to push toward a deeper and more complete understanding of the influences driving customer thinking and choices is especially true for uncovering the insights that are relevant for various product development phases such as market research and concept testing as well as the market introduction phase.

Discussions of the diffusion process for innovations have drawn on ideas presented by sociologist Everett M. Rogers (1995), who has suggested that diffusion curves are essentially normal curves made up of various adopter categories (innovators, early adopters, early majority, late majority, and laggards). The marketing discipline has relied heavily on this approach to categorizing adopters (e.g. Kotler & Armstrong, 2001, p. 200). Although it is tempting to construct ever more complicated typologies of adopters for highly innovative products, Weil & Rosen (1997) relate a simple three-category break-down oriented toward technological products that is basic but effective. ‘Eager Adopters’ view technology as fun and challenging and are drawn to it. These sorts expect to have problems with technology, so when a problem arises they are not daunted by the challenge. ‘Hesitant “Prove Its”’ do not think technology is fun and prefer to wait until a new technology is proven before trying it. Even though they may take some convincing, if you can show these types how something will make life easier, they will consider it. Diffusion among this group is affected by ease of operation since they do not enjoy solving the problems that may come with the new product. Finally, ‘Resisters’ want little, if anything, to do with innovative new technology products, no matter what anyone says or does to convince them—technology is absolutely no fun for these people. Awareness of these types of adopter ‘(pre)dispositions’ can provide useful insights that help guide the development effort (e.g. the design of user-product interfaces) as well as marketing efforts (e.g. product positioning and advertising) during the product introduction phase.

In assessing the market or commercial potential of an innovative new product there are a number of important questions to consider: Does or will diffusion for a particular new product occur in a predictable manner?; Is there such a person as a consumer-innovator?, and can he or she be identified?; and What role will advertising and personal influence play in terms of their effectiveness for new product diffusion? (Robertson, 1967, p. 16; Wilson, Kennedy & Trammell, 1996, p. 62; Urban & Hauser, 1993, p. 222). Beyond these questions, are other less direct questions that relate to the diffusion of innovations. Questions such as, ‘how are consumers likely to use this new product?’, ‘will it be as the product developers envisioned or are there latent needs or social trends that may affect how customers apply or use the new technology offered in a new product?’ These questions are central to a new innovation’s viability and acceptance in the marketplace. Consider, for example, the well-known case of Sony’s BetaMax. Sony launched its BetaMax video cassette recorder for the mass consumer market in 1975. At the time, Sony generally positioned its products by deciding what the best uses would be and then selling those uses to customers

(Cooper, 2000). In the words of Akio Morita, legendary cofounder of the firm that became Sony Corporation, ‘‘We don’t believe in market research for a new product unknown to the public. . . so we never do any. We are the experts’’ (Lyons, 1976, p. 110). Morita, who had been responsible for many successful product launches for the firm, regarded the primary function of the BetaMax product as freeing people from a preset television programming schedule—thus allowing people to ‘time shift’ in order to watch their favorite programs when it suited them rather than at a time that they could not control (Cooper, 2000, p. 4). Unfortunately, Sony missed, or at least underestimated consumer desire to watch full-length feature films at home and therefore did not adjust its product offering to accommodate this desire (e.g. tape length, licensing agreements) (Cooper, 2000). JVC’s product offering was better able to meet consumer needs and thus it eventually won the ‘VCR war’ despite some of the superior performance characteristics of the BetaMax product (Clark & Fujimoto, 1991, p. 4; Cooper, 2000).

Innovation is essentially about change, and diffusion is essentially consumer willingness for change. Fundamental to the change brought by product innovation is how the new offering will interact with the actual needs and desires of consumers. Marketing works across these two elements of the innovation equation (i.e. Innovation Change and Consumer Desire for Change) in order to help produce an optimal result that maximizes everyone’s utility (at least that is the goal for good marketing). ‘Change’ is not, however, a simple uni-dimensional concept. For example, Golembiewski, Billingsley and Yeager (1976) discussed three varieties of change—Alpha change, Beta change, and Gamma change. Alpha change, or what might be called ‘perceptual change’ involves shifts in peoples’ understanding or interpretation of a product or brand (Golembiewski et al., 1976; Wilson et al., 1996, p. 53). This is similar to repositioning a product or brand in an existing framework such as a perceptual map (a representation of the positions of products on a set of primary customer needs; see Urban & Hauser, 1993, p. 205 for a discussion of perceptual maps) and might be accomplished through an advertising campaign (Cooper, 2000), or this type of change could be accomplished via changes in elements of a product’s design (Veryzer, 1997).

Beta change involves a shift in consumer values. Here the frame of reference or context circumscribing a consumer’s consideration of products (or some set or class of products) has changed. For example, when a person receives a significant increase in income the types of products that are considered for purchase may change dramatically (e.g. shift to expensive, high quality products). Thus, the consumer’s ‘ideal points’ have changed rather than this simply involving a change in a product’s position with respect to already established ideal points.

Gamma change involves adding a new dimension for consideration. This has the effect of both defining (or redefining) a new product and is likely to lead to a shift in the ideal points that a market has for products. For example, the Internet, with its ability to make a virtually unlimited supply of information readily available, has changed how people access information and to some extent how they use it. This type of change is what tends to occur in the case of highly innovative products. Here, consumers are faced with more than just a shift in perceptions or values (although these may accompany such changes), rather the very nature of the product and its use are changed and new (Cooper, 2000; Golembiewski et al., 1976; Wilson et al., 1996, p. 53).

Customers' abilities to comprehend the change inherent in innovations is affected by their existing knowledge. The notion of 'mutability' is useful for understanding consumers' abilities for transforming existing knowledge structures (that they perceive as being relevant to an innovative new product they have encountered) so as to accommodate the discrepant information presented by an innovation (Moreau, Lehmann & Markman, 2001). Mutability refers to the conceptual transformability of different features or attributes in a category schema (Love, 1996; Love & Sloman, 1995; Sloman, Love & Ahn, 1998). Mutability depends on both the variability of a feature across category members as well as the number of other features in the (product) category that depend on that feature (Love & Sloman, 1995). As Moreau et al. (2001) point out, in the context of innovative products, the more immutable the feature change, the greater the perceived discontinuity of a product. This has implications for how people process and perceive innovative new products. For example, since people are likely to draw on or transfer knowledge from the product domain they perceive as being closest to the new innovation encountered, this alignment—which may or may not be appropriate—will exert a significant influence on customer assessments of the new product. Further, as Moreau et al. (2001) point out, for discontinuous innovations, expertise in a primary base domain (i.e. an existing product category that is most similar to the innovation in terms of benefits provided) will be negatively related to both comprehension and perception of net-benefits of the innovative new product(s). In their study, these researchers found this to be the case. For the most part, with respect to discontinuous innovations, experts' entrenched knowledge was related to lower comprehension, fewer perceived net benefits, and lower preferences compared to that of novices (Moreau et al., 2001).

Consumers' reactions to innovative new products and their willingness to embrace them are also, of course, driven by the benefit they expect to derive from the products. For discontinuous innovations, however, there may be subtle yet critical currents underlying

peoples' reactions. Such products, which often involve new technologies, frequently require changes in thinking and usage behavior (Veryzer, 1998b). Moreover, by their nature, innovative new products tend to entail a certain paradox in that the trade-off in what they offer (in terms of speed, convenience, etc.) and what they cost (learning time, frustration, complexity) is more apparent to users given the increase across the various product discontinuity dimensions (benefit, technological, consumption pattern) discussed earlier. Such products involve a certain 'paradox of technology'—the very technology that can make us more efficient, may also foster feelings of incompetence and frustration (LaPorte & Metlay, 1975; Mick & Fournier, 1998; Rosen & Weil, 1997; Winner, 1994). Moreover, products like appliances purchased in order to save time, often end up wasting time (Goodman, 1988; Mick & Fournier, 1998). In their codification of the various paradoxes discussed across the technology literature, Mick & Fournier (1998) present eight central paradoxes of technological products. In brief, these are: Control/Chaos (technology can facilitate order, and lead to upheaval or disorder); Freedom/Enslavement (facilitate independence, and lead to dependence); New/Obsolete (provide new benefits, and are rapidly outmoded); Competence/Incompetence (promote feelings of intelligence or efficacy, and lead to feelings of ignorance or ineptitude); Efficiency/Inefficiency (reduce time needed, and increase time required); Fulfills/Creates Needs (help fulfill needs or desires, and reveal unrealized needs or desires); Assimilation/Isolation (facilitate human togetherness, and lead to human separation); and Engaging/Disengaging (facilitate involvement, and lead to disconnection) (Mick & Fournier, 1998, p. 126). These paradoxes play an important role in shaping consumers' perceptions of innovations as well as determining their willingness to adopt new products.

In addition to the various trade-offs or paradoxes that affect consumers' willingness to embrace innovative products, an important aspect of a new product offering—that should be considered in the design stage as well as the later product launch stage—is that consumers develop their own ways of coping with innovations and these can impact diffusion as well. Potential customers may ignore a new technology altogether, delay obtaining the new product, attempt to try an innovative new product without the risk of outright purchase, embrace the product and master it, and so on (Carver, Scheier & Weintraub, 1989; Mick & Fournier, 1998). Furthermore, in evaluating discontinuous new products, there are certain factors that are likely to come into play more than they do for less innovative products. Lack of familiarity, 'irrationality', user-product interaction problems, uncertainty and risk, and accordance or compatibility issues may play a decisive role in customers' evaluations of products in either the development and testing stages or once the

product is introduced into a market (Veryzer, 1998b, p. 144). For example, during the course of one radical innovation development project, managers were struck by how ‘irrational’ customers were in that they often focused on things that the product development team thought to be unimportant. Test customers ignored aspects of a prototype product on which the team had expended a great deal of effort and money. Even though this type of ‘irrationality’ may frustrate product development teams, in the domain of highly innovative products, assumptions must be checked and measured against the metric of those who will be the final arbitrators of success (Veryzer, 1998b).

Beyond consumer concerns that are relevant to the development and marketing of innovative products are more ‘macro’ influences that can affect adoption and thus need to be considered. The substitution of one technology for another is an obvious concern (recall the earlier discussion of S-curves). Along with this, the issue of product complementarity, or when there is a positive interrelationship between products (e.g. a computer printer and a computer), can also be important with respect to product adoption. Thus, in addition to displacing products, new technological innovations often modify or complement existing products that may still be diffusing throughout a given market. This has significant implications for market planning decisions for both products since their diffusion processes are interlinked (Norton & Bass, 1987, 1992). In such cases (e.g. new computer products, electric vehicles) consideration of: (1) whether there is a positive interdependence between a new product and existing products; (2) whether the old technology will be fully replaced by a newer product; and (3) how the size of the old technology’s installed base will affect the speed of diffusion of the new product or product generation, represent critical marketing concerns (Dekimpe, Parker & Sarvary, 2000; Norton & Bass, 1987, 1992).

Diffusion may also be examined from an even more macro-perspective, and in some instances it can be particularly important to do so. For example, researchers like Dekimpe, Parker & Sarvary (2000) have investigated the global diffusion of technological innovations. In their work, they focus on: (1) issues concerning the two-stage (implementation stage and confirmation stage) nature of the global diffusion process as defined by Rogers (1995); (2) the irregularity of a diffusion pattern due to network externalities and/or central decision makers; and (3) the role of the installed base of older generation technologies that an innovation replaces (Dekimpe et al., 2000). As they point out, “for most innovations, the adoption process of each country starts with the implementation stage, which is followed by the confirmation stage” (Dekimpe et al., 2000, p. 49). However, they suggest that for technological innovations within-country diffusion might be instantaneous—due to network externalities

(e.g. established standards) or central decision makers, and as such, the confirmation stage for certain countries may have a zero duration.

‘Innovation’ inherently involves change and thereby at least some degree of disruption and uncertainty. The forces underlying customers’ decisions to embrace an innovative product run deep and are complex in that they occur in both individual as well as societal contexts simultaneously. Adopter dispositions (e.g. ‘techno adopter’ categories) as well as the various paradoxes, evaluation factors, coping strategies, and substitution/complementarity concerns indicate some of the innovation and diffusion challenges that the marketing function must address in order to ensure innovative products that people will choose to purchase and use. It is in understanding these deeper influences that shape customers’ reactions to innovative new products that marketing makes its greatest contribution to the potential that ‘innovations’ represent. This it does by acting as a sort of mediator (or interpreter) between new ideas/technical possibilities and peoples’ needs and wants.

Conclusions

Market vision, or the ability to bridge between technological capability and market need or opportunity, is a crucial ability. It is particularly important for high innovation products because such projects usually involve a significant degree of uncertainty about exactly how an emerging technology may be formulated into a usable product and what the final product application will be. The conceptual framework presented here can help to clarify the innovation and adoption context with respect to the marketing challenge(s). Since such products are often difficult to convey to customers—especially early on in the development process—many traditional market research techniques (e.g. concept tests, focus groups, surveys) may not be useful or valid (Leifer et al., 2000; Leonard-Barton, 1995; Veryzer, 1998b). In this domain, particular care must be taken to make certain that the research that is conducted provides valid input that does not lead the development effort astray. In the case of highly innovative products this means relying more heavily on techniques such as prototype reaction studies. Prototypes are essential instruments for market learning during the course of radical innovation, even beginning with the first formative prototype pushed out by the R&D lab (Leifer et al., 2000; Veryzer, 1998a). They provide a critical means for product developers to assess the product direction and test critical assumptions (Veryzer, 1998a). Such efforts play a key role in the ‘probe and learn’ process that serves to accelerate market learning (Leifer et al., 2000; Lynn, Morone & Paulson, 1996). Apart from these sorts of methods for gaining information to help direct the product development effort, customers can be studied (using various techniques such as laddering which involves successive

questioning to uncover the values or motivations linked to a product, and observational study which essentially involves watching or video taping customers using products in settings of interest) in order to identify and understand latent needs that may suggest product ideas or serve to revise the design direction that a product under development is taking. Customer research also provides a means for determining product specifications since for many discontinuous products established benchmarks do not exist (Leifer et al., 2000). In addition, customer and market research is needed in order to determine optimal levels of various aspects of the product offering such as the price or pricing structure, product positioning, advertising approach, promotion(s), and so on.

Given the challenges inherent in innovation, gaining an understanding of the factors that are likely to influence customer evaluations of a new product and how customers are likely to react to the product is necessary for ensuring a successful market outcome. Marketing provides a necessary and useful function in helping to shape an innovative idea into a product offering that meets the needs and desires of the people who are intended to use it.

Innovation Process in Hungary

Man, I have Spoken
Struggle and Have Face
Imre Madách (Tragedy of Humankind)

Abstract: The pioneering Hungarian pilot innovation survey reveals that the level of innovation in the Hungarian economy is low. This can largely be attributed to the financial stringency imposed by the transition process. Hungarian firms are aware of the importance of developing new products and addressing new markets—though, in practice, they do this largely within the limited Hungarian context. The firms pay little attention to the kind of long-term, strategic thinking about technological change which, alone, can provide the basis for sustained innovatory dynamism.

Keywords: Innovation; Measurement of innovation; Transition economy.

Introduction

‘To be or not to be innovative’ is a fundamental question for the entire world. National economic stability and future prosperity can be secured only if a country has an innovative manufacturing base. The importance of innovation in economic development and competition theory is increasingly acknowledged (Dosi et al., 1988 as the central work), and technological change and innovation have become central topics in economic analysis and policy discussion on economic performance in the industrialized countries (Lundvall, 1992; Nelson, 1993; Porter, 1990; Tidd et al., 1997). In recent years the relationship between competitive performance and technological strategy has been widely explored, to see whether it can account for success and failure, at both micro and macro levels (Carlsson & Jacobson, 1993; Foray & Freeman, 1993; Patel & Pavitt, 1994; Scherer, 1989; Smith, 1991; Soete & Arundel, 1993).

Transforming a less innovative economy into a more innovative one is a great challenge for policy-makers. This general transformation task is much more complicated for the former socialist countries. For any redeployment crucial to understand how systems of innovation work. Theoretical and empirical knowledge are critically important, and tremendous efforts need to be made to develop that knowledge. Empirical evi-

dence on the transition of Hungarian innovation process is also needed.

This chapter concentrates on the introduction of a metric tool of innovations in a post-socialist transition economy, Hungary. Measuring innovation means to measure something, which is extremely complex, a moving target, where many impacts of innovations are hardly measurable.

Conceptual Framework

The common goal of all activities is to measure innovations and provide innovation indicators that can meet the theoretical and policy-related requirements. Policies and innovation fostering measures may be broadly based, touching many aspects of the innovation process, or they may be precisely targeted in order to tackle a particular problem that needs attention.

There are several different approaches and methodologies that seek to measure innovation activities. Looking at international innovation literature as a whole, we find a variety of views on the process of innovation and, the factors that create innovation. Some parts of the literature focus on technological development, technical research and R&D functions (Chesnais, 1995; Dosi et al., 1988; Freeman & Soete, 1997; Grupp, 1998; Rosenberg, 1994; Scherer, 1989).

Information on technical innovation activities maybe based on case-studies, semi-structured interviews,

literature-based innovation indicators and innovation surveys. One crucial element in these methods is that of innovation survey. This instrument has advantages and disadvantages to measure the performance of national innovation capacity—as previous literature has discussed (Archibugi & Pianta, 1996; Arundel & Garffels, 1997; Arundel et al., 1998; Sirilli & Evangelista, 1998; Smith, 1999).

These surveys may employ the ‘*subject approach*’ to collect data on the innovative behavior and activities of the economic unit as a whole, whether or not a unit is a legal entity.

There are several needs for indicators, e.g. technological significance of innovation, quality of innovation, technological nature of the innovations, which cannot be measured with a survey at the economic unit (firm, corporate, factory) level, where each of them can be active in a wide range of innovation projects. Another type of survey may focus on a targeted technology, such as biotechnology, laser-technology and so on. These surveys employ the ‘*object approach*’ to collect data about specific innovations from firm/business unit (OECD, 1997, p. 103) that help to identify possible future innovation patterns.

The present chapter highlights one way of collecting information regarding innovation, namely the *innovation survey* by subject approach (Archibugi & Pianta, 1996; Arundel et al., 1998; Evangelista et al., 1998; Smith, 1992).

The Oslo Manual, developed by OECD member countries,¹ is a guidebook for data collection on technological innovations. It describes definitions, criteria and classifications which are relevant for studies of industrial innovation. Description of measuring aspects, alternative solutions make the *Manual* a starting point of any technological product and process innovation survey design. It contains suggestions and recommendations for national and international innovation surveys. The Manual is the required framework to measure innovations in an internationally comparable way. Common core indicators and common definitions help to avoid unnecessary differences in measurement of different groups of countries.

Internationally comparable indicators need to measure and evaluate national innovation capabilities, and performances. Parallel with the development of the

Oslo Manual, a harmonized innovation survey was developed. (Harmonization has included a questionnaire with set of core questions, survey population, sampling methods, time frame and so on.) The name of this common survey: Community Innovation Survey (CIS), drawn up by the OECD and EU Statistical Office (Eurostat) as a basis for collecting statistically comparable data across countries. The CIS questionnaire has to run in all European Union member countries (survey cost has been partially covered by the European Union) and some other OECD member countries. This accepted international standard furnishes a very sound background, even if many methodological problems and interpretations of innovation surveys have not yet been resolved.

The so-called Community Innovation Survey (CIS) questionnaire is revised for each survey period. The different versions of the questionnaire are named: CIS-1 (surveying period: 1990–1992), CIS-2 (surveying period 1994–1996), CIS-3 (surveying period (1998–2000).

Not only the reference period was different among CIS-1, CIS-2 and CIS-3 (see also Wilhelm in this volume) but the questionnaires and coverage of sectors and size of surveyed units were modified taking into consideration the findings the previous surveys. The CIS-1 focused only on the manufacturing sector, CIS-2 also included the service sector. More attention was devoted to include random samples of small firms, not only to cover the innovative but also non-innovative firms. Each modification has involved a considerable amount of intellectual effort.²

The accumulated knowledge by surveys proved that the Oslo Manual guided innovation survey contributed to an analysis of the dynamics of technological change in the business sphere and, enable policy-makers to investigate more effective ways to maximize the socio-economic and industrial development potential and, to support competitiveness and productivity in market economies.

Considerations on Adaptation in a Transition Economy

There are many newcomers in the surveying innovation arena. Among them, the specificity of transition economies has been originated from the legacy of socialism.

The conundrum of socialist economies lies between relatively well-developed science and inefficient, ad-hoc business enterprises.

The socialist system was very weak in diffusing knowledge and commercialization. The firms in the

¹ Oslo Manual belongs to the OECD Frascati Family of Manuals. The development of Oslo Manual started in the 1980s and the first version of Oslo Manual was published in 1992 (OECD, 1992). Following the experiences the (internationally harmonized) national surveys Manual was thoroughly updated and the revised version was published in 1997 (OECD/Eurostat, 1997). The revision of the Manual is still ongoing incorporating the new knowledge and expertise that have been accumulated about innovation and innovation process through innovation surveys and other investigations of innovation activities.

² Limited part of these efforts are available as scientific publications. Most of them were prepared as discussion papers for Eurostat and OECD working party meetings, European Union project reports and studies for national governments.

market economy sense did not exist in socialist economies. In the context of command economies literature use 'enterprise' which differs from profit-oriented micro-economic organizations of market economy. Situated in a socialist system, this type of late-comer periphery industry was cut-off from the major international sources of technology. They operated in isolation from the world centers of science and innovation and consequently were technologically disadvantaged. The surrounding technological and industrial infrastructure was underdeveloped. The economic actors had little interests in commercializing R&D results (Dyker & Radosevic, 1999; Hanson & Pavitt, 1987; Inzelt, 1988, 1991, 1994a; Jasinski, 2002; Radosevic, 2002). Also, the information system did not contain relevant indicators on innovation. If any science and technology measures existed, they were very different from market economies. The main aims of these measures were to support macro-economic decisions of command economies and, prove the prestige of the socialist world, in bi-polar world system. These interests had a strong influence on the collection, production and use of statistical data, indicators, evaluation, and so on.

In the structural transformation phase of CEECs economic and development, there is a burning need to explore the condition of innovation, and R&D, besides establishing economic stability.

During the process of developing a modern information system for innovation transition economies two different but parallel tasks of modernization require solving: (a) to adopt the traditional metrics of innovation and of related areas through; and (b) to be involved in the development of modern innovation indicators. The involvement in the development of modern indicators is important for all countries of the world.

This chapter deals with the first task, the constructive adaptation of innovation survey for the manufacturing sector in a transition economy. The adoption procedure of innovation indicators is a great challenge for all transition economies.³ Survey attempts are crucial to build internationally comparable information for deci-

sion-makers about product and process technology innovation. Only such exercises can prove the relevancy of innovation surveys (existing standardization of concepts and statistical methodologies) outside the advanced OECD/EU countries and can highlight the need for further development.

Hungary has carried out several important steps for transforming her science and technology (S&T) information system during the past 12 years. One of the very important attempts has been employing the Oslo Manual guided innovation survey. This chapter summarizes the findings of the first Hungarian pilot innovation survey. The Hungarian pilot innovation survey, based on a standard questionnaire, largely operates with the concepts and questions proposed in the Oslo Manual and follows the internationally harmonized questionnaire. This was the pioneering survey in a transition economy. Following several knowledge dissemination seminars (OECD, 1993, Paris; OECD-OMFB, 1996, Budapest) several other attempts have been carried out.

From the mid-1990s CEE transition economies started to attempt surveying innovations in the manufacturing sector (parallel to, revision work to R&D surveys). These exercises on innovation data collection in the manufacturing sector, was based on conception, definitions, classifications of the Oslo Manual. The OECD (Organization for Economic Cooperation and Development) and Eurostat are working in tandem and they involve CEECs in the harmonization of innovation indicators, using the Community Innovation Survey (CIS) questionnaire guided by Oslo Manual standards. The national innovation surveys guided by the Oslo Manual are penetrating into CEECs. After 10 years of transition, there are some fruits of this learning process, however, the level of implementation of OECD/Eurostat standards and the adoption of CIS-1 or CIS-2 questionnaires in national environments of CEECs are different.⁴ EUROSTAT involves CEECs into CIS-4 as full-fledged partners.

Following sections of this chapter highlight some of the findings of the first Hungarian pilot innovation survey, carried out in 1994 and based on 1990–1993

³ In this process the international community has been playing an important role which may shorten the adoption-development phase. Foreign governments and international organizations have been supporting such knowledge-transfer through different channels. The first milestone of knowledge transfer was OECD Vienna/Bratislava Conference, in 1991. It was followed by a series of international training seminars (OECD) for Central and Eastern European experts (in 1993 Paris; 1996 Budapest). The OECD has involved transition economies into several activities (workshops, conferences, on-the-job training). The OECD supported the translation and dissemination of the OECD Frascati Family Manuals as the theoretical framework containing the definition of this process. Many countries started the adoption process by means of a translation and dissemination of the OECD Frascati Family Manuals. The Frascati Manual has been

published in several CEECs. And the availability of these manuals in national languages closed the gap between existing and employed knowledge. In the late 1990s Eurostat involved transition economies (called also newly associated countries) in indicator development process. However, penetration by newly acquired knowledge is not a very rapid process. For example, the Frascati Manual was published in Hungarian in 1996 and the first citations outside Central Statistical Office and academic circles were observed in 1999.

⁴ Data and analytical reports on CEE innovation survey attempts see in: Auriol & Radosevic, 1998; Bazhal, 2002; Csobanova, 2002; EC-Eurostat, 2000; Inzelt, 1991, 1993, 1994a, 2002; Radosevic, 2002; Sandu, 2002).

data,⁵ the first section of this chapter, 'The Main Objectives of Innovation', summarizes the main objectives of innovation. The second section discusses the 'inputs into innovation'. Then the next section goes into the details of the 'outputs of the innovation process'. The fourth section investigates the factors that hamper the whole process. The fifth section makes some concluding remarks. Appendix 1 shows the modifications that were carried out to the OECD/EU harmonized questionnaire to suit Hungarian conditions. Appendix 2 details the main features of the pilot survey, as based on the harmonized questionnaire.⁶

On the scope of the pilot survey, it should be mentioned that most of the 110 respondents were the successors of former state-owned enterprises or co-operatives. There are very few newly emerged small businesses and companies in the sample.

Before presenting the main findings of this pioneering pilot survey it has to be emphasized that the surveying period belonged to the first phase of transition. In transformation of the former socialist economies into market ones, two different phases may define, which are typical in the CEE region. All CEE countries were exposed to the phenomena of Phase I for some years and suffered its consequences. *Phase I* is characterized in the following way: declining economy, decreasing R&D expenditure and R&D staff, the inherited structures that still exist or are under reorganization, strong brain-drain from the country. Many old partnerships were ceasing. At the same time there are many far-reaching changes in the legal system, governmental structure and policies. Institutional building process is going ahead. However, system of institutions is still gap-toothed, enforcement of new laws are still weak. In other words the countries have to overcome on 'transition crisis' for stabilization, development and transformation.

By the late 1990s some of Central and Eastern European countries, including Hungary seem to have reached Phase II and show a consolidated picture. Phase II is characterized: the economy is growing, the R&D expenditures grow again, new structures began to work, company R&D develops again, the brain-drain balance is nearly neutral. The overall macro economic situation provides for R&D and innovation activities.

The Main Objectives of Innovation

The level of innovation in Hungarian industry is relatively low. There is a desperate need for investment

Table 1. Ranking of objectives of innovation (Reference period 1990–1993).

Objective	Number of firms answering 'very significant' and 'crucial'
Improve product quality	71
Extend product range within main field	66
Create new domestic market	62
Extend product range outside main field	56
Improve production flexibility	43
Create new markets within EU	41
Reduce material consumption	41
Energy consumption	37
Environmental damage	35
Other objectives	30

in product design, in packaging, and in the application of technology. In order to improve market positions, you need competitive products.

In this connection, firms were asked to rate the significance of each of 19 possible objectives underlying their innovation activities during the investigated period. The pattern of ranking of these main aims illustrates well the changes in economic environment (see Table 1 above).

It is particularly striking that the highest ranked aim was to improve product quality. The next most crucial objectives show how firms need, at the same time, new markets and changes in their product ranges. Innovating with the objective of opening up new markets abroad was judged to be less crucial than for the domestic market. Multiplying the product range is important, not only in the main field of production activity, but also outside them. Redeployment may lead the firms out of their main fields. The market sectors targeted for innovations are, however, generally very close to the original markets. This allows us to assume that innovations have been more incremental than fundamental. What does come through clearly is that innovative firms are market-oriented, which is a positive phenomenon in a former socialist country. Reducing costs in terms of material and energy consumption is also important, but far less important than the aims mentioned in Table 1. Other objectives, such as reduce production and design consumption, improve working conditions, replace outgoing products were not important for firms during the investigated period.

Inputs into Innovation

The costs of innovation and the breakdown of costs (R&D, acquisition of patents and licenses, and product design) depend largely on the strategy of the firms involved. A firm might be innovative even if it does not invest in resources, for example, in R&D. But it is not

⁵ The project was basically financed by OMF and organized by IKU. The first English version was written during my stay as a Leverhulme visiting fellow at SPRU.

⁶ Until mid-2002, this survey was followed by a feasibility survey in the service sector and by Central Statistical Office pilot survey in the manufacturing sector. Both samples are very different from this one. So they do not allow statistical comparison over time.

Table 2. Ratio of R&D expenditures to sales.

	0%	<1%	1–4%	4–8%	>8%
Number of companies	38	29	21	12	8

possible to avoid spending on introduction, adaptation, market analyzes, and so on. Among the inputs of innovations, the main proportion of expenditure made by the firms questioned went on R&D (see Table 2). Table 2 shows the proportion across the distribution of companies.

It is very rare for companies to spend more than 8% of their sales revenue on R&D (the nation-wide aggregate R&D to GDP ratio was 1.59% in 1990 and just 0.99% in 1993. This declining trend had continued by 1999. The lowest fraction was 0.7%). The absolute scale of their expenditures is modest because these are not large firms. Three quarters of the respondents employed between 100 and 1,000, the remainder of respondents were above 1,000, but less than 5,000. Their average net sale was HUF 650 million (in USD=2.2 million). The surveying period was 1990–1993. These years were the initial years of the first phase of transition: the redeployment of so-called socialist enterprises into firms meant shrinking sizes, changing ownership if the firms have been privatized by multinational companies.

R&D expenditure have usually financed product innovation rather than process development. Only electricity, water, chemical and printing industries spend relatively more on process innovation. The first three cases hardly require any explanation. The case of the printing industry is interesting because it reflects the reconstruction of the industry through the application of new techniques of the last few decades.

The small number of companies expenditure on R&D means that the enterprises have not been compelled by competition to introduce new products and to apply new technologies for the sake of their survival and profitability. Of course, low spending on R&D does not necessarily mean a low rate of innovativeness. The firms were asked to estimate the break-down of their innovation costs. To calculate the sector average of the proportion of different expenditures on innovation, we have to know total innovation costs. Two thirds of the respondents were willing to give total current expenditure on innovation activity. Their resultant data are shown in Table 3, with aggregate figures for manufacturing added for comparative purposes.

After R&D, patents and licenses are the biggest form of expenditure. They are followed by trial production, training and tooling up, which have grown in importance over the transition period. Product design accounts for 8% of innovation expenditure in the manufacturing industry, with the remainder being spent on market analysis. From the point of view of transformation enterprises to firms and, redeployment of sectors, some interesting differences in the way different sectors spend their innovation budgets are observable. For example, rates of expenditure on R&D are relatively low in fabricated metal products, vehicles and transport-equipment industry. The former is a fast-shrinking industry in Hungary, and where it undertakes innovations those are based on licenses. The transport industry is in a mixed position—production of traditional Hungarian products (buses, vans etc.) has been declining, with the firms in the pre-privatization phase in the investigated period. These were reluctant to invest in innovation, and concentrate their efforts rather on seeking new markets and investors. The newly re-emergent automobile industry is a fast-growing one. Its

innovations (new product design, new instruments etc.) are based on foreign laboratories at assembler companies, and suppliers usually get technical support for innovation from their assemblers. This observation is confirmed if we compare these results of the innovation survey with information from other sources relating to the present situation of the former Hungarian industry R&D laboratories that used to belong to different ministries (Goldman & Ergas, 1997). These applied research, experimental development and design institutes have virtually lost their former customers.

The high proportion of trial production, training and tooling-up in some sectors represent a good example of changes in innovation strategies and adaptation to a new environment. Market analysis shares are relatively high in those sectors that used to have high export shares toward CMEA (Council for Mutual Economic Aid) countries.⁷

An important aim of innovations was to extend the product range outside the main product fields. So, it is worth investigating which sectors are chosen by firms when they do this. Respondents seeking to diversify their product range have tended to invest in upstream or downstream sectors (For example food processing company into packaging). That time restructuring strategies have generally followed the old way of thinking, diversification and in-house production of components and instruments, instead of buying outsourcing. These strategies are usually based on short-term profit-seeking activities, and they have less strategic redeployment elements.

Postal surveys can pick out these tendencies, but cannot give enough information for drawing definite conclusions.

⁷ CMEA (also used abbreviation was COMECON) used to be an economic organization. It was established in 1949 to encourage trade and friendly relation among 10 command economies, including the Soviet Union. The organization was dissolved in 1991.

Cooperation Arrangements in R&D Activities

Cooperation in R&D is growing in importance all over the world. Both formal and informal networks are playing an important role in innovation (Freeman, 1991; Meyer-Krahmer & Schmoch, 1998). For knowledge-based economies the key of the whole process is the partnership between universities, the business sector, and among firms. The relationship between innovation and networking is discussed in details by Swan & Robertson in this volume. Innovation survey can focus on few dimensions of this relationship.

The questionnaire tried to investigate cooperation by type of actor and by their geographical origin. From 110 respondents just 55 firms engaged in cooperation agreements in R&D activities with other parties in 1993. If we concentrate on the parties with which such arrangements were formed, we see that research institutes of the Academy of Sciences, universities and sector research institutes are at the top of the list. Customers and suppliers are also frequent collaboration partners, but they come far behind that of knowledge-based institutes, as is usual in market economies among medium-sized tech companies.

Table 4 shows the number of innovators using particular cooperation partners at different regional levels.

Table 4 shows clearly that where universities and R&D institutes and industry R&D laboratories were the cooperation partners, they were most likely to be located in Hungary. In the case of customers and suppliers there was no such tendency.

One of the outstanding characteristics of domestic industry-academy linkages, is that regional cooperation is weaker than nationwide. To some extent this may reflect a pattern of seeking excellence anywhere it is to be had. The distance of potential partners are much less important than their complementary capabilities, the quality of their knowledge (similar phenomenon was observed by Faulkner & Senker, 1994).

Table 4. Entering into co-operation in R&D activities.

Base	Location of Partners			
	Domestic Regional	National	Foreign European Community	Elsewhere
R&D institutes	7	24	3	0
Universities/higher education	8	23	2	1
Suppliers	7	6	10	2
Clients/customers	3	7	7	7
Industry R&D laboratories	3	16	0	0
Consultants	2	6	3	2
Parent/subsidiary company	4	1	1	0
Joint ventures	0	3	2	1
Government laboratories	1	5	0	0
Competitors	1	0	0	0

But taken into account that innovation activities in the sample were usually incremental rather than fundamental, the tendency to weak regional co-operation may have been mainly inherited from the former socialist system. During the years when the industrial structure was centralized, sectors were commonly concentrated in single firms, and even where many units existed in the enterprise, their in-house R&D laboratories were situated at the headquarters. Until the 1970s, universities, Academy of Science, and industry R&D institutes were concentrated in very few regions, mainly in Budapest. The headquarters of enterprises usually established industry-university linkages close to their location. From the beginning of the transition period, until the late 1990s the overwhelming tendency had been towards a decline in university (Academy)-industry relations. At best, companies have been able to preserve inherited links, mostly in Budapest, and have not yet started to seek new partners on a more dispersed basis. Regionalization of the Hungarian innovation system started in the late 1990s however, it still remains one of the main tasks for the near future.

The internationalization of the economy is strongly dependent on the possibilities and results of co-operation in the field of innovation. According to the responses, companies have been able to establish co-operation (in development, testing, and quality control; that is, mainly in R&D services) with foreign com-

panies, but not with laboratories, which reflects international practice.

Sources of Information for Innovation

Among the inputs, the sources of information are very important. As Boly et al. emphasized in this volume, innovation activity is associated with uncertainty. Quality and volume of available information are reducing the risks. Innovation requires managers' ability to select the sources of relevant information.

The questionnaire of innovation survey asked the importance of different kinds of information sources such as market-oriented, R&D related and general information. If we look only at the pattern of responses by sources, that itself indicates a problem. Internal sources (within the enterprise or group of enterprises) were of key importance for 49 out of 89 responding firms (Table 5).

The external sources form three logical groupings: market/commercial sources, educational/research establishment, and generally available information.

In the case of external sources of information, two subgroups are distinguished: national and international. It is reasonable to make this distinction because Hungarian firms are much less internationalized than West European ones. Lack of world-wide communication, sporadic foreign information were important hampering factors of innovations, and lack of competitiveness in the socialist system. As mentioned

Table 5. Ranking of sources of information for innovation by types.

Factors answer	Number of firms which 'very significant' and 'crucial'	
In-house	49 [89]	
External	Domestic	Foreign
	Information sources	
Market/commercial	107 [107]	104 [107]
Clients/customers	55	48
Competitors in your line of business	30	28
Suppliers of materials and components	19	28
Suppliers of equipment	7	25
Consulting firms	1	2
Educational/research establishments	76 [76]	57 [76]
Universities	14	1
Government laboratories (Academy)	6	—
Science and innovation parks	1	3
Generally available information	84 [84]	75 [84]
Fairs/exhibitions	41	32
Professionals conferences, meetings	25	17
Professional journals	24	32
Patent disclosures	14	10
Professional associations, chambers	15	2

Note: Figures in square brackets = number of responses.

Table 6. Share of sales accounted for by products with incremental or significant changes (numbers of respondents).

Share of Sales %	Domestic sales		Export sales	
	Significant	Incremental	Significant	Incremental
Below 1	0	0	1	0
1.0–5.0	15	10	9	8
5.1–25.0	26	25	13	18
25.1–50.0	10	16	6	6
50.1–75.0	4	6	5	8
75.1–100	3	4	7	8
Total	58	61	41	48

earlier the enterprises operated in isolation from the world centers of science and innovation and were behind technologically. The surrounding technological and industrial infrastructure was underdeveloped. The internationalization of the economy was an urgent need. Openness of thinking could help to improve competitiveness. The question is whether political ‘open up’ and governmental measures for internationalization can be found in employing foreign sources of information?

The distinction by national and international sources is more important for periphery countries than advanced ones because the former firms are much less internationalized than West European ones.

Firms usually rated the importance of domestic information higher than foreign, which is a sign that minds are opening too slowly. An important reason for this slowness is the problem of knowledge of foreign languages. Table 5 summarizes the ranking of the various types of information required in the development and introduction of new products and processes.⁸

It is a positive phenomenon that the companies evaluated market information (clients are first, and competitors third) so highly. As regards to domestic sources of information in the rank two of the generally available information are on the second and fourth places. Fairs, exhibitions are second and professional meetings fourth. These events make it possible to meet people and to start building networks (see Swan et al., this volume).

Between competitors, interaction is considered the best way to share information among each other. Almost one third of respondents evaluated competitors in their line of business significantly or crucially important source for their innovation activities.

At the other end of the scale, with very low rankings, are consulting firms, science and innovation parks,

government laboratories and universities. Consulting firms and parks were their own initial phases, building their own capabilities. The government laboratories-university-enterprise linkages hardly existed before the transition period and companies during their own transformation process have not become more hungry for the inventions, novelties. If we take into account the knowledge is becoming the core capability in that competition, the information on new knowledge that is needed for long-term strategy, large changes, and technological breakthroughs, are regarded, at best, as moderately significant sources. The role of professional journals seems to be the most important source of new knowledge.

Comparing the importance of cross-country information sources to domestic ones clearly, observable firms usually rated the importance of domestic information higher than foreign. A small number of companies evaluated foreign market sources ‘very significant’ and ‘crucial’ than domestic ones. The difference is wider in the case of generally available information. An important reason for this slowness is the problem of knowledge of foreign languages. Foreign education and research establishments was a negligible information source for the investigated companies.

There are two important features of employing foreign sources: role of professional journals and technology transfer. Technology transfer (suppliers of materials and components and suppliers of equipment) is becoming an important source of information.

Outputs of the Innovation Process

It is not an easy task to measure innovation outputs. The questionnaire targets the share of sales accounted for by innovative products in a number of ways, namely:

- sales of products by different stages of the product life cycle;
- breakdown of domestic/export sales by three types of products (unchanged, incrementally and significantly changed) (see Table 6);
- breakdown of total sales by newness of innovative products (new globally; new in Hungary; and new or

⁸ The main findings of different innovation surveys show many similarities in relation to sources of information and objectives of innovation. Particularly striking are the similarities between the results of the Irish Innovation Survey and the Hungarian one. (For the Irish results see FitzGerald & Breathnach, 1994) Systematic comparison among smaller European economies seems fruitful.

Table 7. Share of sales accounted for by new products (number of respondents).

Proportion of total sales %	New to		
	Globally	Hungary	Firm
Below 1	2	0	0
1.0–5.0	4	3	1
5.1–25.0	7	10	9
25.1–50.0	6	14	5
50.1–75.0	1	5	5
75.1–100	3	14	28

substantially improved for enterprise only) (Table 7).

It was assumed by the OECD/EU questionnaire that the share of sales accounted for products in the introductory phase would indicate the output of innovation. The product life cycle is not a clearly understood category for many respondents. On the basis of experience with the pilot survey, we shall not use this indicator widely as an output measurement of innovation, because the information based on this indicator is rather uncertain. The quality of responses on the other two indicators is more reliable.

Out of the 110 firms, 82 developed or introduced technologically altered products, and 62 technologically changed processes, during 1990–1993 and 88 intend to develop or introduce technologically changed products or processes in the years 1994–1996.

The data confirms that the main objective of innovation activity is to develop and introduce new products on the domestic market. Breakdown by domestic and export sales of innovative and non-innovative products are very important indicators for less advanced countries. The number of companies which introduced significantly or incrementally changed products is higher in the case of domestic sales than in that of export.

More than 75% of the changed products came from the food, beverage, tobacco and electronic equipment, medical, precision and optical industries. Although a small sample contains many uncertainties, it is worth mentioning these industries because they have a common characteristic—the firms, or their upstream firms (such as assembler and trading companies), have been privatized, and their new owners have started to redeploy production assets to introduce new products on the domestic market. The food industry reacted to new challenges on the domestic market emanating from import liberalization by innovating, to limit the displacement of their products by foreign competition. But they were not able to introduce their new products on (new) export markets. Maybe the reasons are export quotas (European Union trade barriers), licensing restrictions in the case of foreign-owned companies, or weak competitiveness of products. To answer this very

crucial question will require more detailed investigation.

Changed products account for a relatively high proportion of exports in the metal and machinery industries. These markets are shrinking, and it is no longer possible to sell many of the old metal and machinery products.

Incrementally and significantly changed products can also be investigated on the basis of their newness. In the survey, the newness of innovative products was categorized into three groups—‘globally’, ‘in Hungary’, and ‘enterprise/group only’. The ratio of sales of innovations is differentiated between three groups of innovations (Table 7).

Half of the respondents sold altered products that were new only in Hungary or in the firm. If we combine this answer with responses on the product life cycle—in those cases where information seems reliable—most of the products new to firm or only to Hungary were in their maturing or declining phases. These innovations may suffice for short-term survival—they can help the companies avoid bankruptcy, quickly replace lost markets and so on. But they cannot improve international competitiveness, which require breaking out of the old mould.

Factors Hampering Innovation

A review of the innovation survey gives some indications as to why innovation activities and their results are so very limited. A range of 21 possible key impediments can be subsumed under two major factors, with a range of miscellaneous issues completing the picture. Table 8 shows what firms thought were the central factors constraining innovative activity.

Apart from the many changes in the banking system and financial situation in Hungary, the greatest hindrance for firms was the lack of appropriate sources of finance. There was no proper financial system for innovation and development activities. In a matured market economy the financial factors also hamper innovation. However inappropriateness of financial sources is very different between capitalized and undercapitalized countries. In undercapitalized transition economies, the financial market is semi-developed, meaning that many sophisticated financial

Table 8. Ranking of factors hampering innovative activity.

Economic factors	Number of firms with answers of 'very significant' and 'crucial'
Lack of financial sources	80
Innovation costs too high	48
Pay-off period too long	40
Perception of excessive risk	20
Firm factors	
Innovation potential too small	36
Lack of information on markets	18
Innovation costs hard to control	18
Organisational structure of firm	18
Lack or weakness of innovation management	15
Poor availability of external technical services	15
Lack of skilled personnel	14
Lack of information on technologies	8
Resistance to change in firm	6
Lack of opportunities for co-operation	6
Other reasons	
Legislation, norms, regulations, standards, taxation	28
Lack of technological opportunities	21
Uncertainty in timing of innovation	15
Lack of customer responsiveness	14
Innovation too easy to copy	8
No need, due to earlier innovations	2

techniques and measures are missing. During the investigated period very few financial measures have existed in Hungary, which promoted realization of innovation. In the first decade of the transition period, interest rates were high, little funding was available, venture capital had been non-existent. Tax benefits and other state measures directly or indirectly were introduced in the late 1990s after the surveying period. Before that time, public funds contributing to the financing of innovation in Hungary were limited.

All other factors were picked out by a substantially smaller number of firms. The next most important issue—judged to be significant by roughly every second respondent—were excessively high innovation costs and excessively long pay-off period.

But policy-makers must understand that even if a company has enough financial resources, it may remain non-innovative. *Supplying funds for research does not automatically increase the intensity of innovation activities.* In many countries, lack of skilled personnel is becoming an important hampering factor of innovation activity. (For example information and communication technology specialists in Germany, computer illiterate blue-collar workers in the car accessory industry.)

A second block of constraints relates to the potential of the firm to engage in innovation. It is worth mentioning that interviewed firms were much more critical of these firm-level factors than respondents to the postal survey. Almost every person interviewed

face-to-face emphasized: lack or weakness of innovation and inappropriate organizational structure within the firm. Only one in four respondents to the postal survey judged these factors to be a serious impediment. This was the biggest discrepancy between interview and postal survey responses. It may be that self-evaluation in written form was much less critical (or more careful) than in oral form. This highlights one of the limits of the postal survey as a tool of investigation.

A third block of factors hampering innovation can be summarized as general external issues. It is a positive feature that earlier innovations (2) or lack of customer responses to new products and processes (14)—i.e. demand-side problems—do not greatly constrain the innovation process.

Some Concluding Remarks

By the late 1990s some of Central and Eastern European countries, including Hungary seem to have reached Phase II and shows a consolidated picture. According to some experiences in Central Europe, there is a shift of about 2 to 4 years between the recovery of the economy and the revitalization of the R&D. Overall the Hungarian macro economic situation provides an opportunity for R&D and innovation activities.

These results show that the effort put into the Hungarian innovation survey was not in vain. In the new environment of the transition economy it is

rational to collect innovation data according to the Oslo Manual. Internationally comparable indicators are extremely important in the age of globalization. They allow inter-country comparisons.

At least the first phase of the transition period from command economy towards a market economy is a very special environment for measuring such typical market economic phenomenon as innovation. (The period of such transition offers different environment for any type of surveys.) The first period did not offer many grounds for optimism regarding modernizing and improving the competitiveness of the Hungarian economy. But analysis of the factors that hamper innovation may help to prepare a better innovation policy for the future.

Summing up the main conclusions of the survey carried in the first phase of transition:

- the main objectives of innovation are the improvement of product quality, the opening-up of new markets, and changes in products;
- the sources of information rated highly by the greatest number of innovators are those which are closest to the firm: clients and customers, internal sources and even competitors. Educational and research establishments are judged to be significant as sources of information by only a small number of firms. Traditional external sources—fairs and exhibitions, professional conferences, meetings, journals—are judged to be more significant;
- financial factors, including lack of appropriate sources of finance, are evaluated as the most significant impediments to innovation. Another major complex of factors hampering innovation relates to company-specific issues such as inadequate innovation potential, lack of information on markets, problems of controlling innovation costs, and deficiencies in the existing organizational structure of enterprise;
- the pilot survey experiences, reveal that respondents were able correctly to identify the declared market economic definitions.

This pilot survey was one of the first attempts to take a wide-ranging look at the actual levels of product and process innovation in Hungary. This survey has provided a much more comprehensive picture of what has been happening than periodic surveys of R&D performance. Policy-makers need to have reliable information on R&D inputs and outputs, as well as on factors hindering diffusion.

In conditions of transition, initial gambits may lead in many different directions. Government policy has to find ways to create an environment friendly toward innovation and entrepreneurs, and to build a system of guidelines to help locate the best solution for the whole economy. Business firms must create demand for R&D results, and must be capable of utilizing them. They

need to possess an intellectual base that can promote inventions and innovations introduced in other countries. International experiences suggests that the market cannot by itself solve this problem. It must be supported by a general economic policy, as well as by science, technology and innovation policies. The present research can help to lay the foundation for those policies.

The new indicators—time-series and international comparison—can make policy-makers and businessmen better informed, to provide them up-to-date knowledge. The innovation indicators may back up policy-making process and help to change the way of thinking on innovation policy matters gradually in coming years. Transition economies have to go beyond the traditional innovation indicators developed by advanced economies to learn the reasons of low level of collaboration, lower share of new products in export sales, factors constraining innovation which relate to firm potential.

The innovation survey has highlighted some of the key policy questions which have to be answered. The time series on Hungarian innovation activities are still missing. Development of reliable, timing indicators is also a part of the learning process in transformation of policy-making. The pioneering pilot survey was followed by several other pilot surveys in Hungary that brought several problems into even sharper relief, such as market economy is not a guarantee for improvement in innovativeness, financial conditions are crucial for innovations but they are not enough to encourage innovations. Government has to facilitate in many ways companies to upgrade innovative capabilities.

A Profile of the Hungarian Pilot Survey

The process of developing a Hungarian innovation survey questionnaire was a time-consuming process.⁹ The first step was the translation and dissemination of the document *OECD Proposed Guidelines for Collecting and Interpreting Technological Innovation Data* (Oslo Manual, 1992), the theoretical framework containing the definition of the process.¹⁰

Then we developed a Hungarian questionnaire on the basis of an internationally developed, harmonized

one for postal innovation survey work in the OECD (EC) area.

It was decided to run a pre-test of the innovation survey in 1993. We visited some firms and asked members of top management to fill in a draft questionnaire. The pre-testing period was followed by a pilot survey.

The pre-test was done through interview. Every researcher had to fill out the pilot questionnaire and prepare a written report on his or her experiences with the interviews. Thirteen firms filled in the questionnaire and seven others gave valuable, detailed comments on questionnaire design etc.

After the preliminary questionnaires filled in by the firms had been examined and collated, the pilot postal survey questionnaire was developed. That apart, it was necessary to find a suitable register for choosing firms.

⁹ Appendix 2 is based on Inzelt (1993, 1994).

¹⁰ Translation and publication was supported by the Hungarian Science Policy Committee.

Pilot innovation postal survey questionnaires were sent out in January 1994. Enormous methodological experience was built up through the completed questionnaires, the 24-hour hotline, and follow-up phone calls.¹¹

I. The Lifelines of the Hungarian Pilot Survey

Methodology

Kind of survey:	Pilot survey
Survey unit:	Enterprise (mainly innovative firms involved in R&D activities)
Classification:	ISIC Rev. 3 (with some variations below the two-digit level)
Obligatory/voluntary survey:	Voluntary
Size of survey (number of responses):	110
Cut-off-point:	Employees above 100 and/or net sales above HUF 300 million and/ or total sum of balance sheet above HUF 150 million
Questionnaire:	Modified OECD/EC harmonized
Combination with other survey:	No
Population and coverage:	All R&D performing enterprises from the 4000-strong sample of the Hungarian Central Statistical Office (478 in number) were selected. These 478 enterprises operate in various industries Their ownership structure is also diverse (private, state-owned, domestic and foreign joint ventures)
Reference period:	1990 to 1993
Survey method and implementation:	postal survey/phone calls for those missing the deadline
Response rate:	23%
<i>Timing</i>	
Started mailing the questionnaire:	01.02.1994
Finished collecting/ processing data:	May 1994
Results available:	November 1994

¹¹ Reminder letters were largely a waste of money. If firms did not answer the first letter we tried to push them by phone calls in order to achieve a higher response rate. This is a more time-consuming and costly process, but it was the only workable method.

II. Sampling Method and Response Rate

At the time of sampling, there was not an up-to-date listing of Hungarian companies available. Several ideas were put forward as to where to choose the population for the pilot survey from.

- (1) The original idea was to choose them from the list of companies that filed a research and development project with OMFB between 1990 and 1993, i.e. over the period since the new project evaluation system was created following the systemic change (Inzelt, 1993). Unfortunately this list was not available at the time of starting the pre-test.
- (2) In the autumn of 1993 the list of those firms that had filled in compulsory R&D statistical survey forms became available. It was not our specific aim to test the composition of the list, but while pre-testing the questionnaire it became clear that many of the companies on the list had disappeared or redeployed fundamentally (e.g. they had gone into bankruptcy, split up, privatized and regrouped, etc.) Only 50% of the list seemed correct at the end of 1993. (A very common problem with registers under conditions of transition is that they quickly go out of date.) It would clearly have been unreasonable to use such a list for a postal survey. We had to find something else.
- (3) At the end of the pre-test period the list of respondents in the new Hungarian Board of Statistics business survey (3,600 responses from the sample of 4,000) was ready.

This new business survey contained some questions about R&D activities. On this basis we were able to pick out from the list all firms involved in any type of R&D.¹² Their number was 478. This was our target group.¹³ Just 110 firms sent back questionnaires amenable to statistical analysis. (Another 30 firms gave valuable information in letters or by phone.)¹⁴ The response rate of 23% is not very high. But, considering that this was a non-mandatory survey in a transition economy in which trade is not flourishing, and where the key question for many business units is just how to survive from day to day.

¹² Sales from R&D activities, non-intangible assets, gross fixed capital from R&D, direct cost of own production R&D, indirect cost of own production R&D, cost of bought-in R&D activities.

¹³ It would have been useful to investigate not only these, but also a similar number of firms from among those that did not report any R&D activities. Unfortunately, because of financial limitations, we were not able to send out more than 500 questionnaires.

¹⁴ R&D firms as a rule did not give information, but wrote subsequently to ask for the results of the survey.

Innovation under Constraints: The Case of Singapore

Hung-Kei Tang and Khim-Teck Yeo

Nanyang Technological University, Republic of Singapore

Abstract: Singapore is a small island state in Southeast Asia. Historically it was a British colony and trading was its primary economic activity. In the last four decades Singapore underwent rapid industrialization, progressing from being a center for labor-intensive operations to a pioneer in the application of information technology. However, indigenous attempts to innovate so far have had mixed results. This chapter attempts to explore, through four case studies, how constraints of different types could give rise to innovation as well as cause innovation efforts to fail.

Keywords: Innovation; Constraints; Barriers; Path-dependency; Competence; Types of innovation; Singapore.

Introduction

Innovation has been extolled as the ultimate means to achieve competitiveness for companies and nations alike. Companies are warned that either they innovate or evaporate. It is understandable, therefore, with constant admonishments from the eager business gurus and concerned government officials, many executives would feel left out and be afraid to be seen as unenthusiastic if they do not actively initiate, support and fund what appear to be attractive programs and projects for innovation. Hence innovation has become an increasingly popular buzzword.

Innovation can be defined as the process of applying novel but not necessarily brand new ideas for purposeful gains such as productivity, profit or the elimination of problems. It can also be defined as the product of such a process. While innovation can be simply defined, the process of innovation especially in an organizational context tends to be complex (Tang, 1998). And it is even more difficult to quantify and measure innovation (Buderi, 1999). Many companies say they expect innovations from their employees but ironically not every organization is ready or able to exploit the potential of their employees to innovate (Amabile, 1998). Unlike quality control or supply-chain management, innovation is not a management function that can be standardized or operationalized. Nevertheless, a cornucopia of concepts and methods such as those found in this handbook can help to give

some structures and directions to what inherently is a probabilistic and often chaotic process at its core. When an innovation such as the 3M Post-It finally materializes, it is not uncommon that people would say, with the benefit of hindsight, that the idea is simple. The often ignored fact is that, behind every innovation, there is a long history of preparation and struggles. Innovation is seldom easy or instantaneous.

Like entrepreneurship, innovation is often interpreted as pursuing an idea or opportunity, despite or because of, constraints faced. Often opportunities are described optimistically as limitless and project goals are set ambitiously. However, in this chapter it is argued that an organization's optimism and ambition should be tempered by the recognition that there are constraints to its ability to innovate. These constraints, also called barriers, could be internal such as staff and the work environment (Amabile et al., 1996; Roberts & Fusfeld, 1981), or external such as societal and economic factors (Nelson, 1993; Patel & Pavitt, 1994; Shane, 1993). In this handbook, Hadjimanolis gives a comprehensive review and analysis on the barriers against innovation, whereas Major & Cordey-Hayes describe the special barriers faced by small firms. It should be emphasized up front that constraints must not be interpreted completely as final or negative. Many constraints in fact can be interpreted positively because they give impetus to innovations that result in

the removal or mitigation of the constraints themselves. For example, the vast distance between communities in Canada and Finland make them pioneers in satellite and wireless telecommunications respectively. The lack of space is the constraint that propels Japan into miniaturizing many consumer products. The micro-scooter was created by Gino Tsai who described himself having short legs but wanted to move around fast in his vast bicycle factory in Taiwan. However, it would be wrong to assume that there are viable or fast solutions to all constraints. The location of a country cannot be moved. A person could be very creative but without working knowledge in a field he could not be innovative in that field. Hence, it is important first to recognize constraints that can impede or jeopardize efforts in innovation, then remove them, make them irrelevant or turn them into opportunities if possible. Not recognizing the constraints and going against them unknowingly account for many companies' failures in their efforts to produce innovations. Internal and external constraints can also limit the types of innovation a company is capable of producing. Hence knowing how the different types of innovation demand different organizational capabilities is another step toward producing innovations successfully.

There are different ways of classifying innovations and they are used for different purposes (Chesbrough & Teece, 1996; Henderson & Clark, 1990; Hobday, 1998; Tushman & O'Reilly, 1997; see also Sternberg et al., this handbook). For the purpose of this chapter it is useful to classify innovations according to two criteria. The first classifies innovations according to whether it is incremental or radical, the second whether it is autonomous or systemic. Incremental innovations refer to the refinement of existing products, processes and services or adapting them to different applications. Radical innovations are those that offer brand new application, user experience and can potentially set a new standard or even give rise to a new industry. Innovators aiming for radical innovation face great uncertainty in many areas e.g. unforeseen technical difficulties, costing, performance reliability, market acceptance, sustaining initial success. Incremental innovations have far less barriers to overcome. They usually depend on proven technologies or the market and customer requirements are quite well defined.

The autonomous-systemic classification of innovation is determined by the degree of need for complementary assets to develop the technology or the market. Take the case of the introduction of the audio compact disk (CD) in the early 1980s (Nayak & Ketteringham, 1993). The audio CD player would be useless to the consumers if there were no CDs to buy. The CD-player manufacturers and the record companies that provided the contents and recorded the CDs were thus providing complementary assets. Furthermore, to overcome initial resistance to this revolutionary product they recruited leading artists to

record on the new medium. In terms of technologies, Philips was the pioneer in using laser in the playback of contents recorded on plastic disks. However, they were stronger in analog electronics than digital electronics. Hence Sony, which was stronger in digital electronics and solid-state laser, was engaged as a joint developer to give the technology the final and decisive push. This example illustrates the systemic nature of many technological innovations that are the results of collaborators who contribute complementary capabilities. Two other examples are the GSM cellular phone and the personal computer. The former was an innovation developed by many European partners. The latter was developed by IBM with major components from Microsoft, Intel and others. In comparison, an autonomous innovation can be realized by a firm largely with its internal resources. The firm may still need to buy services and parts from other companies but these are widely available and are not core to the innovation.

The Case of Singapore

Singapore is one of the newly industrialized economies and is also notable for its small size, a dot on the map in Southeast Asia. It became a British colony in 1819 and an independent nation in 1965. Situated in the middle of Southeast Asia, it has an area of little more than 640 square kilometers and a small population. The British acquired Singapore as a colony primarily for its potential as a port and a trading post. To date Singapore remains an important trading and transportation hub. However, manufacturing, banking and finance now contribute most to the nation's economy. Singapore is in the ranks of the developed nations in terms GNP per capita and considered very competitive economically according to the rankings of global competitiveness published by organizations such as the World Economic Forum. PSA (Port of Singapore Authority) Corp is the largest container port operator and Singapore Airline is one of the most profitable airlines in the world. For many years Singapore produced more than 40% of the world's hard disk drives and still maintains its position as an important hard disk drive manufacturing hub.

The strategic location of Singapore straddling the Indian and Pacific Oceans and its deep-water harbor pre-destined it to be a great port for the British Empire in the nineteenth and first half of the twentieth century. Its central location in Southeast Asia made it a logical choice as a hub for trans-shipment of goods and intra-regional trade. Hence, Singapore for a long time (except during the Second World War when it was occupied by Japan) was primarily a society of traders and clerks who performed fairly well defined and slowly changing tasks that trading and shipping entailed. There was little incentive for innovation or to be a pioneer. Moreover, the great distances that separate Singapore from the great centers of business

and technological development in the developed world was an impediment for innovation activities in Singapore.

The societal upheaval around the time of independence in 1965 and the subsequent withdrawal of the British military bases produced a sharp increase in unemployment. Concurrently the economic boom in Western economies marked the beginning of the trend of outsourcing labor-intensive manufacturing operations for consumer goods such as electronics and apparels. Faced with the situation, the government adopted the policy of actively engaging the foreign multinational corporations (MNCs) to set up manufacturing facilities in Singapore. Unlike many developing countries that became newly independent at the time, Singapore maintained a free trade policy and generously provided tax incentives for foreign firms that pioneered manufacturing in Singapore, which continues to date.

The early economic policy of Singapore changed the bleak employment situation to almost full employment within just a few short years. However, the majority of the workforce was still lowly educated. The scope for work widened to include manufacturing but the nature of labor-intensive tasks in the factories, which were almost totally transplanted from other countries, did not provide much scope for innovation. The situation gradually changed. Learning from the success of Singapore, other countries in the region also implemented similar MNC-friendly economic policies. That meant the MNCs had more choices for the relocation of their factories. The spread and rise of manufacturing brought economic growth to the region as a whole and thus demand for consumer goods in the regional economies as well. The new development brought both competition and opportunity.

New policies to upgrade the economy were implemented at the end of the 1970s. There was the unique high-wage policy designed to force up wages and drive out low value-added operations. Tertiary education in engineering was quickly expanded to supply the manpower to satisfy anticipated demand for technical staff. There were also the policies to give incentives for companies that computerize, automate or widen the scope of work to include more value-adding functions such as product design. As a result of steady economic development in Southeast Asia, consumer demands for goods increased. At the same time, China was also reforming its economy and opted for a more open-door policy. Hence the regional market for goods became more attractive to the MNCs from the West and Japan manufacturing in the region. Opportunities thus arose for adapting their products for local consumption. In order to encourage foreign MNCs to set up research and development activities in Singapore, the government established research institutes in IT, micro-electronics and life sciences. In 1991 the National Science and Technology Board (now Agency for

Science, Technology and Research) was set up and charged with establishing Singapore not only as a manufacturing hub but also as a center of research and development.

The Cases

PSA Corporation

For many years Singapore has been the second busiest container port in the world after Hong Kong. However, PSA has been the single biggest container operator in the world. It handled 17.04 million TEUs in 2000 (twenty-foot equivalent units of containers) with 6,200 staff. In 1972 the then Port of Singapore Authority became one of the early adopters of container technology, in anticipation of the rising trend of containerization in sea cargo transportation. In the same year PSA's electronic data processing department joined the operations departments to run round the clock, seven days a week. These two events heralded the beginning of the intimate joint development of operational and informational technological capabilities at PSA. Contrary to the commonly perceived image of a government bureaucracy being inefficient, PSA has been a productivity champion and consistently innovative.

Its subsequent corporatization in 1997 was not so much an attempt to boost efficiency, but as an effort to facilitate business expansion, particularly overseas. PSA had to be innovative for two very important reasons—to stay competitive and to maintain a lean workforce. PSA has to stay competitive, despite Singapore's strategic location, because there are up and coming ports nearby that have equal claim to be strategically located. Port Klang, Port Tanjung Pelepas in neighboring Malaysia are eager competitors. PSA has to stay lean with its workforce because for decades Singapore had very tight labor supply, which was a major constraint. In fact while the number of TEUs handled increased from 4.36 to 17 million from 1989 to 1998, the staff strength actually decreased from 7,500 to 6,200. The increase of labor productivity from 583 to 2,746 TEUs per staff was due to technological innovations pioneered by PSA. This upward trend could be traced to a series of research and development projects undertaken by PSA.

In 1987 PSA started collaborating in the application development of expert system (a branch of computer-based Artificial Intelligence) with the recently established the Information Technology Institute. The objective was to capture the expertise of a group of operation planners who had a wealth of tacit knowledge among them, which helped them to map out the optimal sequence and positioning of the containers to be loaded or unloaded in as short a time as possible. For a few months the software developers from the Institute and PSA, and the planners were co-located in order to lower the cultural barrier between the two

groups. The software development project was a success. The result was the first version of CITOS (Computer Integrated Terminal Operations System). Subsequent development by PSA's IT department improved and expanded the functions of CITOS to include berth allocation, stowage planning, yard planning and resource allocation (Tung & Turban, 1996). CITOS was later augmented by electronics and communication systems that included entry/exit gate control on the movement of container trucks, container identification by computer vision, automatic container locating system and communication system with drivers. These were also developed internally with assistance from external experts. In parallel to operations and planning, PSA's IT development teams developed the computer network systems called Portnet and Boxnet that link PSA's computer with that of shipping agents and other business associates to automate various business transactions and information exchange.

LTA (Land Transport Authority, Singapore)

Singapore is one of the most densely populated countries in the world. The lack of land space is a major constraint to Singapore. Controlling the growth of traffic and regulating the traffic patterns in order to reduce road congestion have been high-priority objectives for Singapore's road transport planners. One example of an innovative policy is the Certificate of Entitlement (COE) scheme that requires new car buyers to bid for a limited supply of COEs that entitle them to buy. Another example is the road-pricing scheme, which is a combination of both policy and technological innovation. From 1975 a rudimentary road-pricing scheme had been in place that required motorists entering into the central business district during peak hours to buy a pass at roadside kiosks or designated petrol stations, and to display it prominently on the windscreen. While this scheme was effective in restricting traffic it caused great inconveniences and relied on visual inspection from a distance by traffic police who stood on the roadside to spot offenders driving by at normal speed. So in 1989 the LTA began to explore the feasibility of an electronic road pricing (ERP) system to be implemented not only for the central business district but also on busy sections of expressways. In order not to slow down traffic flow, the introduction of separation barriers between lanes was ruled out.

In 1993, after four years of study the LTA put up a conceptual system design and preliminary specifications and invited proposals from potential suppliers. LTA also engaged experts on electronics and communication from the Nanyang Technological University to be its consultants in the evaluation of the technical merits of the proposals.

Three proposals were received from the vendors but none met the required specifications. The invitation to

propose was repeated in 1995. Again none met the specifications fully, attesting to the gap between state of the art and the stringent requirements. However, this time the consortium led by Mitsubishi-Philips, whose proposed system most closely met the specifications, was commissioned to build a demonstration system. The results were encouraging enough that the supplier was asked to make improvements and be ready for qualification test under realistic traffic conditions in May 1996. The test revealed the prototype road pricing system's susceptibility to electromagnetic interference generated particularly by motorcycles. Further modifications were made and the susceptibility problem was solved. Electronic road pricing is now widely implemented in Singapore. The final ERP system consists of: (a) an in-vehicle, cash-card enabled, electronic transponder that is installed on every road vehicle; and (b) an automatic vehicle identification and debiting sub-system and an enforcement sub-system installed above and beside the road. The system makes clever use of electronics, communications and image processing technology. During designated operational hours, toll is deducted electronically from the cash-card in the in-vehicle unit when a vehicle passes under an ERP gantry. Although Singapore was not the first one to come up with the idea of road pricing, it is the first one that has implemented the most advanced form of electronic road pricing to date in a large scale (Do, 2000).

Creative Technology

Creative Technology is a leading Singapore electronics company that has carved itself a niche in the digital audio player and PC sound card market with a turnover of US\$1.2 billion in fiscal year 2001. Its brand *SoundBlaster* is well known amongst consumers worldwide. However, its takeoff in 1989 was only possible after it expanded its marketing and sales function from Singapore to the USA in the heart of the Silicon Valley. The move was designed to overcome the constraints of having only a small domestic market and the lack of reach to the major consumer markets outside of Singapore.

For many years Creative Technology was a struggling small company like many others trying to develop into a viable enterprise. However, unlike others, it had the ambition of creating its own product with its own brand name from the very beginning. Besides making add-on cards for PCs, it also designed and made its own PC with unique features such as good quality sound. So in terms of the scope of operations, it essentially covered the full range, from product development to manufacturing and marketing, just like the bigger and vertically integrated firms. However after investing very heavily on a new PC, which failed to win customers despite having good sound and Chinese character handling capability, the company was in a quandary. The founder then took the audacious

step of expanding to the USA and set up a one-man operation initially.

Soon after the move, the founder discovered the nascent market for PC sound card. Opportunely, the company had the people with the design and manufacturing experience of a similar but simpler product earlier. So technically, the company was up to the challenge. However, it was a major hurdle to secure the supply of a hard-to-get sound synthesizing IC chip in large quantity. It was only available from the Japanese company Yamaha, which was quite reluctant to sell to the then unknown Creative Technology. This hurdle was cleared after Singapore's Trade Development Board Office in Japan was able to convince the manufacturer that Creative Technology was a bona fide Singaporean company. Another major hurdle was to convince established computer-game software companies to develop games that supported its sound card. After pursuing them tenaciously Creative Technology finally got their support and so customers could buy computer game software that ran on Creative's sound card. In 1989 Creative's *SoundBlaster* sound card became a runaway success in the USA. Subsequently, it nurtured its research and development capability in the USA through a series of acquisitions and thus laid the technological foundation for sustained product innovation (Tang, 1996). Subsequently it also developed its own sound synthesizing IC and thus cut off its reliance on others for this key component.

Goldtron

Goldtron is a medium-size indigenous electronics company in Singapore with a turnover of about US\$100 million in fiscal year 2001. It was traditionally a distributor of electronics components and a contract manufacturer. In the early 1990s the company dabbled in developing its own products. It established the Proteq division to develop home automation electronics. In mid-1990s the market for personal wireless communication began its high growth phase. Sales of pagers increased rapidly because the newer models had more compact design and increased functionality. GSM cellular phones sales began to take off and became the standard in Europe and most of Asia. GSM is the so-called second generation cellular phone system introduced in the early 1990s. GSM phones use digital rather than the analog technology found in the first generation of cellular phones. Seeing the opportunity, Goldtron embarked on an ambitious diversification plan. It aimed to compete internationally with pagers and cellular phones to be designed and manufactured by itself. A new subsidiary, Goldtron Telecommunications, was established and a group of engineers with experience in pager design and radio frequency technology were hired. Consequently the pager was developed successfully. But compared to the cellular phone, the pager was simple and mature technologically.

The building-block technologies in a GSM cellular phone are the GSM protocol, radio frequency, digital signal processing (DSP), audio frequency, micro-controller, battery and power supply. Of these, DSP and the GSM protocol are considered the core technologies. When Goldtron undertook the task of developing its own GSM phones, these core technologies were new to it. Great technical difficulties were encountered and at the end the product cost was too high for Goldtron to compete effectively with the leading brands. Goldtron tried to compensate by introducing what could be considered an innovative product: a cellular phone with a built-in pager. Its phone function would be normally switched off, leaving only the pager turned on to receive incoming message. This way the battery power would last longer. However, battery technology improved rapidly, making the benefit irrelevant almost as soon as the product was launched into the market. Consequently Goldtron's cellular phones found few buyers. So after spending tens of million of dollars the company stopped its product development efforts and abandoned the telecommunication business in 1998. Goldtron became a much weaker company after its failed attempt. After Goldtron's exit, the cellular phone market continued to grow rapidly. In order to capture more market share, some semiconductor manufacturers began to sell DSP chips customized for GSM application thus lowering the technological barrier significantly for newer and smaller players. However, it was too late for Goldtron.

Discussions

Of the four cases covered, PSA and LTA illustrate innovations that resulted from systematic and purposeful exploitation of state-of-the-art technologies successes. The challenges were clear and well defined, and the goals are unambiguous and credible. On the other hand, the remaining two cases are examples of innovation projects undertaken with uncertainty in terms of the market or internal technological capability. The PSA and LTA cases illustrate two fundamental *resource constraints* faced in Singapore, shortage of land and manpower. These constraints are inherent to Singapore's size, which are hard to overcome. However these constraints are exactly the same reasons that drove PSA and LTA to innovate. The nature of the innovations, CITOS for PSA, ERP for LTA, is systemic and infrastructural. The technological innovation of key components contributed to system innovation and breakthroughs. In both cases IT, networking, artificial intelligence and electronics were the key technologies that must be integrated to work together as a system, which leads to dramatically improved performance, productivity and reliability. PSA, because of its internal technological capability plays the role of an innovative system integrator and benefited in the process as it accumulates knowledge in developing and operating such complex systems in the container port

environment. PSA's technological capability also puts it in an advantageous position in expanding its container port operating business to other ports in Asia and Europe. In contrast, LTA lacks internal technological development capability. Despite this *competence constraint*, it succeeded through outsourcing the technology development and system integration. LTA is only a policy and not a technological innovator despite its success with implementing the ERP.

Managing stakeholders' interest is both a constraint and opportunity for PSA. The stakeholders for PSA are the shipping agents, shipping lines and their customers. When there are many stakeholders involved, there are bound to be potential conflict of interest. Conflicts between stakeholders constitute a constraint to innovators of complex systems in that not all stakeholders necessarily perceive an innovation as beneficial to their interest and hence some stakeholders resisted the innovation. Hence in order for an innovation to be accepted, this *stakeholder constraint* needs to be dealt with skillfully. In this regard, the stronger is the innovator's position the better is the chance of the innovation being adopted. Internally PSA's innovations in automation were readily accepted by the workers at home because PSA's business was growing, whereas the supply of port workers was shrinking. Hence job security was not an issue. Externally PSA's reputation as being one of the most technologically advanced as well as one of the biggest and most profitable, gives it a lot of credence when it exports its innovations overseas.

In the LTA case, the stakeholders are, on the one hand, the government agencies that want to minimize traffic congestion and maximize land usage for the transport system, and on the other hand the motorists. Experience in many countries shows that road pricing is not easy to implement, not because of the lack of technology but because of the resistance from the motorists. Singapore is unique because it is a small city-state with a strong government and a citizenry that is used to tough policies for the sake of efficiency. Rolling out road pricing hence is not much a political problem. This is not the case in other countries where social and political desirability weigh heavier than technological or economic feasibility (Button & Verhoef, 1998; Evans & Oswald, 2000). Hence to date, Singapore is still the only country with the most advanced electronic road pricing system in the world. Because of the *social-political constraint* this innovation adopted by Singapore has not yet diffused to other countries. In this sense LTA's innovation has less impact than PSA's.

The above two cases deal with infrastructural innovations in Singapore's public sector and both achieved considerable success. In the private sector, it is more difficult to achieve success due to the lack of experience in innovation both in terms of scale and depth. The Creative Technology and Goldtron cases are

examples of small and medium sized Singaporean companies' attempts in product innovations. The former was a case of success that took the company to another plateau and the latter a debilitating failure that set back the company. The products in question, a sound card for the PC and a cellular phone/pager, are not as big and complex as the PSA and LTA's systems. They were nevertheless very challenging given the limited resources that Creative Technology and Goldtron could command. In fact, the chance of success for product innovation is arguably lower than infrastructural innovations like those of PSA and LTA because there are a diverse range of factors that determine the eventual success or failure of a new product (see Cooper, this handbook).

Spotting the market opportunity for the sound cards occurred only after Creative Technology expanded into the USA. With this strategic move Creative overcame the *market constraint* it was facing in Singapore, a small domestic market which tended to follow trend-setting big markets. Creative also had to overcome the *credibility constraint*. In order to achieve impact upon launch market, i.e. having sufficient supplies of hardware and software, Creative must enlist the support of the sound synthesizer chip manufacturer and the computer game software developers. One of the ironies of innovation is that before an innovation becomes a proven success, stakeholders are sometimes reluctant to accept or support it, even though the innovation will benefit them if it succeeds. This is the dilemma Creative faced before the launch of the *Soundblaster*. Because Creative was a small and unknown company the founder had to put in extra efforts to win the support of the bigger stakeholders: the chip manufacturer and the software developers. In comparison, Goldtron was not a small start-up company when it decided to develop the cellular phone on its own. Nor was it totally unfamiliar with developing new products. However, it did face the competence constraint. The gap between its technological competence and the task requirements was not bridged. This failure underscores the need for innovators to recognize the core competence required for the intended innovation and be prepared to cultivate it over the long haul.

Creative Technology is so far the only Singaporean company that has grown successfully from a small start-up to a billion-dollar sales technology-based company in less than two decades. It is not because Singaporean companies have not been trying. The foreign MNCs driven industrialization in Singapore provided many opportunities for local start-up companies that provide contract manufacturing services, machined parts, jigs and tools. Many of these start-ups have grown into small and medium sized companies. Some have ventured into designing and manufacturing products under their own brands. However, when these companies, such as Goldtron, attempted to diversify by taking on product development or expand overseas,

many failed to replicate the initial success they had enjoyed. Creative Technology's success has been the exception rather than the rule.

The need for Singapore to start up and grow indigenous companies that can compete internationally has been well recognized. But despite the government's efforts to encourage start-ups, help indigenous companies to upgrade and promote spin-off companies from the public research institutes in the last decade, there has been no success comparable to Creative Technology. This lack of success is attributed to the shortage of entrepreneurship, innovations and creative people in Singapore. And the shortage is attributed to the education system and ironically Singapore's own success in creating an economy that had been providing practically full employment in the past. Moreover, there is evidence that the work environment in many local companies and government organizations are not particularly conducive to innovation (Tang, 1999; Thomson, 1980).

One key dimension of the work environment is the type and level of tasks that people are required to perform on their jobs. The types of task people perform determine the scope and the opportunities for innovation. It is through performing challenging tasks that new knowledge and skills are acquired and developed. Over time, this virtuous process builds up an organization's innovative competence (Leonard-Barton, 1995; Nonaka, 1998). However, the gap between the firm's present level of competence and what is required in the task may be too wide to bridge relative to the time, people and other resources available. In such a case the firm would be wise not to undertake the new and unfamiliar task by itself. Instead it should consider various forms of acquisitions of collaboration with firms that have complementary competence (Roberts & Berry, 1985).

A new task can challenge an organization in three ways. First, it can be challenging by requiring the acquisition of a new field of knowledge or a new level of mastery of an existing field of knowledge. Second, it can be challenging because of the need to integrate the work or satisfy the needs of multiple parties, in other words the challenge of dealing with complexity. Third, it can be challenging because the problem to be solved and the solutions to be found are ambiguous and uncertain (Schrader et al., 1993; Yeo, 1995), in other words the challenge of dealing with fuzziness. Thus it can be said that a challenging task has three dimensions: knowledge, complexity and fuzziness.

In the introduction, innovations are described as incremental or radical, autonomous or systemic. The challenges of radical innovation in terms of defining the scope, framing the problem, finding the solutions are full of ambiguity and uncertainty. Systemic innovation calls for the performance of tasks that involve complexity in terms of attending to multiple stakeholders' interest and the integration of different parts

that constitute the innovation. Furthermore, every innovation is characterized by the fields of knowledge it embodies. Without a minimum level of competence in the requisite fields of knowledge, an organization will be greatly impaired in producing the intended innovation. Hence, the ability of an organization to undertake a certain type of innovation is constrained by its ability to perform tasks that are associated with the type of innovation. In order to succeed, an organization therefore needs to align its competence in task performance with the type of innovation intended. This observation is supported by the four cases presented.

PSA succeeded because it has intimate knowledge of container port operations and the internal technological competence to absorb new knowledge. It has also a long history of dealing with tasks of complexity: integrating diverse systems into its daily operations and accommodating the interests of many stakeholders. LTA succeeded in implementing an innovation that was first of its kind, despite its lack of in-depth knowledge of technical systems. It achieved this by outsourcing the tasks of system integration and reduction of technical uncertainty through experimentation. Creative Technology already had sufficient technical knowledge to develop the sound card which was only an incremental and architectural innovation. Nevertheless the systemic nature of the innovation that required the support of an IC chip supplier and software developers was a big challenge to the small company. Goldtron failed primarily because it did not foresee or acquire the new knowledge needed.

Recognizing innovation is a necessity for the next stage of economic development, the government has recently intensified its strategic thrust to promote innovation and entrepreneurship in Singapore (SEDB, 2002). In 1996 the Singapore Economic Development initiated the Innovation Programme with the objective of developing a wide base of indigenous creative capabilities in Singapore. This is to be achieved through strategic initiatives that promote investments in innovation projects and promising entrepreneurial startups. The government itself invests substantial amount of financial commitment to schemes such as the Innovation Development Scheme, Patent Application Fund and Startup Enterprise Development Scheme. However, investing government funds into worthwhile innovation projects and startup enterprises is the only an extension to the government's past practices of channeling resources, particularly money, to what it sees fit. However, trying to nudge the culture at work and study to favor innovation is a fundamentally new endeavor. There are four notable initiatives driving for cultural change:

- the first is for high-level recognition of innovators through the giving out of Singapore Innovation Awards starting 2001;

- the second is for bold attempt to nudge the educational system toward emphasizing creative and critical thinking skills. The opening address (Goh, 1997) delivered by the Prime Minister at the Seventh International Conference on Thinking was a symbolic gesture to signify the intention of the government to overhaul its education system so that students will more likely think creatively and critically in the future;
- the third is to supplement and add diversity to Singapore's limited human capital. Scholarships are given to foreign students especially from the neighboring region to enroll in Singapore's schools and universities. The Technopreneur Pass Scheme is aimed at foreign entrepreneurs who want to start high-tech ventures in Singapore;
- the fourth is a joint government private-sector review of government rules and regulations with the aim of removing obstacles to entrepreneurship in Singapore.

The above initiatives should help to ameliorate the resource and competence constraints on innovation in Singapore. To a certain extent the market constraint is also addressed through the import of foreign talents whose familiarity of the countries of origin should broaden Singapore's market reach. However, these initiatives are still new and the eventual outcome will depend on their implementation.

Conclusion

The case of Singapore and four Singaporean companies have shown that the challenge of innovation includes not only identifying opportunities and committing to innovation but also identifying and mitigating the internal and external constraints that impede the process of innovation. Singapore as a young nation has achieved outstanding infrastructural innovations that are prime examples of system integration. Economically, Singapore succeeded in its rapid industrialization within the last few decades, despite its early competence constraint, by relying heavily on the foreign multinational companies to bring in the management, technology and market expertise. In contrast, many local companies are still constrained by the lack of the same expertise. It continues to be a major challenge for local companies to become innovators and compete globally. The government has recognized the need for a better environment for innovation and entrepreneurship in Singapore and has embarked on several strategic thrusts aimed at making it better.

Continuous Innovation in Japan: The Power of Tacit Knowledge*

Ikujiro Nonaka, Keigo Sasaki and Mohi Ahmed

Graduate School of International Corporate Strategy, Hitotsubashi University, Japan

Abstract: Management practices of innovative Japanese companies, the ‘knowledge creating companies’, has been widely researched and extensively documented. We have begun to look ‘behind the scenes’, and examine more closely the question of ‘what is the basic pattern of innovation in the knowledge-creating companies?’ In this chapter, we will introduce the basic pattern of innovation at Nippon Roche. We argue that learning only or just breaking rules are not enough for continuous innovation. Rather individuals as well as organizations need to possess tacit knowledge.

Keywords: Innovation; Continuous innovation; Tacit knowledge; Knowledge creation.

Introduction

While most companies around the world are still trying to manage the explicit dimension of knowledge using various tools and techniques, Nippon Roche has succeeded in creating knowledge through capturing high-quality tacit knowledge (HQTK), synthesizing tacit and explicit knowledge, and incorporating synthesized knowledge into organizational activities. Nippon Roche is a part of Roche Group, a multinational healthcare company based in Switzerland. The group focuses on discovering, manufacturing, and marketing products and services aimed at addressing the prevention, diagnosis, and treatment of diseases. Nippon Roche, established in 1924 and now employing more than 1,600 workers in Japan, went through a difficult time in the late 1990s, primarily due to low market growth, fierce competition, and institutional changes in the healthcare industry.

To deal with the situation, the company developed a concept in early 1998 called ‘consulting promotion’. This replaced the ‘push sales’ concept previously dominating the healthcare industry. Through this new concept, Nippon Roche made efforts to realize the needs of its customers and offer timely solutions. To

learn about customer needs and create better solutions, Nippon Roche initiated the ‘Super Skill Transfer’ (SST) project in 1998, which focused on people, the creators of knowledge. In naming the project, Nippon Roche considered ‘supersonic transport’ an appropriate metaphor, as the company needed to increase sales productivity at supersonic speed.

The medical representatives (MRs)—the key sales people at Nippon Roche—often contribute to product innovation, as they work in the frontline and improvise with key customers (medical doctors) in the sales process. To succeed in such a competitive marketplace, the MRs need to be able to provide the latest information about healthcare products to their key customers. To deal with the diverse needs of its customers, the development of different levels of MRs was deemed crucial for the company.

Before initiating the SST project, Nippon Roche made efforts to enhance its sales productivity several times by executing conventional training programs, but to no avail. In the past, the company had primarily used different forms of media for communicating best practice, together with role playing at individual branches, but realized that existing tools and techniques were inadequate to facilitate the sharing of the tacit knowledge embedded in individuals.

Nippon Roche initiated and executed the SST project to encourage sales process innovation. In categorizing the sales processes of MRs, the company found that high-performing MRs employed unique

* This chapter is an extended version of an article originally published in Ark Group’s *Knowledge Management* magazine (Vol. 4, Issue 10, July/August 2001, www.kmmagazine.com).

sales processes, and developed their skills through their experiences over time. These skills and experiences were embedded within themselves. Recognizing the importance of this tacit knowledge, Nippon Roche initiated and executed the project in an attempt to transfer such skills to those MRs who were performing less effectively. The passionate efforts of the company have not only contributed to sales process innovation, but also to continuous innovation in the company as a whole. In this article, we will introduce the practices developed at Nippon Roche. We will also briefly discuss how the Nippon Roche case relates to and explains the theory of knowledge creation.

The SST Project

Nippon Roche executed the SST project in an attempt to capture and transfer the HQTK of high-performing MRs, the key sales force of the company, to other MRs within the company. Hiroaki Shigeta, the president of Nippon Roche, championed the project, and his leadership role was critical to its success. At the beginning of the SST project, the company made efforts to analyse the skill gaps between the higher-performing MRs and the average MRs (see Fig. 1). In this process, it categorized the required knowledge and skills, along with the selling processes of the MRs, as follows:

- Product and medical knowledge.

- Targeting the right customers.
- Process of accessing the potential customers.
- Detailing skills.

From the in-depth analyzes, it became clear that the high-performing MRs generally relied on experience (learning by doing), while the average MRs relied on existing information (learning by manual). The critical differences between the high-performing MRs and the average MRs were in terms of ‘access’ to potential customers. The high-performing MRs generally employed the most effective timing to access potential customers, and the access skills of the high-performing MRs were considered as HQTK. Furthermore, the high-performing MRs proved to be very good at contextual practice and improvisation with their customers, and they continuously developed such skills through their personal experiences.

In its journey towards finding an effective mechanism to capture and transfer these skills to other MRs, Nippon Roche initiated the SST project, in an attempt to capture and transfer the HQTK embedded in the high-performing MRs and make it explicit (as far as possible), and incorporate this knowledge into broader corporate activities. As President Shigeta, the knowledge leader of the company, says: “The tacit knowledge that a high-performing MR has should be regarded as a defining factor. Based on his experiences, he knows everything about timing and has the knack of

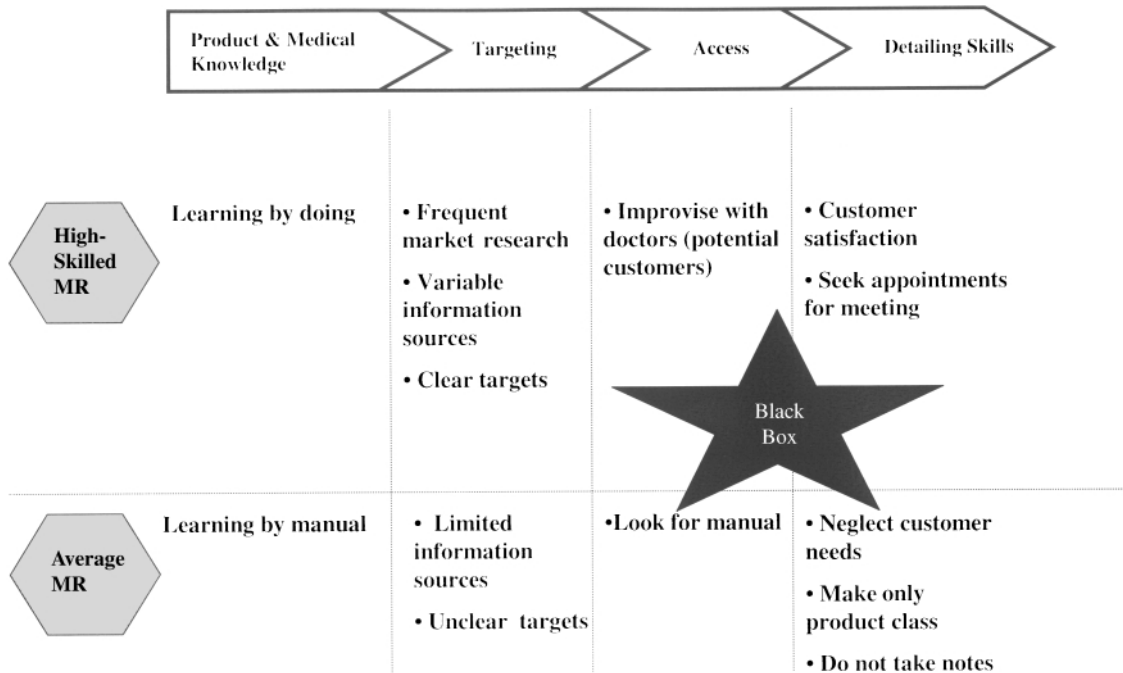

Figure 1. Skill gaps between high-skilled MR and average MR.

(Adapted from Corporate Document of Japan Roche).

getting to know individual doctors. He approaches doctors at the right time, by choosing the moment when his competitors are not around. Considering these models of behavior and action, I do not believe our established methods of training were having enough impact. It was hard to provide MRs with this kind of tacit knowledge through traditional forms of communication, such as training videos. As such, I decided to start up the SST project. I thought we would never be able to improve productivity unless we drastically improved the level of sales skills”.

Instead of requesting help from any of the external consulting firms providing services in the area of knowledge management, Shigeta focused on the theory of knowledge creation, and decided to implement hands-on efforts in the creation of knowledge (see Fig. 2). The collaborative efforts of the participants of the SST project and their distributed leadership made it possible for them to develop an original methodology for creating knowledge that ultimately contributed to

continuous innovation within the company. The marketing division of Nippon Roche was assigned to manage the SST project, and an executive of the company, Nakajima, became the co-ordinator of the project. The following section introduces what they did, and how.

The First Phase of the Project

After analyzing the skill gaps, 24 high-performing MRs from different units of Nippon Roche were carefully selected and gathered at the company’s headquarters. All 24 MRs (the SST members) worked directly under the leadership of the president, Shigeta. They discussed their skills and shared their experiences with other MRs over the course eight weeks. At the very beginning of the program, this process revolved around asking and responding to fundamental questions such as: what is our mission? For what do we exist? What is the ideal role of an MR? The participants were required to devote themselves to thinking about

**Knowledge Creating Activities
(Nippon Roche)**

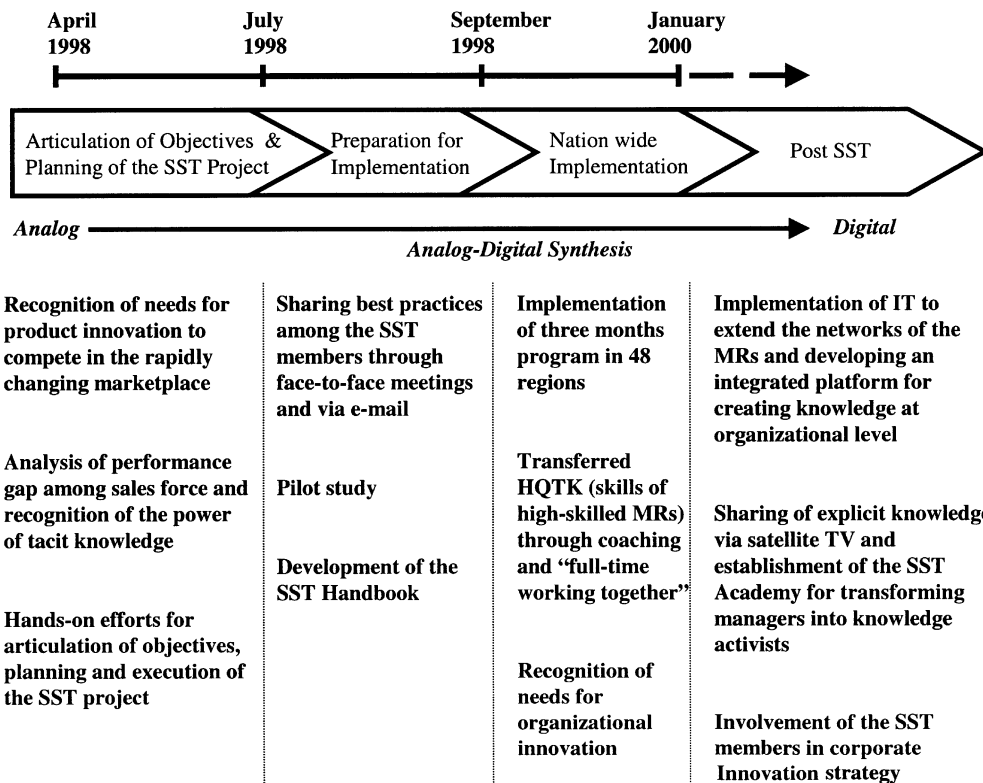

Figure 2. Knowledge creating activities at Nippon Roche.

(Adapted from Corporate Document of Japan Roche).

their own beliefs, articulating their knowledge (particularly tacit knowledge), and sharing with others. They were authorized to review highly classified corporate documents, so that they understood the background of the project and could contribute to achieving its goals.

At the end of the first phase, the project members scrapped the existing sales manual and created a new one by synthesizing knowledge (tacit and explicit) in their own words, by using metaphors and stories. From their experiences in the past, they realized that the use of metaphors and stories was critical for sharing knowledge, particularly tacit knowledge, as such approaches helped people to get inside their own minds and capture context.

Once they had created the new handbook, they experimented with it in the Tokyo area, as a part of a pilot program aimed at improving the handbook. After the experimentation, they refined the handbook further. The meaning of SST, the description of an ideal MR, the methodology to become one, together with evaluation criteria, were all clearly described in the handbook. The MRs considered the handbook to be a guideline for doing the right thing, rather than a manual for doing things right.

The Second Phase of the Project

Teams of three were seconded to different branches of the company for a period of three months. In their study, the SST project participants had found that a team of three was the optimal size to allow critical decisions to be made quickly. During the three-month nation-wide implementation period, the major activities of the SST members included:

- gathering preliminary information;
- prioritizing critical issues;
- interviewing managers;
- interviewing frontline employees;
- planning activities with average MRs;
- receiving confirmation from branch managers;
- visiting potential customers with the average MRs;
- attending meetings in which the results of the initiatives were reported;
- follow-ups after four months and six months.

The SST members also attended monthly meetings at the headquarters of the company and discussed the most desirable characteristics of an MR, as well as ways to ensure the continuous improvement of the program. It was recognized that the whole-hearted commitment of participants is critical for the creation of new knowledge.

The SST members (the selected MRs) went to different branches of the company without having any kind of legitimate power. They were not given any administrative staff to take as support, extra facilities to use, or any spare money to spend. All they had with them was their 'expert power'—the skills and experiences embedded within themselves. They helped other

MRs to capture HQTK, making it explicit as much as possible. The high-performing MRs transferred their tacit knowledge (skills and experiences) to other MRs by utilizing a variety of different mechanisms (for example, on-the-job-training, workshops, exchange experiences meetings, storytelling, etc.). The major purpose of their visits to the individual branches was not to temporarily improve performance, but rather to transfer the HQTK they had developed through their own experience.

Tacit knowledge needs care, love, trust, and commitment for it to be transferred. The project members shared tacit knowledge through socializing with other MRs at the branches, not by forcing them to learn, but by working closely with them (for example, by visiting potential customers together). The creed of the SST was 'you can't move people unless you do first, convince them, let them try, and then praise them', a well-known quote from Admiral Isoroku Yamamoto. The project members accompanied the MRs for one full week. They decided to work together full-time, realizing that socialization on a full-time basis allowed the observation, sharing, and experiencing of realities together, and such efforts were considered critical for the capturing and transferring of tacit knowledge. Also, they knew that it would take time to understand the particular context in which each MR worked; it takes time to build trust and it takes time and requires passionate effort to transfer tacit knowledge. Through working closely with the high-performing MRs, the average MRs were able to capture the knowledge (particularly tacit knowledge) needed to enhance their performance.

Evaluation of the Project

The SST project ended in January 2000, and the sales performance of the branches soared after its completion. Nippon Roche concluded that the participants of the project had become 'more valuable assets to the company'. The project motivated MRs and facilitated the capturing of the HQTK embedded in individuals, as well as the conversion of tacit knowledge into explicit, and the incorporation of synthesized knowledge into key organizational activities within the company. After coaching by the more experienced MRs, the less experienced MRs started looking within themselves with a different perspective. They started contributing to the entire organization through the creation of new knowledge.

Another remarkable outcome of the SST project was the further development of the SST members themselves. Since they were assigned to help the average MRs to capture their skills and experiences, they were also able to look at themselves from the viewpoint of others. The coaching activities helped them to redefine the knowledge (tacit) embedded within themselves. 'We brought our own experiences to the discussion and created a sort of standard for our oral presentations. We

collaborated and kept updating our presentations, and these continued to become more effective. I think we could improve our level of skills further, to the extent of fundamentally altering the entire company . . . I knew that the top management of the company would like to achieve this' (SST member).

Although the SST project was designed and executed to help average MRs to capture the HQTK of high-performing MRs for sales process innovation, the power of tacit knowledge captured the attention of those at Nippon Roche. The SST project converted individual knowledge into organizational knowledge, and the experience suggested the need for enhancing the management capabilities of managers in the separate branches. The project also clearly indicated the need for improving the links between corporate headquarters and the branches. Through initiating and executing the SST project, people involved in the project realized the importance of changing the organizational and management infrastructure of the company.

Following the successful completion of the SST project, Nippon Roche recently established the SST Academy. The goal of the academy is to develop the skills of sales managers, exploiting the know-how that has emerged from SST experiences in the past. Its target is to transform managers into leaders—knowledge activists—to provide distributed leadership in knowledge-creating processes. The SST members who contributed to organizational innovation at Nippon Roche are now playing the role of key knowledge activists within the company, and their next assignment is to contribute to corporate strategy innovation, based on knowledge creation. Nippon Roche recently announced its 'best value provider' vision, which places an emphasis on product innovation with customers.

To provide best value to its customers, Nippon Roche is now attempting to implement information technology (IT) to extend the networks of the MRs. Along with tacit knowledge, the company is now also focusing on sharing explicit knowledge via satellite TV, with the ultimate goal of developing an integrated platform for creating knowledge throughout the branches across the country. Nippon Roche has also recently formed a separate department, the Oncology Area Management Group (OAM), the mandate of which is not only to provide product knowledge, but also knowledge about the latest trends in the relevant fields. The company has also established a team, the eNR, which focuses on innovation relating to the customer relationship management (CRM) systems of the organization.

The SST Academy, OAM group, and the eNR team are three major initiatives executed by Nippon Roche after the remarkable success of the SST project. In our view, recognizing the power of tacit knowledge and making efforts to create knowledge through capturing

HQTK, synthesizing tacit and explicit knowledge, and incorporating the synthesized knowledge into corporate activities have contributed not only to sales process innovation, but also to overall organizational innovation at Nippon Roche.

The Theory of Knowledge Creation and the Nippon Roche Case

To create knowledge for continuous innovation, organizations need to adopt a holistic approach. The critical components of the theory of knowledge creation include:

- the SECI model;
- the concept of *Ba*;
- knowledge assets;
- leadership issues.

We know that tacit knowledge is subjective and experience-based. Tacit knowledge is highly personal and is deeply rooted in action and in an individual's commitment to a specific context (Nonaka, 1991). It is hard to express in words, sentences, and numbers. In the words of Michael Polyani, "we can know more than we can tell" (Polyani, 1966). However, explicit knowledge is objective. It can be expressed in words, sentences, and numbers. We understand that continuous innovation is the product of new knowledge that is generated from synthesizing tacit and explicit knowledge, and this synthesis depends on SECI, *Ba*, knowledge assets, and leadership (see Fig. 3).

The SECI Model

The SECI model describes knowledge creation as a spiral process of interactions between explicit and tacit knowledge (Nonaka & Takeuchi, 1995). In this model, S stands for socialization; E for externalization; C for combination; and I for internalization.

Socialization may start in different forms. It can occur within or outside an organizational boundary. In this process, through interactions between individuals, tacit knowledge can be created and shared. In the externalization process, tacit knowledge is made explicit through dialogue and reflections among individuals. When tacit knowledge is made explicit, knowledge is crystallized. But the successful conversion of tacit knowledge into explicit knowledge depends upon the use of metaphor, analogy, and model. Combination is the process of converting explicit knowledge into more complex and systematic sets of explicit knowledge, through interactions. And in the internalization process, explicit knowledge is converted into tacit knowledge. In this process, explicit knowledge is shared throughout the groups and organization, and converted back into tacit knowledge within individuals. This tacit knowledge becomes the valued asset of the organization (see Fig. 4).

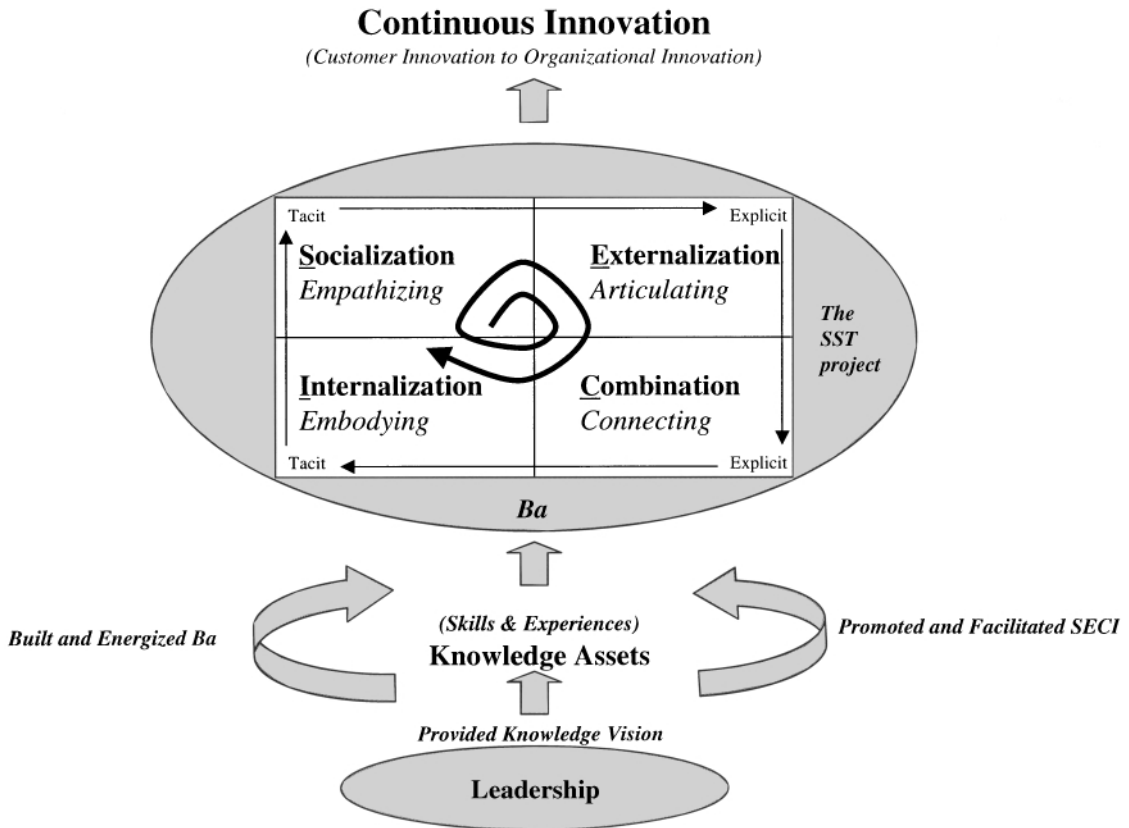

Figure 3. SECI, *Ba*, knowledge assets, and leadership in the Nippon Roche Case.

Knowledge creation is a continuous process of dynamic interactions between tacit and explicit knowledge. Articulating (converting tacit knowledge into explicit) in the externalization stage of the SECI process and embodying (converting explicit knowledge into tacit) in the internalization of the SECI process are the critical steps in the spiral of knowledge. “Knowledge creation is a craft, not a science” (von Krogh, Ichijo & Nonaka, 2000). In the Nippon Roche case, after recognizing the power of tacit knowledge, the company started making hands-on efforts towards the creation of knowledge. In the knowledge-creating process, knowledge conversion was carried into practice, and the converted knowledge made personal skills and experiences (tacit knowledge) more rich and contributed to creating new knowledge at an organizational level.

The Concept of *Ba*

Knowledge creation needs a context. The Japanese word *Ba*, which roughly means a place, provides a shared context for knowledge conversion (Nonaka & Konno, 1998). *Ba* is not necessarily just a physical

space; it can be equally a mental, a physical, or a virtual space. We understand *Ba* as a shared context in motion, a dynamic place where knowledge emerges. The most transcendental characteristics of *Ba* include synchronicity, resonance, kinetics, empathy, and sharing body knowledge. These characteristics of *Ba* are critical for sharing HQTK, embedded in individuals, and creating knowledge collaboratively.

Ba exists at many levels, and these levels may be connected to form a greater *Ba* that provides energy and quality in knowledge-creating processes. In a good *Ba*, participants get involved with whole-hearted commitment. When they get involved with such passion, they can see realities from a different perspective, deeply rooted in their own beliefs. Such commitment and involvement of participants of *Ba* are critical for sharing HQTK and creating knowledge.

The SST project itself was considered to be a *Ba* in which the medical needs of customers were redefined at the beginning. Then, monthly section meetings were also considered to be *Ba*, in which the SST members shared knowledge. *Ba* at different levels helped to create the contexts that were shared among individuals

The SECI Model of Knowledge Creation and Utilization

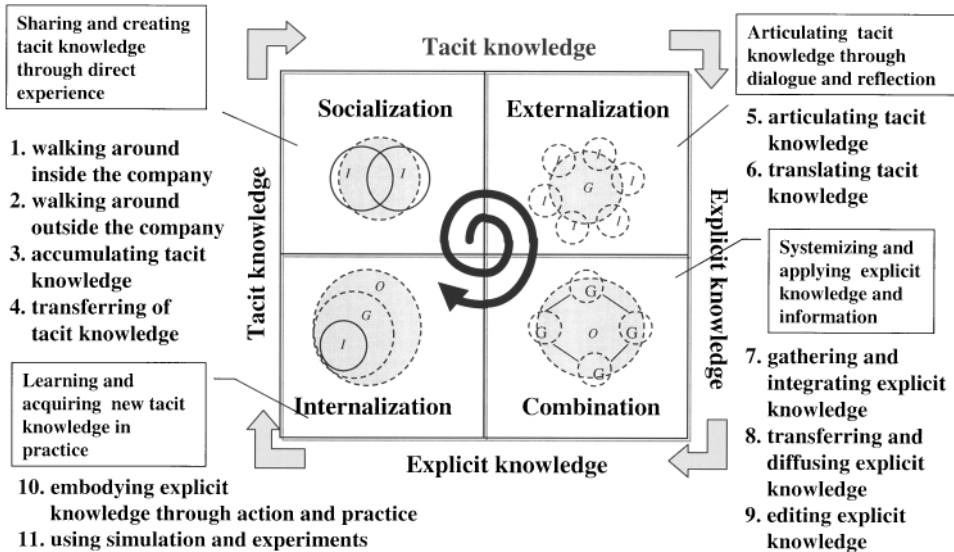

Figure 4. The SECI model of knowledge creation and utilization.

and teams at Nippon Roche. Tacit knowledge was first shared among individuals (the MRs) and then converted into explicit knowledge in the form of the SST handbook. The project helped expand individual, as well as organizational knowledge, through enriching the knowledge of individuals and teams. As a part of the SST project, various *Ba* were connected and expanded. The outcomes of the efforts went beyond knowledge creation at project level and contributed not only to sales process innovation, but also to organizational innovation.

Knowledge Assets

Knowledge assets are both inputs and outputs of an organization’s knowledge-creating activities (Nonaka, Toyama & Konno, 2000). Different kinds of knowledge assets are continuously generated and utilized in knowledge-creating processes. Knowledge assets that are generated from *Ba* include: love; conviction; energy; business concepts; product concepts; design concepts; documents; manuals; specifications; intellectual property; skills; experiences; and organizational culture.

Recognizing the value of tacit knowledge as an asset, and synthesizing such knowledge (particularly skills and experiences) are critical for continuous innovation. The Nippon Roche case clearly shows the importance of recognizing such knowledge assets (particularly the tacit knowledge embedded in the high-performing MRs) and of making an effort to capture and synthesize the HQTK embedded in people.

Leadership

Leadership roles that contribute to recognizing, capturing and transferring HQTK, synthesize tacit and explicit knowledge, and incorporate synthesized knowledge into organizational activities, are now one of the major management issues in the knowledge-creating company. In knowledge-creating processes, a single charismatic leader is not enough. A team of knowledge activists—in other words, distributed leadership of knowledge activists—and their collaborative efforts are critical for creating knowledge. The team of knowledge activists includes knowledge leaders and knowledge producers.

The knowledge leaders provide vision for knowledge creation (Nonaka, Toyama & Konno, 2000). They promote the capture and synthesis of knowledge assets (tacit as well as explicit); promote and facilitate the knowledge spiral (SECI); and build and energize *Ba*. In our view, the collaborative efforts of knowledge leaders and knowledge producers are critical in knowledge creating processes. In the Nippon Roche case, Shigeta played the role of knowledge leader. He provided knowledge vision, recognized knowledge assets, built and energized *Ba*, and promoted and facilitated SECI, the knowledge spiral.

The knowledge producers—Nakajima and the SST members—also played critical roles at Nippon Roche. In the SST project, Nakajima’s leadership role as co-ordinator of the project was very important. The SST members played the role of coach for other MRs. They transferred their skills and experiences to other MRs

through coaching and by working closely with them. They helped the average MRs to capture HQTK, and synthesize tacit and explicit knowledge for sales process innovation. In our view, the distributed leadership and collaborative efforts of Shigeta, Nakajima, the SST members, the average MRs, and the members of the support team and the follow-up team made it possible for the company to create knowledge that contributed not only to sales process innovation but also to continuous innovation at Nippon Roche.

Conclusions

Knowledge is now widely acknowledged to be a source of competitive advantage, and a great deal of attention surrounds knowledge management research and practice. We believe that creating knowledge through the synthesis of tacit and explicit knowledge is more important than managing knowledge (explicit knowledge). Nippon Roche has made it clear that organizations can benefit from recognizing the power of tacit knowledge, creating knowledge through capturing the HQTK embedded in people, making it explicit, and incorporating synthesized knowledge into key organizational activities.

We know that individuals create knowledge through collaborating with others in groups/teams in an organizational context. In today's competitive and complex business environment, helping individuals to achieve their full potential and contribute new knowledge is a critical management issue. Although coaching, mentoring, and storytelling are receiving increasing attention from KM researchers and practitioners, alone these techniques are not enough to ensure the creation of knowledge.

Through introducing the SST project, Nippon Roche facilitated the knowledge spiral (the SECI model), implemented the concept of *Ba* (the SST project), and exploited knowledge assets (skills and experiences of the high-performing MRs) to create new knowledge. The outcome of the SST project went beyond sales process innovation at the project level. It contributed to

continuous innovation at an organizational level. In our view, recognizing the power of tacit knowledge and making efforts to create knowledge through capturing HQTK, synthesizing tacit and explicit knowledge, and incorporating the synthesized knowledge into corporate activities, distributed leadership and collaborative efforts among the people involved have contributed to continuous innovation at Nippon Roche.

The key lessons for researchers and practitioners in the field of knowledge management are quite simple: just managing knowledge (explicit knowledge) by using existing tools and techniques is not enough for continuous innovation. Organizations seeking continuous innovation must recognize the power of tacit knowledge, make efforts to capture HQTK, synthesize tacit and explicit knowledge and incorporate synthesized knowledge into key organizational activities. They also must nurture and facilitate knowledge activists to play distributed leadership roles as synthesizers of knowledge. In short, to enhance competitive advantage in today's rapidly changing business environment, organizations must recognize the power of tacit knowledge and make efforts towards creating knowledge, rather than just managing it.

Innovation in Korea

Sunyang Chung

*Institute for Technological Innovation (ITI), School of Business Administration,
Sejong University, South Korea*

Abstract: Korea's development has been based on its innovation capabilities. Since the end of the 1960s, it has been making great efforts to increase its innovation potential. In three decades, Korea has been able to formulate and implement a competent national innovation system that is composed of academia, public research sector and industry. Korea has increased national R&D resources in order to improve the national innovation system. The economic crisis in the fall of 1997 did not have a severe impact on the country's innovation potential. Instead, it has become a driving force to increase the innovation potential of the Korean national innovation system.

Keywords: Innovation; National innovation system; Korea; R&D; Innovation policy.

Introduction

Korea has developed remarkably since the beginning of its history of economic development. Many excellent products in international markets, e.g. CDMA, semi-conductors, automobiles, and steel, are made in Korea. Success has been based on its capabilities of technological innovation. Korea has accumulated its strong innovation capabilities since the end of the 1960s, and, especially in the 1980s and hereinafter, such innovation capabilities have been transformed into new products and services that are competent in international markets. Korea's efforts to enhance its innovation capabilities are characterized by the very close cooperation among major actors. Here, the government has played an important role. The role of government in innovation promotion has been called its innovation policy, and it has made a great contribution to the development of Korea's national economy.

In many countries, the role of government in enhancing innovation capabilities has been a focus of innovation studies and practices. There are several definitions of innovation. Schumpeter (1934) defines innovation comprehensively as something new in product, process, organization and market. In this chapter, we refer to innovation as technological innovation, so that science, technology and innovation will be used interchangeably. Since the beginning of governmental activities in the areas of science, technology, and innovation the discussion of the legitimation of governmental intervention has been a focus of research (e.g. Ewers, 1990; Fritsch et al., 1993; Gielow

et al., 1985; Meyer-Krahmer & Kuntze, 1992). Many attempts have been made to prove positive or negative results by evaluating specific innovation public measures. In economic reality, there has been a strong resemblance between the innovation policies of different countries (Chung & Lay, 1997; Roobeek, 1990). The hectic competition in the area of technological innovation has led countries to imitate each others' innovation policies. There are numerous instances of countries having modeled their innovation policies or policy contents according to those of other countries, which have been considered successful.

It seems that one of the important reasons for this imitation of innovation policies lies in insufficient, unsystematic research in the area of innovation policies. In particular, there have not been sufficient studies on those of developing countries like Korea. If we recognize the role of innovation in Korea's economic development, there would be a strong demand to learn Korea's innovation policy. In view of the radical change taking place in the technological and economic environment and the strong competition between countries, it is very important to satisfy this learning demand. A rational innovation policy could be defined as a policy that met this demand on institutional learning.

However, it is very important to remember that such learning demand should not be confined to innovation policy *per se*, but, it should extend to institutional frame conditions around innovation policy. If we want to learn successful innovation policy, we should

understand why this policy has been successful. Any successful and rational innovation policy should be based on country-specific S&T frame conditions (e.g. Chung & Lay, 1997; Porter, 1990; Vickery & Campbell, 1989). The emphasis on national innovation frame conditions stems from the institutional approach to technological innovation. It is a relatively recent phenomenon to emphasize the importance of the institutional frame conditions surrounding science, technology, and innovation activities (see e.g. Freeman, 1987, 1988, 1989; Lundvall, 1988; Majer, 1977; Nelson, 1988; Nelson & Winter, 1977, 1982). Now, these national institutional conditions for technological innovation are referred to as a *national innovation system*.

Even though there have been many studies on national systems of innovation, they have been carried out at a general level. Detailed analysis on specific actor groups in a national innovation system has not been systematically analyzed. More importantly, they have concentrated on analyzing national innovation systems of developed countries (e.g. Nelson, 1993). Insufficient investigation has been made specifically on national innovation systems of developing and less developed countries. As developing countries have been trying to establish more efficient national innovation systems in order to catch-up to developed countries, it would be also very interesting to look into developing countries' national innovation systems. Also, from successful developing countries we can identify important policy implications that might be useful for not only developing but also developed countries.

One of most interesting countries to learn from would be Korea, which has been one of the fastest growing economies in the world. Korea's economy has been developed, based on its accumulation of innovation capabilities. Many innovation actors could accumulate their innovation capabilities to a large scale, especially based on the active innovation policy of the Korean government. However, it was confronted with an economic crisis in the second half of the 1990s so that it had to be under the IMF jurisdiction in the fall of 1997. During the IMF jurisdiction period, Korea's economy experienced a deep recession. However, Korea could overcome this crisis much faster than expected, and it could regain a strong economic driving force, which is comparable to, and even much stronger than, that before the IMF jurisdiction. In this period of overcoming the crisis, science, technology, and innovation have played an essential role.

The purpose of this chapter is to analyze Korea's efforts to enhance innovation capabilities since the beginning of its industrialization. Special attention is paid to how Korea has overcome the IMF jurisdiction in the late 1990s and what kind of role innovation has played in this overcoming process. As a research framework we will adopt a concept of a national

innovation system. We will analyze the Korean national innovation system according to its major innovation actor groups, i.e. government, academia, public research sector, and industry. As there have been only a few researches on Korean national innovation system (e.g. Chung, 1996; Chung & Lay, 1997; Kim, 1993), this chapter would be very helpful for understanding the dynamism of the Korean national innovation system.

This chapter consists of six major parts. An introduction, 'National Innovation System' deals with the concept of a national innovation system as a theoretical framework of the chapter. Here, we will briefly discuss definition, purpose, and compositions of national innovation system. In 'Role of Government', we will analyze the role of government, which is also a major actor group in the national innovation system, in accumulating innovation capabilities since the beginning of Korea's industrialization. The strong role of the government in enhancing innovation capabilities is an important characteristic of Korean innovation system (Chung & Lay, 1997; Kim, 1993). We look into how Korea's innovation policy has been developed in the process of its industrialization. 'Division of Labor Among Innovation Actors' is concerned with the division of labor among actual innovation actor groups, i.e. academia, public research sector, and industry. Statistics on national R&D resources are used in this analysis. Special attention will be placed on what kind of role of these innovation actors played in overcoming the IMF jurisdiction in the late 1990s. 'IMF Jurisdiction and Korea's Innovation Potential', based on previous analysis, deals with the impact of the economic crisis during the IMF jurisdiction on the Korea's national innovation system. In 'Conclusions', we will summarize the characteristics of the Korean national innovation system and draw some meaningful implications for other countries.

National Innovation System

At present the concept of a national innovation system (NIS) is a frequent topic of discussion in innovation policy research (see e.g. Chung, 1996; Chung & Lay, 1997; Freeman, 1987; Lundvall, 1992; Nelson, 1988, 1993; Patel & Pavitt, 1994). The scholars in this area emphasize interactive learning between knowledge producers and users for the generation of innovations and the role of nation state for it. They also argue that an institutional framework plays an important role for interactive learning which leads to innovation. As a relevant institutional framework for innovation they concentrate on the analysis on the national level. If we agree that S&T and innovation policy targets at enhancing national competitiveness, this concept will be very relevant for this purpose and also for an analysis on competitiveness at national level.

There are several definitions of national innovation system. As Lundvall (1992) illustrated, there can be not

only a broad definition, which encompasses all inter-related institutional and non-institutional factors which are concerned with generating, diffusing, and exploiting innovations, but also a narrow one, which includes organizations and institutions in searching and exploring, e.g. R&D departments, technical institutes and universities. In this chapter we follow a narrow definition for the effective analysis of national innovation system. We define a national innovation system as a complex of institutions, i.e. actors, in a nation, which are directly related with the generation, diffusion, and appropriation of technological innovation.

Under this definition we can identify four groups of actors in a national innovation system, i.e. business firms, public research institutes, universities, and government. The first three categories are actual research producers who carry out R&D activities while government can play the role of coordinator between the research producers in terms of its policy instruments, visions and perspectives for the future. The relative importance of these four groups in a national innovation system differs according to the history and country-specific frame conditions of the national innovation system. In general, the government plays a more important role in emerging or developing national innovation systems than in existing ones. Innovation policy is crucial in formulating a new national innovation system and improving its innovation performance.

In the concept of a national innovation system, the inter-relationship or interaction between innovation actors is very important. Most countries prepare for important policy measures to promote these interactions. Such efforts could be measured by the R&D resources of a national innovation system. Looking into the relative distribution of the R&D resources among innovation actor groups, we can identify their relative importance in a national innovation system.

From the terminology *national*, we can easily assume that national innovation systems will differ between countries. Some authors have already performed international comparisons of various national innovation systems with explicitly using terminology of national innovation system (e.g. Edquist & Lundvall, 1993; Nelson, 1993) and without using this terminology (Martin & Irvine, 1989). Historically developed, national innovation systems vary and should vary greatly from one country to another (e.g. Chung, 1996; Chung & Lay, 1997; Ergas, 1987). Therefore, creative learning from other national innovation systems is needed to refine and improve any national innovation system. This implies that, in order to gain a reasonable understanding of a national innovation system, a kind of historical analysis should be applied. In general, the target of learning has been confined in the national innovation systems of advanced countries. However, we should make an effort to learn from the successful innovation systems

of developing countries. Under the rapidly changing economic and technological environment, only a national innovation system that has a strong demand on learning could be competent and successful.

Although broadly divisible into four groups of innovation actors, a national innovation system is not easy to grasp because they consist of numerous and diverse institutions and organizations. However, the concept of national innovation system is very helpful to analyze them, because it is based on the institutional theory, which emphasizes the possibility of institutional learning. We argue that the analysis of a national system of innovation should at least examine the role of the government and the division of labor among research producers, i.e. academia, public research sector, and industry. Based on the careful analysis on these actors and institutions, we can identify some important characteristics of a national innovation system.

Role of Government

In Korea, the government has been playing a very important role in almost every aspect of society. As a centralized country, the Korean government has increased its efforts to enhance innovation capabilities. Korea has specific innovation policies that could be interesting to foreign countries. Several methods might be adopted to classify and describe the historical role of the central government in the area of science and technology. It could be described in terms of changes in the administration of a central government or in terms of decades. According to our studies, there has been a tendency of changing policy directions in many countries with the change in decades (Bruder & Dose, 1986; Chung & Lay, 1997). The Korean government also has had a tendency to adopt some major new policy programs with the turn of decade. There have been some studies and reports on the historical development of Korean innovation policies, e.g. MOST (1990), OECD (1996), and Chung & Lay (1997). They discuss the role of government in Korea's accumulating innovation capabilities in terms of decades. Table 1 shows the role played by the Korean government in science, technology, and innovation in terms of decades.

In the 1960s

It was not until the beginning of the 1960s that national efforts for the promotion of science, technology and innovation were initiated in line with the *First Five Year Plan for Economic Development*, which was introduced in 1962. Since then, the Korean government has intervened very strongly in the areas of science, technology, and innovation. The government has applied a strong technology-push approach in the construction and improvement of the national system of innovation. Korean economic policy in the 1960s was characterized by import substitution and export

Table 1. Role of Korean government in national innovation system.

Periods	Characteristics of Korean innovation policies
1960s	<ul style="list-style-type: none"> • beginning of scientific education
1970s	<ul style="list-style-type: none"> • beginning of S&T infrastructure construction • construction of government-sponsored research institutes • technical, scientific and further education • beginning of industrial R&D
1980s	<ul style="list-style-type: none"> • promotion of key technologies through <i>National R&D Program</i> • activation of industrial R&D • mass production of highly-qualified R&D personnel • expansion of S&T-related ministries
1990s	<ul style="list-style-type: none"> • expansion of R&D resources and their efficient utilization • promotion of academic innovation potentials • introduction of regional innovation policy • introduction of Research Council system
2000s	<ul style="list-style-type: none"> • enactment of <i>Basic Law of Science and Technology</i> • selection and concentration on major technologies (5T) • coordination of innovation policies • basic research and welfare technologies

orientation. At this time, automobile production (1960), ship-building (1967), mechanical engineering (1967), and electronics industry (1967) were the central concern of governmental promotion (see Byun, 1989; Song, 1990). In order to activate this economic policy effectively, an institutional framework in the area of science and technology began to be established, for example:

- the foundation of the Korea Institute of Science and technology (KIST) in 1966, which carries out R&D activities, especially in the technology areas mentioned above;
- the passing of the Science and Technology Promotion Act in 1967;
- the establishment of the Ministry of Science and Technology (MOST) in 1967, which has the task of formulating and implementing science and technology policy.

At the same time Korean universities attempted to produce as many engineers as possible, because there was a great shortage of qualified engineers, who were indispensable for the development of the Korean economy. Korea's national innovation system concentrated on the digestion and imitation of imported technologies from advanced countries. There were no concrete S&T policy measures and programs in Korean system. Most technological and innovation needs were covered by KIST, which was the only research institute in Korea.

In the 1970s

In the 1970s the Korean government placed the main emphasis of its industrial policy on the establishment and expansion of heavy, chemical, and export-oriented industries (Byun, 1989; Song, 1990). These industries

were technology-oriented and needed a certain level of domestic technological and innovation capabilities. With a view to meeting the needs of these industries, the Korean government founded several corresponding government-sponsored research institutes, e.g. Korea Institute of Machinery and Materials (KIMM), Korea Research Institute of Chemical Technology (KRICT), and Electronics and Telecommunication Research Institute (ETRI). These government-sponsored research institutes in addition to KIST were the grounding stones of the Korean national innovation system.

During this period, the major emphasis of the innovation policy shifted from the simple imitation of imported technologies to their complex adoption and the domestic development of simple, less complex technologies. Creative imitation started in this period (Kim, 1993). The Korean government implemented a series of strong policies for producing researchers and engineers as many as possible, who were needed by these strategic industries. Some policy measures were initiated to further train these engineers. Some big Korean industrial enterprises, especially those in the industries mentioned above, began to carry out their own R&D activities.

In the 1980s

The 1980s were characterized by a very strong increase of industrial R&D activities within the Korean national innovation system. Using several policy instruments, the Korean government motivated industrial enterprises to establish their own R&D institutes, so that the number of private research institutes rose dramatically from 53 in 1981 to 966 in 1990 (KITA, each year). In line with this strong increase of industrial R&D capabilities, the government tried to shift the Korean

industrial structure away from traditional branches towards high technology areas.

In 1982 the Korean government initiated the first big project in the areas of science, technology, and innovation, the *National R&D Program*. This program aimed at developing not only high technologies but also large technologies (MOST, 1987). In this program the industrial key technologies that industrial companies could not deal with alone were developed through joint projects, especially between industrial companies and government-sponsored research institutes. As a result of strong R&D efforts in the public and private sectors in this period, Korea could attain a certain level of innovation capabilities to compete with advanced countries in some advanced technology areas like semiconductor (STEPI, 1991).

Since the end of the 1980s, several ministries, the Ministry of Commerce, Industry and Energy (MOCIE), the Ministry of Environment (MOE), and the Ministry of Information and Telecommunications (MOTI), became concerned with science, technology and innovation. In 1987, the Ministry of Commerce, Industry and Energy (MOCIE) initiated the *Program for Nurturing Industrial Technology Base* for the first time among S&T-related ministries except the Ministry of Science and Technology (MOST). Following the MOCIE, other ministries started to initiate their own programs. It made a great contribution to enhancing innovation capabilities in many industrial sectors. However, the problem of resource duplication had started during this period, as these ministries competed very strongly with each other to collect more innovation resources.

In the 1990s

Despite the greatly increased importance of industry, in the 1990s, the Korean government intervened in the areas of science, technology and innovation more actively than before. Based on some successes in the last decade, the Korean government recognized the importance of S&T and innovation in economic development. The government tried to step up national R&D expenditures, with the result that in 1991 the share of national R&D expenditures in Gross Domestic Product (GDP) exceeded 2% for the first time in the Korea's history (MOST, each year).

Based on the strong increase in industrial R&D capabilities, in the 1990s, industrial companies took over major areas of R&D activities, which were previously performed by government-sponsored institutes. As a result, during the 1990s there were frequent reorganization, merger and disorganization of Korean public research institutes. Criticism on the role of public research institutes rose in this period (Chung, 2002; Chung et al., 2001; Kim et al., 2002; Song et al., 2001). Therefore, in March 1999, the Korean government introduced a new public research system, the

Research Council system, by benchmarking the Germany's *Gesellschaft* system.

In this period, the Korean government very strongly promoted R&D and innovation capabilities of Korean universities, which had been the weakest point of the Korean innovation system until this period (Chung, 1996; Chung & Lay, 1997; OECD, 1996). In order to strengthen academic R&D capabilities, the government has initiated the Excellent Research Center (ERC) program for the most advanced research centers in universities in 1990. This program consists of Science Research Centers (SRCs) in the area of basic science and Engineering Research Centers (ERCs) in the area of engineering and applied research. When a center in a university is accepted as an excellent research center, it can be supported by a very large amount of money for ten years. As there was a hierarchy in the level of research capabilities in Korean universities, a few best universities, especially in Seoul, dominated the excellent research centers. Therefore, the Korean government initiated the Regional Research Center (RRC) Program in 1995 in order to strengthen the R&D and innovation capabilities of universities in other regions outside of Seoul. As of 2001 there are 25 SRCs, 34 ERCs, and 45 RRCs (MOST, 2001). These centers have played an important role in enhancing R&D capabilities of Korean universities.

In the middle of the 1990s, a new policy direction arose in Korean innovation policy. The Korean government initiated a regional innovation policy. Korea developed in the middle of capital city, Seoul, and its outskirts. The development of politics, economy, society and culture was centered in these areas, so that the regional level of industry, science and technology was still very low. The central government was always a dominant player in innovation policy and there had not been a regional S&T policy in Korea. Even in 1999, the R&D budget of the total regional governments represents only 6.8% of the national S&T budget (MOST, 1999). Korean research organizations are located in and around Seoul and in Dae-Duck Science Park, which is about 200 Km south of Seoul. Nowadays, however, regional governments have recognized the importance of S&T for the economic development of their regions, especially since the inauguration of the *Local Government System* in March 1995. As of 2000, eight among 16 regional governments established an independent organization for promoting technological and innovation capabilities in their regional administrations (Chung, 2002; MOST, 1999). We can say that Korea is in the early stages of its regional innovation policy.

In the 2000s

Turning to the 21st century, Korea initiated a very ambitious plan to enhance technological and innovation capabilities more systematically. The Korean government enacted a comprehensive law, the *Basic*

Law of Science and Technology, in January 2001, which aimed at more systematic promotion of science and technology. According to this law, the *Basic Plan of Science and Technology* should be formulated and implemented every five years (MOST, 2001). This plan comprised of detailed S&T plans of all S&T-related ministries. Based on the law, the first *Basic Plan for Science and Technology* was formulated in December 2001. This plan had a comprehensive goal and implementation strategies for enhancing technological capabilities for next five years, e.g. from 2002 until 2006. According to this plan, Korea aims at reaching the top 10 countries in the areas of science, technology, and innovation (MOST, 2002). In particular, Korea selected six technology areas, i.e. information technologies (IT), biotechnologies (BT), nanotechnologies (NT), space technologies (ST), environmental technologies (ET), and cultural technologies (CT), which will be essential to the knowledge-based 21st century.

As technological innovation was promoted by many ministries and large amounts of money was invested in science, technology and innovation, it was necessary to coordinate innovation policies among major S&T-related ministries. Therefore, the *Presidential Committee on Science and Technology* was established in 1999 to better coordinate innovation policies among ministries. This committee is originated from the *Committee of S&T-Related Ministers*, whose chairman was Minister of Science and Technology. Because there had been strong competition in innovation policies, especially sector-specific ones, between ministries, it was impossible to attain effective policy coordination under this old committee. However, much better coordination was anticipated, as the chairman of this new committee was the President of Korea.

In addition, regional innovation policy gained an important priority in the Korean innovation policy, especially those of the Ministry of Science and Technology (MOST) and the Ministry of Commerce, Industry and Energy (MOCIE). Special attention was placed on enhancing region-specific technological capabilities that could be transformed into a regional comparative advantage. With regard to the policy goals, future-oriented goals, e.g. enhancing the quality of life in terms of science, technology and innovation, were seriously pursued for the first time in the Korean innovation policy. That implies that the Korean government fully recognized the importance of science, technology and innovation in the development of Korean economy and society.

Division of Labor Among Innovation Actors

A national innovation system can be described in terms of their national R&D resources, which reflect not only the history of the development of the system itself, but also the division of labor between research producers, i.e. innovation actors. In this section, we will discuss national R&D resources in Korea since the beginning

of the 1980s. Special focus is placed on the development of Korea's national R&D resources since the middle of the 1990s. This section describes the dynamics of the Korean national innovation system. There are two kinds of statistics on national R&D resources, i.e. national R&D expenditures and number of researchers. The former can be classified into sources and uses of R&D expenditures. In this chapter we will analyze these statistics in depth in order to grasp the dynamism of the Korean national innovation system.

(1) R&D Expenditures

The short history of the Korean national innovation system is confirmed by examining its national R&D resources. Until the beginning of the 1980s, Korea invested very little in R&D activities. Korean national R&D expenditures in 1980 only amounted to 0.58% of GDP. However, national R&D expenditures rose dramatically over the 1980s, so that in 1990 about 1.91% of GDP was spent on national R&D activities. This is equivalent to an annual increase rate of 31.2% over this period. In the 1990s, the importance of technological innovation had been widely diffused in Korean society (Chung, 2001b). The total R&D expenditures in 1995 were 94 billion won, which amounted to 2.50% of Korea's GDP. Korea continues to be one of the countries that make a strong investment in R&D activities. There are not many countries, even advanced ones, that are comparable to Korea.

In the 1990s, until the IMF jurisdiction in the fall of 1997, the total R&D expenditures had increased dramatically. The years 1995, 1996, and 1997 showed an annual increase rate of over 10%, especially 1995 that showed a 19.6% increase rate. However, 1998, showed a 7% decrease rate, just after the IMF jurisdiction. Such a decrease in national R&D investment was for the first time in the history of Korean S&T and innovation development. However, the decrease rate was not so severe, as it was only 7%. Only 1998 showed a decrease rate, and the year 1999 turned to an annual increase rate of 5.2%. In particular, the year 2000 showed 16.2% of increase rate, which was very comparable to the year 1996 before the IMF jurisdiction. This implies that Korea has not been influenced very much by the IMF jurisdiction. As a result, Korea's total national R&D expenditures in 2000 were 138 billion won. The share of total national R&D expenditures in GDP in 2000 was 2.78%. This implies the Korea was one of the most significant R&D investing countries in the world, even after the deep recession.

When we look at the sources of national R&D expenditures, the private sector has played a far more significant role in R&D financing than the public sector, especially since the beginning of the 1990s. However, until the end of the 1970s, Korean national R&D expenditure had been financed predominantly by

Table 2. Sources of Korea's national R&D expenditures.

(Unit: hundred million Won)								
	1980	1990	1995	1996	1997	1998	1999	2000

Source: MOST (Each Year), *Report on the Survey of Research and Development in Science and Technology*, Seoul.

the public sector. In 1980, about 50% of national R&D expenditures were still publicly financed. However, the role of the public sector diminished in the 1980s as a result of the strong increase in financing by the private sector. Thus, the ratio of public to private financing was about 15.9% vs. 84.1% in 1990. This implies that the private sector recognized the importance of technological innovation more strongly than the public sector did. In fact, industrial companies established their own R&D institutes and increased their R&D expenditures to a large degree.

The sharing between the public and private sector in R&D financing changed from 19% vs. 81% in 1995 through 23% vs. 77% in 1997 to 25% vs. 75% in 2000. This indicates that in the 1990s the public sector increased its financing more than the private sector did. Private companies could not increase its R&D expenditures because the recession resulted from the IMF jurisdiction. They were influenced more strongly by the recession than the public sector. When we look at the trend of R&D expenditures according to sectors, the public sector has always increased its financing in R&D activities. In particular, it increased annual R&D investment in the middle of the 1990s: 41.3% in 1995 and 34.7% in 1996. Even in 1998 it increased R&D investment at a rate of 7.1%. This implies that the public sector in Korea recognized the importance of science, technology, and innovation in overcoming the crisis in this period. However, it is safe to say that the public sector was also influenced by the IMF jurisdiction. The annual increase rate declined sharply during the IMF jurisdiction period and it did not recover after the jurisdiction, i.e. in 1999 and 2000.

The private sector was strongly influenced by the IMF jurisdiction. Before the IMF jurisdiction the Korean private sector had shown over 10% of annual increase rates of R&D investment. However, in 1998, the private sector showed a decrease rate of 11.2%. This suggests that the Korean private companies

decreased a very significant portion of their R&D investment because of the recession in the IMF jurisdiction period. We could also see the declining trend of R&D investment in the private sector since 1995. The rate declined from 15.4% in 1995 to 10.1% in 1997. This indicates that the Korean economy was in recession even before the IMF jurisdiction. Also, Korean industrial companies did not take technological innovation seriously enough to overcome the recession in this period.

However, in 2000, the private sector showed a much higher level of increase rate. Showing a 19.2% annual increase rate, the private sector made greater R&D investment in 2000 than in the middle of the 1990s. In means that Korean companies, having experienced the economic crisis in the late 1990s, recognized the importance of R&D activities to overcome the recession and to enhance their competitive advantage in globalized international markets. Korean companies implemented an aggressive R&D and innovation strategies after the IMF jurisdiction period.

Looking at the national R&D expenditures according to the performing sectors in the national innovation system, we can see the changes in the division of labor in the Korean national innovation system since the beginning of the 1980s (see Table 3). Until the end of the 1970s almost all Korean R&D activities were carried out by public research institutes. At this time the industrial R&D infrastructure was not in existence in Korea.

Even in 1980, the public research institutes were still absorbing 49.4% of national R&D expenditures, while the share of industry was only 38.4%. However, as in the financing of national R&D resources, the role of the private sector in national R&D activities increased continuously over the 1980s. As a result, Korean industry was utilizing 74.0% of national R&D expenditures in 1990. This confirms the strong increase of R&D capabilities of Korean industry. For example,

Table 3. National R&D expenditures by sector of performance.

(Unit: hundred million Won)

	Total R&D exp.	Public research sector			Academia			Industry		
		Amount	Increase rate	Share	Amount	Increase rate	Share	Amount	Increase rate	Share
1980	2,117	1,045	6.4%	49.4%	259	56.6%	12.2%	813	37.2%	38.4%
1990	32,105	5,917	23.9%	18.4%	2,443	6.6%	7.6%	23,745	18.8%	74.0%
1995	94,406	17,667	15.3%	18.7%	7,709	26.6%	8.2%	69,030	20.2%	73.1%
1996	108,780	18,956	7.3%	17.4%	10,188	32.2%	9.4%	79,636	15.4%	73.2%

the number of Korean industrial private research institutes increased from 53 institutes in 1981 to approximately 1,200 institutes in 1991 (KITA, each year). As a result, the industry took over the leading position in the Korean national system of innovation from the public research institutes. The Korean universities, however, always played a very minor role in the national innovation system in the 1980s. Only 12.2% of national R&D expenditures were utilized by the universities in 1980 and their role diminished further in the 1980s. In 1990, the share of universities in the total R&D expenditures was only 7.6%. As a result, the share of national R&D expenditures in 1990 was 18.4% (public research institutes) vs. 7.6% (universities) vs. 74.0% (industrial companies).

During the 1990s the share of innovation actor groups in national R&D expenditures changed. The share of R&D expenditures among public institutes, universities, and companies changed from 18.7% vs. 8.2% vs. 73.1% in 1995 to 14.7% vs. 11.3% vs. 74.0% in 2000. Private companies were the greatest R&D performing actors and their role had not changed during this period. However, private companies decreased their R&D expenditures in 1998 (-9.9%) and, by having 6.8%, the increase rate in 1999, just after the IMF jurisdiction, was much smaller compared to that before the IMF jurisdiction. Korean private companies were strongly affected by the recession in the IMF jurisdiction period. However, Korean private companies showed a very high level of annual increase rate in R&D expenditures, i.e. 20.5% in 2000, which was bigger than that of 1995. This suggests that Korean companies reached again the level of R&D intensity in the middle of the 1990s and showed even stronger R&D activities. As a result, the portion of private companies in national R&D expenditures in 2000 was 74.0%. It was greater than that of 1995 (73.1%).

In the 1990s, the role of public research institutes declined. The public research institutes' portion in

national R&D expenditures declined from 18.4% in 1990 through 18.7% in 1995 to 14.7% in 2000. The role of public research sector declined especially in the second half of the 1990s. In fact there was a strong structural reform in the Korean public research sector in the beginning of 1998, which resulted in the reduction of research potential of public research institutes (Chung, 2001a). It is confirmed by the decrease rate of this sector's R&D expenditures in 1999 (-5.7%) and also by the very small increase rate in 1998 (1.5%). In 2000 the public research sector showed only 2.7% of annual increase rate, which was far smaller than that of 1995, i.e. 15.3%. All these statistics on the public research sector showed that its role has declined remarkably during the 1990s and such a trend is still continuing. Considering the successful role of the Korean public research institutes in the history of the Korean economic development, it is a challenging issue for Korea how to enhance the role of public research institutes in the Korean national innovation system from quantitative and qualitative perspectives.

By contrast, Korean universities increased their R&D activities during the 1990s. As mentioned above, Korean academia had been the weakest area in the Korean national innovation system, especially before the beginning of the 1990s (Chung & Lay, 1997; OECD, 1996). However, Korean universities increased their R&D potential on a very large scale especially during the second half of the 1990s (see Table 3). The portion of Korean universities' total national R&D expenditures increased from 8.2% in 1995 to 11.3% in 2000. In particular, more than 25% of the annual increase rates were shown before the IMF jurisdiction. As a result, Korean academia could play a relevant role in the Korean national innovation system since the middle of the 1990s. The impact of the recession on academic research was not so severe, as only a 0.5% decrease rate was shown in 1998, shortly after the year

of IMF jurisdiction. However, Korean academia showed a 13.1% of annual increase rate in 1999 and 9.1% in 2000. Nevertheless, Korean universities were influenced by the recession to a degree, because the annual increase rates after the recession were much smaller than those before the IMF jurisdiction period.

(2) R&D Manpower

We can also see the transformation of technological innovation activities in Korea in terms of R&D manpower. Table 4 shows the trend in the number of researchers of the Korean national innovation system. In 1980, the Korean system of innovation comprised only 18,434 researchers. During the 1980s the number of researchers rose rapidly to 70,503 researchers in 1990. This corresponds to an annual increase rate of 14.4%. In particular, the number of highly-qualified researchers increased during this period. In 1980, academia was employing 47.0% of the total researchers, so that it was the biggest employer of Korean researchers. The second biggest employer was the industry by having 27.9% of total researchers. It is worth noting that public research institutes were still employing about 24.9% of researchers in 1980.

During the 1980s, as shown in the financing of national R&D resources, the role of the private sector in national R&D activities increased continuously. As a result, in 1990, Korean industry became the biggest employer for researchers by having 54.9% of total researchers. It was due to the strongly increased establishment of private research institutes. In fact, the Korean government implemented several policy measures to induce private companies to employ researchers. For example, a researcher who had a master degree could be exempt from military service if he had been employed in a private research institute for

five years. However, Korean universities were also very important employers for researchers during the 1980s, especially for researchers with a Ph.D. degree. But their role had been diminished in the 1980s, and in 1990 universities employed 30.3% of total researchers in Korea. Still public research institutes had a significant proportion of Korea's researchers by having 14.8% of the total researchers in 1990.

During the 1990s the number of Korean researchers more than doubled. In particular, there was an increase of more than 30,000 researchers in the second half of the 1990s. However, 1998 showed a 6.3% decrease compared to the previous year. This implies that the IMF jurisdiction had a severe impact on the number of researchers in the Korean national innovation system. However, 2000 showed a very strong increase in researchers. Compared to the previous year, there was an 18.9% increase in the number of researchers in the Korean national innovation system as a whole. During this period, there were some changes in the share of researchers among major innovation actor groups in Korea. The share of researchers among public research institutes, universities, and private companies changed from 14.8% vs. 30.3% vs. 54.9% in 1990 through 11.7% vs. 34.8% vs. 53.5% in 1995 to 8.7% vs. 32.3% vs. 59.0% in 2000. This shows that private companies increased the number of researchers to a large scale, while public research institutes decreased dramatically.

Private industry has been the biggest employers of researchers in the Korean national innovation system. Especially in the first half of the 1990s, Korean companies increased the number of researchers. The number increased from 38,737 researchers in 1990 to 68,625 researcher in 1995. However, during the second half of the 1990s, Korean companies were not so

Table 4. Number of researchers by year.

(Unit: person)

(Share)	(27.9%)	(54.9%)	(53.5%)	(54.0%)	(53.9%)	(50.9%)	(52.3%)	(59.0%)

Source: MOST (Each Year), *Report on the Survey of Research and Development in Science and Technology*, Seoul.

aggressive in employing researchers because of the recession in this period. In particular, in 1998, the year just after the IMF jurisdiction, there was a remarkable decrease in researchers by having an 11.6% decrease rate. However, around the end of the 1990s, Korean companies were very aggressively recruiting researchers in trying to overcome the recession. In particular, the year 2000 showed a 33.9% annual increase rate of researchers. As a result, in 2000, 59% of the total researchers were employed by the industry. This implies that Korean companies recognized the importance of science, technology and innovation in overcoming the recession and enhancing their competitiveness. In line with the increase in R&D investment, Korean companies increased well-qualified researchers to a remarkable scale.

In contrast, Korean public research institutes decreased the number of researchers in the 1990s. There were several years that the number of researchers in this sector decreased, e.g. 1995, 1997, and 1998, compared to the previous year. In the same period, other sectors, i.e. academia and industry, increased researchers except the IMF jurisdiction period. Between 1995 and 2000, it showed a reduction of about 10,000 researchers in the public research group. In particular, 1998 shows a decrease of 2,598 researchers, which was about 17% of the total researchers of this sector. We can ascribe two reasons for this. First, in this period, the Korean government demanded a strong and radical structural transformation in the public research sector. During this transformation period, many researchers had to leave public research institutes (Chung, 2001a). Second, there was a strong gale of start-ups in Korean society, so that many well-qualified scientists and engineers left institutes and started their own venture companies. In 1999, however, there was an increase (11.1%) of researchers in this sector, but 2000 showed a weak decrease. This indicates that the Korean public research sector was under a strong transformation process during the IMF jurisdiction.

Finally, Korean universities were always important employers for researchers in the 1990s. Korean academia increased researchers steadily and, in 2000, 32.3% of the total researchers were employed by this sector. In particular, academia was always the biggest employer for researchers with Ph.D. degrees far outnumbering other actor groups. Over 75% of these well-qualified researchers were employed by academia. Considering that academia expended just slightly over 10% share of the total national R&D expenditures at least in the second half of the 1990s, Korean universities had always possessed too many researchers, especially those with Ph.D. degrees. Therefore, it would be desirable that academia reduces the number of well-qualified researchers, and additionally more R&D investment should be made to academia. In summary, the Korean government should prepare for relevant measures for the virtuous flow of researchers

from academia to industry in order to strengthen the national innovation system.

IMF Jurisdiction and Korea's Innovation Potential

It is interesting to investigate more systematically whether, and how much, the economic crisis during the IMF jurisdiction influenced the Korean national innovation system. Just after the IMF jurisdiction, many experts expected the Korean economic crisis to last a long time, because the main reason being there was a structural problem in the Korean economic system. However, Korea overcame the economic crisis in a much shorter period than most expected and regained its economic vitality by the turn of the new century. We could ascribe the main reason for this to the continuous increase in innovation potential of the Korean national innovation system.

Figure 1 summarizes the trend of innovation capabilities of the Korean national innovation system since the middle of the 1990s. It depicts both national R&D expenditures and the number of researchers according to major innovation actor groups. It also shows the similar trend between R&D expenditures and number of researchers before and after the IMF jurisdiction. According to Fig. 1, the unexpected economic crisis towards the end of the 1990s did not have a severe impact on the Korean national innovation system. The recession under the IMF jurisdiction did influence innovation activities of the Korean national innovation system. In 1998, just after the IMF jurisdiction, the total national R&D investment recorded a decrease of 7.0% compared to the previous year for the first time in the history of the Korean national innovation system. There was also a 6.3% of decrease in the number of researchers in the same year.

Looking into major actor groups, the industry was most severely influenced by the IMF jurisdiction. Compared to 1997, it decreased R&D investment by approximately 9.9% and research investment by about 11.6% in 1998 also for the first time in Korea's industrial development. The Korean public research sector was also affected by the deep recession, but not as severe as in industry. However, it had to lay off many researchers in this period so that there was a 17.1% of decrease in the number of researchers in 1998. However, academia was not affected by the recession, even though there was a slight decrease in R&D expenditures and manpower. Overall, the deep recession under the IMF jurisdiction made an influence on innovation activities of the Korean industry and public research sector.

However, the impact of the deep recession on the Korean national innovation system lasted just one year, i.e. 1998 or at the longest, two years until 1999. By the turn of the new century, Korea regained its dynamism and innovation capabilities. In 1999, just less than 2 years after the IMF jurisdiction, the Korean national innovation system regained its innovation vitality to the

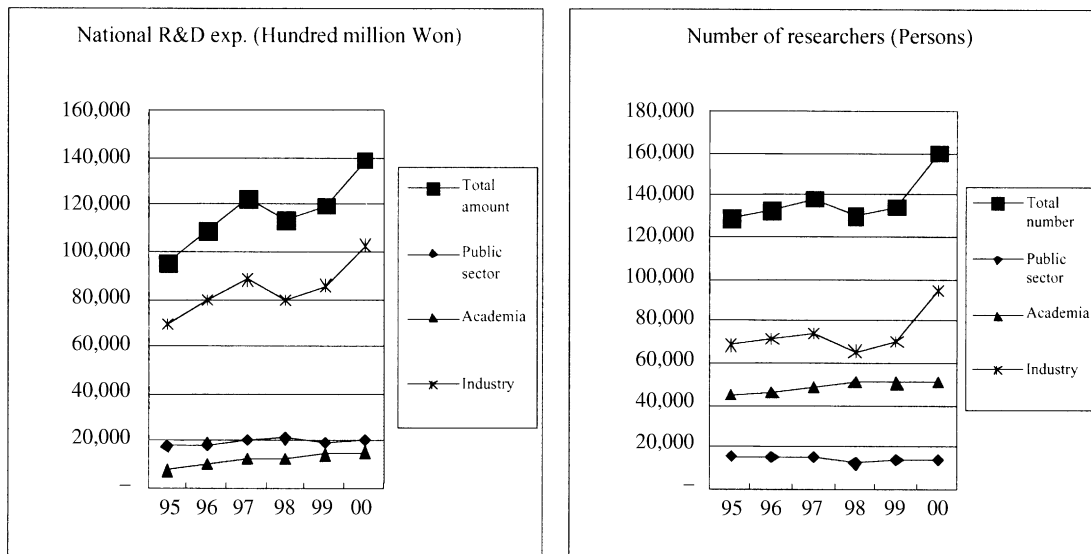

Figure 1. Impact of IMF jurisdiction on the Korean national innovation system.

level of 1997 before the IMF jurisdiction. In particular, 2000 showed much stronger innovation capabilities compared to those before the IMF jurisdiction. This implies that the unexpectedly quick overcoming of the recession was mainly due to the strong increase in innovation capabilities in the Korean national innovation system.

Many studies argue that in the recession period organizations including the *nation* have a tendency to decrease their R&D and innovation capabilities that are not directly related to short-term performance. However, this was not the case for Korea. Korea did not decrease its investment in R&D and innovation activities and even increased it to a remarkable degree. For example, the Korean government increased its annual R&D budget approximately 15% per year after the IMF jurisdiction, even though it had to retrench its annual budget significantly. In fact, just after the IMF jurisdiction, there was a consensus in Korean society that the deep recession in that period came from the low level of innovativeness of the Korean economy, i.e. the low efficiency of the Korean national innovation system and the boosting technological innovation is the only way to overcome the economic crisis. As a result, Korean society made a great effort to improve the efficiency and effectiveness of the Korean innovation system by increasing R&D investment and refining institutional frame conditions of the innovation system.

It is interesting that the Korean industry, which had been most strongly influenced by the recession among innovation actor groups, increased its innovation capabilities to a remarkable degree after the IMF

jurisdiction. In 2000, Korean industry reported a 20.5% of increase in R&D expenditures and 33.9% increase in the number of researchers compared to the previous year. This indicates the high level of dynamism and innovativeness of Korean industrial companies. Having experienced the difficulties in international markets in the middle of the 1990s, Korean companies recognized the importance of technological innovation in enhancing their competitiveness and made a greater effort to increase their innovation potential. Such efforts to increase innovativeness have resulted in the strong competitiveness of Korean industrial companies in international markets nowadays.

Conclusions

Korea's development has been based on its innovation capabilities. In this chapter, we investigated how Korea has accumulated its innovation potential since the beginning of its industrialization. Special focus was placed on the second half of the 1990s because the Korean economy was under the deep recession in this period. We analyzed whether innovation capabilities were diminished in this period and how important a role innovation played in Korea's overcoming the recession. Some of results can be summarized as follows.

First, in about three decades, Korea could formulate and implement a competent national innovation system comparable to that of advanced countries. Due to the short history of its economic development, Korea's national innovation system had many structural weaknesses. But Korea has overcome these weaknesses and now can implement a relatively competent and

dynamic national innovation system. Figure 2 shows the historical development of Korea's national innovation system according to major actor groups, i.e. academia, public research sector and industry. In the 1960s, Korea did not have a national innovation system at all, and only one public research institute, the Korea Institute of Science and Technology (KIST), established in 1966. In the 1970s, only the public research sector was operating in the national innovation system as there were 13 major public research institutes in major technological and industrial areas. There were no industrial innovation activities and academia had no R&D capabilities.

However, Korea could formulate a national innovation system in the 1980s because industrial companies started to increase its R&D and innovation capabilities. In this period, the Korean government initiated a *National R&D Program* in order to promote interactive learning between industrial companies and public research institutes. However, it was not until the 1990s that Korea could have a satisfactory national innovation system. As Korean academia secured its R&D capabilities in the 1990s, Korea's national innovation system had three major actor groups: industry, public research sector and academia. It took about three decades for Korea to have a relatively competent national innovation system. However, it is unbelievably quick because an institutional setting, especially at national level as a whole, takes an enormous amount of time and resources. This prompt establishment of a national innovation system has played a key role in enhancing Korea's economic competitiveness.

By the turn of the new millennium, Korea made a great effort to enhance the efficiency and effectiveness of its national innovation system. The Korean government has refined legal and institutional frame conditions to further accelerate R&D and innovation

activities of major innovation actors and to activate interaction between innovation actor groups. Korea has also increased its R&D and innovation investment to a remarkable degree. As a result, Korea is now one of the most R&D-investing and innovative countries in the world. This means that Korea's national innovation system has been enlarged and its efficiency has increased greatly, compared to the 1990s. Figure 2 depicts this trend in the 2000s.

Second, in the development of the Korean national innovation system, the government has played an essential role. Since the beginning of its industrialization the Korean government has implemented a series of policy measures to enhance innovation capabilities of Korean innovation actors and to activate an interaction between them in the national innovation system. This strong involvement by the Korean government has led to the remarkably quick establishment of the Korean national innovation system. Such strong involvement of the government has been possible because Korea has been historically a centralized country. Since the mid-1990s, Korean regional governments have participated in promoting innovation activities in their regions (Chung, 2002; MOST, 1999). As efficient regional innovation systems constitute a competent national innovation system (Chung, 2002), this strong involvement by Korean regional governments in addition to the central government will make a great contribution in enhancing the performance of the Korean national innovation system.

Third, public research institutes have played a very important role in the development of the Korean national innovation system. As discussed earlier, Korea has established its innovation system based on the public research sector. The public research sector has been a very important policy tool for Korea as a developing country that tries to establish its own

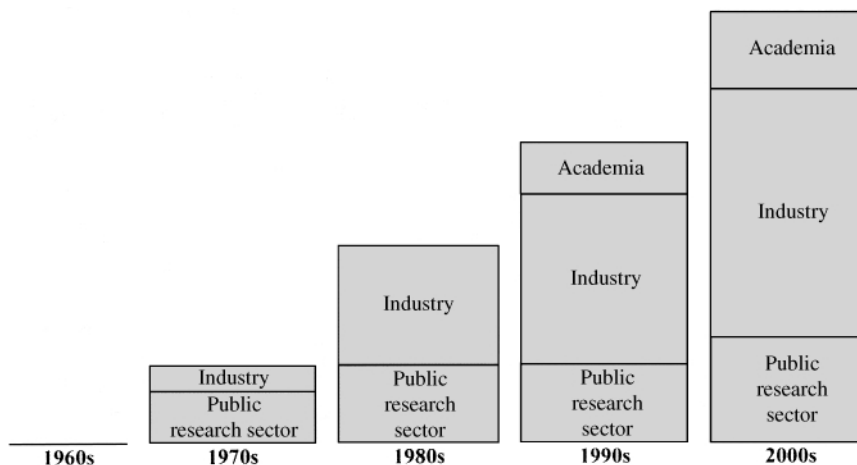

Figure 2. Development of Korean national innovation system.

national innovation system. However, the Korean public research sector has had to re-orient its mission, and role, since the beginning of the 1990s because industry has increased its innovation capabilities since the 1980s and academia has accumulated its R&D capabilities since the beginning of the 1990s. Considering that the public research sector has been playing a pivotal role in the national innovation system, its strategic re-orientation based on rapidly changing technological and economic environment is indispensable for the competent national innovation system for Korea. Based on the strong innovation capabilities of public research institutes, Korea could formulate and implement an excellent national innovation system, which consists of academia, public research sector, and industry (see Fig. 2). Only a few advanced countries, e.g. Germany, the United States, and France, have such a balanced national innovation system.

Finally, the unexpected economic crisis at the end of the 1990s did not have a severe impact on the Korean national innovation system. The recession under the IMF jurisdiction in the fall of 1997 did influence innovation potential of the Korean national innovation system. However, the deep recession affected the Korean national innovation system for just one year, i.e. 1998 or at the longest, two years until 1999. By the turn of the new century, Korea regained its dynamism and innovation capabilities. In 1999 just one and half years after the IMF jurisdiction, the Korean national innovation system regained its innovation capabilities to the level of 1997 before the IMF jurisdiction. In particular, 2000 showed much stronger innovation capabilities compared to those before the IMF jurisdiction. This implies that the unexpected quick overcoming of the recession was due to the strong increase in innovation capabilities in the Korean national innovation system. Korean industry, which was most strongly influenced by the recession among innovation actor groups, increased its innovation capabilities to a remarkable degree after the IMF jurisdiction.

As a whole, Korea is a very innovative and dynamic country. It has established and implemented a relatively competent and dynamic national innovation system in a very short period. Korea has invested a lot of resources in order to enhance the efficiency of its national innovation system and increase the innovation capabilities of major innovation actors. The innovation system as a whole and its major actors are very innovative and produce a lot of innovative results, products and so on. We can ascribe the dynamic development of the Korean economy in this globalized economy to the efficient national innovation system. In the meantime, Korea has made a great effort to learn from the successful national innovation systems of advanced countries, and finally it can have a relatively competent national innovation system. However, considering the hectic competition between countries to

attain and implement a better national innovation system in the world, Korea should continue to learn from other advanced national innovation systems.

Regional Innovations and the Economic Competitiveness in India

Kavita Mehra

National Institute of Science, Technology and Development Studies (CSIR), India

Abstract: In today's world of global economy with no territorial boundaries, the regional resources and capabilities are also playing a crucial role. The tacit knowledge based innovations are territorial specific because of its embodiments in individuals, in its social and cultural context. This fact may be responsible for not making the globe a homogenous entity and thus, let the developing nations retain their identity. The chapter highlights the cases of regional innovations from diverse locations in India, true to the region and bound to local culture and resources. Innovations make the enterprises economically competitive and sustainable and thus, in specific cases, preserve local art and craft as national heritage.

Keywords: Innovation; Tacit knowledge; Regional innovation; Learning by doing; Economic competitiveness; Entrepreneurial innovation; R&D based innovations.

Introduction

In the present era of global economy, national boundaries are diminishing leading to movement of resources not only across regions of a nation but also across countries. However, the aspect of regional capabilities has too gained importance in the spatial framework of economic competition. The awareness of the social embeddedness of economic interaction (Grabher, 1993) has given a further impetus to the recognition of the regions as a main territorial framework for learning and knowledge based economic growth. The core argument is that tacit knowledge—with its crucial role in innovation—is highly territorial specific because of its embodiments in individuals, its social and cultural context and therefore it requires proximity (Geenhuisen & Nijkamp, 2000; Nonaka et al., this volume; Pan & Scarbrough, 1999). Badaracco (1991) refers to the tacit knowledge as embedded knowledge, embedded in the psyche of the individual or the culture of organization (or region) and relationships amongst individuals. Hildreth et al. (2000) describes the tacit knowledge as soft knowledge comprising experience and work knowledge and that resides only within individuals. Nonaka (1991) considers tacit knowledge as highly personal and that it is deeply rooted in action and in individual's commitment to a specific context

(see Nonaka et al., this volume). The exploitation of that tacit knowledge along with its interaction with the new knowledge (flowing into through various channels) in a specific region leads to economic competence of that region. The realization of this very fact perhaps may be responsible for not making the globe a homogenous entity in the coming period. This way it may help developing nations retain their identity for which they are striving very hard.

The economic gaps among regions do reflect differences in the regions ability to compete, which increasingly depends upon the innovative capacity of production units and regional systems as a whole (Fagerberg & Verspagen, 1996; Fagerberg et al., 1997; Neven & Gouyette, 1994; Quah, 1996). The process of technological accumulation takes place at local or regional level, even in the era of globalization, and the technological spillovers tend to be highly concentrated at geographical level (Evangelista et al., 2001, see Gibson et al., this volume). This is why regions have become fundamental units of analysis in the cost/benefit evaluation of the economic integration and in the studies, which look at the process of economic convergence (or divergence) in Europe (Evangelista, 1996; Evangelista et al., 2001).

Concept of Innovation and its Relevance in Regional Economic Development

This section elaborates upon the concept of innovation and related issues. Innovations are new ideas in the business of producing, distributing and consuming products or services (Beije, 2000). The most general definition of innovation is 'the process to undertake a change in one or more of many aspects of production, distribution, and consumption of economic goods' (Beije, 2000, p. 22). Schumpeter (1961) has made a classification of innovation that is more practical, consisting of: (1) new products; (2) new processes; (3) ways to penetrate new markets; (4) new supply sources or distribution methods; and (5) industry. It contains all basic categories of ways in which the entrepreneur can earn money by undertaking new activities. In addition to that, there are innovations in other areas beyond these five categories, such as use of new management practices and organization structure, developing and retaining skilled personnel, organization culture, securing financial resources, managing interface with government and other external agencies (Mehta & Joshi, 2002). Wilhelm (this volume) notes that innovations are the results of innovation processes and innovation activities; innovations exist as products, processes and organizational structures.

The importance of innovation at micro level lies in the increase of profits or market share by individual firms. The importance of innovation at macro level goes further. Technical change is initiated by innovations, but its effect ultimately depends on the extent to which one innovation may stimulate a whole chain of subsequent innovations. An important role in this respect is played by the relationship between the creator and users of new technology (Beije, 2000). Innovator can be a person or an organization. The change of any type (e.g. technological) he brings forward is basically a new knowledge.

Economists usually put the emphasis on innovation, not on invention. Innovations have a larger sphere to show the newness through so many activities of the production unit. It may be the combining of the existing activities in new ways in a more beneficial way (Beije, 2000). Therefore, innovations largely reflect the role of innovator, which is more important in terms of economic benefits. Schumpeter (1961) first emphasized the role of innovator, considering it to be crucial for the economy in the process of technological change. Inzlet (this volume) through pilot innovation surveys in Hungary, found that the role of innovations in the Hungarian economy is low. She concluded that the reason for this is the type of role played by innovators. Innovators rely more on market needs than on R&D inputs through links with academia or other firms.

Drucker (1985) discusses innovation in relation to entrepreneurs. Innovation is a specific tool of entrepre-

neurs, the means by which they exploit change as an opportunity for different business or different service. Entrepreneurs need to search purposefully for sources of innovation, the change and their symptoms that indicate opportunities for successful innovation. They need to know and to apply the principles of successful innovation (Drucker, 1985).

Innovation is the act that endows resources with a new capacity to create wealth (Drucker, 1985). Innovation creates resources and also changes the value and satisfaction obtained from the resources by the consumer. Drucker (1985) discussed this in the case of Japan wherein the country became the big economic power by adopting creative imitation, importing the low cost technology and adopting it instead of undergoing increased R&D and new product development. He considered this phenomenon as social innovation and concluded that the Japanese success was primarily based on social innovation.

With poor infrastructure in R&D and limited scope for higher education, entrepreneurs in developing countries—even though they may be imitators—play an important role. They provide a distinct thrust to economic growth. Regional disparities create social and political problems that must be addressed, especially in countries with federal constitution where 'regions' and the gaps among them correspond fairly closely to states or provinces. National economies are aggregations of regional economies, which vary widely in the degree of integration among them. In some countries some regions are more closely integrated with the world economy than with other regions in the same national economy (Higgins & Savoie, 1988). One can substantiate this fact by taking the case of India as nation and Bangalore & Hyderabad as the regions within India, which are very well linked to the world economy through information technology. Similarly, Ahmedabad is specialized in gems, jewelry and in textiles also, the region is well linked to the world economy. There are numerous other examples of regional developments in India. Regions are integral part of the structure of national economy and thus ultimately of the global economy.

National economic systems cannot be understood nor effective policies formulated and plans can be made, without understanding the regional structure. If one considers regions as such regional economic systems, one may assert that regions can only survive if their participating systems (such as political system and legal system) are also able to survive. All participating systems are actors in the whole system (the society) and are influenced by its environment (Brandt et al., 2002).

In parallel, the worldwide economic system is made up of many sub-systems that are connected with each other by customer-supplier chains (Brandts et al., 2002; Fig. 1). The system's ability to survive depends on the ability of sub-systems to survive. The nation wide

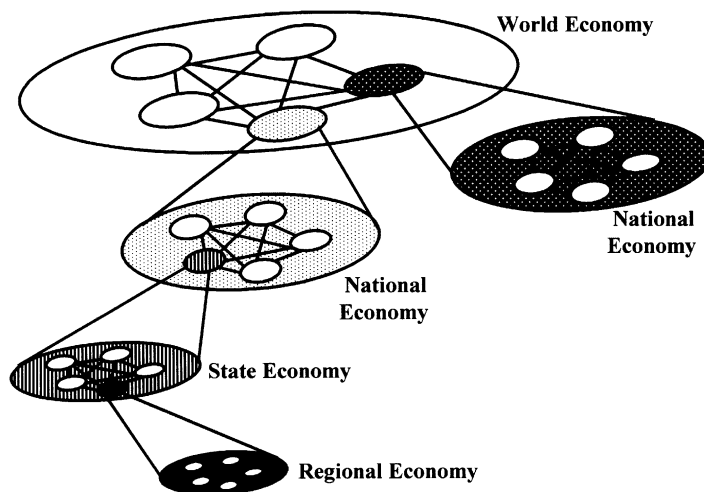

Figure 1. Role of the regional economy in the global economy

Source: Brandt et al., 2002.

economic systems have started to cooperate with each other through international networks. As a matter of principle, these different (nationwide) systems and their sub-entities are to be understood in their relations as of equal weight or equal importance for their survival. In this context, the overall aim of economic politics should be to assist regions and regional enterprises to survive.

According to Higgins & Savoie (1988), accelerating growth of national economy as a whole requires an attack on the problems of retarded regions. Some kinds of resource management—natural and human—are best studied and executed at the regional level because the package of resources involved are best defined in terms of space. Examples are river valleys, mining and forest areas, drainage systems, transport systems etc. As a specific example, Ganga river basin (in India) management is best understood by the regions in the north of India along the river. Each region (as space) has its enrichment or scarcity of resources and that region over the period develop specialization to utilize or manage the uniqueness.

There could be various approaches to regional development. Broadly, it could be regional resources based development, more relevant for present period of global economy, when one can capture the resources from anywhere and make use of it for the regional development. Example of the later situation is the information technology based regional developments (e.g. Bangalore & Hyderabad in India) when the technological achievements at global level have been put together with the local infrastructure development so that those cities have become linked to the global economy. The regional comparative advantage approach has been popular among policy makers

(Higgins & Savoie, 1988). It represents, potentiality at least, a no-cost regional development policy. Regions will grow and specialize according to what they can do best, and government will not waste funds attempting to reproduce the industrial structure of highly developed regions in all slow growth areas. It promises self-sustaining economic activity (Higgins & Savoie, 1988). The same concept has been used in the present chapter in discussing various models of innovations in India.

In today's world, the need remains that to fully realize the regional potentialities and to make them economically competitive, even if such regions are not directly linked with the global economy, they have to be linked to the national economy in a more impact-full way. For that, regional innovations—specific to local resources and skills embodied in the culture—play a crucial role. The following account discusses a few of the many models of regional enterprise innovations experienced in India.

Models of Regional Innovations in India

India is a vast country comprising varied regions with a variety of resources. Particularly art, craft and culture as well as the natural resources, are specific to each region. Regional innovations are thus, an outcome of culture, resource-based activities and these have evolved due to limitation in supply of resources, sustenance in the market, diffusion of culture and art across regions and learning by doing. There are cases of both types: entrepreneurial efforts, as well as organized attempts due to the flow of R&D from public funded research institutions to upgrade regional capabilities. It is the blending of traditional capabilities with modern technologies to make the regional occupations

more remunerative ones by providing efficient production, innovative products or processes, new designs and new markets. The cases discussed for entrepreneurial type of innovations reflect the way in which enterprises have been benefited by the changes (i.e. innovations) introduced by entrepreneurs (see Conceicao & Heitor, this volume). The chapter discusses three types of regional innovations in India as cases building towards regional economic competitiveness.

- (1) Innovations in small scale enterprises set up in the Gujarat region, with and without any formal R&D efforts.
- (2) Innovations in the informal sector—the agriculture, in and around Delhi (Uttar Pradesh)—non-planned and non-R&D based activity.
- (3) Innovations based on the inputs from public funded R&D laboratories (Council of Scientific and Industrial Research—CSIR). Modernization and up-gradation of traditional art and craft.

Innovations in Small Scale Enterprises—Gujarat Region

Gujarat is a major centre for innovations happening at the grass root level with strong cultural influence. The enterprising behavior is largely attributed to typical culture comprising of traditions, values beliefs and attitudes of the region. The growth of the Indian textile industry without any tariff protection, which is competitive with British textile industry, is proof of the vigor of Indian entrepreneurs from Gujarat. Gujarati culture has put a prestige value on business. These factors, together with Western ideas and Western contacts, created a new ferment in Gujarat's economic development in the 19th century, which still continues today. They provide a distinct thrust to economic growth: for example, the modern textile industry in Gujarat—and especially in Ahmedabad—was developed as an imitation of a British textile industry. It has contributed a great deal to the Indian economic growth for the past 150 years. The entrepreneurial class consolidated itself socially, as well as economically, and relatively small, close knit agencies, often supplemented by caste ties, made further expansion possible. As managing agents, they applied the profits of one mill to the requirements of new ones and solicited public and private deposits to cover the major capital requirements.

The creative genius of Indian entrepreneurs does not lie in inventing new products as much as in inventing new forms of organization and management (such as managing agency system) and in creative imitation and modification of foreign products. It is the same principle in Japan, the imitation of relevant outside R&D—as mentioned earlier—has been considered as social innovations by Drucker (1985). Recognizing the problem, Bert & Hoselitz (1963) remarked that in an

underdeveloped economy, in addition to the Schumpeterian innovators, even imitator-entrepreneurs have a distinct role to play. They provide, he feels, a fillip to the process of economic growth, sometimes having as strong or perhaps even a stronger impact on economic growth as real or alleged innovators. Even the multiplicity of entrepreneurs—lacking in creative genius of inventors, but possessing all other characteristics of successful entrepreneurs—is desirable for underdeveloped economies.

In a broader definition of innovation, relatively novel ideas, which are novel in local context, can also create competitive advantage and large-scale economic and social change in the region. In Gujarat, there are innovations of such kind, which fit in Schumpeterian (1961) framework of five categories of innovations, namely product innovation, process innovation, market innovation, supply source innovation, and innovation regarding industry organization. Entrepreneurial ventures in Gujarat rarely have formal R&D set-ups, but a collaborative relationship is established with research and academic institutes or laboratories to make available testing facilities and information available. Some entrepreneurs have used semi-finished and unsuccessful research of others. Gujarat, however, needs to develop innovative ways of managing the R&D efforts without having formal departments.

Entrepreneurs have tested the feasibility of new ideas before investing in them through their informal networks. It was observed further that since childhood their family members, who are in this particular business, train them and skills are passed on from generation to generation. Mehta & Joshi (2002) describe the culture and region specific characteristics of entrepreneurship and innovativeness.

Cases of Enterprise Innovations in Small and Medium Enterprises in Gujarat

Gems and jewelry. Diamond processing is a traditional craft and one of the oldest industries in India. The main features of this industry are low investment, low level technology used and high employment. Gujarat accounts for more than 80% of diamond processing business. The processing is done through indigenously manufactured and manually operated machines. R&D efforts during the last six years by two Indian Companies, Sahjanand Laser Machines and Gitanjali Laser House, have resulted in the development of laser processing machinery for diamond processing. Use of these machines will reduce manual error considerably and will also decrease the chance of weight loss. Therefore, this technology has been attracting more and more people as it is eventually reflected in better prices. Indian R&D in this field has been able to give the diamond an advantage on the export front by giving an edge in quality, product mix and price. In the last ten years alone, the diamond industry exports have gone up from US\$830 million to US\$4400 million.

The diamond and gems entrepreneurs undertook process innovations to make use of locally available skilled labour or different quality of locally available raw material, to reduce costs or improve quality. They developed laser kerfing and sawing machines to make it labour-intensive in place of capital-intensive machines imported from abroad. This is a cost-effective, low capital process of diamond polishing in a local situation where skilled labour is easily available and cheap. Israel may use fully automatic, innovative diamond machinery, while India uses non-perfect diamonds like macles, distorted crystals, 'near gems' or 'near industrials' processing which are not easily amenable to automation. Gujarat entrepreneurs have developed machinery to suit these applications and also to take advantage of cheap skilled labour.

Gujarat entrepreneurs also succeeded in structural innovations. Structural innovations are how work is organized, which can enhance competitive advantage of an enterprise. For example, entrepreneurs in Surat Diamond Industry have a lean organization structure with labor on contract allowing them greater flexibility in terms of workload and skills. Also, owner-manager role of the entrepreneurs allowed innovation in cost control, quality assurance and market development.

Rajkot Oil Engine Industry. The first manufacturing unit of the diesel engine, was created and developed by Umakant Pandit in 1951. Today, Rajkot has found a place among the leading industrial centers of the country. Over the last 40 years, it has become one of the main centers for production of diesel engines and its spare contribution is substantial to the total production of oil engines in India as a whole. Rajkot has made progress in the export of diesel engines and spares worth more than Rs. 500 million to the Middle East and several African countries.

Forty years ago, there were approximately 25 units in the field of engineering. There was an acute shortage of diesel-engine spare parts. Those engineering units which were engaged mostly in repairing and overhauling of the different types of diesel engines besides casting and machining of iron and non-iron metal. Many entrepreneurs were also importing certain parts of diesel engines, manufacturing some of the parts here and assembling the slow-speed vertical diesel engine. The machines at that time were imported from Lister, U.K. In time, gradually, the production of almost all the different parts of the oil-engines commenced in Rajkot itself. This was the beginning of production of diesel-engines as a whole in Rajkot. Umakant Pandit was the pioneer in establishing the foundation stone of this industry in Rajkot. Then a spree of entrepreneurs came into the picture, like P. M. Diesel Ltd., which is now one of the leading diesel engine manufacturers in the world. Today there are approximately 4,000 small-scale industrial units engaged in the production of diesel engines, spares and engineering goods.

Rajkot contributes more than 70% to the production of slow-speed diesel engines (Lister type). The annual production of 150 units engaged in the manufacturing of Lister type of diesel engines is more than 240,000 of slow-speed diesel engines. The Lister type engines are mainly used in agriculture. Of late, the production of Peter-type engines has also been increasing, with the annual turnover of about US\$25 million. The diesel engine industry provides employment to more than forty thousand workers.

Entrepreneurship in Rajkot today is a combination of two styles. While the astute and tenacious spirit of the first generation entrepreneurs is unmistakable, there is a new wave of professionalism amongst the second generation of entrepreneurs who are opening new windows of opportunity. The people here are by nature entrepreneurial, hard working and have keen engineering skills. And added with this also comes the commercial sense, which creates a critical combination of success. All these skills have enabled Rajkot to produce and sell at competitive prices all over the country as well as to overseas market.

A major form of supply source innovation is vertical integration where an enterprise manufactures its own raw material. This is prompted by shortage of supplies. In case of Rajkot Diesel Engine Manufacturers, a unique system for supply sources is developed. In Rajkot, when the industry started, everything was sourced from outside by way of imports or purchased in other parts of India. Today Rajkot has more than 600 ancillary units for the supply of raw material, components and assemblies. This is a classic case of ancillarization and vendor development.

The product innovation identified in Gujarat mainly relates to product modifications of existing products and introduction of new products locally. Rajkot Diesel Engine manufacturers are other examples where they adopted Peter type high speed diesel engine designs from Lister type designs to suit local changing environment, which helped them to capture 70% share of diesel engine markets in India. Besides this, entrepreneurs in the diesel engine industry at Rajkot are in touch with the latest information, they maintain quality and they also know the market pulse too. The market needs new and innovative products every day. Modernization of products and plant is the only alternative to that. And the entrepreneurs take all the steps to modernize their plants and machinery.

The structural innovation made by Gujarati entrepreneurs in engineering, gems and jewelry, ceramics, brass parts and cooperative entrepreneurship is the formation of clusters and networking. In both industrialized and developing countries there is increasing evidence that clustering and networking can help small and medium scale enterprises (SMEs) to boost their competitiveness (see Swan et al., this volume). Groups of firms working together are better able than isolated firms, to rapidly develop product

niches, access export markets and offer new employment opportunities. The cluster development concept is important in the establishment of cooperation linkages between firms, their raw material and equipment suppliers, sub-contractors, customers and service providers. The cooperation of specialized firms enables collective efficiency and enhances the ability to innovate new processes and products.

Innovation in the Agriculture Sector (Delhi and Nearby Areas, Uttar Pradesh). Emergence of Floriculture in Open Field Conditions

This case is to illustrate entrepreneurial skills of Indian farmers and their innovativeness in capturing the market demand for good quality cut flowers. It depicts the diffusion of new technology in a farming community, so as to lead to a technological change, is dependent on culture-based informal channels of communication and the tacit-knowledge driven entrepreneurial spirit of a few. Adoption of floriculture amongst traditional crops like wheat and sugarcane growing farmers was an imitation (innovation) of 'green house technology' for their open fields which was based on the exploitation of tacit-knowledge of farming, learning by doing, awareness amongst the farmers and other similar reasons. All these developments are proving farmers as innovators and responsible for bringing farm level technical change.

Entrepreneurial Skills of Farmers

Agriculture is the backbone of developing economies. In India, agriculture is the largest economic activity and in the top position in providing work and jobs to people. The 'New Strategy' for agricultural development in India was initiated in 1966, which in essence called for the implementation of High Yielding Varieties Programme (HYVP). These technological breakthroughs brought spectacular changes in agricultural production. The large increase in production of food grains recorded after 1966–1967 is described as 'Green Revolution' (Sadhu & Mahajan, 1985).

The entrepreneurial spirit of farmers can be regarded as a key to this revolution; perhaps they knew the potential of their lands and need for the adoption of new technology. The response of farmers in the use of HYVs and other inputs had been enthusiastic. They were confident of their tacit-knowledge of farming and were willing to capture the opportunity for change.

The technological change brought a shift in the minds of illiterate but 'scientifically informed' farmers, making them realize the importance of high quality seeds and other farming inputs for increasing the productivity of same land. In the Indian history of agriculture, the role of 'green revolution' is a landmark as it has made India more than self-sufficient in wheat grain production in spite of continuous population growth. However, the higher productivity of land gained by adopting HYV seeds of wheat has now

produced a saturation in the benefit level to farmers. The 'alert farmers' of India have thus remained on the lookout for other opportunities for higher economic returns. Popularity of the floriculture sector amongst traditional crop (wheat and sugarcane) growing farmers appears to be one such case during the early 1990s.

During those years, the focus of the Indian government was to promote green house cultivation of flowers for export purpose so as to capture the international demand of cut flowers and add to India's foreign exchange earnings. At the same time, policies towards liberalization of economy were also introduced in the country. As a result, a number of multinational companies were selling superior quality planting material for flowers and also the greenhouse technologies to start the green house enterprises by Indian entrepreneurs. Volumes of greenhouse based produce, meant for export, started appearing in domestic markets too and Delhi market showed high demand. The moment when some traditional farmers of a village Khatoli—nearly 100 km away from Delhi—learnt of the availability of imported bulbs of superior quality flowers and the demand of superior quality cut flowers in the market, they decided to venture into it. It was not for 'green house' based production. It was purely to replace their traditional crops (wheat and sugarcane) in the open fields with floral cultivation. Indian farmers went ahead in the business of flower cultivation by themselves without any guidance and experience of growing exotic bulbs in open field conditions. They started with small plots of cultivation for experimentation. Once they succeeded in growing the crop and selling it, they expanded the area of open field cultivation. For marketing, initially farmers faced exploitation by the middlemen as cut flowers are perishable commodity and they do not have any controlled temperature arrangements to store flowers. So, the middlemen were taking away the produce at throw away prices for sale to retailers or bulk buyers and were earning substantial profits. Ultimately, farmers succeeded in locating and establishing the market for direct sale in Delhi. It was a newly created market by the flower growers from Delhi and the nearby region, Uttar Pradesh. Achievement in this front had also followed an innovative route (Mehra, 2002). Gradual success in establishing the market for the sale of cut flowers, encouraged the adoption of floriculture by more and more farmers. By now, most of them have devoted a major portion of their land to floriculture activity, and some of them have even gone ahead by taking more land on lease for flower cultivation. Over this period, they exhibited 'learning by doing' innovations through several examples such as regulating the flowering time of the crop, manipulation of more number of crops of tuberose per year or in storage of bulbs etc. We can thus say that farmers have acted as innovative entrepreneurs.

Technical Change in Socio-Cultural Context

It was not a government plan to promote open field cultivation of superior (from imported bulbs) cut flowers for the domestic market. Only the alertness of the scientifically informed farmers led to the change. They came to know about the availability of planting material through each other. The fear of competition is not felt amongst them for marketing of their agricultural produce. Marketing of cut flowers is a difficult task as it is a perishable commodity and they do not have any air-conditioned storage facility. Even then the farmers of the same village were sharing their knowledge. This is the reflection of the culture and the practice of villages of being together and sharing. Most of the growers cum sellers of Khatoli village have gained information/knowledge for floriculture only from their colleagues. As a result, today the Khatoli village is the largest producer of tuberose for Delhi and nearby markets. Khatoli is a village in Muzafar Nagar district of the state Uttar Pradesh in the North of India. Like industrial clusters, Khatoli has emerged as the tuberose cluster during the 1990s. In the context of agriculture, the term cluster has perhaps been used for the first time describing cultivation of flowers in Khatoli (Mehra, 2002) due to the following reasons. First, in Khatoli, almost all farmers are engaged in floriculture activity, mainly specializing in tuberose. Second, farmers have become such experts in growing tuberose that now a substantial supply of flower from Khatoli is available during the winter season. Before, virtually no tuberose from Khatoli or nearby areas was seen in the winter months in the Delhi market. Finally, until the beginning of 1990s, Calcutta was a big supplier of tuberose to Delhi market. At present, the enormous production of tuberose in Khatoli has replaced the supply from Calcutta to Delhi and, in addition, the flowers are also sent to other regions for sale. This all happened due to the rapid diffusion of the popularity of the flower cultivation amongst the farmers. Reason for the popularity was the more profitability in adoption of floriculture over growing conventional crops—wheat and sugarcane. An indicative comparative economic analysis of the investments/returns in floriculture versus wheat and sugarcane crops clearly explains the reasons of adoption of floriculture by farmers (Mehra, 1999). It is the exploitation of tacit-knowledge of farming, learning by doing, awareness amongst the farmers, informal channels of communication, the faith of the community, and in each other are some reasons to prove farmers are innovators and responsible for bringing technical change to farming.

Thus, an Indian farmer, though not formally educated, is alert and sensitive to opportunities leading to higher returns. This is another type of innovation model observed in the informal sector. After green revolution, the boom in the domestic floriculture

market offered the opportunities to innovative farmers to discover entrepreneurial skills, building upon their tacit-knowledge of the framing practice. They proved themselves to be successful entrepreneurs, and in some cases innovators, too. This type of enterprise is possible due to the socio-cultural system of the village. A closed-knit system of informal communication amongst farmers makes it possible to launch such a technical change at the community level. Such changes definitely have a bearing on the socio-economic status for the betterment of the region.

Modernization and Upgrading of Traditional Art and Craft Skills: Interventions of Public R&D Institutions

In a country like India, one finds great diversity in art and culture. Each region depicts a culture with specific art and craft. Performers of that art are called artisans or craftsmen. The main occupation of the rural population in India is either agriculture or art/craft work. Artisans are practitioners of tacit-knowledge—uncodified knowledge, which is passed on from generation to generation. Historically, artisans can be considered as the institutions of excellence of human skills as they have been utilizing the local resources in the best possible way for making mostly utility items showing the skill and the sense of aesthetics of artisans. The creative art of the artisans is the source of meeting their meager needs. Artisans had been playing a significant role in the rural economy. However, in recent years, one notices a declining trend among the regions. There could be various reasons for this, but the prime factor appears to be without innovation the traditional modes of operations are still being used. This has resulted in low returns, which dissuades the artisans to follow the traditional practices. Perhaps the solution to this problem lies in the incorporation of modern Science and Technology into the traditional practices. The process should happen in such a way that a blending of the new technology with the traditional one takes place. It would serve: (a) to preserve the national heritage (the human skill, the tacit-knowledge of artisans); and (b) to enhance the earnings of artisans for better living by bringing efficiency in the processes, cost effectiveness, diversity in the product lines and better opportunities for commercialization. This way it would lead to regional economic development.

There is a number of public funded R&D laboratories such as Council of Scientific and Industrial Research (CSIR) and many others, which have made conscious efforts to look into the problems of regional nature, technological or other *types*, to cater to the needs of production units of various industries.

Cases from West Bengal—Bankura

Bankura is a district of West Bengal and, apart from agriculture, its vast population is engaged in the tradition of producing handicraft products like fishing

hooks, brass and bell metal products, bell mala, pottery (terra cotta), dokra, conch shells, baluchari saree, stonewares, slate carving and bamboo products. The preponderance of artisan oriented small-scale industries constitutes about 60% of the registered Small Scale Industries.

National Institute of Science Technology and Development Studies (NISTADS) set up a S&T field station at Bankura during 1982. A number of projects are being handled by this center to upgrade the technology of artisans and to promote the commercialization of artisan products. The field station of NISTADS is trying to provide help to artisans not only in terms of newer and better technology (with the help of different CSIR laboratories like Central Mechanical Engineering Research Institute in Durgapur, National Metallurgical Laboratory in Jamshedpur, and Central Glass and Ceramic Research Institute in Calcutta) but also in terms of procurement of materials and assistance in marketing of their products.

Baluchari Saree weaving—towards modernization. Baluchari is traditional form of handloom silk saree woven in Bishnupur in Bankura district. Saree is an Indian woman dress, which is a designed cloth of 6.0 m × 1.25 m. A baluchari is characterized by artistic designs on the borders of the saree. These designs consist of motifs of different sizes depicting the sculptures made on the historical temples or monuments in India. For making one saree, 15–18 weeks time is required. The traditional process is thus very labor intensive and expensive with the limitation of modifying or rectifying the design during the process or sampling of different color combinations. The practice of weaving of baluchari type originated at ‘Baluchar’ in Murshidabad of West Bengal on the patronage of the nababs of Murshidabad (Das & Mukhopadhyay, 1995). They tried to portray imageries of muslim rulers, the courts and ‘harems’ on the spread of these sarees. During the 18th century, designs were biased by Persian miniatures. During the 20th century, designer Sri Das introduced paintings of famous Ajanta-Ellora caves as designs on baluchari sarees in Bankura. These days, paintings and sculptures of various famous temples and historical places are used as designs for weaving baluchari saree. The border of a saree even speaks the story of an epic. These days Jacquard looms are used in which intricate designs are coded and punched on long chains of Jacquard cards. As these punched cards control the movement of the warp on the loom, designs come up on the saree with greater ease.

The process of Baluchari Saree weaving. The process of baluchari making and the stage-wise labor costs involved are as following:

- *Designing stage*—Cost involved varies from Rs.3000 to 6,000 (US\$600 to US\$120).

- *Preparation of card-deck for Jacquard loom:* Cost involved (labor+material)—Rs.12,000 to 15,000 (US\$240—300). For an exclusive design, the cost may go beyond Rs.20,000 (US\$400).
- *Preparation of silk threads*—coloring, plying, sizing and polishing. The process costs around Rs.100 (US\$2).
- *Weaving:* Done on hand looms normally by using two shuttles. Cost of weaving one saree—Rs.400–500 (US\$8–10).

In all the four stages described above, maximum labor is involved in designing and punching of cards. The process of Baluchari saree making has the following limitations:

- Labor intensive process; limited designs; defects in the designing cannot be detected in the initial stages of saree weaving; testing of color combinations without weaving can not be done *and* limited colors are offered to the customer. Product variation (other than saree such as scarf, neck tie or napkin etc.) is not there because the designer is tuned for designing a saree. He never thought of demand for any other product than traditional product (saree).

Since the same card deck is used a number of times (approximately 100 times), the designing cost is divided by the number of pieces produced. On average, a baluchari saree costs Rs.2,500. Every year, six to eight designs are released in the market.

Steps towards modernization of the Baluchari Saree weaving. Participation of NISTADS project team at Bankura with the artisans brought all limitations into the limelight. The survey conducted, revealed that due to the above limitations, the art was diminishing. Designers were going towards simpler motifs. The younger generation were also found not too willing to follow the family tradition due to low returns. Thus, the need for modernizing the process was realized at two levels: designing and card punching (Mehra & Mukhopadhyay, 2000):

- *At designing level:* With the advent of computerization and extensive use of CAD by professionals in designing, NISTADS made an attempt to get a software, MADHU, developed for baluchari designing by Entrepreneurship Development Centre at Indian Institute of Technology (IIT) in Kharagpur. It was to reduce the designing time and make the process more flexible in terms of the size of motifs, their arrangements on the saree and also to use designs for making diverse products. With the help of the MADHU package, it may be possible to design a full saree within two to three days. Once the software at the designing level, has been developed, a program for the sensitization of users is going on in the field. The feedback of users has gone into the improvement

of the software package. At present, the new technology is showing to be acceptable by the users.

- *At card punching level:* If Auto-card punching is introduced; the cost would substantially come down as efficiency of card punching would increase by 20 times or more. Council of Scientific & Industrial Research and Department of Science & Technology, Ministry of Science and Technology are also looking into this aspect.

Brass metal craft—Dokra casting. Dokra artisans of Bankura, where 36 families in all and now the largest cluster in West Bengal, live in a small village called Bikna just outside Bankura town. In the Dokra metal casting process, craftsmen use bees wax and hot metal that permits them to give a metal shape to the creative images visualized by them as an artist. Dokra work is carried out by both, men and women. Skills by children are acquired through imitation and instruction. CSIR has found it important to improve the skills and processes for efficient and cost effective production. NISTADS field station has helped these craftsmen in the following way (Roy & Mohapatra, 2002).

- Skill up-gradation for making of alloys of different non-ferrous compositions.
- Development and application of high collapsible molding material for making the master mould.
- Introduction of direct pouring techniques that facilitates production of a bigger casting in a single firing.
- Introduction of improved finishing tools.

All these inputs are the outcome of the participation of R&D laboratories of CSIR in identifying the problems and providing solutions for the economic betterment of the craft work in the region.

Dokra craftsmen were facing a specific problem in firing of the artifacts in open furnaces that they use. There was evaporation of metal and resulted in a 20% increase in the input costs. During 2001, NISTADS in consultation with senior artists from the village, designed and commissioned five pucca furnaces in three sizes for community use. This step has been effective in creating social, economic and creative impact. New furnaces have brought a noticeable social change—better interaction amongst individuals in the community (Kochhar, 2001).

EU-India Project on Cross Cultural Innovation Networks

India is a developing country with limited financial resources but rich in natural resources along with diversity of cultures across various regions in the country. The European Union is a group of countries with diverse cultures and resources. India's vastness as a country is comparable to EU. To look into these issues, a special EU-India project was initiated during October 1999, sponsored by EU. The project is 'Cross

Cultural Innovation Network' and is being managed by Project Director, Prof. Karamjit Gill (University of Brighton, U.K.). The project partners include scholars from U.K. (Brighton and Wales), Germany (Aachen), Italy (Bologna), Denmark (Lyndby), NISTADS (CSIR, India), Delhi University (Delhi), Gujarat (Ahmedabad, India), and Punjab (Ludhiana, India). The project focuses on the value-added applications of university and R&D institutions research into the area of social and economical change, regional models of innovations, role of cultural aspects in innovation process, entrepreneurship skills development, and their transferability between cultures and regions. Cultural aspects in this context emphasize the social, economic and communication environments in which technology or regional art is designed and applied to solve problems. The observations made by the project partners across countries (Gill, in press) reflect remarkable variations in innovations and development across regions due to influence of regional specific cultures and knowledge based practices within India, as well as in Europe. The project is developing a 'virtual network' consisting of distributed knowledge base residing within the partner institutions. EU-India network website has been launched to bring the synergy of the knowledge of different partners and to act as a tool for sustainability and future EU-India collaborations. Through multimedia, traditional knowledge, which is in practice at the grass root level across regions in India, has been captured for the diffusion purpose across cultures. The project has resulted in bringing out a special issue of the International journal *Artificial Intelligence (AI) & Society* on entrepreneurial innovations, mainly from India for which I was a guest editor. The special issue, dwells upon some aspects like exploring the ways how to be innovative to compete in the international market—may it be educational innovations to create qualitative and competitive manpower; or industrial enterprises/clusters to bring out new products with customer orientation; or cooperatives with new organizational innovations creating new products as well as opportunities for employment at the grass root level. The percolation and diffusion of new coded knowledge and its symbiosis with tacit knowledge in the small and medium enterprises of the Indian traditional sector has been a unique factor and has been mainly responsible for the innovation and technical change in India (Mehra, 2002).

Conclusion

India is an ancient civilization with a rich heritage. It has a vast storehouse of knowledge in various fields, particularly in tacit form, but general awareness of which is inadequate. In the present scenario of globalization and liberalization, international competition is compelling the enterprises and organizations to be dynamically innovative which is only possible through a knowledge society—a learning society

committed to innovation (Conceicao & Heitor, this volume; Kharbanda & Mehra, 2002). The slogan must be—innovate at all levels of human activity, be it economical, social or cultural.

The focus of this chapter was on three different models of innovations—At SME level, where the role of entrepreneur remained important. The case described regional (Gujarat) specific culture of entrepreneurship encompassing all Schumpeter's (1961) types of innovations. Innovation is associated with 'creativity' but also with initiative and risk taking (see Conceicao & Heitor, this volume) and that qualifies to be as 'entrepreneurial innovation', well observed in the first two types discussed (SME and the unorganized sector—the floriculture). The imitation of the British cotton industry (which can be referred to as social innovation) has also been observed in Gujarat and led to the establishment of a successful textile industry in that region, where the role of entrepreneur-innovator has been very significant. The ability to learn and put knowledge to work by entrepreneurs has been well observed in the process of the development of Gujarat region (see Gibson & Conceicao, this volume).

The second case highlighted, how the process of innovation in an unorganized sector took place and led to a technological change. In this case, innovators-farmers 'imitated' new technology (that can be considered as a social innovation) for greenhouse production. It reflects their entrepreneurial skills, alertness and the application of tacit-knowledge. Farmers for growing flowers mainly relied on their farming experience. Their tacit-knowledge regarding farming was the determining factor for their adoption of floriculture. They succeeded by combining that knowledge with new knowledge (information about new technological inputs such as high quality planting material etc.) the way Nonaka et al. (this volume) have described in the case of Nippon Roche. Gibson and Conceicao (this volume) have discussed the combination of tacit-knowledge with the new one for creation of wealth in the form of combining 'skills' and 'ideas'. The diffusion of change is bound to the social structure and culture, informal channels of communication, faith of the community in each other. This depicts the flavor of culture of rural farming communities that is true to India.

The third case discussed the role of formal R&D of public R&D laboratories in up-grading the skills of artisans. It was based on the targeted role of R&D laboratories of those regions to look for the resources of the regions and the problems faced to be economically competitive. Solutions to the identified problems have been provided from time to time and training and modernization have been carried out to make the occupations more profitable for the better living of crafts men and also to preserve the regional art and craft as national heritage. There are countless examples to show the way *in which* small enterprises producing

ethnic goods have undergone change—in terms of product diversification or variations in the product design and color to capture the larger markets or in the usage of raw material due to shortage of resources. All these developments happen through various channels of information (public agencies or non government organizations (NGOs) so as to make the enterprises more competitive and sustainable.

One can conclude from the above cases that in the age of global economy, the described regions also function as collectors of and repositories of knowledge and ideas and provide the underlying environment or infrastructure, which facilitate flow of learning and knowledge. Van Geenhuizen & Nijkamp (2000) discuss learning capabilities of regions as their ability to create, attract, absorb and act upon new knowledge. The cases described in the chapter reflect these issues, each region has different ways to innovate depending on its knowledge base, circumstances and available resources. Innovations and economic competitiveness in the discussed cases had no direct link with the global economy. It is tacit-knowledge, along with some new knowledge, and availability of lower order competitive advantage (e.g. use of technologies, economies of scales easy to duplicate or imitate, as described by Porter (1990) help in building up the economic competitiveness and thus, the sustainability of the region. These peculiar regional and cultural based, enterprise innovations distinguish one part of India from the other. Such patterns allow the world as a whole to maintain national identities in the era of global economy.

Acknowledgments

I would like to thank Professor Dhawal Mehta, the Director of the GLS Institute of Business Management in Ahmedabad for sharing information on Gujarat cases discussed in the chapter. I also wish to thank the European Union for its financial support, Professor Karamjit Gill, Chief Coordinator of the EU-India Project 'EU-India Cross Cultural Innovation Network' at the University of Brighton for initiating the project and creating the network of European and Indian partners in the project, making it possible to look into various models of innovations and the entrepreneurship. I extend my thanks to all the partners from India and Europe for collectively looking into the regional culture based aspects of enterprise innovation and sharing observations and experiences. It has provided an insight into important aspects of building competitiveness of regional economy. Thanks are also due to Professor Rajesh Kochhar, Director NISTADS for providing all support to undertake the work.

Innovation Process in Switzerland

Beate E. Wilhelm

z-link, Zurich, Switzerland

Abstract: Many politicians and scientists in Europe declare that today's innovation process is inefficient, which is reflected in a lack of transformation of scientific knowledge into commercialized products and processes. They hold responsible a kind of bottleneck for the missing exchange between science and economy. Fostering the utilization of scientific knowledge via organized technology transfer from universities to industry is the most popular aim of technology policy in Switzerland. But does this really solve the problem—and is the real problem based on the lack of that kind of transfer?

Keywords: Innovation system; Innovation process; Knowledge and technology transfer; Switzerland.

Introduction

Politicians in Europe are still complaining about the innovation gap, caused by the insufficient valorization of scientific knowledge into innovative products: they call it the 'European Paradox' (CEU, 1993, 1995). Its implicit message is as follows: scientific knowledge is the basis for innovative products, which in turn are the basis for economic development at regional, national, and international levels. While scientific knowledge reaches a high competitive level, mainly in natural and technical sciences, the output of new, global high competitive products is assessed to be poor (EC, 1995; Federal Council, 1997, 1998). How does that happen? They hold responsible a kind of 'bottleneck' for the missing exchange, and transfer from science to economy (CEU, 1993, 1995; Ellwein & Bruder 1982; Ewers et al., 1980; Federal Council 1997, 1998; basics: Grimmer et al., 1992; Hauff & Scharpf 1975). This missing exchange results in much less innovation as the output of innovation process. But does fostering this kind of transfer really solve the problem? The findings presented in this chapter discuss the asymmetries and misunderstandings with respect to today's 'knowledge and technology transfer' as an instrument for pushing the innovation process in the case of Switzerland.

For a better understanding of the so-called 'European Paradox', it is helpful to discuss the following issues. First, definitions of innovation and innovation processes in firms are considered. Second, the innovation process on a macro-level regarding all systems

involved (like the system of higher education and public research, i.e. 'science system', the industries and political system) is described and explained in light of recent findings in innovation research. Third, the related question about how government supports innovation is discussed. Finally, conclusions are drawn and recommendations are given about further needs in the development of national innovation systems.

Conceptual Issues

The attempt to define innovation has to be regarded as a permanently developing and adapting process, which is not finished yet, and perhaps never will be. There is a wide range of definitions of innovation—from very complex to very minimalist definitions about innovations, always containing something new (Kuhn, 1967). But up to now, there is no generally accepted single definition of innovation.

Innovations exist as *products* as well as *processes* and as *organizational structures*. In terms of *products* and *organizational structures* innovations are regarded as a result. In distinction to this meaning *innovation process* has a twofold meaning: First, innovation process as a procedure intended to result in innovative products¹ in firms and organizations. Therefore often different kinds of innovation activities, interaction and feedback-loops are needed. In this sense innovation

¹ The term 'product' is used to cover both: goods and services.

process or innovation activities are a main precondition for innovative products. Besides that micro-level-perspective innovation process is also considered on a macro-level where innovation activities and interaction between and among scientific,² industrial, and political systems is analyzed and explained. Second, innovation process in firms or among firms and other organizations means, to do a process in an innovative way, for example a new production process such as 'just-in-time'. In this sense, innovation process can be regarded as an implemented innovation. There exist close connections and interdependencies between both aspects: the making of innovations has impacts on the results of innovations, as well as intended innovation results shape the way of making innovations.

During the last 15 years some progress was made in understanding innovation process in Europe, particularly by the experience gained from the first round of national innovation surveys conducted in 1991 to 1993. The Organization of Economic Co-Operation and Development (OECD), the European Commission (EC), and Eurostat offer a definition of technological innovation as follows: 'technological product and process innovations comprise implemented technologically new products and processes and significant technological improvements in products and processes' (OECD, EC & Eurostat, 1996, p. 31). Innovations always have to be new or significantly improved to be counted as innovation. But up to now, a clear-cut definition is not possible because of the complexity of innovation and because of the variations in the way it occurs. A minimalist basic definition of innovation process (on a micro-level) is that 'innovation is a complex, diversified activity with many interacting components' (OECD, EC & Eurostat, 1996, p. 24).

Throughout economic literature, technological aspects of innovations are focused. This is due to findings of macroeconomic studies and technology portfolios showing direct connections between export of high-technology products and gained export position of nations (in detail see Section 3; Grupp & Legler, 1987; Soete, 1987). However, the growing influence of non-technical innovations and of the service sector is leading to more awareness and knowledge about its impact and contribution on and activities in innovations. OECD, EC and Eurostat are well aware, that organizational, social, and non-technical innovations are innovations too. Therefore, they take steps to improve the measurement basis to grasp these kinds of innovations in future national innovation surveys too (OECD, EC & Eurostat, 1996).

Innovation as Result

Process and product innovations include a very broad spectrum of phenomena, which appear at the level of enterprises, sectors of industry, or even at regional level. Besides that, innovation can appear in all fields of human endeavor. In this sense the 'disc player' is a product innovation, whereas the implementation of 'new public management' in local government is a process innovation, which might be also considered as a structural innovation.

Innovations are differentiated by their *degree of novelty* from 'radical' to 'incremental' innovations (OECD, EC & Eurostat, 1996). The common understanding of radical innovations is to shape large changes whereas incremental innovations have to be seen as step-by-step improvements and by doing so proceeding the change continuously. History of technology shows, that radical innovations like the steam engine, automobile, and personal computers, did not emerge from one day to another, but were results of a long-term research and development process, often lasting decades and always bearing high risks and open ends.³ But once the breakthrough succeeded, the impact of radical innovations has the potential to be very extensive, namely in their spatial reach and in their permeation of society and economy. Closely connected with their degree of newness, innovations are also discriminated by their *spatial reach* as well as by their *organizational-structural reach*. In the sense of *spatial reach*, innovations can be new just for a single person or an enterprise; it can be new for a region, for a whole nation or for an international alliance, or even for the whole world (see Fig. 1).

However, findings in national and international innovation surveys show, that incremental innovations are the most common, most widespread and the usual way to innovate (Arvanitis et al., 2001, 1998; Bosworth, Stoneman & Sinha, 1996; Eurostat, 2001). Product innovations new to the world, average about 4% of sales revenues in the manufacturing industry in Switzerland, whereas, innovations significantly improved and new to the firm average approximately 34% (Arvanitis et al., 2001). Products, which are not innovative because they were not significantly improved, come to about 63% of sales revenues. For the service industry, this share is about 89%, compared to 11% for innovative products. In the EU the share of innovative products new to the international markets is about 7% in average (Eurostat, 2001).

Organizational-structural reach means innovations, which are new for sectors of industry, specific technology communities, organizational systems, and institutional settings. Innovations can also contribute to

² Scientific system as it is used in Europe includes all universal disciplines as well as the universities themselves and public funded R&D institutions.

³ For computers see for example Rojas & Hashagen (2000).

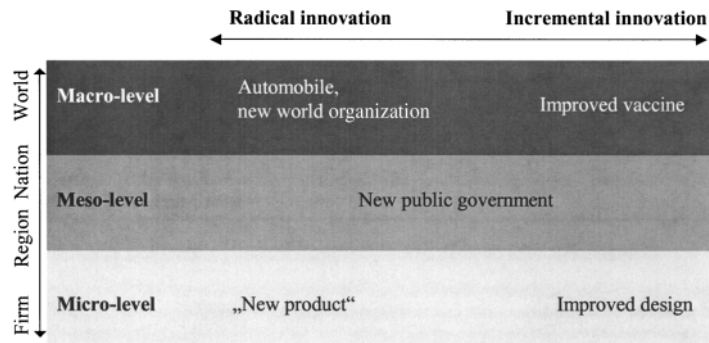

Figure 1. Spatial reach and degree of novelty of innovations.

improving the landscape of institutional and organizational structures. For example, networks between different kind of protagonists and institutions are an innovation for regions and their development, changing the organizational and may be also the institutional structure. This kind of innovation, namely networks, is situated between the market system and the hierarchical system (i.e. government). The profile, structure, and organization of networks differ between each unit analyzed. Networks are able to support innovation processes and innovative activities in enterprises, in government, and in non-profit organizations by developing regional competitiveness and more innovative structures (see Swan et al., this volume). However, networks are also able to hinder the emergence of innovative structures, namely if organization or codes of conduct of networks are deadlocked and established (for example Grabher, 1993). In this light, the link between innovation as results and innovation process is obvious: innovative structures are regarded as a favorable precondition in fostering innovations. This is described in detail in the National Innovation System of OECD (1997).

Both kinds of differentiation, namely by spatial and organizational-structural reach, bear asymmetries between reach and localization of their own 'making'. That makes it hard to grasp, identify, and allocate these innovations and their respectively impacts.

In categories of radical innovation to incremental innovation, products and processes are only counted, if they were implemented or commercialized (OECD, EC & Eurostat, 1996, p. 31): 'technological product and process (TPP) innovation has been implemented if it has been introduced on the market (product innovation) or used within a production process (process innovation). TPP innovations involve a series of scientific, technological, organizational, financial and commercial activities. The TPP innovating firm is one that has implemented technologically new or significantly technologically improved products or processes during the period under review'. The notion of 'implementation' in the definition given above is a very important

condition. It also says that innovations exist before and after their implementation respectively their valorization. In other words, innovation activities do not automatically lead to innovation results. Internal factors like, for example, managerial decisions, financial cuts, organizational restrictions, insufficient technological information, lack of specialists, as well as external factors like changed market situations may emerge as obstacles and ultimately hinder the completion and implementation of innovations. Regarding the difference between failed and successful innovation, there is little knowledge about the ratio to what extend firms have invested in innovations, and what is the gained success out of these efforts. Up to now data about the impact of commercialized innovations is only available by their sales revenues.

Innovation Process on a Macro-Level: About the 'Making of Innovations'

Previously, *innovation process* (on a macro-level) was described as a cascade of scientific knowledge: starting from a (technical) invention made by scientists at universities, being improved or/and transformed by applied scientists and marketing specialists then being implemented and produced by enterprises (see Fig. 2) (Mensch, 1975). The inventory power was attributed to single persons, mostly professors (type 1). Up to now the Swiss education, research, and technology policy program for the years 2000 to 2003 is based on this theoretical background (Federal Council, 1998). In this process there is a clear distinction between the liabilities of universities and universities of applied science (UAS). Universities are in charge of excellence in basic research and in teaching, and regarded as the main input factor for generating new knowledge (Federal Council, 1998). UAS are assigned to a sandwich position as a 'mediator and valorizer' between basic non-oriented science and the commercial side of firms. They have to develop applied problem solutions especially for small and medium sized enterprises (SME) in their very regions—about 99% of all enterprises fall in this category, not only in

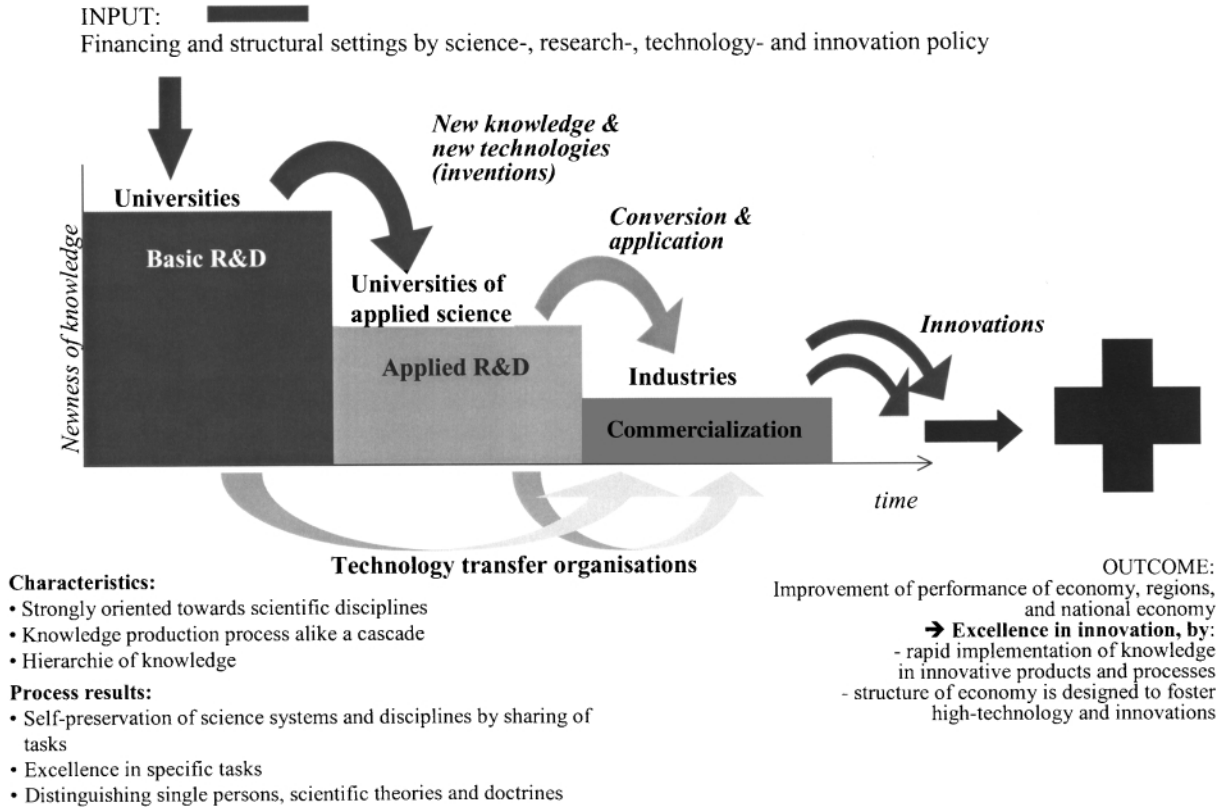

Figure 2. Linear model of knowledge production and innovation.

Switzerland but also in the European Union.⁴ Therefore universities of applied science are supposed to use their wide-spread, exhaustive structure to reach each SME in all regions of Switzerland. Finally this applied knowledge shall be utilized by enterprises buying these applied problem solutions, produce new innovative products, and diffuse by selling it. To fulfil their sandwich position, UAS have to be engaged in networking with universities to ensure the flow of basic knowledge to themselves.

To unify both types of universities in their efforts to foster innovation processes, they are regarded as 'equivalent but different'—different with respect to their main tasks (Federal Council, 1998). Politicians suppose the time distance between gaining results of research from universities and competitive new products on the markets (i.e. 'time-to-market') being much too long (Federal Council, 1998). Therefore, they intend to foster technology and knowledge transfer from universities to industries but also from universities to universities of applied science. That process is supported by technology transfer institutions not only established in universities, but also in UAS.

The model, as shown in Fig. 2, is based on the assumption, that innovations rely on scientific knowledge and know-how, which again is regarded as result of R&D. In the end innovation process is equated with knowledge production process, and simultaneously also equated with scientific knowledge production process.

Nowadays, innovation process (on a macro-level) is understood as a process of complex interactions between different kind of protagonists and institutions (type 2). The commission of the European Union describes the innovation process as follows (CEU, 1995, p. 8): "It is no linear process with strictly separated steps, which are connected by an automatically step by step procedure, but it is more a system of interchanges, a system of to- and from-movements among single functions and protagonists, whose knowledge and experience increase and complements one another" (see Fig. 3). This definition and perception of innovation process will be used further in this chapter. For a better understanding of innovation processes, it is important to know for each innovation system, based on regions, industrial branches and so on, which protagonists are involved at which time, what are their specific contributions and why it is so.

Although, no specific pre-conditions for starting innovation process are listed in the Oslo Manual or Frascati Manual, the OECD therefore claims other sources, namely the book about national innovation systems (OECD, 1997). One definition (besides others)

given there about a national innovation system is: "... the elements and relationships which interact in the production, diffusion, and use of new, and economically useful knowledge ... are either located within or rooted inside the borders of a nation state" (Lundvall, 1992 in OECD 1997, p. 10). All definitions listed there, point out the role of interactions or networks between different institutions—like university institutes, research laboratories, enterprises, trade associations, business promotion institutions and so on. Differences among these definitions appear in focusing specific aspects of interactions or results out of these interactions. It is striking that virtually no differentiation of innovation systems exists, for example describing structured procedures in different constellations. Besides, each definition equates innovations with technologies, being explicit or implicit.

Also, recently, studies about new production forms of knowledge have appeared. Mostly looking from the point of science, authors located in fields of social science have analyzed and stated changing structures of interactions between science on the one hand and technology and economy on the other hand. This structural change is expressed twofold: science is opening up to needs and demands from economy, technology and society, whereas innovations in technology, economy, and society are more and more based on scientific knowledge (Caracostas & Muldur, 1998; OECD, 1998; Stokes, 1997; Weingart, 1995). Some authors even describe a shift towards more interactive and more dependent and tighter relations between science, industry, and politics (Leydesdorff & Etzkowitz, 1998). A new form of knowledge production emerges as a result of these structural changes: knowledge is no longer seen as isolated part embedded in the linear sequence of basic research, applied research and diffusion, but emerges in the context of application and application demands (see Fig. 3) (Gibbons et al., 1994; Nowotny, 1996; Nowotny, Scott & Gibbons, 2001). This new application oriented knowledge production is called 'mode 2' in contrary to the traditional, linear academic knowledge production, called 'mode 1'. As science intends to contribute in problem-solving in future, science activities have to be much more transdisciplinary to even be able to do so (Gibbons et al., 1994). The part of unscientific knowledge production is 'somehow' implicitly woven in the network approach of 'mode 2'. Further, the authors assume, that the old model of innovation process is disintegrating for the benefit of the new model (Gibbons et al., 1994; Nowotny, 1996; Nowotny, Scott & Gibbons, 2001). But this shift in knowledge production has first to be empirically tested. Do both types already exist, and if yes, since when and to what extent, are there patterns of precondition for their respectively existence, and so on.

The expansion of knowledge production as 'mode 2' also brings up an important aspect of task sharing

⁴ For Switzerland see: http://www.statistik.admin.ch/stat_ch/ber06/bz01/actuel/dact01.htm 'BFS: Betriebszählung 2001'; for the European Union see: http://europa.eu.int/comm/eurostat/SME_statistics.

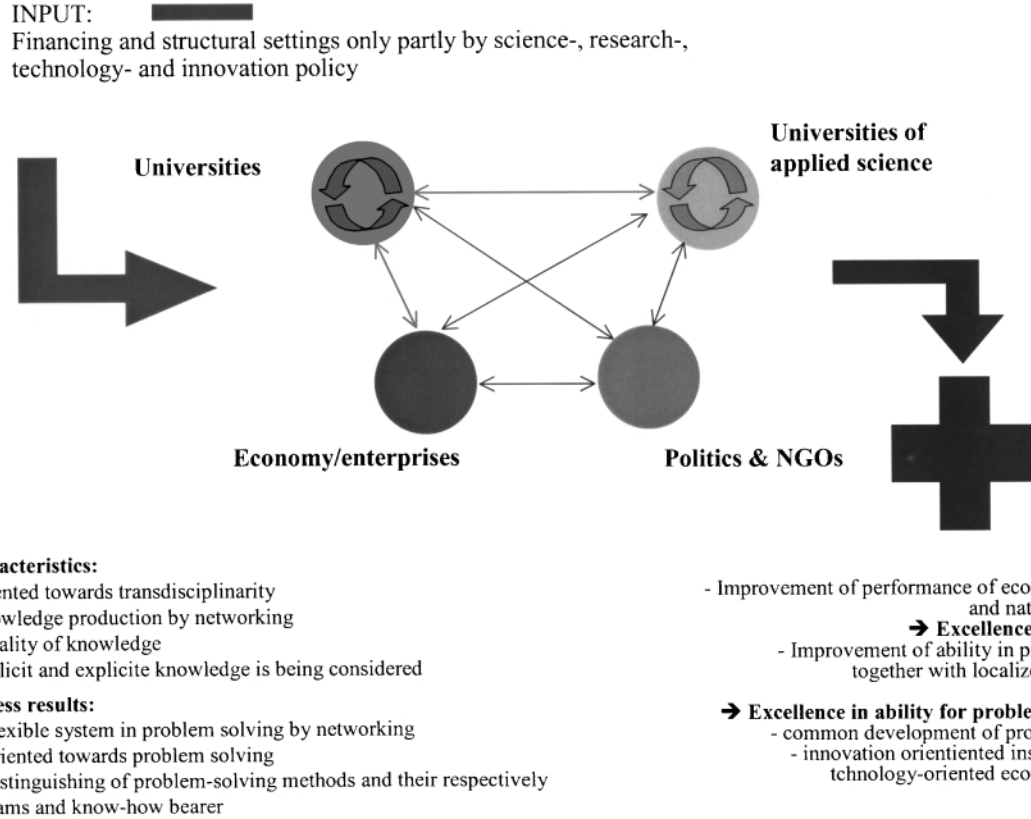

Figure 3. Network model of knowledge production and innovation.

between universities and universities of applied science in Switzerland. As soon as universities are also doing application-oriented research as universities of applied science, this factor is not discriminating both types of universities sufficiently. For universities, it is supposable, to put the focus more on application oriented basic research whereas, universities of applied science put their focus on applied research and its implementation. But this kind of job sharing implies a continuum and a co-ordinated interface between both types of universities, which up to now is unlikely to happen. Last, but not least, this is due to the fact that universities of applied science do not offer the same 'disciplines' and fields of activity as universities. However, the difference in the respective fields of activity is a chance for differentiation. For universities, the emerging approach of transdisciplinarity can be a starting point for problem-solving and oriented basic research.

In Europe scientific knowledge and know-how production is supposed to be based on a strict neutral, objective and perception-oriented R&D-process at universities. The outcome of this process shapes out in different kinds of artefacts and is reflected in knowledge carriers. Carriers of scientific knowledge are graduates and employees, who bear explicit (or codified) knowledge as well as implicit (or tacit) knowledge. Therefore, knowledge and technology transfer is always a people business, where people are involved and affected directly or indirectly by different forms of structures and frameworks, such as incentive systems (e.g. 'publish or perish' fixed with a minimum of publications dedicated for selected scientific communities in appropriate journals; newness; originality). This process of scientific knowledge production is examined in fields of science and technology studies,⁵ especially in the field of social construction of scientific perception. Although, this process is not examined exhaustively, the emergence of scientific knowledge so far can be considered as a product of purely neutral, objective and perception-oriented scientific processes (Felt, Nowotny & Taschwer, 1995). As scientists are driven by doctrines, theories, trends, and personal attitudes there is always a risk in lack of 'neutrality' and 'objectivity'. This has to be born in mind whenever looking at scientific knowledge, knowledge and technology transfer from science to industry and others.

About Diffusion of Innovation: Knowledge and Technology Transfer

The most common known type of knowledge transfer from universities and R&D institutions to industry is the transfer of graduates to industries. Of course, graduates do not exclusively switch over to industry: In

Switzerland after one year of graduation, approximately 43% of university graduates (without UAS) are working in industry, whereas 41% are working in public services, which includes universities⁶ (Diem, 2000). All types of knowledge transfer regarded as typical in the linear cascade model of knowledge transfer (type 1) are shown in Fig. 4. The common understanding of knowledge transfer focuses on R&D studies, consulting and information exchange, which is regarded as one-way transfer flow from science to industry. Instruments for these forms of knowledge transfer are R&D cooperations between science and industry, and innovation cooperations, which additionally include other forms of input and transfer necessary for innovation processes.

About Measuring Innovations

Ministers for science and technology policies of the OECD call for improved indicators to measure better innovation performance and other related output of a knowledge-based economy. In order to do so, the Oslo Manual was developed and first published in 1992 (second edition in 1996 and further updates). The Oslo Manual is mainly intended to develop the measurement of innovations and innovative activities across countries for a better understanding of innovation processes. By doing so it is necessary to understand what innovation and innovation processes are about before being able to measure it. Therefore a great deal of (scientific) knowledge and expertise resulting from the first and second Community Innovation Survey (CIS 1: 1993 to 1994 and CIS 2: 1996 to 1997) of the EU about innovation process was taken into consideration.

Innovation surveys and technology portfolios are the main instruments to measure the performance of the specific national innovation and technology capacity. Up to now innovation surveys are mainly measuring input, output, and throughput factors for innovations in single enterprises. Innovations are only counted and regarded as useful if they have entered the market and/or the enterprises and—in general—have been valorized (see sub-section 'Innovation as Results'). Enterprises, that still have not finished their innovative activities or only have failed innovations, were not counted as 'innovative' in innovation surveys. It is obvious, that this exclusion covers only parts of innovations and especially innovation activities that happen in total. Innovation activities as preparative activities for technological innovations are listed in the Oslo Manual as follows (OECD, EC & Eurostat, 1996):

⁵ For an overview of science and technology studies see for example Felt, Nowotny & Taschwer (1995); Edge (1994); Jasanoff et al. (1994).

⁶ Another 2% start up their own business, another 2% are working in NGOs, 10% remain unemployed and about 3% have a job prospective. But to know more about the destination of graduates, either a long-term survey or a survey across different years of lag towards graduation would be necessary.

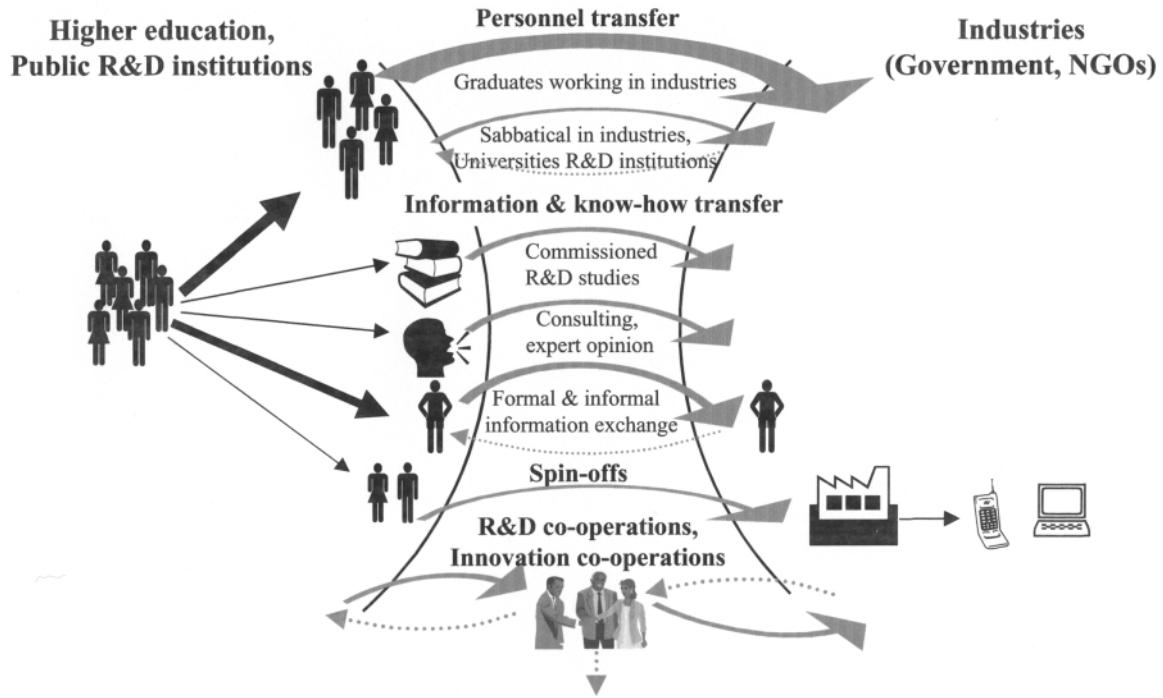

Figure 4. Types of transfer in linear knowledge production and innovation.

Notes:

- (1) Thickness of arrows sketches each transfer flow roughly in its extend (for Europe).
- (2) Dotted lines indicate transfer flows additionally considered in network model of knowledge and technology transfer.

- Acquisition and generation of relevant knowledge new to the firm, including: R&D; construction and testing of prototype; software development; acquisition of embodied technology; acquisition of disembodied technology and know-how.
- Other preparations for production, including: tooling-up and industrial engineering; industrial design; other capital acquisition (e.g. acquisition of machinery, tools); production start-up.
- Marketing for new or improved products.

Some of these activities are borderline cases, for example design, training, marketing, software, which were only counted, if they were carried out only for innovation purposes. Furthermore, even the new edition of the Oslo Manual only recommends measures regarding 'technological innovation' like products and processes, for the measurement of 'organizational innovation' is classified as very difficult, highly firm-specific, hard to summarize and therefore hard to compare. Being aware that measurement of innovative activities mainly focuses on technological innovations it is obvious that the service industry is not addressed ideally. Up to now, there are still no exhaustive nationwide surveys in the wide field of social, organizational and structural innovations in middle Europe, neither considering industries nor services, public services or non-governmental organizations.⁷ Up to now, innovations are also not measured on an exhaustive macro-economic level on their respective impact. For the first time service industries have been considered in the EU innovation survey of 1996–1997, in the Swiss innovation survey 1996 (Arvanitis et al., 1998; and further in 1999; Arvanitis et al., 2001), in the Netherlands (Brouwer & Kleinknecht, 1996), and in Germany (Ebling & Janz, 1999). the EU innovation survey of 1996–1997 has considered only a few service industries, namely wholesale trade, traffic, telecommunication, credit and insurance industry, data processing and database, and architecture and engineering companies. Facing these limited service industries considered, the Swiss innovation survey from 1999 covers nearly all private service industries, including service industries for enterprises and R&D for example (Arvanitis et al., 2001).

Data in the innovation surveys shows, that enterprises in the service sector analyzed do have less expenses for innovations (2.8% of total turnover) compared to enterprises in industrial sector (3.5% of total turnover) (EC, 2001). Of course there is a wide spectrum of different expenses between the EU-countries and between both sectors. However, this finding must not lead to the general conclusion of service industries being less innovative. It has to be interpreted carefully: first, the service sector analyzed

is not complete. Second, the importance of single innovative activities in service and industrial sector cannot be equated or directly measured with the amount of expenses, because some innovation activities are not just more expensive than others but not necessarily more important. This fact holds also true for comparisons between the different kind of innovative activities between the service and industrial sector.

Based on new knowledge about innovations, additional needs arise for analysing innovations by their impact, by the role of diffusion, by the sources of information for innovation and their obstacles, by input factors, as well as the role of public policy in innovation and the gained output (OECD, EC & Eurostat, 1996). And there also exist different innovation strategies by industrial branches and industrial clusters, which raises a need for analysing these differences (Arvanitis et al., 2001; Wilhelm, 2000). All these discriminating factors help in a better understanding of innovations and their emergence.

Focusing on output measurement is also not sufficient for a better understanding of how innovations develop, who is involved and so on. OECD and Eurostat are also aware of the necessity of feeding the debate about innovation policy and gathering much more information and analysis of many aspects of innovation for better supporting innovation activities: 'ideally, a comprehensive information system should be constructed that covers all types of factors within the innovation policy terrain' (OECD, EC & Eurostat, 1996, p. 25). Therefore, in future, it is intended to do both: collecting data based on indicators, which will be able to cover some more parts of innovation activities as well as collecting more qualitative information by case studies. Hopefully, procedural aspects of innovation activities are one of the main aims of future investigations in case studies. Case studies therefore are useful if they are conducted, co-ordinated and adjusted, for example by conducting cross-industries studies or cross-countries studies.

Although a great deal about innovation processes still remains unknown or just with a poor understanding, the today knowledge about it is much more sophisticated than 10 to 20 years ago. For a better understanding of the 'making of innovations', processes of technical and especially non-technical innovations have to be analyzed and differentiated. With respect to the implementation of this knowledge in R&D-, technology-, innovation-, and education policy other important aspects arise: how does knowledge about innovation processes diffuse into governance, namely to the main policy decision-makers, and what happens in the 'black box' of political decision-making especially in innovation policy. Standard definitions about innovation and R&D as given in the Oslo Manual, Frascati Manual or the Green Paper are basic orientation guidelines for

⁷ For a review of the state of the art in service innovation research see Küpper (2001).

government in single member states. But it does not mean, that the design of the respective policies, especially of innovation policy, is automatically based on this knowledge! This is important, because measures and programs as 'output' of this black box are often based on implicit assumptions about innovations far from current (scientific) knowledge (Hofmann, 1993). The understanding of innovation can be differentiated as follows: (a) innovation processes as they objectively happen;⁸ (b) innovation processes as they are partly described and reflected in innovation surveys, case studies and so on and as they are interpreted, described, and explained by researchers, scientists, politicians, and others; and (c) assumptions about innovation processes reflected in activities and measures to foster innovation processes by politics.

In the following sections, innovations are looked at closer to find some answers about the role of innovations, what is known about innovations, and by whom.

Why Innovation? The Role of Innovations for National Economies

For the general purpose in a better understanding of innovation it may help, to embed the complex innovation phenomena as a whole in the context of research and innovation policy and national economic development. Therefore, it is necessary to analyze and evaluate political statements, programs and measures regarding to foster innovation.

Innovation is widely regarded as the most important factor for developing economies, to raise the competitiveness of enterprises up to national economies, and in the long-run to raise the welfare for the inhabitants of national economies. This 'chain reaction' is roughly sketched in Fig. 5.

First, a general distinction has to be made: the 'direction of effects' in Fig. 5 shows the innovation process: (1) and its diffusion; and (2) as it is understood and partly supported by research and innovation policy programs measures in Switzerland. The main reason for putting R&D at the beginning of this 'chain reaction' as shown in Fig. 5 lies in statistical relevant findings of positive connections between technical standards and gained export position (Grupp & Legler, 1987; Soete, 1987). Technical standards again were found being mainly based on R&D in technological fields. Studies have identified different branches characteristic in high amounts of R&D and ranked on top positions in export (BMBF, 2002 (annual volumes); Grupp & Legler, 1987; Soete, 1987). As the average value of R&D in all branches was found to be 3.5%, all

branches under this level were called 'low-tech industries', branches with an amount between 3.5% and 8.5% were called 'higher-tech industries', and such with more than 8.5% were called 'high- or top-tech industries'. That is the reason why technological based R&D was supposed to be the main source of good performing industries and therefore it was assumed to be good for the whole nation. As a consequence of this finding key industries with high levels of R&D have been identified and classified to be worth being supported by technology and innovation politics.

The finding of the connection between 'technical standard and gained export position' described above is correct to some extent but not sufficiently exact. R&D can lead to technological innovative products and processes in an enterprise, which gain high commissions and therefore, have positive effects on its employees; but it does not always happen or automatically—which makes an important difference! This short-gripping understanding of innovation expresses a lack of knowledge of what happens in the 'black-box', i.e. in 'the making of innovation'. As we know today R&D is not the only source for innovations (Acs & Audretsch, 1993; Eurostat, 2001; Felder et al., 1994; Grupp, 1997): approximately 57% of all expenses for innovation activities are spent on their own R&D in large sized industrial enterprises, whereas the share is only about 25% of all expenses for innovation in small and medium sized enterprises (SMEs) (Eurostat, 2001). Especially buying and implementing new machines and new equipment is taking about 50% of all innovation costs. For SMEs new machines, design, experimental testing, and construction development are more important factors for being innovative than R&D (Biegelbauer, 1997; Bosworth, Stoneman & Sinha, 1996; Eurostat, 2001; Licht & Stahl, 1997). As innovative products mainly result out of step-by-step improvements of existing products or processes or as results of combinations of already existing products they are often products of design, marketing, customer-relationships or a combination of these factors, especially in small and medium sized enterprises. Therefore, factors like design, experimental development, marketing, and other innovation activities have also to be included in a definition of innovation activities, as it is done in the Oslo Manual (OECD, EC & Eurostat, 1996).

Up to now, no theory is able to prove the neo-classical assumption between well-being enterprises and well-being nations exactly (Ehrenberg, 1995). One relevant indicator for breaking off this simple linear logic is the phenomena of job-less growth. Thurow claims a threat of industrial growth by simultaneously stagnating job opportunities in the USA (Thurow, 1996). Economic growth between 1991 and 1995 in Europe did not lead to a decline of the unemployment rate either, contrarily, the unemployment rate rose from 8.2% to 10.9% during this time (Eurostat, 1997b).

⁸ Of course, 'the real innovation process' has always to be regarded as a social construct which can never absolutely be objective. Here, it is meant as the infinite search for 'objectivity' or 'truth' of at least some researchers.

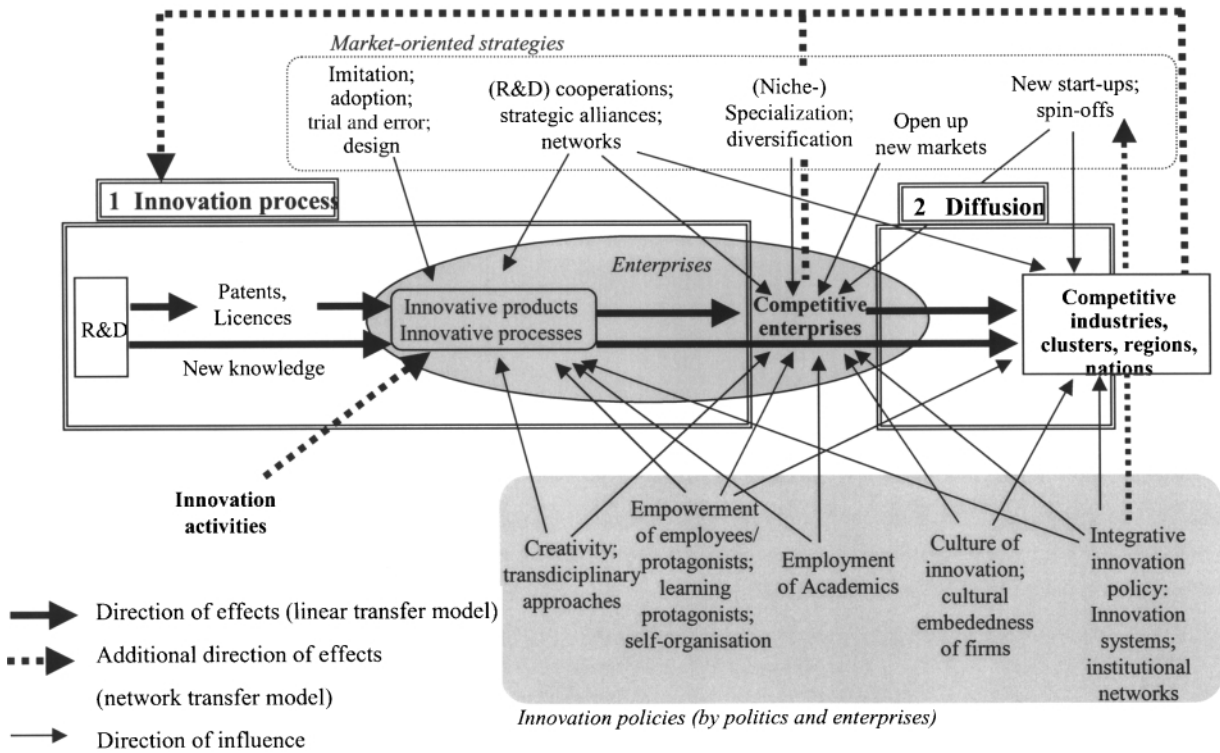

Figure 5. Influences on innovations and effects of innovations.

However, job-less growth is again no phenomena that can be observed neither in all industrialized countries nor in all countries in Europe (Christoffel, 1995; OECD, 1996a; Weeber, 1995, Wolter & Curti, 1996). It is realized that there does not exist an automatic or mechanistic way of showing how economic growth is effecting employment (or vice versa) (CEU, 1993b; Ehrenberg, 1995; Oppenländer, 1994; Walterskirchen, 1994; Wolter & Curti, 1996).

The findings of 'knowledge as the main source of innovation' and at least national welfare has only recently emerged, and led to innovation policy regarded as amalgam of science, technology, and industry policy (OECD, EC & Eurostat, 1996). The logic of good performing industries that benefit the whole nation is common place, but enlightens just parts of its underlying connections: strategies of innovation processes in enterprises are changing by becoming internationally oriented and are therefore dis-embedding from their former innovation network (Sauer & Lang, 1999). This may lead to a phase out of personnel and/or institutional responsibilities of single enterprises and at last to an erosion of innovation networks.

A main aspect of impact of innovations is, that innovations bear two sides of a medal or in other words innovations are a paradoxical phenomenon: not each progress for enterprises means progress for its employees or its region. For example: on the one hand a technologically new production process in an enterprise produces an enormous raise of sales; on the other hand it costs a lot of people their jobs. But, innovations also can improve both: the performance of the enterprise as well as the job-situation of employees. In all cases it is necessary to put the impact of innovations into context and therefore, take several aspects of impact into account. However, this depends on the point of view one takes, and it also depends on the demarcation regarding space, time, and which type of costs and effects of innovation are taken into account. This means the 'location' of impact, and—closely connected—the duration of impact, are regarded the main discriminating factors for impact of innovations in general.

The following section sheds some light on the involved systems and protagonists and their role in innovation process in Switzerland.

The Swiss Landscape of Tertiary Education, R&D and Innovation

Compared to other states in Europe, measures and instruments for supporting innovation and innovation activities are less differentiated and much less multifaceted in Switzerland. Innovation policy in Switzerland is even formally in-existent up to now and also the awareness about the necessity of innovation policy is hardly developed (Freiburghaus et al., 1991). Instead, education, research, and technology policy offers measures and instruments also supporting inno-

vation activities. This has to be considered, when using the term of 'Swiss innovation policy' later. Swiss innovation policy is still focusing on R&D as the main input factor for innovation. Whereas in most middle and northern states of Europe, the network approach for supporting innovative activities has been implemented and supported in different ways for a considerable time.

Innovation Policy

Innovation process is regarded to take place mainly between science and economy being directly involved (see arrow B and B' in Fig. 6). Civil society claims nowadays to having more influence and more rights to a say in directions of scientific activities like R&D. Organized by political activities like 'round table discussions' between science and society (partly with industries) as well as 'platforms for society' have been started. As this is a new measure it is not sure, whether government will continue to support it, and whether it will have an impact on innovation activities in science in future.

The role of politics is trying to influence the direction of innovations by setting up the required general conditions, also by financing parts of innovation activities, virtually all in science (see arrow A in Fig. 6). Swiss research and technology policy makes it its business in mainly strengthening R&D in science (arrow A) which is expected to help industries and economy most (arrow B). In Swiss politics mainly two departments are responsible for R&D and technology and innovation policy, namely the Department of Inner Affairs and the Department of Economic Affairs. In the Department of Inner Affairs the Federal Office for Education and Science and the council of both technical universities and its four annex-institutions are connected in the Group of Science and Research. They are mainly in charge of universities and scientific research, whereas the Federal Office for Vocational Education and Technology as part of the Department of Economic Affairs is mainly responsible for the universities of applied science, for innovation, and for technology transfer. Its main instruments therefore are the Commission of Technology and Innovation and the Section for Universities of Applied Science. The Swiss National Science Foundation (SNF) is another instrument for mainly supporting basic research. Therefore approximately 80% of its budget is spent on non-oriented as well as oriented basic research projects by research programs, whereas the remainder is spent on research associates and different activities in the fields of basic science, e.g. support of science conferences. Although organized as a foundation the SNF is fulfilling its tasks by order of the federal state, represented by the federal office for education and science.

The Swiss Council of Science and Technology (SWTR) is the main organ of science, research, and

technology policy for the Swiss Federal Council and for federal government, namely for the Department of Inner Affairs and the Department of Economic Affairs. However, members of SWTR are determined by the Federal Council and not by the universities or universities of applied science itself. Although, the SWTR is supposed to be an independent organ, neither influenced by interests resulting from faculty nor by industrial affiliations, each member of the SWTR council is simultaneously either a professor at university, or a decision-maker, or a person with wide influence in one or more industrial enterprises. As national universities and universities of applied science are mainly financed and determined by the cantons, the SWTR could be of great significance for co-ordination of scientific concerns among science institutions and the federal government and its respective departments. However, up to now issues dealt by SWTR are dominated by basic aspects on scientific systems, but neither by aspects of applied science, nor by elaborating concepts or exhaustive consulting activities for politicians.

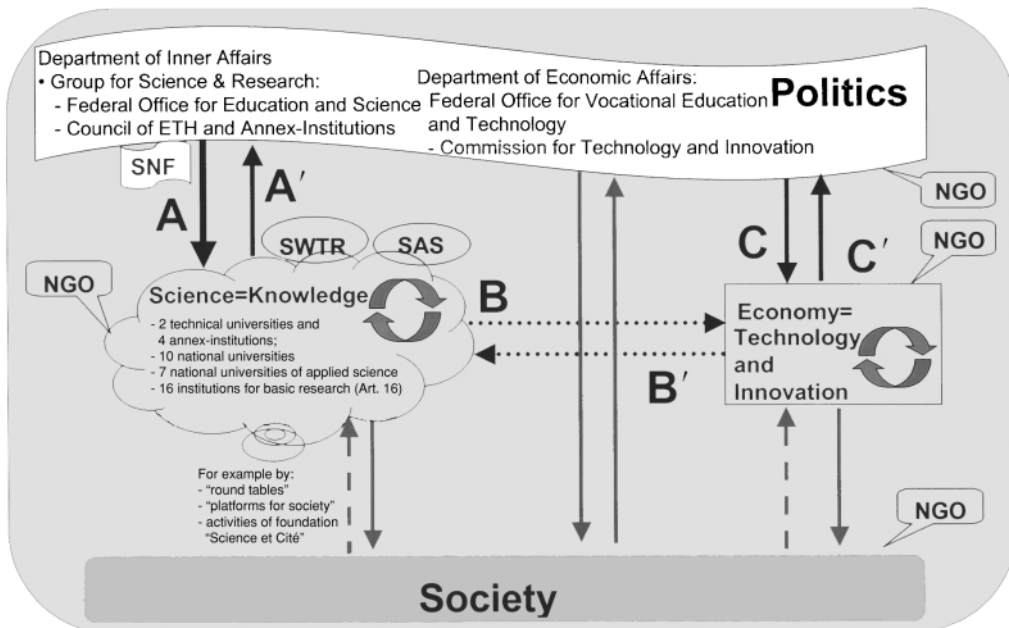

Industries are also influenced and determined by general set-up of policies, like policy programs and instruments, taxes, laws about venture capital and so on (C in Fig. 6). Industries again are able to influence innovation policy by their specific pressure groups and

by militia system which here means direct influences of leaders in economy who are at the same time leaders of parties, leaders in the national or cantonal government system or members of scientific councils (C').

Education, research, and technology policy ('innovation policy') in Switzerland is based on a diffusion-oriented approach (Federal Council, 1997), whereas innovation policy in the EU is program-oriented manifested in five years termed research and technology frame programs. In Switzerland all governmental measures aim to directly or indirectly influence the emergence and diffusion of new and technology-relevant knowledge (BFK, 1992; Federal Council, 1997, 1998). Therefore mainly universities, federal technical universities⁹ and research institutions conducting basic research¹⁰ are supported. Additionally, federal government also conducts research in its own governmental institutions (or resorts) but it also delegates liability of research support to different

⁹ As described in the section on 'R&D Structure and Expenses' in more detail.

¹⁰ This includes four research institutions, so called annex-organizations—which are closely connected to the two federal technical universities, as well as 19 institutions named in the law about research, article 16, which are assigned to fill gaps in the Swiss 'basic research landscape'.

.....➤ Weak ties in knowledge transfer and therefore weak ties in innovation processes
 —➤ Weak ties in knowledge transfer in a wider sense

ETH: Swiss Technical Universities; NGO: Non-governmental organizations; SAS: Swiss Academies of Science; SNF: Swiss National Foundation; SWTR: Swiss Science and Technology Council

Figure 6. Involved subsystems in innovation processes in Switzerland.

institutions.¹¹ Between federal and cantonal government there is a kind of job-sharing, as universities and universities of applied science are in charge of the cantons and mainly financed by them. Federal government takes the role of strategic thinking and developing concepts about science, R&D, and technology development, whereas the cantons are in charge of its operative implementation. As Switzerland is strictly based on principles of federalism and subsidiarity, the cantons have huge autonomy in the respectively implementation.

The approved education, research, and technology policy program for 2000 until 2003 intends to spend about 11.8 billion CHF¹² to reach the goal of fostering research and technology. From this amount about 1.92 billion CHF or 16% are dedicated for applied research, for supporting research and technology in SMEs, and for exchange between science and society. With the education, research, and technology policy program mentioned above five main aims are intended to succeed (Federal Council, 1998).

- (1) Development of Swiss higher education networks between universities, technical universities, and universities of applied science (UAS) to mainly foster the interactions among them for at least a better performance of technology transfer.
- (2) Integration of these networks into international cooperation for also being competitive and attractive for foreign students and to participate at international knowledge networks.
- (3) Supporting excellence in education and research by fostering competition among higher education and research institutions, by establishing more performance-oriented basic financial contributions for higher educational institutions, by establishing national centers of excellence in higher educational institutions, by conducting evaluations for quality control in technical universities.
- (4) Quantitative and qualitative development of networks of higher educational institutions with respect to the raising amount of students by better preparing and educating students in abilities they need in their later job-life and therefore, by also making UAS more attractive for students.

¹¹ Institutions for research support are Swiss National Science Foundation (for support of basic research), Commission for Technology and Innovation (for support of oriented research, mainly for universities of applied sciences and for development of competences in UAS), four scientific academies (for support of exchange between scientific disciplines and between science and society), and other institutions to support a few selected fields of research.

¹² Without expenses for education on the secondary level, for education programs of the EU (secondary level), for contributions to international organizations, and without contributions for the European Space Agency (federal council, 1998). All these expenses added makes a total amount of 14.12 billion CHF for the period 2000 to 2003.

- (5) Valorization of knowledge of these institutions, mainly by fostering the efficiency of technology transfer of UAS, by fostering the generation of spin-offs, and by supporting the Swiss Network on Innovation which again supports to raise the efficiency of technology transfer at Swiss higher educational institutions.

The Federal Council states a large gap between gained research results from universities and having this knowledge transformed into competitive products. For this reason it aims to foster the exploration of the potential which it recognizes being inherent in these research results (Federal Council, 1998). Therefore the Federal Council intends to improve the return on investment (ROI) of publicly funded research activities in universities and to improve the transfer processes in UAS (see Fig. 2).

In the following section, general R&D input data is considered, before financial structure of R&D financing and realization is regarded for Switzerland. After this a closer look on innovation activities and knowledge transfer is taken based on results of R&D—and innovation surveys as well as on studies about exchange and networks between science and industry. As this contribution focuses on exchange, knowledge, and technology transfer between science and enterprises, it emphasizes more on input factors as preconditions for innovative activities, than on output and outcome of innovative activities.

R&D Structure and Expenses

As one intends to localize innovation activities and R&D as part of it, one has to fall back on results of innovation surveys as well as on results of R&D surveys. The Swiss Federal Office for Statistics (BFS) is collecting data about R&D in universities and other public research institutions and organizations, whereas data about R&D in private industries in collected by Economiesuisse, the main association of Swiss economy (organized privately) and BFS together. The indicators in science and technology (S&T) used by the Swiss Federal Office for Statistics are organized in five sections (BFS, 2001a):

- (1) S&T context: indicator: human resources for S&T in Swiss society;
- (2) S&T input: indicators: R&D personnel—R&D expenses—sources for R&D;
- (3) S&T process: indicator: participation at 3rd and 4th (. . .) frame program of the EU;
- (4) S&T output: indicators: patents registered—technological balance of payments; balance of trade of high-tech industries;
- (5) S&T impact: indicators: none.

One of the most popular indicators is input-oriented, like R&D financing and R&D personnel. With respect to a better understanding of innovation processes,

indicators as listed above, are relevant but insufficient. Therefore, results of innovation surveys as well as qualitative studies have to be added, in order to complete the knowledge about innovation processes, which is indispensable for policy making.

R&D Expenditure in General

Switzerland spends approximately 2.7% of its gross domestic expenditure in R&D during 1996 which is much higher than the average value of OECD with 2.2% and of EU with 1.8% in 1997. Sweden spends much more on R&D, namely 3.9% in 1997 and the USA about 2.8% in 1998 of its gross domestic expenditure (OECD, 1999: MSTI database). At the same time Switzerland has 55 researchers per 10,000 labour force, which is equal to the average value of OECD and a higher than average value of EU with 50. The highest amount of R&D labour force are in countries like Japan (92), Sweden (86), Finland (83), Norway and Iceland (both 76), and the USA (74). Although, these data used here, do neither help in comparison nor tell anything about the efficiency and the outcome of any of these expenses. Therefore, they should have to be set in its specific context, and compared much more in detail with respect to its impact and efficiency, which should be done between specific (technological) industries or other issue clusters. Although Switzerland has one of the highest rates of patent application, and one of the highest rates of industrial R&D, the share of high-technology industrial goods in export is comparatively small (Schmoch, Grupp & Laube, 1996). In general, Switzerland has gained good basics and export positions in medium-technology industries but has not reached a high position in specific high-technology industries, which are regarded as key-industries (Hotz-Hart & Küchler, 1996).

Where does all the money come from that is spent on R&D in Switzerland? Private industry bears about 67% of all R&D expenses in Switzerland, whereas federal government contributes about 19%, and cantonal government about 8% of all expenses for R&D, 3% are contributed by abroad, and 3% are contributed from other sources (data for 1996; BFS, 2001a). Hence, the share of R&D expenses is virtually equal to the share of R&D personnel: about 69% of all R&D personnel are working in the private industry, and 29% in higher education institutions. The rate of industrial financed R&D in Switzerland is above-average, compared to other OECD countries where the total average value is approximately 62%. In Japan the share of industrial financed R&D is about 68% and in the USA it is about 59% (data for 1997; OECD, 2000).

Financing R&D at Universities (Without Universities of Applied Science)

In Switzerland three kinds of universities are existing, which are financed, regulated, and controlled different:

two federal technical universities (FTH), one in Zurich and one in Lausanne, which are mainly financed by the federal government. Both federal technical universities additionally have funds from projects and acquisitions, which again are mostly public funds. Ten cantonal universities and seven universities of applied science (UAS) have mixed financial sources, most contributed by cantons where the respective universities are located, by federal funds as well as by projects. UAS have been transformed of former technical, economical, and governmental higher educational schools. But up to now, UAS still suffer from these old structures based rather on a more school-oriented institution than oriented towards an applied-science and education institution: Most of the lecturers in UAS are obligated to participate in a high share of teaching and extended vocational training. Institutional structures, rules, and incentives for applied R&D still are missing at UAS. Compared to universities, UAS have a flat hierarchy, being reflected in a lack of institutional structure and assistants, which also prevent activities besides teaching. Also comparing the law about universities (here without technical universities) and UAS differences between liabilities of both are shrinking: both types have the task to offer services to enterprises or government, both have to be actively doing transformation of knowledge. Although the last mentioned aspect is not formulated for universities, the transformation of knowledge has to be carried out in the field of research¹³ (also it is not clear how fields of research are defined).

All universities are mainly financed by public funds (see Fig. 7): about 80% of the whole university expenses are covered by the regular university budget (in 2000), which is public money from the federal government and the cantons. Of which about 2% are fees from students (BFS, 2001b). The balance of 20% of university expenses is derived from acquisition activities in a competitive way for public and private funded money.¹⁴ This 20% are composed of 6% from Swiss National Science Foundation (SNF) and 14% from other public sources, private industries, and non-profit organizations. Universities are financed by commissioned work from industry and public services

¹³ Federal law about supporting universities and about cooperation between higher education institutions; effective date 1.4.2000.

¹⁴ There is only one exception within the share of financial sources between universities: The highest share of acquisition funds is featured by the University of St. Gall: 43% of its total budget in 1999 consists of 34% from private enterprises and 9% from other private and non-private sources. All other universities reach a maximum of nearly half of it (BFS, 2001a, 2001b). Although, one has to be aware that the highest amount of funds from private enterprises is acquired by the University of Geneva with about 75.9 millions of CHF compared to 38.5 millions of CHF at the University of St. Gall.

Figure 7. Expenses for R&D by source of financing in Switzerland, 2000.

Source: Data: BFS 2002; BFS 2001b; BFS/Economiesuisse 2001.

for 14% whereas this share is about 8% for UAS¹⁵ (average value for 2000; BFS, 2001a). So at the moment the situation is more the other way round than it is supposed to be: universities are also active in applied research while UAS are still unable to conduct the main part of applied research.

In the year 2000 about 94% of expenses of FTHs are financed by the federal government, compared to about 24% of expenses financed by the federal government and 58% financed by cantonal government (18% by others) at cantonal universities (BFS, 2001a). These differences in financing regulatories between cantonal universities and UAS on the one hand, and FTHs and their annex-institutions on the other hand appear to be unbalanced. Cantonal universities have to negotiate their main budgets with cantonal governments, whereas FTHs are financed automatically by federal funds. This also implies, that FTHs are financed by taxes from all inhabitants, whereas, cantonal universities and UAS have to be financed mainly by inhabitants of the respective cantons plus some countervailing duties from other cantons. Some politicians and executives of cantonal universities and of UAS therefore, strive to maintain fairness through adaption

¹⁵ Financial data between universities and UAS is hard to compare, as it is structured and aggregated in different ways.

of the existing financing regulatories among all universities.

In general, these differences in financing are an expression of esteem for natural and engineering sciences being the most important science basic for Swiss industries. Therefore a few highly promising technology fields are promoted under the condition to reach excellence and to keep or reach world leadership in these fields.

Measuring R&D Activities in Universities

As universities are non-profit organizations their income flow should be equal to the output flow—although universities are able to accumulate reserves. This general standard can be applied on the financial flows as well as on the activities financed by the specific financial sources. In other words, money from acquisition from enterprises is supposed to be spent for applied R&D or services as instructed. Existing statistics are about time expense in universities, in fields of teaching and further education, R&D, and other activities. The average values of work time by fields of activities are listed as average, as they do not differ significantly between cantonal universities and FTHs, but mainly among each single university: the

average values of work time is about 35% for teaching and further education, 48% for R&D, and about 17% for ‘other activities’ (data for 2000; BFS, 2001c). Although big efforts were made to gain these data, some crucial weaknesses still remain. First, the method of gaining this data is kind of ‘rough sketching’: as a lack of detailed working hours registration in most universities, the data about working hours are based on assumptions and guesses conducted by some personnel working in university administration. Second, the shares of work time spent by fields of activities are insufficient: They do not allow to draw connections between the sources of funds and the respective and accurate activities therefore conducted. For example, definitions of R&D and ‘other activities’ do not distinguish between basic or free R&D and oriented and applied R&D conducted for enterprises or public services. Also the definition of ‘other activities’ contains ‘services’ (like expertise) conducted for enterprises and other customers. For this reason it is virtually unknown, how much oriented and applied R&D is already conducted in universities, and how much basic or free research is left at universities and its faculties or disciplines.

In other words, applied research and services are already existing in universities but not sufficiently reflected in research, technology, and innovation policy with respect to differentiation between universities and UAS. Data does not exist about innovative activities in universities which may be in cooperation with external partners. Universities are still not in charge for proving their efficiency towards public money spent. No longer can this be regarded as a ‘*pièce de resistance*’ of old linear-transfer-model-thinking, wherein universities and their activities in basic research and teaching are ‘*per se*’ supposed to be the most useful precondition for innovations following.

Financing R&D in Industries

Also not surprisingly, private industry finances its R&D mainly itself: In the year 2000 Swiss industry spent 7.71 billions Swiss Francs for R&D conducted in their own enterprises (intramuros) (BFS & Economiesuisse, 2001). The sources of R&D financing in industry are composed of 91% from industry itself, 6% from foreign countries, mainly through participation in EU programs, 2% from the public sector, and about 1% from other organizations in Switzerland. Additionally, Swiss industry has spent another 1.7 billions Swiss Francs for mission oriented R&D, for supporting R&D, and for gaining know-how for further R&D (extramuros). These R&D mandates are spent for external institutions located in Switzerland and abroad (extramuros). Approximately 7%, or 125 million Swiss Francs, of these industrial expenses extramuros are spent on universities, which makes about 3% of all expenses of universities—without UAS. About 23% are spent on other enterprises for R&D, and about 65%

are spent for R&D on different institutions¹⁶ abroad. Regarding all R&D expenses of Swiss industry of about 9.5 billions Swiss Francs (intra- and extramuros) the amount spent on universities in Switzerland is shrinking to 1%.

Research activities in industry are focused on two industrial branches, namely machine industry, pharmaceutical and chemical industry. They include 70% of all industrial expenses on R&D (intramuros) and about the same share of industrial R&D personnel (BFS & Economiesuisse, 2001). Compared to 1996 the amount of R&D personnel in 2000 has risen by 11 percentage points, which is virtually the same as the amount of R&D expenditure, risen by 12 percentage points.

As seen, there exist very little financial flows for R&D between private industry and universities: Private industry in Switzerland spends about 125 million SFR for mission-oriented R&D conducted in universities (in 2000). These flows have to be regarded as one indicator for interactions and knowledge transfer between both sub-systems. Financial flows based on R&D—as described above—make clear, that there is a huge industrial R&D system and a smaller scientific based R&D system. Both systems are separated with very little cross-overs: there are only a few R&D commissions from industry to universities or vice versa. Altogether these data are important hints that industry prefers to conduct R&D on its own and for its specific needs and purposes. It would be interesting to know, whether, and if yes, how the rate of commissioned R&D from industry to universities—mainly UAS—will change, as soon as UAS have developed their R&D potential.

Resulting in what is required: (1) Defining R&D and innovative activities at universities and at UAS is essential. This could be carried out in a sense of an Oslo Manual for universities and UAS; (2) to create a basis of measuring innovative activities and R&D at universities, better data about researcher’s activities should be collected and assigned to their funding better than before. Therefore, a system of working-hours registration should be implemented; and (3) contacts and links between universities, their institutes and enterprises should also be measured and mapped more systematically for example by acquired funds, by kinds of contacts, and by regions.

To find out, whether industry or science between them has a need in interactions, knowledge and technology transfer and who really uses them, these forms of contact are discussed the following section.

Innovations: Structure and Expenses

In addition to the structure of financing R&D, innovation surveys are another source for interactions and knowledge transfer between science and economy. It is

¹⁶ These institutions may contain universities as well as enterprises and others.

not intended to describe the whole structure of innovation landscape in Switzerland here. Instead only a few remarks about innovations in Switzerland shall be made. Therefore, the innovation survey from Switzerland with data from 1997 to 1999 (Arvanitis et al., 2001) is compared with the innovation survey from EU with data from 1996 to 1997 (Eurostat, 2001). In all states compared, large differences can be seen between manufacturing and service industries being innovative (Table 1). But as the measurement of innovative activities focuses on technological innovations, the question still remains, whether or to what extent are service industries less innovative than manufacturing industries or whether service industries have to be measured differently.

Manufacturing industry in the EU spends about 3.7% of its total revenue for product and process innovations, in the service industry it is about 2.8%. Again, the range between single member states is huge: it differs in the manufacturing industry between 1.8% in Portugal to 7% in Sweden, in service industry it differs between 1.1% in Portugal and 4.7% in Denmark. Companies in manufacturing industries in Switzerland have the second highest expenses as a share of total revenue, namely about 6% (data for 1994–1996), after Sweden with 7%, followed by Denmark with about 5% (data for 1996–1997) (OECD, 2001). In the services sector two different data exist for companies in Switzerland: one far below average, namely 1.7% of innovation expenses as a share of total sales (OECD, 2001) and one significantly above average, namely 3.5% (Arvanitis et al., 2001). The United Kingdom with 4% and Sweden with 3.8% have the highest shares of expenses for innovation activities (Arvanitis et al., 2001).

How many innovators are there in Switzerland internationally compared? All the following data contain average values, bearing the potential of large differences between different industries and between single enterprises.

In general, Switzerland ranks among top three innovative states in Europe. The share of innovative enterprises rises with the size of enterprises: For example in the manufacturing industry in Europe about 43% of small enterprises, 58% of medium sized

enterprises and about 79% of all large enterprises are innovators (Eurostat, 2001). This pattern can also be identified for service industry but on a lower level, namely 36%, 48% up to 73%. For Swiss manufacturing and service industries there is also a dependency between the size of enterprise and being an innovator, although it is a little less pronounced than the average of EU, especially with respect to the manufacturing industry. The ranges are from 77% for small enterprises up to about 82% for big enterprises in manufacturing industry, and from 58% up to 87% for large enterprises in the service industry. Very small enterprises from 5 to 19 employees are in average less innovative in both kinds of industry.

Compared to the less pronounced dependency between size of enterprise and being innovative there is a very pronounced dependency between size of enterprise and carrying out R&D: large enterprises are much more often conducting their own R&D than small and medium sized enterprises (Arvanitis et al., 2001; Eurostat, 2001). This is valid for Switzerland, for the whole EU and also for manufacturing and service industry in the EU, although the differences among service industries are not that distinctive. In Swiss manufacturing industry about 49% of all firms are doing their own R&D whereas about 18% of all service industries conduct R&D (Arvanitis et al., 2001). These data differ between firm sizes as well as between single industries and between countries.

Obstacles claimed to oppose (more) innovation activities by firms are: costs and risks for innovations, which are considered as being too high, problems in financing innovation activities, mostly based on a lack of own capital, lack of qualified personnel, and governmental regulations (Arvanitis et al., 2001). Universities and other R&D institutions are affected here only in the fields of ‘qualified personnel’, which is an important obstacle for firms. In other words, firms hardly address obstacles in a lack of knowledge and technology exchange with firms.¹⁷ This is an average

¹⁷ However, this kind of obstacle was not listed in the questionnaire of the Swiss innovation survey directly, but there was open space for further factors and acknowledgements.

Table 1. Share of innovative enterprises.

Share of innovators (in per cent)	Manufacturing industries				Service industries			
	total	small	medium	big	total	small	medium	big
Switzerland (1999) ¹	71	*	*	*	54	*	*	*
EU (1996–1997) ²	51	43	58	79	40	36	48	73
—Ireland	73	68	78	85	58	60	49	87
—Denmark	71	64	76	91	30	24	45	71
—Germany	69	63	70	85	46	41	60	83

Source: ¹ Arvanitis et al., 2001; ² Eurostat, 2001; * no data available because of different arrangement in groups.

opinion of innovative as well as non-innovative firms. That means first, obstacles can differ in their relevance for single industries and firms as well as for SMEs in general, as they suffer more in financing and in a lack of technology support than others. Second, it also means, that non-innovators are probably not able to fully incorporate these obstacles, because they do not know the relevance of these factors for innovations. This aspect is indeed reflected in obstacles like 'high costs and high risk', which is considered less important of non-innovators than of innovators. This leads to the assumption that the more experience firms have on innovations, the more their perception and knowledge about obstacles of innovation rise.

Innovation surveys conducted prove, that innovations cannot be equated with R&D (Arvanitis et al., 2001; Eurostat, 2001; Felder et al., 1994). As in the Swiss manufacturing industry about 71% of all enterprises are innovators, the share of enterprises doing R&D is about 49% (Arvanitis et al., 2001). In the service sector the share of innovators is 55%, whereas the share of enterprises doing R&D is 18% on average. That means many innovations in both industrial sectors are based on non-R&D activities. In the EU about 53% of all enterprises in service industry are innovative without doing R&D, whereas this share is about 30% in manufacturing industries.

With respect to the average values of innovators in Swiss industries as listed in Table 1, the highest share of innovators in manufacturing industry is in paper and wood industry, in electronic and electrotechnical industry, in textile industry, in chemical industry, in engineering, and in food industry (namely between 74% and 98%). In service industry electronic data processing and R&D companies, banks and insurance companies, hotel and restaurant industry, and service industry for companies are innovative above average, namely between 57% and 66%. These shares are early results of the decision each enterprise has to make when answering the questionnaire of innovation surveys, whether it has implemented innovations in a certain period under review: yes or no. That answer does not tell anything about the amount or intensity of innovative activities nor does it tell anything about the level of implemented innovations (like for example regarding the newness of innovation). Therefore, the intensity of innovation activities should be taken into account. While Eurostat considers the amount of expenses spent for innovation activities (Eurostat, 2001), the Swiss innovation survey constructs a complex indicator for innovation performance of each single industry, considering innovation intensity and non-innovative enterprises by each industry (Arvanitis et al., 2001). Therefore, about 23 single indicators for manufacturing industry and 19 for service industry are taken into account. Measured by this complex indicator in the manufacturing industry, vehicle construction industry, electronic industry, textile industry, engineer-

ing, and chemical industry have the highest innovation performance. In the service industry, the ranking as mentioned previously in this section is still valid except for the hotel and restaurant industry which does not any longer, perform above average.

Innovation Output

The ratio of sales of innovations has to be differentiated between innovations, which are new for the world and innovations, which are new or substantially improved for the enterprise. In contrast to this definition used in the innovation survey in Switzerland, Eurostat combines the category 'new or substantially improved for the market' and adds another category 'new or substantially improved for the enterprise' (Eurostat, 2001, 111 ff.). So the ratio of sales of innovations new to the world is 3.6% in Switzerland, and the one of innovations new or substantially improved for the enterprise is 37%. The total average in ratio of sales of innovations 'new or substantially improved for the market' is about 7%, and the one of innovations 'new or substantially improved for the enterprise' is about 26% in the EU (Arvanitis et al., 2001).

In general, a positive correlation is stated between being innovative and growth of sales. It is found to be more significant for product innovations than for process innovations (Arvanitis et al., 2001). Furthermore, firms being more innovative are performing better than firms being less innovative. Innovation activities are also found to correlate positive with highly qualified personnel and negative with low or unqualified personnel. For input factors no correlation could be found, whether positive or negative. This also means, that R&D in general does not play an all decisive role for innovations. But one of the most crucial findings is, that innovation activities are strongly affected by business cycles (Arvanitis et al., 2001). That means innovation activities depend more on positive business activities—or at least expected positive business activities—instead of generating them.

Contacts and Knowledge-Flows between Science and Economy

As already mentioned in the section 'R&D Structures and Expenses' industries as well as science each have its own research system. Universities are financed up to an average of 14% maximum from economy. Most of these contract activities conducted by universities are supposed to be applied R&D. Besides R&D-projects different forms of contacts and knowledge flows between both systems exist, which not necessarily are paid for or paid fully for and therefore cannot be measured by expenses sufficiently. In the EU innovation survey two main forms of information and knowledge sources are distinguished: (1) cooperation for innovation, composed of R&D-project cooperations, both sides being actively involved, and other

innovation project cooperations; and (2) Using different sources for obtaining relevant knowledge for being innovative, for example, the own enterprise, clients and competitors, universities, and exhibitions (Eurostat, 2001). In contrast to point 1, Swiss innovation survey in 1999 is just measuring cooperation in R&D-projects and –activities but no other innovation project cooperations (Arvanitis et al., 2001).

Considering all enterprises in Switzerland carrying out R&D, which is on average 49% in manufacturing and 18% in service industry, together about 31% have R&D cooperation partners. The share of having R&D cooperations is approximately 27% in manufacturing and 37% in service industry. These shares of cooperation partners just refer to companies with their own R&D activities, which is less than one third of all enterprises. The respective partners for these R&D cooperations are listed in Fig. 8.

Most partners for R&D cooperation are suppliers of material and customers, followed by university-level institutions. The most pronounced R&D cooperations between firms and scientific institutions can be stated in electrotechnical industry, where 86% of all enterprises have cooperations. The highest rate of R&D cooperations in the service industry with scientific institutions have services for enterprises with about 52%, whereas in the service sector banks and insurance industry have the lowest rate. Although there is no differentiation made between different forms of R&D cooperation with the respective partners, some forms of cooperation exclude some kinds of partners. Here it is obvious to consider universities and other university-level institutions as partners for typical forms of R&D

contracts, in order to conduct R&D projects in common by sharing resources, as well as for informal information and for technology exchange, or more exactly: for exchange of technological know-how. R&D cooperation like joint-ventures as well as minority stakes with universities are not imaginable. These forms of cooperation are confirmed by the reasons for choosing these cooperations: for firms, the main reasons for R&D cooperations with universities are ‘having access to specialised technology’, ‘gain complementary’, and ‘shorten development processes’ (Arvanitis et al., 2001).

The low rate of industry-partners in other R&D institutions in Switzerland is also due to the fact, that besides universities only a few research institutions exist. Even they are mainly engaged in basic research, and only very few institutions are specialised in applied R&D. That means firms in Switzerland almost solely have a choice between university-level institutions and other enterprises, like consultants, for R&D Partnership. Second, firms have little choice between institutions specialised in applied, non-basic-oriented R&D, which are not university institutions. In other words, the gap between R&D knowledge of companies and R&D knowledge of science and higher education institutions is not bridged sufficiently in Switzerland because of the absence of institutional thickness.¹⁸ In

¹⁸ For the term ‘institutional thickness’ see Amin & Thrift (1993). In short, it means the existence of diversified institutions, being preliminary and downstream oriented along the chain of value added as well as supporting institutions by providing knowledge, information, consulting and assistance.

Figure 8. R&D cooperation partners for firms in Switzerland, 1999.

Source: According to Arvanitis et al. (2001).

general, networks of innovation between science and economy are not supported intensively by Swiss politics. Therefore, the connections between economy and science in Switzerland are regarded as improvable (Schmoch, Grupp & Laube, 1996).

Besides the forms of R&D cooperation listed above, there are some more forms existing, regarding R&D as well as innovation activities. For example technology exchange does not include other possible forms of technology exchange between universities and enterprises for example, loan or donation of machinery from industry and conducting studies by students in return. These forms of cooperation are already existing, being explicitly formulated or not, as studies for Switzerland, Germany, and Austria have proven (Balthasar et al., 2000; Wilhelm, 2000). Other forms of cooperation between firms and universities are already existing, like financing or sponsoring chairs or institutes at universities, but are still a single case phenomena in Switzerland.¹⁹

By default of data about cooperation partners in innovation activities for Swiss industries, some results from CIS 2 survey in Europe are presented (Eurostat, 2001). This is done to enlighten the meaning and importance of cooperation partners in innovation activities compared to cooperation partners for R&D (see Fig. 8). In Europe about 51% of all enterprises in manufacturing industries and 40% of all enterprises in services are innovative, about 27% of all innovative enterprises in manufacturing industry and 24% in service industry have cooperation in innovation processes (Eurostat, 2001). These shares differ somewhat between the EU member states. The most important groups of cooperation partners for innovative activities are located in the own affiliated group, followed by partners at clients and suppliers. Universities and other R&D institutions are also accepted as innovation partners on fourth and fifth rank. In all industries the five main aims are intended to reach by innovative activities, namely to improve product quality, to extend the variety of products and to open up new markets, to reduce labour costs, and to make production more flexible.

Information Sources

The innovation process is a multifaceted process, which is influenced by different kinds of information sources. The questionnaire of innovation surveys in Switzerland as well as in EU asks for the importance of different information and know-how sources for the respectively innovation activities in each company. However, this does neither correspond exactly with the use of these sources nor with the contentment about

this source nor the contentment resulting from the use of these sources. With respect to the real use of different information or knowledge sources their respective importance can be over- or underestimated. It is important to consider the respective question regarding information sources in both innovation surveys is different and therefore hard to compare directly.²⁰

Information sources first have to be distinguished between such as the own firm (internal) and such being external (including firms of affiliated group). The Swiss innovation survey of 1999 does not consider internal information sources in its questionnaire, which is hard to understand, as internal information source is known to be the most important information source. Considering external information sources, three components have to be differentiated: knowledge and information from other firms (like customers, suppliers, competitors, joint ventures), science-based knowledge and information from universities and other R&D institutions, patent specifications etc, and information open for the public (e.g. exhibitions, conferences, literature, computer-supported information systems). In all cases implicit (or: embodied) and explicit (or: disembodied) knowledge is asked for and used by firms.

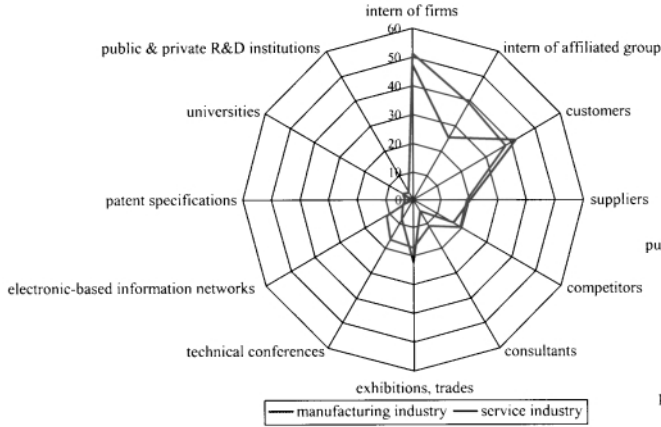

In Switzerland, companies along the value-added chain are regarded as most important information sources for innovation activities (see Fig. 9). Also general information sources open for the public, for example exhibitions, are regarded as an important source, although this explicit named source is more relevant to the manufacturing industry rather than to the service industry. Universities are considered to be less important than issue conferences and literature, but more important than other R&D institutions. This may also be due to the fact of few R&D institutions existing in Switzerland.

For every other firm in the EU the intern knowledge source in the own company is very important (Eurostat, 2001; Fig. 9). The most important external source is the one of customers. Generally said, companies along the value-added chain and competitors are playing a crucial role as information source for innovations. Universities and other R&D institutions, patent specifi-

¹⁹ For example the chair of Entrepreneurship at the University of Lausanne.

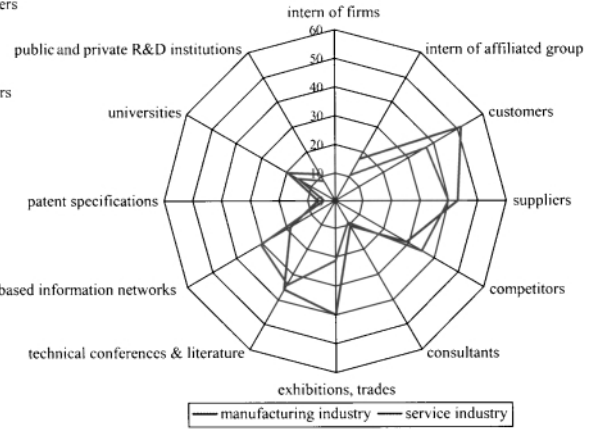

²⁰ In the CIS 2 survey, information sources are judged on a scale of 1 to 4, where 4 is considered as 'very important source', and only rank 4 is taken into account. Information sources are judged on a scale of 1 to 5 in the Swiss innovation survey, where 4 is considered as 'important source' and 5 is considered as 'very important'. Here both ranks (4 and 5) are taken into account. Furthermore, Swiss innovation survey regards companies with five employees or more, whereas CIS 2 considers only companies with 20 employees or more. It is assumed, that these very small sized companies use less information sources and therefore results for Switzerland could be underestimated.

Information sources (intern and extern) relevant for innovation in EU, 1996-97

Share of listings of information sources, considered as "very important" (rank 4 on a scale of 1 to 4)

Information sources relevant for innovation in Switzerland, 1999

Share of listings of external information sources, considered as "important" and "very important" (rank 4 and 5 on a Lickert-scale of 1 to 5)

Figure 9. Information sources relevant for innovation activities in Switzerland, 1999, and in EU 1996–1997.

Source: Data based on Eurostat, 2001; Arvanitis et al. (2001).

cations, and even consultants are regarded as far less important. It is obvious, that these institutions are not able to provide much information and know-how necessary for direct and short-term implementation for innovation activities. Results from Swiss innovation survey prove, that universities are accepted as important R&D cooperation partner although they are not a very important source for information in innovation activities (Arvanitis et al., 2001). In general, universities, R&D institutions, and patent specifications are regarded as important but not the most important source for R&D. They offer complementary scientific and technological know-how and access to know-how to shorten development processes in companies. But they are not regarded as important knowledge source for innovation activities. But there are some large differences in the ranking and importance between different external information sources, among Swiss innovation survey in 1996 and 1999. These differences may be caused by cyclical variations. In any case they make it hard to compare and to come to conclusions about the real importance of these sources.

As there are only a few indicators in innovation surveys measuring innovation activities mainly at the interface between science and industry other relevant studies like case studies have to be drawn on. Empirical surveys concentrating on different forms of cooperation and information exchange between universities (and other R&D institutions) and firms or networks of different protagonists in R&D and innovation activities are rare. There are a few results from these surveys presented here in short, always focused on interaction between universities, other R&D institutions and firms or networks.²¹

Case Studies About Knowledge Transfer and Interactions Between Universities, R&D Institutions and Firms

Audretsch & Stephan (1996) focused on the importance of spatial closeness between universities, scientists and biotechnology firms in the USA for cooperation. They state a positive influence of spatial closeness on the emergence of cooperations, but this influence is far from being overwhelming. Also, the importance of closeness depends on the kind of collaboration, which is for example much more important for very intensive collaboration being the co-founder of a new start-up than for project cooperation.

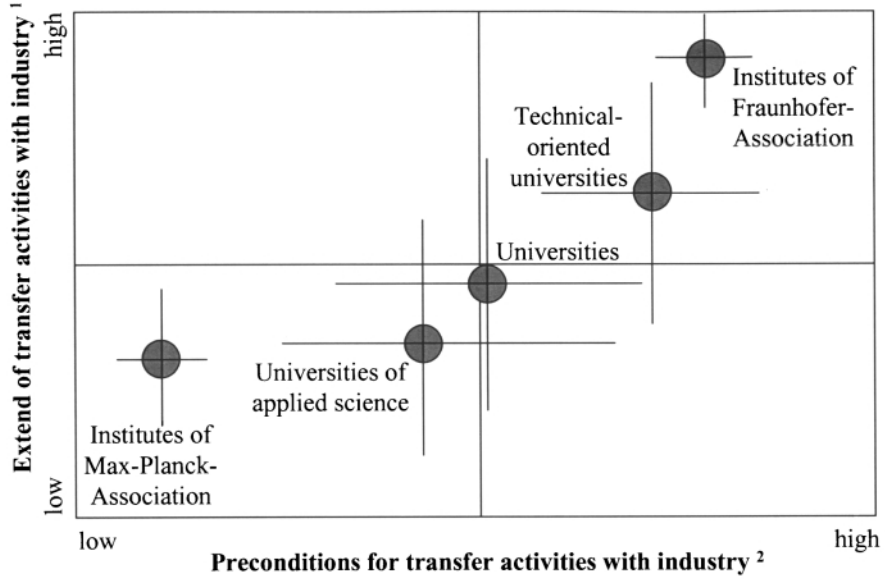

Fritsch & Schwirten (1998) analyzed forms and extend of collaboration between universities, universities of applied science (UAS), other R&D institutions, like Fraunhofer-Institutes, Max-Planck-institutes, institutes of so called 'blue list', and firms in

three regions in Germany.²² Therefore, in total 246 chairs or institutes were examined only in disciplines supposed to be able to foster innovation processes in industries. Asked about whether each chair (at universities and UAS) or institute (other R&D institutes) ever had some collaboration with firms in the period between 1993 to 1995 about 78% of all institutions agreed. However, this does not tell anything about quality and intensity of these collaborations. Among all institutes asked, R&D institutions outside universities work together with firms most frequently (91%), followed by chairs of UAS (83%) and by chairs of universities (74%). However, about 34% of all firms in these respective regions asked did work together with universities, UAS, and other R&D institutions in the period under review. For research institutions the most important sources to initiate collaboration with firms are 'personnel contacts of employees' (39%), 'approach of firms' (29%), 'contacts on exhibitions and congresses' (14%), whereas 'place of contacts by transfer institutions' are only 4%. The use of electronic databases is marginally less than 1%. So the common organized technology transfer institutions and their acting as a broker shows only little potential impact in this field. The role of R&D institutions is to support firms in the early stages of innovation activities, namely in the development of new ideas and concepts. Here, in all phases of innovation activities other R&D institutions play a crucial role in supporting firms. Spatial closeness is beneficial for collaboration but not crucial.

Czarnitzki, Rammer & Spielkamp (2000) have a similar survey concept like Fritsch & Schwirten (1998): They asked approximately 850 research institutions at universities, technical oriented universities (TOU), universities of applied science (UAS), and 4 R&D institutions outside of universities ('others') in natural and engineering science in Germany about their interactions with industry. These interactions are commonly understood as knowledge and technology transfer. The authors concentrated on intensity of interactions, the forms of transfer used, obstacles and problems of knowledge and technology transfer. Figure 10 shows the main finding of this survey, namely a

²² The regions analyzed were Hannover, Baden, and Saxony. To even be able to assess the extend of cooperation of 'other R&D institutions', it is important to know about their financial structure: universities and UAS in Germany are principally financed similar as in Switzerland: about 14% of their total expenses of 35.7 billion DM (about 18 billion Euro) are financed by acquired third-party-funds. However looking at other R&D institutions, only institutes of the Fraunhofer-Association are designed to conduct applied R&D and therefore have to finance themselves mostly by acquired third-party-funds, which up to now have a share of about 60% of their whole expenses (this share does not consider four Fraunhofer-institutes operative in defense-oriented R&D; BMBF 2000).

²¹ For a sample of studies about structure and intensity of mainly technology-oriented transfer in Germany see also Schmoch, Licht & Reinhard (2000).

1 = Considered as:

- influence of industry on orientation of R&D in universities etc.;
- interactions with industry;
- labour force turnover to industry
- third-party funds from industry

2 = Considered as:

- kind of orientation of R&D (basic, applied, experimental)
- financing structure of institution
- technical specialization
- qualification structure of personnel
- size of research unit

Figure 10. Typology of research institutions in Germany in terms of interactions with firms.

Source: According to Czarnitzki, Rammer & Spielkamp (2000).

typology of all research institutions analyzed with respect to their interactions with industry. There, Fraunhofer-institutes and TOU show the highest rates in interaction with firms as well as the most favorable preconditions for these interactions. Although in Germany (as well as in Switzerland), UAS are supposed to play a crucial part in knowledge transfer, but as can be seen here, they have worse preconditions and less interactions with firms than universities. Obviously UAS are still unable to fulfil their task in applied R&D and intensive interactions with firms, although they have been in operation for more than 30 years. The main obstacles for this weak link between UAS and firms are indicated by UAS in too much teaching, which plays a very crucial role therefore, and in a lack of qualified personnel. Additionally the payment structure of UAS personnel is discriminating compared to the one of universities, which may also cause the weak position of UAS stated²³ (Schmalholz in: Schmoch, Licht & Reinhard, 2000). Institutes busy in applied and industry-oriented R&D and therefore significantly financed by acquired third-party funds have much more interactions with industries than other institutes. The connection between R&D orientation, financial structure of R&D institutes and their extend of interaction activities with industry is also stated by further studies²⁴ (Balthasar et al., 2000; Wilhelm, 2000).

Hellmer, Friese, Kollros & Krumbein (1999) examined innovation activities of SMEs in two regions in north Germany and their use of, and relation to, cooperations for gaining innovations in three industries.²⁵ They found that on the one hand SMEs rely on cooperation in innovation activities, because of their small resources. But on the other hand the risk of failure of resource intensive cooperation is much too high for SMEs. Therefore, SMEs have less coopera-

tions than large sized enterprises. Most of their product innovations are incremental, based on development of existing products, partly as a result of collaboration with clients. The few existing cooperations are oriented towards technological excellence and competence of the respective partners but they are not primarily oriented towards partners located in their specific region. This is also valid for cooperations with universities and other R&D institutions. Regional cooperations among firms in their innovation processes are stated to be much less pronounced than theoretical frameworks about regional innovation networks and cooperation suggests. For the few cases of spin-offs from R&D institutions examined here, the authors also found out, that they are located close to their former employer, if further cooperation or exchange is wanted. Again, the excellence in technological or other forms of know-how is a decisive factor for cooperation, as well as trustful personnel contacts to well-known institutes and colleagues.

Peters & Becker (1998) observed the effects of academic research on innovation activities of firms in the German automobile supply industry. They found that the contribution of academic research to innovation activities in firms is less relevant than industrial sources, but for R&D cooperations, universities are the most likely partners. However, they conclude that R&D cooperations, between universities and firms seem to have a positive impact on the improvement of existing products and processes rather than the development of innovations.

In total, these studies about interaction and collaboration between universities, R&D institutions and firms revolve around structures and intensity of interactions. Yet, they do not allow general conclusions about the extent, the efficiency and impact of these collaborations and interactions. Aspects of impact are mainly considered as economic impact in appropriate studies.

Economic Impact of Public Funded Basic R&D for Innovation Processes in Industry and for Economic Growth

The discussion about knowledge-based society shows an increasing need for knowledge and for know-how about how to handle this knowledge. Therefore, it seems obvious, that there is an increasing need in academics and their scientific knowledge—although the knowledge of the knowledge based society cannot be automatically equated with scientific and academic knowledge. However, the return on investment in higher education and scientific R&D is fostered by politics by fostering knowledge transfer. Knowledge transfer is politically and economically intended to result in improving and fostering innovation activities in firms may also be in other institutions of government NGOs. But all gained effects and impacts resulting out of knowledge transfer are yet to be examined. Different

²³ Schmalholz concludes, that UAS are still a young kind of R&D infrastructure, only in operation since 1969 (in the western part of Germany), which is too short in time to be able to have established an equivalent but different kind of university, and being accepted in industry as much as universities. But it is not comprehensible, why 30 years should not be enough to gain this position.

²⁴ For Switzerland up to now there are no extensive and basic studies about knowledge and technology transfer available. Interaction between engineers in firms and universities and different kinds of R&D and transfer institutions were examined for two branches, namely mechanical engineering industry and plastics processing industry for Switzerland, Austria and Baden-Württemberg (in Germany) (see Balthasar et al., 2000; Wilhelm, 2000).

²⁵ The two regions examined were the region of southern Lower Saxony and the region of Oldenburg county. Therein co-operation structure of SMEs in mechanical engineering industry, electrical industry, and precision engineering and optical industry were surveyed. 37 expert interviews conducted with member of the executive board of these SMEs are empirical basis of this survey, which therefore has to be judged as more qualitative survey.

approaches of impact studies revolve around these issues in economic literature: (1) studies about economic impact of public funded basic research (e.g. Cohen, Nelson & Walsh, 2000; Jaffe, 1989); (2) studies about economic impact of public funded infrastructure (e.g. Conrad & Seitz, 1994; Mintz & Preston, 1993); (3) studies about economic and regional impact of public funded infrastructure such as universities (most of them are case studies: e.g. Fischer & Wilhelm, 2001; Pfähler, 1997, 1999); (4) studies about economic and regional impact of knowledge-spillovers and technology transfer (e.g. Acs, Audretsch & Feldman, 1999; Beise & Spielkamp, 1996; Feldman, 1999; Frey & Bruggler, 1984; Griliches, 1992; Saxenian, 1994); and (5) studies about private and social benefit of higher education (e.g. Bassanini & Scarpetta, 2001; Borland et al., 2001; Temple, 2000; Wolter & Weber, 1998).

Salter & Martin (1999) present a review on economic benefits of publicly funded basic research as mentioned in point (1) above. In the literature three main methodological approaches can be stated: first, econometric studies, second, economic surveys, and third, case studies. Econometric studies of course, always bear methodological limitations, based on specific assumptions about impact correlation and based on demarcations involved protagonists and correlations are regarded. In these studies assumptions about R&D impacts on industry have mostly been supposed to be very substantial. Therefore, the results of these studies show huge ranges in their social rate of return, which means the benefits of public funded basic R&D, which accrue to the society: The ranges are between 10% to 160% with a concentration around 50% (Salter & Martin, 1999). However, in some spatial economics there is only weak evidence of positive externalities for university research (Acs, Audretsch & Feldmann, 1992; Anselin, Varga & Acs, 1997; Jaffe, 1989). Anselin, Varga & Acs (2000) found evidence of sectoral and regional differences of positive externalities from R&D.

Mansfield made a survey about the benefits of recent academic research for firms, published in 1991, and a follow-up study published in 1998. In the first study a sample of R&D managers from 76 U.S. firms were asked for the proportion of a firm's products and processes over a ten-year period, which could not have been developed without academic research. The sample of the second study was 70 U.S. firms. In 1991 he found, that about 11% of new products and 9% of new processes could not have been developed without academic research within this time period (Mansfield, 1991). That share of new products and processes, based on academic research account for 3 respectively 1% of sales. The follow-up study shows an increasing importance or influence of academic research: Now about 15% of all new products and 11% of all new processes could not have been developed without academic R&D within this time period (Mansfield, 1998). These

products and processes account for 5% of total sales for the firms examined. These are very optimistic findings compared to a survey conducted by Beise & Stahl for 2,300 firms in manufacturing industries (Beise & Stahl, 1999). They found about 5% of all new products and processes are based on support of academic R&D. They also stated, that small firms are less likely to use academic support and R&D, which is also a main result in nearly each innovation survey conducted.

Economic surveys and case studies show that economic benefits of public funded R&D can take a variety of forms—they all vary within the scientific field, technology and industrial sector. The emergence of new and perhaps useful knowledge, out of public funded basic R&D is one type of benefit, but not necessarily the most important one. Also, new instrumentation and methodologies, skills incorporated in graduates, like tacit and codified knowledge, access to networks, to experts and information, as well, as gaining the ability to solve complex problems by participation in basic research. Finally, the creation of spin-off companies is considered as a further form of benefit resulting from basic research (Salter & Martin, 1999). All these benefits are also listed and partly incorporated in the types of knowledge transfer as seen in Fig. 4. In general, a great heterogeneity in the relationship between basic research and innovation is stated, so that no simple model of economic benefits from basic research is available (Salter & Martin, 1999).

Regarding the impact and benefits of universities for their specific regions, there is strong evidence found in the literature of local academic technology transfers. But regarding the effects of university technology transfer on local economic development the evidence is still vague (Varga, 1997). The impact study about knowledge transfer between the University of St. Gall, their region and up to international regions and protagonists even intensifies this vagueness (Fischer & Wilhelm, 2001²⁶): The region directly and significantly benefits from expenses of students and employees and of university administration for office equipment and so on. But the benefits from knowledge transfer are vague. Measured by commissioned R&D studies, R&D cooperations, consulting and other services for customers, approximately 5% to 10% of this commissioned work is carried out for clients in the region of this university. This also holds true for further education

²⁶ The study was conducted for the accounting year 1999, therefore, data is based on this one year. Compared to other regional impact studies about universities this study is based on origin data in important issues and not only on estimations. Additionally, a study about spin-offs of graduates and former employees of universities in the region on St. Gall was conducted (Thierstein/Wilhelm/Behrendt, 2002). This is the first one revolving around this issue, which was conducted in German speaking countries—as far as the authors found out.

seminars, which are demanded by about 10% from people of the region. Also seminar papers, diploma and doctoral theses rarely have a regional context and are seldom conducted in regional localized firms or institutions (about 3%). However, spin-offs and personnel transfer shed another light on transfer structure. An additional study was conducted in order to measure the total amount of spin-offs, generated since the existence of the university within today's structure, and since the operational existence of its Alumni organization in 1963 (Thierstein, Wilhelm & Behrendt, 2002). Although, the total amount of spin-offs could not be calculated from the survey, the number of spin-offs founded in St. Gallen, where the university is located, was surprisingly high: It was virtually as high as in Zurich the largest city in Switzerland. But translated to inhabitants, the most spin-offs were founded in St. Gallen.²⁷

Summary

To sum up, the equation of scientific knowledge production process with innovation process bears an asymmetry in the understanding of innovations: scientific knowledge production is not primarily intended to result in innovations. Innovations are not only based on scientific knowledge but often by innovation activities in firms and by interactions and feedback-loops between the 'unscientific' and the scientific knowledge production systems. As there is a need in bridging the gap between science, industries, and governmental systems in order to meet future demands in problem-solving knowledge generation, the innovation system in Switzerland has to be improved. First and generally accepted is a need for developing innovation policy, which includes better coordination between science, industrial, and government systems and also society demands. Coordination among these systems has to be supported by appropriate incentives for protagonists involved, mainly within the science system. Still there is a lack of robust knowledge about innovation processes, innovation systems, and knowledge transfer including, basic aspects of its structure, impacts and flows. Also the implementation of structures of intermediates, designed to bridge the gap between science and industry (as carried out in the Fraunhofer-institutions in Germany), should be considered in this context. Therefore, basic and action-oriented studies, political concepts, strategies, and knowledge about developing innovation systems are required. Last but not least, the results of these studies then have to be secured so as to have an impact on developing innovation policy.

The existence of two large but separated R&D systems in science and industries connected with very

little financial flows, leads to reflections about their respectively structure, knowledge flows and their aims. The enormous R&D system in industries is hardly known by its fields, its know-how and findings, and its structure. But to know this is crucial under the aspect of the generation of new knowledge and know-how in networks of relevant protagonists. However, this requires studies about the whole R&D landscape and structure in Switzerland as well as conceptual thinking and studies about how to connect both systems more intensively and effectively. Therefore, a kind of 'R&D database' should be created and established on a national level being oriented internationally to offer matching processes between demand and offer. That also would ease self-organized interactions among both R&D systems on a national but also on an international level. The need for conceptual studies and implementation is required under the aim of 'problem-solving' as completion—not replacement—for generating epistemological knowledge.

In the context of knowledge production, another question is raised about job-sharing between universities and UAS and their respective tasks. The Swiss concept about 'equally good but different' bears some unsolved aspects. As UAS are also supposed to do applied R&D in order to mainly support SMEs in their respective region, reality shows that UAS in Switzerland are still focused on job-oriented teaching. Swiss politics will have to reconsider the task of UAS and universities or it will have to raise the support for UAS, enabling them to fulfil their tasks in applied R&D, knowledge and technology transfer.

As R&D are only part of innovative activities, the focus has to be broadened to other forms of interaction between universities, firms, government, and other kind of institutions. Innovation surveys, as they are conducted up to now in Switzerland, reflect the linear model of knowledge and technology transfer, by asking firms as receiver and for utilization of scientific knowledge. Therefore this shows a limited insight of all innovation activities and processes taking place. Innovation surveys therefore, have to be broadened to all kinds of relevant protagonists in an innovation system (e.g. universities, other R&D institutions, government, NGOs) and their network of information and knowledge flows.

Nowadays university institutes are more and more dependent on third-party funds. Reductions in public basic budgets for higher education are used as an incentive to rise acquisition activities of universities and their interaction with firms, as new financing source and may be as sponsor of university chairs. But this measure cannot be applied on all disciplines equally, as industrial partners or just markets, are not available for all disciplines in the same dimension. However, that approach causes strong initiative and self-organisation of university institutes and its employees and of course the abilities and skills to do

²⁷ Of course, this spread of spin-offs cannot be considered as representative: from 10,430 graduates addressed, about 1,396 answered; therefore 29% indicated to have founded a firm.

so. However, universities need markets for their knowledge or may even have to develop them first. New fields of disciplines and markets may arise in the intersection of different disciplines. These new markets could open up for oriented basic as well as for applied R&D and even for implementation. Therefore, alternative validation rules and career paths in universities and in UAS have to be developed. Up to now validation rules and the career paths hinder interactions between science and industries as they are marked by teaching and 'publish or perish'. This rule even holds true for some UAS, which is contradictory to the tasks and aims of these universities. In both types of universities the development of new forms or at least broadening the spectrum of career paths is essential.

As innovation processes are known not to proceed in a linear way, the task of transfer institutions has to be reconsidered. The old concept of commercialization of scientific knowledge has to be completed and partly replaced. Given that universities want, or have to, raise their third-party funds, transfer institutions need a profile more in initiate and moderate interactions between university, industry, government, and other institutions. At the same time, transfer institutions should keep their supportive role in juridical and business consulting and coaching, accompanying project partners along their activities.

Systems of Innovation and Competence Building Across Diversity: Learning from the Portuguese Path in the European Context

Pedro Conceição and Manuel V. Heitor

*Center for Innovation, Technology and Policy Research, IN +, Instituto Superior Técnico,
Technical University of Lisbon, Portugal*

Abstract: Innovation, a broad social and economic activity within the emerging learning societies, transcends any specific technology, even if revolutionary, and is tied to attitudes and behaviors oriented towards the exploitation of change by adding value. We analyze the ongoing Portuguese path towards an innovative society, characterizing innovation in Portugal within the European context. We conceptualize 'learning' and the process of knowledge accumulation, as a framework to understand the new demands for being innovative. We conclude by suggesting elements for innovation policies for Portugal, arguing for the need to promote *systems of innovation and competence building*.

Keywords: Systems of innovation; Learning society; Competence building; Techno-economic paradigms.

Introduction: Framing Innovation Practices and Theory Building

The understanding of innovation adopted in this chapter encompasses the way in which firms and entrepreneurs create value by exploiting change. Change can be associated with technological advances, but also with modifications of the regulatory framework of industry, shifts in consumers tastes, changes in demographic makeover, or even major alterations of global geopolitics. Further, in the current socio-economic context, innovation increasingly means the ability to cope with uncertainty in diversified environments, which are particularly influenced by social and institutional factors (see, for example, Conceição, Heitor & Lundvall, 2003; Smith, 2002). To choose such an ambitious definition of innovation presents important challenges. First, it calls for an analysis of many economic, social and institutional issues. Our effort cannot attempt to deal with these issues comprehensively. We will rather attempt, throughout the chapter, to discuss important trends that are likely to influence innovative performance in the presence of diversity, looking at the specific environment in which Portuguese firms conduct their business, and conse-

quently, determine the conditions and opportunities for innovation in the European context. The choice of such an ambitious definition of innovation limits equally the extent to which clear-cut solutions and recommendations to enhance the innovative performance of a country or region can be provided. Our hope is that by raising and discussing some selected questions, and concerns, we contribute to a better awareness of possible weaknesses and potential strengths of the Portuguese system of innovation within a diversified European environment.

It should be noted that innovation is a shared goal of countries within the European Union and even beyond, including other European countries, namely those that are candidates to becoming members of the EU in the coming years. We argue that this unified goal requires policies that are designed in an integrated and systemic way, but that are implemented with diversified actions. 'Policy integration' should occur across a 'portfolio dimension', since innovation policies require coordination across several areas: science and education policies; social and health policies; environmental and industrial policies; employment and market regulation

policies. However, the implementation of policies designed in an integrated way need, in a multi-country and multi-cultural context, to consider differences across countries, regions and cultures, thus requiring action diversification. In fact, balancing action diversification with policy integration involves significant problems that extend into the very systemic nature of the relationships between country governments and the role and mission of multi-national political institutions, apart from specific regional and local contexts.

Many contributions in recent years have confirmed the perception that the success of developing systems of innovation, either at national or regional levels, depend on the creation, dissemination and accumulation of knowledge, which per se are fundamental factors for the promotion of economic growth (Conceição, Heitor & Lundvall, 2003; Swan et al., this volume). However, the scarcity of empirical data on intangible economic factors makes it extremely difficult to demonstrate the growing importance of knowledge. Economic growth has traditionally been explained as being the result of increases in the labor and capital factors, with technological change contributing as an exogenous—that is, ‘outside’ of the realm of economic modeling-factor (Solow, 1997, for a recent review). However, the challenge posed by the endogenous growth theories to this traditional approach (see, for example, the review in Aghion & Howitt, 1997) have led to a need to rethink how these three factors influence the process of economic development. This rethinking has been taking place, in part, by bringing together other perspectives on the process of the relationship between technological change and economic growth, such as the evolutionary theory (Nelson & Winter, 1982) and the perspective of techno-economic paradigms (see discussion below).

Our inspiration to frame the process of knowledge accumulation comes from the contribution of Lundvall & Johnson (1994), who introduced the simple, but powerful idea of *learning*. Lundvall & Johnson (1994) suggest that a ‘learning economy’, rather than a ‘knowledge economy’, describes better the way in which knowledge contributes to economic development, promoting innovation. The fundamental difference between the two terms is associated with the fact that the former considers a dynamic perspective. According to Lundvall & Johnson (1994), some types of knowledge do indeed become more important, but there is also knowledge that becomes *less* important. There is both knowledge creation *and* knowledge destruction. By forcing us to look at the process, rather than at the mere accumulation of knowledge, Lundvall & Johnson (1994) add a dimension that makes the discussion more complex and more uncertain, but also more interesting and intellectually fertile.

Following the concept of the learning economy, which is further demonstrated in the volumes edited by Archibugi & Lundvall (2001) and Conceição, Heitor &

Lundvall (2002), innovation is the key process that characterizes a knowledge economy understood from a dynamic perspective. Lundvall & Johnson’s (1994) learning economy is about new knowledge replacing old knowledge. This dynamics is very close to Schumpeter’s concept of ‘creative destruction’, which is a standard description of the innovation process. Innovation is associated with creativity, with the generation of new ideas, but also with initiative and risk-taking. Innovation entails bringing new ideas to fruition in the marketplace, satisfying demands or creating new needs, in a process that improves overall welfare.

Beyond innovation, we also consider in this chapter the need to look at competence, as the foundation from which innovation emerges, and which allows many innovations to be enjoyed. In other words, competence contributes both to the ‘generation’ of innovations (on the supply side of the knowledge economy) and to the ‘utilization’ of innovations (on the consumptions side of the knowledge economy). Competence is also fueled by innovation itself. Competence is associated with skills and capacities, both individual and collective ones. When we consider competence, we focus on ‘higher order of skills’ Carneiro (2003). These generic skills include higher levels of education, but also capacities that are more generic, such as creativity, risk-taking, and initiative.

This chapter is organized in seven sections. Following this introduction, we consider innovation in Portugal within the European context. To better understand this case study, we introduce, in ‘Looking at Innovation Over Time and Across Space: The Techno-Economic Paradigms Approach’, the analysis of innovation over time and across space, looking at the techno-economic paradigms approach. This leads us to conceptualise, in ‘The Learning Society: A Framework to Understand the New Demands for Being Innovative’, ‘learning’ as a framework to understand the new demands for being innovative. Then, in ‘Deepening our Understanding of Learning towards Innovation: Building on the Economics of Knowledge’, we briefly discuss the fundamentals of the economics of knowledge in order to attempt to deepen our understanding of learning towards innovation. In ‘Fostering Systems of Innovation and Competence Building: The Challenges of Inclusiveness’ we build on the conceptual framework of the previous sections to frame innovation policy, namely in the Portuguese context within a diversified European environment. ‘Summary and Conclusions’ provides a brief summary and conclusion.

Characteristics of Innovation in Portugal

The measurement of innovative performance of an entire country—in a way, comparable across the diverse realities of many countries—is a demanding challenge, which has been addressed in Europe by a

joint effort of the OECD and the Eurostat through the development of innovation surveys according to a set of criteria that values cross-country comparability of results (see Conceição & Ávila, 2001). Portugal has been an integral part of this effort. This European effort is designated by Community Innovation Surveys (CIS), and its framework of enquire has been adopted both in official and autonomous research surveys in many countries, from Eastern European countries to Latin America (Inzelt, in this volume, describe the Hungarian experience, for example).

By giving more importance to cross-country comparability, the CIS loses somewhat of its potential ability to probe into the dynamics of innovation within each country, since it only asks broad and generic questions, which can be accepted to have similar meanings in different economies. However, it provides a reliable way to compare national innovative performance across countries. Figure 1 shows the overall innovative performance of countries in Europe measured by the shares of firms that have introduced innovations over a

two-year period (with reference to the period 1995–1997, as quantified through the CIS-2 example). The horizontal axis indicates innovative performance in manufacturing, and the vertical axis—in services. The results show a general close relationship between innovation in services and in manufacturing, since countries are located across a 45-degree diagonal. In general, innovation rates are lower in services than in manufacturing.

Portugal appears towards the bottom of performance, being the least innovative country in manufacturing. However, in services, Portugal innovates more than Belgium, Finland and Norway. Slightly more than a quarter of Portuguese manufacturing firms are innovative, while almost 30% of service firms are innovative. Here again we can see an indication of the duality: unlike other countries, services in Portugal—which have grown as a share of the economy at rates higher than the EU average—are more innovative than manufacturing firms, which are still largely dominated by traditional sectors of the

Figure 1. Innovative performance of EU countries for the period 1995–1997.

Source: Conceição & Ávila (2001).

Portuguese economy (such as the textile sector, for example).

Knowledge of the process of innovation in Portugal, and of the way in which it contrasts with the innovation process in Europe can be gathered from other aspects of CIS. Thus, Fig. 2 shows that Portuguese firms rely much more on resources external to the firm (as, for example, information sources for innovation process) than European firms (on average).

Figure 3, however, shows that issues related to high costs and difficulties in funding are much more prominent in Portugal than on average in Europe.

Even though there is a large consensus across Europe that the lack of qualified personnel is the most important factor hampering innovation (Fig. 4), still this factor pales behind high innovation costs and lack of financing as a deterrent of innovation in Portugal.

However, it is important to look at the diversity that exists within Portugal. We concentrate on manufacturing only. Even within manufacturing, though, there are substantial differences across sectors (Fig. 5). The machinery, electrical and optical equipment sector exhibits almost 50% of innovative firms (the rate of innovation in this sector is comparable to the average rate in countries such as Italy and Norway).

Innovation in Portugal seems to be associated with a number of characteristics of the firms in a way that conforms both with theory, and to results in other countries. A descriptive analysis of the results of CIS show that size classes of large firms have a higher share of innovative firms than size classes composed of small firms. A descriptive analysis also shows that firms that are part of a group of companies, show higher rates of innovation. Combining these two variables in a multivariate model, with the dependent variable being dichotomous (1 if the firm has innovated, 0 otherwise) shows, without any other conditioning variables) that large firms and firms that are part of a group do have higher probability to innovate (that is, actually introducing an innovation) than small firms and firms that are not part of a group of firms (first column in).

However, as we saw above, there is large diversity of innovative performance across manufacturing sectors. Still, when industry dummies are added to the model (second column in) none shows up as significant. This can be interpreted by saying that the sector effects are not strong determinants of innovation (when the size of the firm and whether the firm is part of the group are included).

However, when we consider only two groups of firms—those that are high or medium high technology, on the one hand, and those that are low or medium low technology, on the other—the results show that firms in the high/medium-high technology group do indeed exhibit a much higher probability of innovating than the average firm (note that the coefficient associated with the dummy for the low/medium-low technology firms is not significant).

The results indicate the existence of duality, as explained in further detail by Conceição & Heitor (forthcoming). Note how large and statistically significant the coefficient associated with high/medium-high technology is, even after controlling for the size of the firm and the fact that it may belong to a group. Thus, more sophisticated firms in markets with higher demands seem to have a substantially higher probability of innovating than other firms. This is not tied, one should stress, to a mere ‘sector effect’ (the sector dummies were not significant), it is really a characteristic of a large group of sectors that have in common belonging to the high/medium-high technology category. The duality here is clearly substantiated.

Naturally, other factors, beyond size and belonging to a group, influence innovation and Conceição & Heitor (forthcoming) report also on the effect of the firm level of productivity and the importance of exports. Both of these variables are known to have important effects on innovation and the results tell exactly the same story: when the differentiation is made according to the technological intensity, the duality comes up again, not as strong as before (part of the variation is now picked-up by productivity), but it is still present.

Of course, the models above have merely descriptive value; we do not make any claims in terms of causality, much less explanation. They are understood as showing the correlations among the variables included. It is known, for example, that several of the variables are simultaneously determined (namely innovation and productivity; on this see Conceição & Veloso, 2002). Thus, the point we make is that, even controlling for a number of characteristics that influence innovation, there is a clear duality in terms of probability of innovating when considers technology intensity as a criteria for differentiating firms. This duality appears to be a clear characteristic of the Portuguese society, which in turn must be understood within a diversified European context.

The question which does arise is related with the ability of Portugal to cope with the accelerated rate of technological change, in a way that will allow fostering innovation. This is a complex and evolving question, which requires a better understanding of the process of technological change, as described below.

Looking at Innovation Over Time and Across Space: The Techno-Economic Paradigms Approach

The interaction between the emergence of new technologies and the larger economic and social patterns of behavior can be understood, following Schumpeter (1934), as a process of *creative destruction*. At a first approximation, this statement is obvious: new technologies disrupt, and often replace older ones. At a higher level of analysis, the implications of new technologies are broader. The impact is often felt not only as a replacement of old for new technologies, but brings

Figure 2. Sources of information for innovation.

with it opportunities for new firms and difficulties for existing firms, the obsolescence of some occupations and shifts in the structure of employment, changes in the terms of trade between regions and countries. However, it is clear that not all advances in technology are disruptive to the point of creating substantial changes in economic and social conditions. In fact, most technological advances and innovations make their impact felt in a relatively smooth way, when analyzed from a macro perspective.

One way to conceptualize the interaction between technological change and shifts in economic conditions, together with the process of sometimes disruptive innovations, but most often smooth adoption and diffusion of new technologies, is the idea of techno-economic paradigms. The discussion that follows is based on Freeman, Clark & Soete (1982), Freeman & Perez (1986), and Dosi (1988). A techno-economic paradigm embodies a relatively stable cluster of core technologies, around which innovation and economic activity take place. The core technologies have a strong impact in the economy and society, being defined as core given their potential for generalization and penetration across a wide number of products and processes, across all sectors of economic, and often human, activity.

Within a paradigm, the core technologies are virtually unchanged over time, but this does not mean that there is not economic and technological progress.

On the contrary, these core technologies provide a positive heuristic that defines the knowledge and incentives for innovation and economic activity to occur. At the same time, this progress is inherently limited by the conditions set by the interaction of the core technologies with the dominant modes of economic activity, from the organization of firms, to the distribution of employment. Therefore, progress exists within a certain techno-economic paradigm, but occurs within a framework defined by a set of core technologies and modes of organizing economic activity.

Thus, within a paradigm, innovation occurs as the core technologies become more and more pervasive and influence ever-wider realms of production and distribution. When a major technological advance occurs, disrupting the existing core technologies and modes of economic operation, then a new techno-economic paradigm emerges. The displacement of the core technologies of the old paradigm creates a new wave of invention and innovation and is no longer tied to the previous paradigm core technologies. The emergence of a new core technology requires, and creates the opportunity for, an entire new set of small and incremental innovations that permit the widespread usage of the new core technologies. Thus, when a shift in techno-economic paradigm occurs, we have not only a 'substitution effect', but also an expansion of the creative frontier that allows the emergence of new

technologies and enables, in the end, a shift to yet another techno-economic paradigm.

Additionally, beyond the technological and purely economic factors, the social and institutional frameworks that fit a certain techno-economic paradigm may not be adequate for a new one. Indeed, the process of emergence of a new techno-economic paradigm results from the interaction of the technological, economic, institutional and social spheres. Having just a new technology coming in may not have any effect if a set of changes in the other dimensions does not accompany the technological novelty. A certain set of institutions and social features may provide enough contexts for innovation within a certain paradigm; in other words, it is not necessarily needed to create institutions and social rules at the same pace that technological innovation progresses. But when there is a shift in techno-economic paradigm, a new institutional framework may be needed.

A number of authors, working together and independently, developed the theory of techno-economic paradigms beginning with Schumpeter, who argued that the expectations of profits would drive the 'entrepreneur' to innovate (see Freeman, Clark & Soete (1982), Freeman & Perez (1986), Dosi (1988)). The entrepreneur's drive towards innovation is motivated by the temporary monopolistic position from which the innovator would benefit. Schumpeter (1934) regarded this position as temporary because the advantages from this privileged position would eventually 'perish in the vortex of the competition which streams after them', since other firms would copy the innovator. Schumpeter (1934) called this process *creative destruction*. Therefore, for Schumpeter, innovation appears at the forefront of economic progress, driving prosperity. In a later version of these same fundamental ideas, Schumpeter refined this earlier simplistic version of an entrepreneur in a perfect market composed by a multitude of competing firms that destroy any persistent market advantage. In his final work Schumpeter (1942) acknowledged that some large corporations could sustain a market advantage by an institutionalization of the effort to innovate through the establishment of large R&D facilities.

The reinterpretation of Schumpeter's fundamental ideas of innovation as a process of disequilibrium in the broader context of techno-economic paradigm is due primarily to Christopher Freeman and his co-authors. Often called a 'neo-Schumpeterian' approach, this perspective is articulated, as mentioned, in Freeman, Clark & Soete (1982), Freeman & Perez (1986), Dosi (1988) and, more recently, in McKnight et al. (2000), to cite a few representative examples. Freeman and his co-authors generalized the concept of Schumpeterian innovation to the national level, making an analogy between innovation at the firm level and a

change in a techno-economic paradigm at the country level (Freeman, 1988; Freeman & Soete, 1997).

This macroeconomic definition of innovation corresponds to what is, at the firm level, a radical innovation. Under this extreme, there are milder types of innovation, such as incremental innovations, that correspond, at the micro level, to improvements in existing products and processes. Freeman (1988) builds a similar hierarchy for his macro analysis of innovation, leading to a conceptual framework that has some similarity to the evolutionary perspective of Nelson & Winter (1982).

It is important to stress two important dimensions of the techno-economic paradigm theory: *time* and *space*. Time is, indeed, crucial, as we saw, since the process of technological change and its economic and social impact is seen as a progress, more stable within a certain techno-economic paradigm, and very different across techno-economic paradigms, which differ over time. Space is equally important, since it is not clear that a certain techno-economic paradigm will not affect all the regions of the world similarly. Certainly there will be different rates of adoption of new core technologies when there is a paradigm shift, or even, within a paradigm, different ways in which specific innovations and modes of economic organization develop in different countries and different regions. Some countries may originate or lead the development of a new techno-economic paradigm, and others may lag behind, or even stay closer to the 'older' rather than the new techno-economic paradigm.

An important idea joining the time and space dimensions of the techno-economic paradigm theory is that of technological trajectories within national innovation systems. The idea of trajectories in national innovation systems (developed, with a comparative analysis across countries, in Nelson, 1991, for example) is because each country follows its own developmental path, within the general framework of the existing techno-economic paradigm, but also—and this is crucially important—influenced by the past history and specific conditions of the local context.

This brings to the discussion the asymmetries in country performance, which according to our interpretation advanced in earlier papers, can be seen as being dependent on what we could call with generality knowledge accumulation through 'learning' processes. Conceptually, the foundations for the relationship between learning and economic growth are well established in the recent literature (Bruton, 1998), and stem from a combination of the pure neo-classical perspective of growth with the Schumpeterian view. Learning is reflected in improved skills in people and in the generation, diffusion, and usage of new ideas. Likewise, organizational learning reflects social processes driven by collective cultures and appropriate management attitudes. The ability to continuously

generate skills and ideas (which is to say, to accumulate knowledge through learning) is the ultimate driver of an economy long-run prospects (World Bank, 1997).

The fact that countries have different levels of income is clearly self-evident. Therefore, it is equally obvious that each country has followed its own trajectory, within the context of an existing techno-economic paradigm and the specific innovation system of the nation. We look here at some evidence on the translation of different paths in the economic performance of countries. But we begin with an interpretation of the major techno-economic paradigms, illustrated in Table 2.

The table shows five important techno-economic paradigms. While the paradigms presented result from one interpretation, they serve now to illustrate with some empirical evidence the features of techno-economic paradigms presented before. Let us consider, for example, the first techno-economic paradigm. This corresponds to the emergence of the Industrial Revolution, as mechanization was increasingly incorporated in manufacturing, especially in some industries such as textiles. However, the technologies well diffused and used within this paradigm presented some important limitations for the increase of the scale and output of the productive activity. Most firms remained small and local. Process control was poor and hand operated machines did not allow for output of reliable quality. Naturally, advances in steam engine technologies and

machinery were already taking place, but it took a long time until they were ready for fruition. When these important technologies matured to the level that made their economic utilization possible, they became the core technologies of the second techno-economic paradigm. The new techno-economic paradigm based on steam engine and on machinery ameliorated some of the previous limitations, and created in itself the germ for new types of economic organization, as the table details.

If we cross the techno-economic paradigms with geography, then we start joining together the ideas of technological trajectory and national innovation system. The two first techno-economic paradigms were led by Britain. In this context, the U.S. and Germany, for example, were 'latecomers'. Still, they became leaders in the third techno-economic paradigm, with Japan also leading in the fourth and the U.S. arguably retaining the lead alone in the fifth, although we will be looking at this claim in more detail later.

Still, the manifestations of the current differences in the paths followed by different countries are dramatic. Even taking a set of relatively homogeneous countries, such as the OECD, shows great disparities in income per capita and productivity. Productivity, in a way, is probably the best indicator of the extent to which a nation is taking full advantage of the conditions provided by the existing techno-economic paradigm. A recent study by Ark & McGuckin (1999) tackles international comparisons of productivity and income

Table 2. Tentative sketch of major techno-economic paradigms.

Approximate Period	Description	Key Sectors	Economic Organization
1770s to 1840s	Early Mechanization	Textiles, Canals, Turnpike Roads	Individual entrepreneurs and small firms; local capital and individual wealth
1830s to 1890s	Steam Power and Railway	Steam Engines, Railway, World Shipping	Small firm competition, but emergence of large firms with unprecedented size; limited liability corporations and joint stock ownership
1880s to 1940s	Electrical and Heavy Engineering	Electrical Engineering, Chemical Process Industries, Steel ships, Heavy Armaments	Giant firms, cartels, trusts; mergers and acquisitions; state regulation and enforcement of anti-trust; professional management teams
1930s to 1980s	Fordist Mass Production	Automobiles, Aircraft, Consumer Durables, Synthetic Materials	Oligopolistic competition; emergence of multinational corporations; rise of foreign direct investment; vertical integration; technocratic management styles and approaches
1970s to . . .	Information and Communication	Computers, Software, Telecommunications, Digital Technologies	Networks of large and small firms based increasingly on computer networks; wave of entrepreneurial activity associated with new technologies; strong regional clusters of innovative and entrepreneurial firms

Source: Adapted from Freeman & Soete (1997), Table 3.5.

in a particularly careful way, especially in finding comparable measures across countries. They also link labor productivity with output per capita following a common decomposition procedure. While the relationship between these two variables may seem obvious, in fact there are many subtleties involved. For example, a country that is very productive but where workers engage in productive activities fewer hours than a less productive country can result in an output per capita that is higher in the second country. Table 3 shows the results presented in this work. Column (1) indicates labor productivity and column (8) provides the level of GDP per capita.

Portugal and Turkey have the lowest hourly labor productivity rate of the OECD. Portuguese hourly productivity is about half of the OECD average. Productivity in Greece is 19 points above Portugal's and Spain's productivity is 28 points above the Portuguese hourly labor productivity. Still, when one looks at column (8), Greece's GDP per capita is actually lower than Portugal's by two points and Spain's GDP is only 11 points above Portugal's.

The decomposition of the table shows the variety of effects involved. Column (2) shows the impact of the number of hours worked. The summation of columns (1) and (2) produces the GDP per person employed. We see that Spanish and Japanese workers work longer hours than in most of the other countries. Per worker productivity in Spain, measured as GDP per worker, raises almost to the OECD level. Portuguese workers also work long hours, adding 2 points to the per hour productivity measures. In Italy, France, The Netherlands, Norway and the United Kingdom less hours of work reduce per employee productivity. Standards of living are determined not only by the number of hours worked and the productivity of each hour of work, but also by the 'number of mouths to feed'. The effect of the labor force participation connects per worker productivity and GDP per person. It is the effect of the labor force participation, for example, that brings down the income per capita of the productive and hard working Spanish workers: the combined effect of unemployment and the low level of labor force in the working age population take 26 points to the per worker productivity. The same happens in Greece, where 12 points are taken to the per worker GDP. In Portugal, both the effects of hours worked and labor force participation are small and positive. It is, therefore, clear that the real challenge to increase the level of GDP per capita in Portugal is not so much a reduction of unemployment or, more generally, an increase in labor force participation (as in Spain, for example), but that it is really the increase in the fundamental hourly labor productivity. To understand impact of these differences on innovative performance and, consequently, to derive innovation policies, it is important to look at the new demands for being innovative, to which we turn in the next section.

The Learning Society: A Framework to Understand the New Demands for Being Innovative

Recent models of long-term economic growth have been able to explain the increase in per capita income in developed countries (see Johnson, 2000, for a summary perspective, and Landes, 1988, for a broader treatment) with extremely parsimonious models based exclusively on the growth of knowledge. The factors behind the increase of knowledge are equally simple: the increase in population and the emergence of specialization in the production of knowledge. Kremer (1993) uses a model exclusively based on population growth, where more people means that there are more individuals capable of making a significant discovery and that the larger the population the larger the benefits from those discoveries. In other words, technological improvements make population growth possible which, in turn, creates more possibilities for new discoveries. A slightly more complex model by Hall & Jones (1999) includes also the effect of the specialization of growing proportion of the population in activities associated exclusively with the creation and transmission of knowledge. This entails the need to include *institutions* and *policies*—a combination that the authors call *social infrastructure*—which, according to this model, explain difference across countries in their level of knowledge generation and income per capita.

The gradual transition towards knowledge-based economies has intensified in the last part of the 20th century. According to the OECD (1999) more than 50% of the OECD countries' GDP is associated with knowledge-based industries.¹ Lundvall (2000) asserts that the intensity of the acceleration of knowledge creation and diffusion requires a more dynamic characterization. In Lundvall's opinion, we should speak about the emergence of a *learning society*.

In summary, while much attention has been devoted to specific technologies, namely to digital technologies in recent years, the association between information technologies and augments in productivity remains ambiguous. Still, it is undeniable that the spread of the computer and the Internet is changing in profound ways the way people and firms behave and interact, with important consequences for policy and strategy. A more fundamental change at the start of the new millennium is the increasing importance of knowledge for economic prosperity. This feature of current developed countries corresponds to the continuing of a trend of acceleration of the importance of the creation and diffusion of knowledge throughout the century. Beyond digital technologies, other technological breakthroughs, in many areas from the life sciences to

¹ Even if the definition of knowledge-based industries is rather generous, including a large part of services and the high and medium-high technology manufacturing.

the many fields of engineering, are likely to be seen in the future (see Coates, this volume).

In this context it is important to look both at the *level* of the measures that indicate the extent to which a country is engaged in the knowledge economy and to the *growth* in recent years. Figure 6 provides a first illustration, with the horizontal axis representing the intensity of knowledge-based industries in the mid-1990s and the vertical axis the growth rate of these industries in the previous decade.

Most countries are clustered at the bottom of the figure, with growth rates between 2% and 4% a year. The horizontal distribution of the countries shows Germany, the U.S., Japan and other leading developed countries to the right, with Spain and Greece to the left. In this context, Portugal and Korea stand out. The intensity of the knowledge-based industries in these countries is relatively low, especially for Portugal, which has the lowest level of knowledge-based industries. However, the growth rates for Portugal and Korea are remarkably higher, with the knowledge-based industries in Portugal growing close to 7% a year, and Korean knowledge-based industries at more than 12% a year. The rate of growth of knowledge-based industries in comparable periods was of 3.1% for the European Union and of 3.5% for the entire OECD.

The difference between the growth rates of Portugal and Korea is not as extraordinary as it may seem. In fact, the business sector as whole rose in Korea at 9.1% a year, while in Portugal the growth rate of the entire business sector was 4.6%. Consequently, the difference between knowledge-industries growth rate and the entire business sector growth was of 2.3% for Portugal (or 50% of the business sector growth rate) while in Korea the difference was 3.4% (a higher difference, but only 37% of the entire business growth rate). The case of Portugal and Korea are relevant because they are illustrative of latecomer industrialization and may represent indications of the process through which these latecomer countries become engaged in the new techno economic paradigm.

Turning our attention only to information and communication technologies (ICT), Fig. 7 presents essentially the same framework of the previous figure, but now with the intensity of ICT expenditure in 1997 on the horizontal axis and the growth rate of this intensity from 1992 to 1997. Again, most countries are clustered in the bottom of the figure, with growth rates below 4%. The levels, as indicated by the horizontal distribution of countries, confirm the perception that the U.S. is a leading country. The expenditures on ICT as a percentage of GDP in the U.S. are about 2% above the European average. Individual countries, such as Sweden, outperform the U.S., but most countries lag behind.

But, as with knowledge-based industries, the growth rate in expenditures provides a different picture. In fact, Portugal is the leading OECD country in the growth

rate of ICT expenditure from 1992 to 1997, with a growth rate of more than 10%. Most of this growth rate can be accounted for by increases in expenditures in telecommunications (about 9%). Expenditures in IT services and software are particularly low, below 1%. Only Turkey, Greece and Poland have shares of expenditure on IT software and services below the Portuguese value. The growth in this category has been equally dismal, below 2% a year.

Returning to the conceptualization of the knowledge-based or learning economy that we presented earlier, it can be said that, fundamentally, the performance in this knowledge-rich competitive environments in terms of innovative performance depend on the **quality of human resources** (their skills, competencies, education level, learning capability) and on the activities and incentives that are oriented towards the generation and diffusion of knowledge. But beyond human capital, which corresponds to the **aggregation** of an individual capacity for knowledge accumulation, developing a collective capacity for learning—as suggested by Wright (1999) in the context of the U.S.—is as, if not more important, than individual learning. Instead of individual or even aggregated human capital, a further important concept for learning seems to be *social capital*, as analyzed by Conceição et al. (2000), among others.

The importance of social capital, while still controversial, is increasingly being seen as an important determinant of economic performance and, especially, of innovation and creativity. Temple (2000) discusses the impact of education and social capital together as determinants of growth. Temple (2000) argues that there is a growing number of works suggesting that social capital is at least as important as education as a driver of economic growth.

Education is often used as a proxy for human capital. For social capital, the equivalent indicator is the level of 'trust'. Figure 8 shows the results of a survey conducted in the early 1990s on each country's citizens' perception of the internal level of trust. Respondents in each country were asked if their countrymen could be trusted, and the percentage that replied yes is reported in the chart.

The next question is, then, to find out what are the determinants of social capital. Glaeser (2000) suggests that education is strongly associated with social capital, which indicates that an important component of policies aimed at increasing social capital necessarily needs to go hand in hand with policies aimed at increasing the educational level. The reason is not only the fact that there is an association between human and social capital, but also the fact that being in school provides a context for social interaction and learning that has important spillover effects in strengthening social relationships and networks. Alesina & Ferrara (2000) confirm the important role of education as a determinant of social capital, but show also that beyond

individual characteristics, the characteristics of the community are equally important. These characteristics include dimensions associated with the way people compare themselves with each other, such as income inequality.

One other important dimension of the learning society includes the activities expressly oriented towards the generation and diffusion of knowledge. It is, as with education, risky to reduce a complex set of activities to a single educator, but the national effort on research and development provides an indication of the commitment, at the country level, to activities explicitly oriented towards the generation of new knowledge. These activities tend to occur in institutions, such as universities and research labs, or within institutional settings, such as the R&D unit within a firm, that provide incentives that foster the specialization on exploration and discovery, as well as exchange of knowledge (Conceição & Heitor, 1999).

Figure 9 shows both the scale and the intensity of national expenditures on R&D for several OECD countries, with the horizontal axis, representing the scale of the expenditure, having a logarithmic scale. The relationship between scale and intensity shows decreasing returns: as the scale of the investment grows, the increase in intensity also grows but at a decreasing (in fact, logarithmic) rate. The results also suggest that there are **three different** 'paths' in which this relationship is expressed.

In the lower left-hand corner of the figure we identify a line that includes the Southern European countries. The thick line in represents a simple fitting of the position of most countries. Nordic countries have a path of their own, with a much higher responsive intensity to increases in scale. For Ireland the scale of R&D expenditure is almost the same as for Portugal, but the intensity for Ireland is comparatively much higher. The large intensity of R&D expenditures in Ireland is largely due to the fact that the R&D that is performed in the business sector, which in 1997 accounted for almost three-quarters of the total R&D expenditure in Ireland. Ireland showed the largest increase in business R&D expenditure of all OECD countries in the 1990s, at an annual growth rate of close to 20%. However, most of this growth is being driven by foreign affiliates doing business in Ireland. The share of foreign affiliates in manufacturing R&D in Ireland in 1995 was close to 70%. This large share indicates a very low capacity of domestic firms to innovate. Ireland is, in this regard, an exception, since for most OECD countries domestic firms take the largest share of R&D performed in the business sector.

R&D efforts are understood as an input; an important outcome of R&D expenditures is scientific papers. Scientific articles are, in themselves, important to diffuse and deepen innovation. Figure 10 shows the same countries as Fig. 9, and the horizontal axis is also

the same: the logarithmic absolute expenditure by country. In Fig. 10 the vertical axis is also presented in logarithmic scale. As when we analyzed scale and intensity of R&D, we fit a straight line, which fits well with the data.² Given that both axes are in logarithmic form, scientific production follows a power law, a feature known to be associated with scientific publications.

R&D expenditure is an important indication of the commitment and resources a country devotes to knowledge production and diffusion, but the growing importance of knowledge extends beyond those activities traditionally associated with creativity and learning. Innovative performance, in particular, depends on conditions that foster technology-based entrepreneurship. Mechanisms such as venture capital and high growth start-up stock markets (like the NASDAQ) are ways to mobilize private capital for investment in knowledge economies (Soete, 2000). Gompers & Lerner (1999) show that venture-capital backed start-ups appear to have a disproportionate positive impact on innovation.

However, following Antonelli & Calderini (1999), 'the internal bottom-up learning process based upon the improvement of design and technological processes plays a major role in feeding the continual introduction of technological and organizational innovations'. In this respect, the authors conclude that technological knowledge is embedded in the specific circumstances in which the firm operates, and its generation is the result of a joint process of production, learning and communication, of which R&D activities are only a part (Conceição & Ávila, 2000; Evangelista, Sandven, Sirilli & Smith, 1998). In more general terms, the analysis of the innovative performance of countries in the learning society calls for the need to consider all the processes of learning (both 'formal' and 'informal', in the nomenclature of Conceição and Heitor, 1999) and to better understanding the economics of knowledge.

Deepening our Understanding of Learning towards Innovation: Building on the Economics of Knowledge

The paragraphs above show that, from a systemic perspective of innovation, *learning* is understood, broadly, as *knowledge accumulation*. There are different levels of 'learning entities', from individuals, to organizations, to whole economies. A first important step in our discussion is the clarification of our conceptual understanding of terms such as 'knowledge' and 'learning', often loosely used with dramatically different meanings. The recent paper by Johnson et al. (2002), following the work of Cowan et al. (2000), provides further evidence for the need to clarify these concepts. This conceptual clarification of

² The R-squared is 0.95.

our understanding of learning as knowledge accumulation is the objective of this section.

We find it useful, as developed in more detail in Conceição & Heitor (1999), to follow Nelson & Romer's (1996) differentiation between ideas and skills, or software and wetware, to use these authors' nomenclature. The conceptual difference between *software* and *wetware* lies in the level of codification. While ideas correspond to knowledge that can be articulated in words, symbols, or other means of expression, skills cannot be formalized, but always remain in tacit form (see Nonaka et al., this volume). Under this taxonomy, knowledge may be divided into two worlds (Johnson et al., 2002): the world of codified ideas (*software*) and the world of non-codified skills (*wetware*).

The difference in the level of codification has implications in terms of the 'economic properties' of the two types of knowledge that we consider. The most important implication is associated with the differences in the rivalry associated with the consumption of each type of knowledge. Since the knowledge underlying *software* is codified, it is easily articulated and reproduced by simple, inexpensive means. Consequently, rivalry in the consumption of software is low. By contrast, the transmission of skills (*wetware*) is complex, expensive, and slow. Skills result from a combination of factors, ranging from their largely innate quality, through individual experience, to formal training. Thus, rivalry is comparatively higher in the consumption of wetware.

The differences in rivalry between *software* and *wetware* have important implications for knowledge production. Dasgupta & David (1994) suggest that there are basically two alternatives for the production of software. The first consists of **intervention by the state** in the production of ideas, by means of direct production, or by subsidizing production, such as funding of university R&D. The second alternative consists of granting property rights for the creation of ideas, that is by defining regulations for **intellectual property** specific instruments that include patents, registered trade marks and copyright (see Conceição & Heitor, 2001; Conceição, Heitor & Oliveira, 1998, for a more comprehensive analysis). Therefore, the production of ideas requires more complex institutional mechanisms than those provided by the market. As for skills, the market provides a large proportion of the incentives needed for their production, at least when these are analyzed in isolation, although with important limitations (see, again, Conceição & Heitor, 2001).

We bring our own understanding to the process of knowledge accumulation when the interaction between software and wetware is explored. The idea of **interaction** between ideas (software) and skills (wetware) is what, in our understanding, defines learning. Analysis of the interaction between ideas and skills leads us to explore the learning processes associated

with the generation of each type of knowledge in a more integrated and dynamic way, beyond the mere accumulation of ideas and skills, each in isolation. Our view is yet another perspective on the ongoing debate between the complex and multifaceted interaction between different types of knowledge. Recent manifestations of this debate include Johnson et al. (2002), in which they contest the implicit assumption of Cowan et al. (2000) that codification always represents progress.

Indeed, according to Freeman & Soete (1997), ideas and skills are no more than two sides of the same coin, two essential aspects of the accumulation of knowledge. New ideas spur the development of the skills required to use those new ideas. The bridge from the production of ideas to the usage of ideas is established by producing new skills. Increased use of an idea, which requires its diffusion, will lead to a constellation of other ideas, aimed at improving and extending the initial idea, which will lead to the need for further skills and so on, in a self-reinforcing cycle that leads to the accumulation of knowledge. The accumulation of knowledge results from the production, usage, and diffusion of both software and wetware, in an interactive learning process that leads to knowledge accumulation, as initially proposed by Conceição & Heitor (1999).

Learning Processes and the Accumulation of Knowledge: The Interaction between Software and Wetware

According to Solow (1997), the formalization of the process of economic development in the new growth theories follows the conceptual structure originally proposed by Arrow (1962). It is worth looking briefly at Arrow's analysis, as it contains the kernel of the reasoning behind the idea of economic development as a learning process. Instead of following the orthodox thinking of his time, which attributed to technological change the component of growth that could not be explained by the accumulation of labour and capital factors, Arrow argued that experience in the use of capital led to an increase in the knowledge used in production. In plainer terms, Arrow drew up a relatively simple model in which workers in a company learn by using the means of production, thereby increasing the company's productivity.

In this way learning, that is the accumulation of knowledge, appears as the driving force behind the increases in efficiency, which lead to economic growth. It is interesting to note that Arrow chose an informal way of learning, learning by doing, as the basis for his reasoning. It should also be noted that in this model knowledge is accumulated only in the form of skills. The contribution of the new economic growth theories has been precisely to extend this reasoning to other types of learning, as well as to the accumulation of ideas, starting from when Romer (1986) showed the wider implications of Arrow's arguments.

Table 4. Accumulation of knowledge and learning processes in the new growth theories.

		Learning by			
		Formal processes		Informal processes	
		Education	R&D	Experience (by-doing)	Interaction
Accumulation of	Software (Ideas)		Romer (1990) Grossman & Helpman (1991)		
	Wetware (Skills)	Lucas (1988)		Arrow (1962) Romer (1986)	

Thus, Lucas (1988) also analysed the accumulation of knowledge in the form of skills, but this time putting forward education as a formal learning process. In turn, Romer (1990) and Grossman & Helpman (1991) constructed models in which the accumulation of ideas results from effort put into research, another formal learning process. In this context, Table 4 summarizes how these contributions fit into a framework of possibilities which relates the accumulation of knowledge to the different kinds of learning that can lead to this accumulation. The construction of this table was also inspired by Foray & Lundvall’s analysis (1996), in which they placed particular emphasis on the formation of networks of personal and professional contacts, which result from processes of social interaction, the fourth process in Table 4.

This table also illustrates three other points. First, is the analysis that remains to be made in respect of the empty boxes. Second, examination of the dates of the contributions reveals that the emphasis at the beginning of the 1990s was on the study of the accumulation of ideas through R&D, a tendency that has become stronger in recent work (see Romer, 1991, 1993, 1994).

There are at least two reasons for this. On one hand, the study of informal learning processes is more complex and less amenable to empirical testing. We are accordingly left with the study of the accumulation of ideas through R&D, since the role of education has already been extensively researched since the theories of human capital appeared in the 1960s. On the other hand, the really striking aspect of the times in which we live is the increasing codification of knowledge, and the potential of the ‘digital economy’ and the ‘information society’ (Romer, 1996; Foray & Lundvall, 1996).

It is important to note that the potential of the ‘digital economy’ is strongly reflected in the existence of increasing returns, which leads to phenomena such as the apparently unstoppable growth of companies that trade in ideas, such as Microsoft. Indeed, the economic value of an idea is associated with its market potential

(Romer, 1996). As has been seen, it can be extremely expensive to produce ideas, but they are cheap to distribute. The first disk containing the Windows operating system cost Microsoft several million dollars (the entire cost of development), but all the rest cost less than a dollar each. Since there is a vast market and costs, after initial development, are low, the only limit to Microsoft’s growth is the size of the market itself. Arthur (1994) points out that the fact of increasing returns, besides being linked to the non-rivalry of ideas, is reinforced by the phenomenon, originally explored by David (1986), known as ‘lock-in’. In the case of Microsoft, ‘lock-in’ took place when the Windows operating system became established as the virtual industry standard. As can be seen, there is much to explore concerning the impact on growth of the accumulation of ideas, but our concern at the moment is to examine the boxes in Table 4 that remain empty, particularly the interaction between ideas and skills.

It is thus time to begin moving into territory that is still being explored, which requires reference to contributions from other groups of economists concentrating on the study of economic growth. Before pursuing this theme, we should note the difficulties that have beset the new economic growth theories. The main criticism is linked to their lack of empirical evidence, despite the intellectual validity of their arguments (Pack, 1994). Mankiw (1995), in a relatively recent assessment, even suggested a return to Solow’s traditional formulation. However, according to Soete (1996), empirical difficulties should lead not to a reduction in efforts to pursue the new concepts further, but rather to a recognition that new indicators and quantitative methods must be found that are more appropriate for the knowledge-based economy.

One crucial aspect of the accumulation of knowledge is the interaction between ideas and skills, which gives rise to the learning processes in Table 4. Indeed, according to Soete (1996), ideas and skills are no more than two sides of the same coin, two essential aspects of the accumulation of knowledge. Herbert Simon,

quoted by Varian (1995), puts the argument as follows:

“What information (in the sense of ideas, according to our terminology) consumes is rather obvious: it consumes the attention of its recipients. Hence, a wealth of information (that is, of ideas) creates a poverty of attention, and a need to allocate that attention efficiently among the overabundance of information sources that might consume it”.

In other words, many good ideas are useless if the skills needed to use them do not exist. Studies by Pavitt (1987), Nelson (1996), and Rosenberg (1990) follow the same line of thinking. Nelson (1997) describes various circumstances, in which individuals, companies, universities, and other institutions have made use of their skills in order to increase their accumulation of knowledge, acquiring further skills as well as ideas. The main implication of this argument is that the interdependence between ideas and skills casts doubt on the idea that the market supplies the necessary incentives for the production of skills, where these were analyzed in isolation. It seems, therefore, that there is greater scope in the knowledge-based economy for institutional arrangements and public policies that

go beyond the logic of the market (World Bank, 1998).

Although to a great extent skills result from the innate characteristics of an individual or from the history of an institution or a country, they also depend on the learning processes (education, research, experience, social interaction) in which these entities are involved (North, 1990). Without skills, ideas may be irrelevant, and without ideas, there is no need for new and better skills. Analysis of the interaction between ideas and skills understandably brings us to explore learning processes in a more integrated and dynamic way, beyond the mere individual accumulation of ideas and skills set out in Table 4. To illustrate the close and complex interdependence between ideas and skills, Fig. 11 shows the interactions between these two kinds of knowledge.

At this point we should stress that our analysis would be enriched by drawing from the large output of scholarship that originated from the cognitive sciences and from the education sciences on learning. However, this project lays outside the aim of this paper, since we do not intend to contribute to a theory of learning. Our purpose is rather to propose a simplified framework to model the dependency between software and hardware,

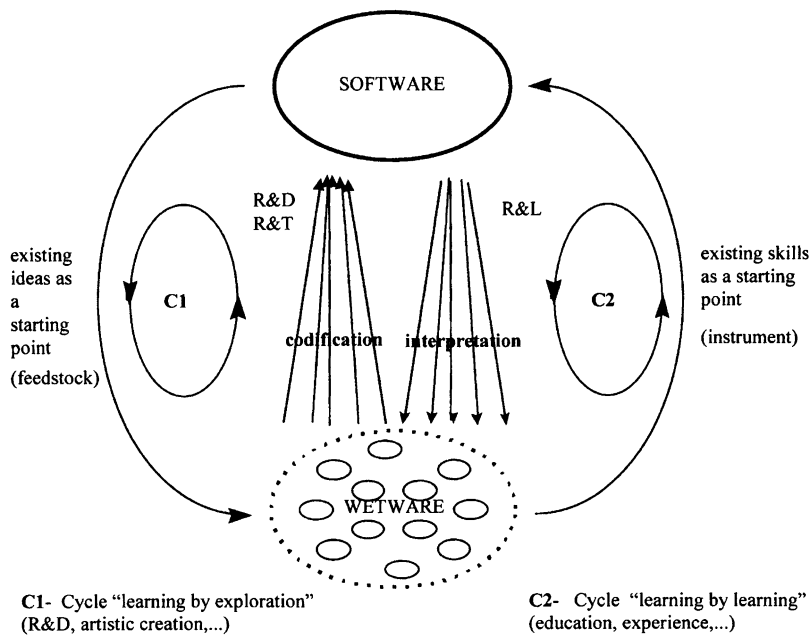

Figure 11. Diagrammatic representation of the interaction between learning processes and the accumulation of knowledge, identifying the various aspects of university research (notably Research & Development, Research & Training, and Research & Learning, as analysed by Conceição & Heitor, 1999).

Notes: R&D—Research and Development; R&T—Research and Training; R&L—Research and Learning.

suggesting that it is through this interaction that new knowledge is generated, that is, learning occurs.

From Fig. 11 it can be seen that while skills appear as a cluster of small ovals, reflecting the individual nature of the skills of people and of institutions, ideas appear as a single oval. This represents the indivisibility of ideas (David, 1993), meaning that, once created, an idea remains at least potentially accessible everywhere, and there is no need to rediscover it—hence the common expression ‘There’s no need to re-invent the wheel’.

Figure 11 shows several learning processes that have been analyzed in various places in the literature. Again we should stress that we have been selective in the way we chose the types of learning processes that are depicted in the figure. Our objective is not to be exhaustive, but rather to emphasize the learning mechanisms that are more directly related to the functions of the university, as will become clear in the next section.

Thus, there are two main cycles:

cycle 1—codification of knowledge (Foray & Lundvall, 1996), the result of progress in information technology, telecommunications and the scientific and technological base; that is, the great number of existing ideas that are the starting point or ‘feedstock’ for new ideas to be constructed using existing skills;

cycle 2—interpretation of codified knowledge (OECD, 1997), using existing skills as a starting point or instrument to decode the ideas which are being studied or used, leading to improved skills.

Cycle 1 covers learning processes that result in the codification of knowledge, which is the generation of new ideas. Specific examples include R&D and artistic creation. In both cases, ideas are generated as a result of a process of exploration, in science or in search of a form of expression. This type of learning is convergent, meaning that on the basis of different and unique skills, ideas are generated that have the potential for common use.

Cycle 2, however, relates to learning by assimilation of knowledge, which results from activities such as education, experience, and social interaction. Through interpretation of these ideas, different skills emerge. Imagine a mathematics class: all the students are using the same book, they attend the same classes, they do the same exercises. However, the ways in which they assimilate and interpret these are different, meaning that the learning process is divergent. Schon (1987) and others expand on the inner workings of this type of learning, but we keep our discussion at a more superficial level.

The main conclusion of this section, as shown in Fig. 11, is that the accumulation of knowledge, which is the basis for economic growth, is the result of a series of complex processes, in which there is considerable

interdependence between the accumulation of ideas and of skills. It is necessary to examine the role of the principal institutions of contemporary society and to attempt to determine how they fit into these processes. Conceição & Heitor (1999) show how this conceptual understanding can be used to analyze broad historical interactions between knowledge and development (such as in the evolution of China and Europe, Landes, 1998) as well as the adoption and diffusion of specific technological innovations (such as standards of video-tape recorders). The model also acknowledges the indivisibility of ideas, as proposed by David (1993) (once created, an idea remains at least potentially accessible everywhere, and there is no need to rediscover it).

This conceptual understanding of the learning processes is critical to draw implications in terms of the complex relations associated with the building-up of innovation systems (Christensen, 2002). In this chapter we next develop, the importance of stimulating innovation (generation of ideas) and the parallel importance of developing competencies, within an overall framework looking at inclusiveness.

Fostering Systems of Innovation and Competence Building: The Challenges of Inclusiveness

The analysis presented above considers a context in which the wealth and well being of individuals, organizations and nations is increasingly based on the creation, dissemination, and use of knowledge in a way to foster innovation. This fact is reflected in the trend in developed economies towards an increasing investment in advanced technology, research and development, education, and culture. As a consequence, concepts such as learning ability, creativity and sustainable flexibility gain greater importance as guiding principles for the conduct of individuals, institutions, nations and regions. Against this background, and emphasizing concepts such as the non-rivalry of information and the externalities associated with education and research and development, this section builds on the notion of localized technological change and the need to develop an agenda to promote the inclusive development. This is particularly appropriated to understanding the dynamics of innovation in much of Portuguese industry, which is heavily characterized by the so-called ‘traditional sectors’.

Following Antonelli & Calderini (1999), ‘the internal bottom-up learning process based upon the improvement of design and technological processes plays a major role in feeding the continual introduction of technological and organizational innovations’. In this respect, the authors conclude that technological knowledge is embedded in the specific circumstances in which the firm operate, and its generation is the result of a joint process of production, learning and communication, of which R&D activities are only a part. In these terms, current evolutionary economics

has shown the importance of path dependence of economic processes, in that it is at the core of selection mechanisms between competitive firms and technologies (Metcalfe, 1997). Competition is therefore the result of the rate of change of market share, apart from being dependent on differences in the rates of growth of individual firms. The result is a fully endogenous process, which, in the presence of increasing returns, gives rise to a strong interdependence between specialization and diversification. The direct implication for innovation policies in Portugal is the important, but limited role of demand at the firm level in assessing the amount of incentives for firms to introduce technological innovations. In more general terms, the analysis call for the need to feeding all the processes of learning, implementing technological cooperation among firms and between firms and research institutions, and on the process of on-job-training of the workforce. Technological centers specifically designed to sustain localized processes of technological change might play an important role in this context. However, it is important to clearly emphasize the important role of the science and technology system, S&T, in fostering innovation, as well as the related implications for public policy.

In these terms, although there is an emerging set of literature on technological innovation and industrial economics looking at the distinctive features and institutional characteristics of European regions (e.g. Gambardella & Malerba, 1999), there have been few attempts to build analytical frameworks to improve understanding and to allow the development of well-sustained technology policies for less favored zones and late industrialized European regions, such as those of Portugal. In fact, the neo-classical approaches in industrial economics have emphasized the analysis of the microeconomic behavior of firms and built theories specialized in the American and Anglo-Saxon systems and related market dynamics. However, evolutionary economics have attempted to improve our understanding of learning processes and the role of institutions in economic development, but have not specialized on the specific historical context of European regions, namely those characterized by late industrialization (e.g. Cooke & Morgan, 1998). Building on the evolutionary approaches and system theory, the concept of 'national system of innovation' (e.g. Edquist, 1997; Lundvall, 1992; Nelson, 1993) has led to numerous studies of individual European countries, but there is still a long way to go in order to assess the specificity of transition economies and late industrialized regions and countries, including Portugal.

The various aspects above include heterogeneous approaches to innovation, but consider 'change' at the center of the analysis. This has been considered throughout the entire chapter, but taking into account that firms' competencies are characterized by stability and inertia and, therefore, lock-ins and competence

traps are expected to occur, in that successful firms may be driven by their success in existing technologies to disregard new alternatives. Other important aspect to take into consideration is that the phenomena of increasing returns and path-dependence affect the nature of the innovation processes and the dynamics of industries in Portugal, and Europe.

Among the various aspects raised earlier, it should also be noted that the sectoral specificity in the organization of innovative activities, on one hand, and the specific characteristics of local systems of innovation, on the other hand, are expected to play a significant role in shaping the organization of innovative activity in Portugal. The prevalence of one effect over another depends on history and competitiveness of firms and their degree of internationalization.

The Importance of Stimulating Innovation

The section above made explicit the way in which we understand learning as knowledge accumulation, which is a result of a complex set of learning processes where there is considerable interdependence between the accumulation of ideas and of skills. We now turn for the analysis of innovation as the concept that best fits with the idea of the knowledge economy understood from a dynamic perspective.

It is by now well understood that the early conceptualizations of innovation as a linear process were clearly insufficient to describe the complexity and contingency of the innovative effort of people, firms and countries (Dosi, 1988; Kline & Rosenberg, 1986; Nelson, 1993). Still, what is surprising is the extent to which the linear perspective still informs much of today's public perceptions about innovation, as well as policy design and implementation. The reliance on simple and direct indicators such as expenditure of R&D by the private sector, and the obsession in some circles associated with improving these types of indicators, reflects the dominance of the linear perspective.

We do not question the importance of these and other indicators, but it should also have become clear by now that they provide an incomplete description of the innovation process and are tied to the linear perspective (see, for the continuation of the linear perspective, Guellec & Pottelsberghe, 2000). Romer (1990, 1993) recognizes the importance of what he calls *appreciative theories* of growth and innovation in helping more formal approaches to better describe the richness of the innovation process, but somehow the link has been hard to accomplish.

The link between the complexity of the innovation process and the special economic characteristics of knowledge, and of conceptualizations of the learning process such as the one advanced in 'Deepening our Understanding of Learning towards Innovation: Building on the Economics of Knowledge', could be a bridge. In fact, Romer (1990) and Nelson & Romer

(1996) construct a theory of endogenous growth drawing on the non-rival nature of ideas. Dasgupta & David (1994) advance new ideas about the economics of science building also on the same principles associated with the special characteristics of knowledge. Thus, the conceptual understanding of learning advanced in 'Deepening our Understanding of Learning towards Innovation: Building on the Economics of Knowledge' of this chapter could serve more than just being an interesting modelling tool, allowing the development of new conceptual approaches. It could also become a useful guide for policy, especially in light of the still predominant domination of the linear model. In a series of papers, Conceição & Heitor (2001) have explored the implications of the conceptual model presented in 'Deepening our Understanding of Learning towards Innovation: Building on the Economics of Knowledge' to advance policies associated with innovation (that is, the generation of ideas, or software). We turn, next, to the other side of our conceptual model of learning: the importance of wetware.

The Relevance of Competence Building

Competence is the foundation on which innovation is generated and diffused. Competence is associated with individual skills, but also with collective capacities. It is also on competence that a learning society can be constructed and sustained in order to foster innovation. Some suggest that technological change is (or has become) skill-biased (Autor, Katz & Krueger, 1997). Empirical work supporting the skill-biased technological change conjecture includes studies such as Krueger (1993). Thus, for some, the connection between innovation and competences is primarily understood as being related with this hypothesis.

However, the skill-biased technological change hypothesis is far from being uncontroversial, as the discussion that follows shows. From a conceptual point of view, critics note that the treatment of technological change rarely goes beyond asserting that new technologies, and especially computers, are responsible for a steady increase in the demand for skills (Galbraith, 1998). Technology is conceptualized as in the linear models of innovation. Criticisms based on empirical analysis include DiNardo & Pischke (1997) and the realization that there is a mismatch in the timing of the increase in inequality and the spread in the diffusion of computers, and the fact that the increased adoption of information technology has not noticeably contributed to increased productivity (see Galbraith, 1998, for a comprehensive review). Alternatives to the skill-biased technological change include the perspective advanced by Bresnahan (1999), who proposes an organizational complementarity between information technologies

and telecommunications (ICTs) and highly skilled workers.

But the relationship between competences and innovation is not only seen through the skill-biased technological change perspective. And competence building also entails much more than formal skills. For example, Dore (1976) differentiates 'education' from 'schooling', which refers to 'mere qualification-earning', leading to an 'educational inflation' spiral. Several other authors (e.g. Boudon, 1973; Bourdieu & Passeron, 1970; Bowles & Gintis, 1976; Jencks, 1972) are similarly skeptical about a direct relationship between increases in the level of education and economic performance. The differences between the economists of human capital and these other authors, who come primarily from sociology, remain until today. In fact, some of the critiques have important parallels with economic perspectives, such as Bourdieu & Passeron's (1970) theory of the social filter, whereby schools work as filters to preserve and maintain social and educational differences, and the 'inheritance of inequality' perspective of Meade (1964).

However, if one is ready to accept the existence of a labor market where wages reward, at least partially, productivity and skill, Katz & Murphy (1992) provide strong evidence that supply and demand go a long way in explaining the patterns in the evolution of inequality. Most of the recent studies on inequality focus on a single-country longitudinal analysis of the evolution of the dispersion of income. Examples of the same methodology applied to other single country studies include Schmitt (1995) for the U.K., and Edin & Holmlund (1995) for Sweden.

This discussion clearly highlights the link between competence (skills, education), and innovation (technological change) towards inclusive learning. The connection between education, skills and competence, on the one hand, and the learning society, on the other, must consider the manifold interconnections between competence and the learning society and links them with the broader context of the anxieties and concerns, hopes and expectations that we live with today.

An important issue is to know what it takes to be part of the learning society. We may not know exactly what the learning society is, but we do know that there are requirements to be part of it. We need, in particular, to build competence, of which skills are a part. However, for some cases, the need for new skills is not associated with technological change, but with an organizational change, and the new skills provided are not particularly intensive in specialized knowledge. It is important to stress this point because the discussion can easily be drawn into the skill-biased technological change discussion. Naturally, technological change does indeed play a role in increasing the demand for 'a higher order of skills', but there are other elements of change driving this demand. What is hardly questionable is

that those that do not possess the skills nor the ability or possibility to acquire them become excluded.

The Need for a Dynamic National Science Base

Pavitt (1998) noted that innovation studies confirm Tocqueville's idea that technological change would require the development of publicly funded basic research and associated training. In this context, analysis has shown that the main practical benefits of academic-based research are not 'easily transmissible information', but it involves the transmission of tacit and non-codifiable knowledge, with tendency for geographically localized benefits (e.g. Katz, 1994). Furthermore, following Hicks (1995), countries and firms benefit academically and economically from basic research performed elsewhere only if they belong to the international professional networks that exchange knowledge. This requires high quality foreign research training and a strong presence in basic research, mainly because academic research is certainly not a 'free good', although it has some attributes of a 'public good'. In this context, Pavitt, among others (e.g. Mowery & Rosenberg, 1998; Narin et al., 1997), conclude that 'public expenditure on academic research is a necessary investment in a modern country's capacity for technical change'.

It is also clear that one must consider the nature and extent of the influence of national patterns of technological change on the national science base. The analysis suggests the co-evolution of scientific performance with national technology and economy (Pavitt, 1996).

Casual observations have, however, shown that patterns of scientific strength and weakness are strongly influenced by the nature of the societal and technological problems to be solved. In any case, current understanding of the complexities of the knowledge bases that underlie future technological knowledge base is very limited.

If any conclusion can be taken with direct application to Portugal, it is that allocation to resources between broad fields of science should remain incremental, and that inadequacies in the rate of technological change should not be claimed to academic research. However, important questions remain to be solved, mainly in terms of the way academic governance influence the performance of basic research activities, and the linkages between basic and applied disciplines. Also, the way the demands for knowledge influence research policies remain to be examined.

It is clear today that one important dimension of the knowledge economy includes the activities expressly oriented towards the generation and diffusion of knowledge. It is, as with education, risky to reduce a complex set of activities to a single educator, but the national effort on research and development provides an indication of the commitment, at the country level,

to activities explicitly oriented towards the generation of new knowledge. These activities tend to occur in institutions, such as universities and research labs, or within institutional settings, such as the R&D unit within a firm, that provide incentives that foster the specialization on exploration and discovery, as well as exchange of knowledge. If it is unquestionable today the critical role of the national S&T systems, it is also clear that they do not represent by themselves a true measure of innovation, namely in socio-economic terms. This has led us to broaden our analysis and to attempt to relate current practices for the evaluation of S&T with innovation measurements and other social measures.

A Policy Exercise: Promoting Innovation in Portugal

Recent work within the framework of the OECD International Futures Program suggests two broad policy-related conclusions which apply not only to OECD countries in general, but to a large extent also to the case of Portuguese regions. The first is that if one is to build on the opportunities offered by the considerable progress that has been made in key technological sectors, if one is to reap to the full the economic benefits of rapidly integrating markets and the emerging knowledge society; and if solutions are to be found to tackling the challenges that the management of such a rapidly changing world raises, then what is needed are innovative, creative societies. The second is that in achieving that higher degree of innovativeness and creativity, policy will matter. The way ahead does not necessarily mean less government, not less policy but—certainly in some key areas—different policy.

The reservation 'in some key areas' is important. Just because we are heading into a rapidly changing world in the coming decades does not mean that we have to throw out all policies and make a completely fresh start. Indeed, some policies that have proved their worth in the past may well continue to do so in the future. However, it is clear that in other policy areas at least incremental adjustments are called for, and in yet others some radical new thinking is required. This provides, in fact, a simple but convenient framework for looking at the role of general policies in the future and their implications for innovation: (1) policy continuity; (2) policy reform; and (3) policy breakthroughs.

In this context, we present below four main groups of strategies to be considered for Portugal, which, per se, reinforce the need to develop innovation policies:

- (1) *Human Capital for Innovation*: Substantial investments in human capital, and mainly at the basic and secondary levels, will continue to be a main target to promote and nurture innovation if the skill and qualification requirements of future jobs are to be met. This will require imaginative new ways of organizing education and validating people's

knowledge. Regarding the Higher Education System, our work suggests two important ideas. First, we propose that the institutional integrity of the university needs to be preserved. Universities are a special type of learning organization specialized in producing and diffusing knowledge in unique ways. Second, we argue that, important as universities are, they are not enough to guarantee prosperity, and there is a need to promote a diversity of organizational arrangements, even at the higher education level. Indeed, this organizational diversity could be a major contributor to ensure the institutional integrity of the university. In addition, it is concluded that the allocation of resources between broad fields of science should remain incremental, in a way that the aim of policy should be to create a broad and productive science base.

- (2) *Institutional Renewal for Innovation*: The evidence from OECD suggests the value of structural and regulatory reforms in supporting the development of innovative and creative societies and economic growth. Among dominant factors, we envisage the role of market liberalization, and market opening, including the privatization of critical infrastructures. The process is to be implemented together a comprehensive program of organizational renewal, namely at the State level, and in a way to promote the establishment of cooperative agreements towards the establishment of social capital. Fiscal incentives for network organizations and a new regulatory framework for employment protection and market regulation should be attempted.
- (3) *Networking and Corporate Strategies for Innovation*: a framework for devising and implementing strategies in business environments typical of transitional economies, such as those in the Portugal, is to be considered taking into account clustering effects. The low level of 'thrust' typical of the Portuguese society is a major barrier, that is to be overcome along the enterprise chain value and making use of aggressive 'product development strategies', together with specific factors as: time to market; market and technology; product and process innovation; increasing returns markets; managing environmental complexity; managing organizational change; devising knowledge strategies.
- (4) *Alternative Forms of Financing Innovation*: different funding forms to be used in Portugal, including offset and countertrade tools, are conceived in order to promote and develop different approaches to innovation within national companies. Traditional means in financial innovation tends to be 'outdated' on the 'new' economy context. Although national security is not a priority, activities such as coast inspection, citizen protection and rescue, and humanitarian programs, are some

examples of the existing need for the country and, at the same time, to consider the use of offsets to foster economic development. Beyond offsets in processes for buying military equipment, countertrade should be considered as well for purchase of civil goods and critical infrastructures, such as the new Lisbon international airport. The research carried out aims to launch guidelines the benefits for the Portuguese economy of the innovative use of tools as offset and countertrade to increment new forms of cooperation between existing firms and new technology based firms creating multipolar, interdisciplinary and market driven networks.

Summary and Conclusions

This chapter addresses complementary aspects of relevance towards improved understanding of innovation in an emerging learning society. It focus on Portugal within a European scene, considering a context increasingly characterized by uncertainty and diversified environments, which are particularly influenced by social and institutional factors. Under this scope, our understanding of innovation encompasses the way in which firms and entrepreneurs create value by exploiting change. This leads us to question the traditional way of viewing the role that contemporary institutions play in the process of economic development and to argue for the need to promote *systems of innovation and competence building* based on learning and knowledge networks.

We describe a conceptual understanding of the relationship between *learning* and *knowledge accumulation*, leading to *innovation*. Our analysis led us to suggest that while the role of institutions needs to be re-examined, the variety of demands and the continuously changing social and economic environment is calling for **diversified systems** able to cope with the need to produce policies that nurture and enhance innovation in the emergent learning society.

In addition to the various arguments used in this chapter derived from emerging concepts associated with the economics of knowledge, a growing body of literature illustrates the importance of demand conditions to allow for technological diffusion in the network society. It is through the diffusion process that technological innovations are translated into wide economic impact, as more and more people and firms consume and use the new products or processes. And if we accept that this increasingly generalized usage of technological innovations fuels, not only increases in well being, but also the conditions to generate further innovations, one cannot escape the importance of demand conditions for economic and technological prosperity in the emerging learning society.

In fact, historians of economic evolution have shown that demand conditions were crucial in the process of early industrialization in the U.S. For example,

Rosenberg (1994) describes the demand conditions that were conducive to the earliest stages of industrialization in the 19th century. In fact, in Rosenberg's (1994) argument, they were crucial to create a new industrial system out of an agricultural society. An important component of the demand conditions was a relatively high level of income per capita and, equally crucial, a relatively egalitarian distribution of the marginal income available beyond the one needed for subsistence. Inspired by this analysis of the interaction between inequality and technology, we believe the concept of *system of innovation and competence building* discussed in this chapter should be further analysed to improve understanding whether, with the current wave of technological innovations, there is also a relationship between levels of inequality and the rates of diffusion of technology. The argument we are advancing here is that social cohesion, beyond the issues associated with ethical judgement and justice, may also be of importance to the learning society.

Innovation should then be understood as a **broad** social and economic activity within the framework of the learning society. It should transcend any specific technology, even a revolutionary one, and should be tied to attitudes and behaviors oriented towards the exploitation of change by adding value. Recent work within the framework of the OECD International Futures Program suggests two broad policy-related conclusions. The first is that if one is to build on the opportunities offered by the considerable progress that has been made in key technological sectors, if one is to reap to the full the economic benefits of rapidly integrating markets and the emerging knowledge society; and if solutions are to be found to tackling the challenges that the management of such a rapidly changing world raises, then what is needed are **innovative**, creative societies. The second is that in achieving that higher degree of innovativeness and creativity, policy will matter. The way ahead does not necessarily mean less government, not less policy but—certainly in some key areas—**different** policy.

The Taiwan Innovation System

Chiung-Wen Hsu and Hsing-Hsiung Chen

*Industrial Economics and Knowledge Center, Industrial Technology Research Institute,
Taiwan, R.O.C.*

Abstract: The Taiwan innovation system is continually contributing to technology-based industrial development in Taiwan. This chapter discusses the most representative characteristics of the innovation system, that is: (1) the Technology Development Program of the Ministry of Economic Affairs illustrating the industry innovation policy; (2) the R&D and technology diffusion strategy of the Industrial Technology Research Institutes; (3) the Hsinchu Science-Based Industrial Park's method of technology commercialization; and (4) the recruitment of overseas experts and the cultivation of talent to supply human resources to academia. Finally, we outline the practical achievements of the formation of the Taiwan integrated circuit industry.

Keywords: Innovation system; Government-supported R&D project; Technology transfer; Industrial technology development.

Introduction

Industrial development is the motive force behind economic growth. Industrial development is also a result of international economic competition. Development of technology-intensive industries is often the guiding principle of government for a developing country with limited natural resources and a small-scale domestic market. To assist technology-intensive industries, it is often necessary to subsidize research institutes and provide tax incentives. In addition to encouraging universities to diffuse knowledge for industrial development, the cooperation of industry, government, universities and non-profit research institutes in order to develop technology-intensive industries is critical for a national innovation system in an economy such as Taiwan's, with limited scientific and technological resources. Innovation almost always means the creation of a product, service, or process that is new to an organization. It is the introduction into the marketplace, either by utilization or by commercialization, of a new or improved product, service, or process. In this chapter we define innovation as not being new to the world, that is, it is viewed as the first use of an idea and its exploitation or commercialization within Taiwan.

The Taiwan economy has progressed from the agricultural society of the 1940s to light industries, such as consumer goods, in the 1950s, and then on to heavy industries, such as the petrochemical industry, in

the 1960s. At the beginning of the 1970s, the government along with local and foreign scholars recognized that Taiwan, an island nation with scarce natural resources and a limited domestic market, should set up an export-oriented strategy for economic development and should develop high-technology industries so that economic development could be maintained. However, in the 1970s, it was anticipated that no existing industry in Taiwan could lead the way in developing high-technology industries into the future for more than ten years. A consensus was achieved among representatives of industry, government, and academia, that the government should assist in the initial development of high-technology industries. The strategies used to build up an innovation system for high-tech developments were as follows:

- (1) in order to enable domestic industry to obtain a foundation for high-tech development, government, enterprises and experts and scholars from universities and non-profit research institutions pooled their talents, trying to build an innovation system for the development of high-tech industry;
- (2) a high-tech industry with development potential and wide inter-industry interdependence was selected as the target to be developed. And then, the key technology in the industry to be built up was selected as the subject to be developed. The key technology was the one likeliest to increase

greatly the industrial competitiveness of Taiwan. After an effort of some 20 years, the success of the innovation system for high-tech industrial development in Taiwan has been widely recognized. Among many other achievements, the computer industry here has grown to be the third largest exporter in the world, surpassed only by the USA and Japan. In addition, the production volumes of more than ten products now rank first in the world, e.g. notebook personal computers (PCs), hand-held scanners, and modems, to mention a few examples. Taiwan has also become the world's fourth-largest producer in the semiconductor industry. Taiwan is ranked first in the integrated circuit (IC) design sub-industry. In addition, the liquid crystal display (LCD) industry has grown rapidly in Taiwan. The electronics and information industries have now become the leading industries in Taiwan.

The main purpose of this chapter is to introduce the Taiwan innovation system's main characteristics. This chapter is organized as follows: first, the innovation system in Taiwan will be described; then, the most representative characteristics of the innovation system will be examined, including: (1) the industry innovation policy of government; (2) the technology research and transfer strategy of the research institutes; (3) the technology commercialization method of the Hsinchu Science-Based Industrial Park (HSIP); and (4) the recruitment of overseas scholars and the cultivation of talent in universities; and finally, the IC industry in Taiwan, in terms of the Taiwan innovation system, will be discussed as a case study.

The Innovation System in Taiwan

The Concept of a National System of Innovation

The concept of a national innovation system (NIS) originated from Schumpeter's discussion on the importance of innovation to economic development (OECD, 1997). Among scholars who have studied this topic, some of the more renowned academics are Freeman (1987), Lundvall (1992), and Nelson (1993). They each define a national innovation system from different research points.

Freeman (1987) defines a national innovation system as '... the network of institutions in the public and private sectors whose activities and interactions initiate, import, modify and diffuse new technologies' (Freeman, 1987, p. 1). He discusses the interplay between activities that lead to advances in technology and the organizations in the public and private sector that comprise the national system. He applies the concept of national innovation to show how Japan at that time maintained its superiority in some industries over other countries.

Lundvall says, "... A system of innovation is constituted by the elements and relationships which

interact in the production, diffusion and use of new, and economically useful, knowledge ... and are either located within or rooted inside the borders of a nation state" (Lundvall, 1992, p. 2). He studies this subject from the perspective of institutions that, taken together, make up the national innovation system, as well as from the microcosmic point of view of the individual.

Nelson calls the national innovation system "... a set of institutions whose interactions determine the innovative performance ... of national firms" (Nelson, 1993, p. 4). Basically, the focus of his research is to compare innovation systems adopted by various countries.

The Organization for Economic Cooperation and Development (OECD) discusses and compares interactions among the various players in the national innovation system, in order to gauge how effectively those interactions are at facilitating the flow of knowledge in the greater technology sector. Four types of interaction between different constituents of the innovation system are compared: (1) interactions among enterprises; (2) interactions among enterprises, universities and public research laboratories; (3) diffusion of knowledge and technology to firms; and (4) movement of personnel (OECD, 1997).

Although there are several definitions of a national innovation system (see Grupp et al., this volume), they can be classified into general and mission-oriented definitions based on formulating goals (see Conceição & Heitor, this volume). The general definition encompasses all interrelated institutional facilitators that create, diffuse, and exploit innovation in the nation. The mission-oriented definition includes organizations and institutions directly related to research and exploring technological innovations, such as enterprises' R&D departments, universities, and public research institutions, enabling policy-makers to develop policies and measures that promote successful innovation (see Mehra, this volume).

In this chapter, the mission-oriented definition is followed. It understands innovation to mean technological innovation and defines a NIS as a complex of innovation facilitators and institutions that are directly related to the generation, diffusion, and commercialization of technological innovation and also the interrelationship between innovation facilitators. The major concern in this concept is how Taiwan can formulate an effective national setting of major innovation facilitators and how to motivate networking among them in order to generate and commercial innovation effectively.

The Framework of the Taiwan Innovation System

In order to build up the foundation of high-tech industry for domestic industry, a joint effort by government, industry, university and research institutes is required to operate the innovation system for stimulating the development of high-tech industry. The

primary elements in the Taiwan innovation system are as follows.

(1) *Promoting the Establishment of Applied Research Institutions*

When considering R&D organization, the Taiwan government referred to the approach of foreign countries such as Japan's Agency of Industrial Science and Technology (AIST). This was established in 1952 (renamed the National Institute of Advanced Industrial Science and Technology in 2001) as a governmental organization. Korea's Institute of Science and Technology (KIST) was established in 1966 as the first public research institute, but not as a government agent, in order to attract overseas Korean experts to return to the country. To insure the operational flexibility of research institutes, and to free research institutes from government control, Taiwan decided to establish non-profit organizations to carry out technological innovation tasks. The first applied research institute, the Industrial Technology Research Institute (ITRI), was established under a special act, whose primary purpose was to enhance industrial technologies. A number of organizations were established based on the requirement of the development of domestic industry, like the Institute for Information Industry (III) in 1979, and the Development Center for Biotechnology (DCB) in 1984.

(2) *Government Subsidized R&D Funds*

Applied research institutions rely on government funding to conduct R&D. The 'Science and Technology Development Program' was formulated at the First National Conference on Science and Technology in 1979. (The Conference is a nationwide meeting held every four years by delegates from industry, government, academic and research institutes. It focuses on major issues concerning the development of science and technology.) In the program, it was mandated that the Ministry of Economic Affairs (MOEA) should allocate budgets for the Technology Development Program (TDP) and subsidize the non-profit applied research institutes to carry out the R&D of industrial technologies. The requirement was to achieve the optimal goal of stimulating the development of high-tech industry and upgrade the industry's competitiveness.

(3) *Setting up a Science-Based Park*

Since Taiwan had no experience in developing a high-tech industry, copying strategies from abroad was thought the best course of action. One of the measures proposed by the government was to set up a science-based park, and Silicon Valley, the most successful science-based park in the world, was taken as a model. The Government built up HSIP near ITRI, National Tsing Hua University

and National Chiao Tung University, to be the main arena for realizing the industrialization of science and technology (S&T).

(4) *Recruitment of Overseas Academics*

After the founding of R&D institutions, government budgets and the science-based park, there was only one remaining critical element: human resources. Although Taiwan had always placed emphasis on education and had excellent human resources, compared to other advanced countries, Taiwan was still far behind at that time. To make it worse, Taiwan had no practical experience in areas of R&D of S&T, fabrication and operations, and information gathering. To recruit overseas academics and professionals was the most effective way to achieve these goals in a short term.

From the above analysis, we formulate a framework for the innovation system in Taiwan, as shown in Fig. 1. Four primary elements can best represent the characteristics of the Taiwan innovation system.

- (1) TDP (of MOEA) will be used as an example to explain the industrial innovation policy of the government.
- (2) ITRI will be used to gain insight into the R&D and technology diffusion strategies of research institutions.
- (3) HSIP will be used to give examples of the application and commercialization of S&T.
- (4) Recruitment of overseas scholars, experts, and cultivation of professional talent will be used to explain how academic institutions supply human resources.

This chapter first examines in broad outline the development mechanism of the Taiwan innovation technology in 'The Taiwan Innovation Development Mechanism'. Then the focus shifts to a microcosmic analysis of the way in which the individual institutions making up the innovation system interact with one another. Interactions between the key players of technological innovation (the industry, universities and research institutes) that lead to technology diffusion, the actions of talented professionals, international knowledge exchanges, and other kinds of interactions are examined in detail from 'The Industrial Innovation Policy' through to 'The Technology Commercialization Method Utilized in HSIP'. Finally, 'Innovation in the Taiwan IC Industry' will use the IC industry in Taiwan as a case study to show that the Taiwan innovation system at various stages of development may require varying degrees of assistance and input from industry, government, academia, and research institutions.

The Taiwan Innovation Development Mechanism

How S&T Policies are Formulated

Science and technology strategies in Taiwan are based on the consensus achieved at National Science and

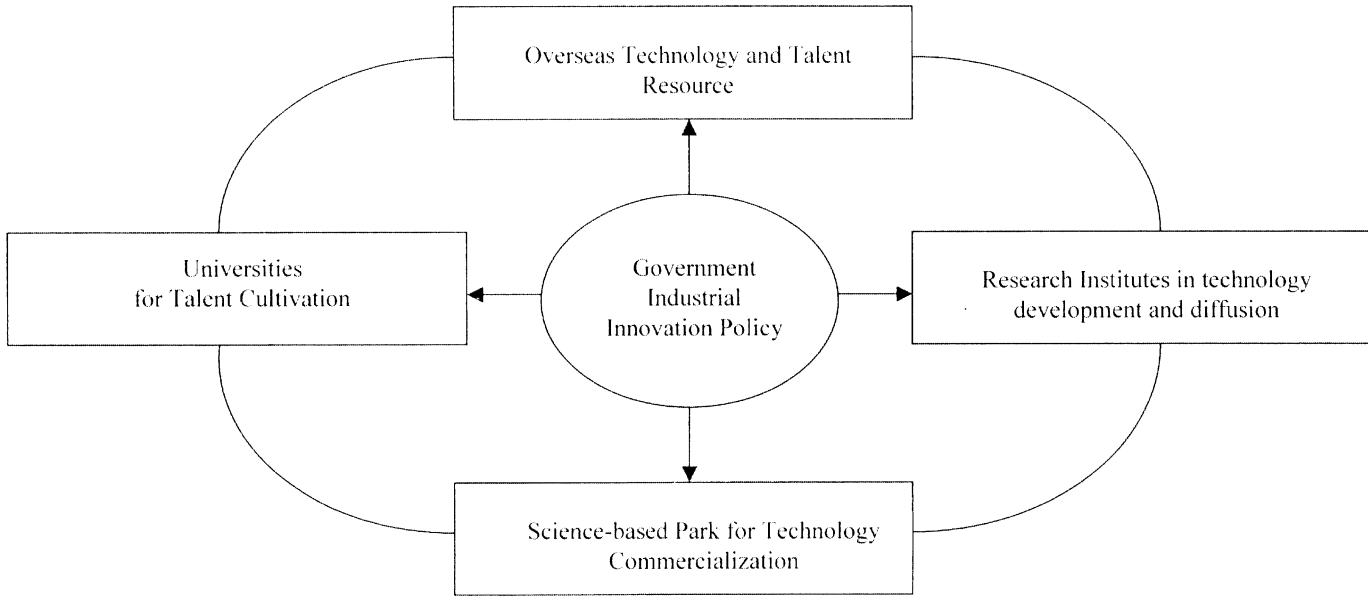

Figure 1. The framework of the Taiwan's innovation system.

Technology Conferences, Science and Technology Advisory Board Meetings, high-tech focus strategy Review Boards, and other major conferences. The following section introduces the formulation of S&T policies in Taiwan from the point of view of major conferences and action plans (NSC, 2000a).

(1) *National Science and Technology Conferences (NSTC)*

The NSTC has been held every four years since 1978. The proceedings of the conference are used to form national policy, as was the case in the sixth NSTC held in 2001, which led to the *National Science and Technology Development Plan (2001–2004)*.

Headed by the Executive Yuan Premier, the sixth NSTC preparatory committee consisted of 47 agency heads, Executive Yuan S&T advisors, and representatives of industry, legislature, universities, and research institutions. Overall responsibility for planning, preparation, and execution was put in the hands of the National Science Council (NSC), Executive Yuan. The preparation for the conference took the form of the following four stages:

- (a) formulation of overall planning concepts by the NSC. A Coordination meeting of relevant agencies was held, to set the main directions and focal points of the conference;
- (b) the content of the various topics, subtopics, and discussions outlines was decided;
- (c) three coordination meetings with the deputy heads of relevant agencies by the NSC, and the first preparatory committee conference by the Executive Yuan were arranged;
- (d) at the conclusion stage of the conference, after each of the topics had been discussed, specialists and scholars were instructed to jointly devise specific, feasible programs or suggestions on the basis of preparatory conference conclusions.

(2) *The Science and Technology Advisory Board Meeting of the Executive Yuan (Cabinet)*

Held annually since 1980, the Science and Technology Advisory Board Meeting gives the Science and Technology Advisory Group a chance to make policy recommendations concerning major issues involving the nation's S&T development plans and inter-agency R&D operations.

(3) *The Strategy Review Board (SRB) Meeting on Important Technology, Executive Yuan*

The Executive Yuan has held annual electronics, information, and telecommunications strategy review board meetings since 1992. Since 1997, the Strategy Review Board Meeting on Biotechnology has been held annually. In 2002, the SRB meeting included discussions of technology considered important for national development. It designed a

flexible development mechanism for the requirements of industrial development in Taiwan.

The Organizational Framework of S&T Development

The Taiwan S&T development policy was set up on the principle of comprehensive planning and the assigning of tasks to the relevant agencies. The NSC set up by the Executive Yuan, is responsible for the overall implementation of S&T development, while the Ministry of Defense (MOD) looks after defense technology. The Ministry of Economic Affairs (MOEA) takes care of industrial technology and the Ministry of Transportation and Communication (MOTC) is concerned with transportation, telecommunication, and meteorological technology. In addition, various colleges and universities under the administration of the Ministry of Education (MOE) are engaged in basic and applied R&D. A science and technology advisory office or similar office of the Executive Yuan has been founded within each ministry in order to plan and control science and technology development activities (NSC, 2000a).

Measures aimed at fostering the development of technology have already been implemented. For example, the NSC promoted the establishment of the Hsinchu Science-Based Industrial Park so as to create a beneficial R&D environment for the private sector.

Research and development organizations can be classified on the basis of whether they perform basic research, applied research, technology development, or commercial/applications realization. See Fig. 2 for a schematic view of the assignment of tasks between promoting and implementing organizations.

The Industrial Technology Development System

Being the main agency responsible for industrial technology development in Taiwan, the MOEA transfers the results of research to the private sector for product development and commercialization via technical assistance, information diffusion, and manpower training. Industrial technology development is conducted primarily via in-house R&D and secondarily via technology acquisition. To promote the technological upgrading of industry, the MOEA is working to strengthen interaction between industry, government, universities, and research institutions, as Fig. 3 shows.

The role of the research institutions is to interact with the private sector via technology transfer and collaboration with the private sector; they also assist the private sector in technology development by providing technical assistance, technical information, and personnel training. As for academia, the NSC has sponsored specific topics for research projects that enable universities to assist the private sector in technical assistance and personnel training. On the government's part, the development of applied research has been carried out by: (1) programs sponsored by the NSC, e.g. joint research project within industry-

Level of R&D \ Responding agency	Promotion	Implementation			
	Government	Universities and Research Institutes		Non-Profit Research Institutes	Industry (Including Science-Based Industrial Park)
Basic Research	<ul style="list-style-type: none"> • Academia Sinica • Ministry of Education • National Science Council 	Labs of Academia Sinica	Universities

Source: The Annual Report of Science and Technology by NSC.

universities, innovative technology research programs and target-oriented research programs; and (2) programs administered by the MOEA, e.g. importing technology from foreign projects, and TDP. To aid industry, measures for commercialization and applications have been drawn up, such as *the Regulation Governing Assistance in the Development of New Products* by the MOEA.

Universities and research institutes transfer the results of their R&D to the private sector in various forms. In addition, interaction between overseas corporations and research organizations benefit industry through the introduction of new technologies, joint research, overseas investments, and strategic alliances. The MOEA provides subsidies, matching funds, and tax deductions to encourage the private sector to engage in R&D. The Taiwan industrial technology development focuses mainly on the in-house R&D efforts augmented by introduced technologies. The emphasis is on positive interactions among industry, government, universities and research institutes, with the goal of optimizing the facilitation of industrial technology innovation.

The Industrial Innovation Policy

Taiwan industry consists mainly of small and medium enterprises (SMEs) with weak R&D capability, and because of the small scale of the domestic market, the government assumes the role of developing new technologies (see Inzelt, this volume). An annual budget is allocated for the Technology Development Program (TDP) to assist the technology development effort in industrial innovation. The budget grew from NT\$10 billion in 1992 to NT\$15 billion in 2000, accounting for 20.2% of the total government R&D budget, and 12.1% of private R&D funds. This shows the effect of the government budget on industrial innovation (NSC, 2000b).

TDP plays an important role in the development of key technologies for industrial needs. Its objectives are the establishment of new industries by cultivating professional human resources, developing markets and capital, as well as the upgrading of existing industries. Therefore, TDP has been established for the following reasons: first, and primarily, to support the development of new technologies such as biotechnology and pharmaceuticals; second, to support growing industries such as software engineering and communication and thirdly, to support mature industries such as textiles.

The scope of TDP can be categorized by five areas:

- (1) the development of key technologies, parts and components to promote new industries;
- (2) the automation and modernization of conventional industries to speed up transformation;
- (3) the establishment of inspection facilities;
- (4) the promotion of technology for the conservation and efficient use of water and energy;

- (5) the promotion of technology for environmental safety and protection to improve the quality of life (MOEA, 2001a).

To enhance the effects of TDP, the results from R&D are passed on to the private sector through various channels. During the process of an R&D project, the private sector receives the R&D results by attending the early stages of the project, collaborating, or receiving subcontracts. At the end of the program, the R&D results are transferred to the private sector through patent licensing and technology transfer. The exchange of information, seminars and conferences, talent diffusion, and various forms of industrial services, are ways of building up interface channels between research institutes and the private sector. These channels also serve as the means of diffusing results from R&D to the private sector. In particular, the diffusion of talent is a direct way of providing technology to the private sector.

The TDP Mechanism

In order to ensure success in its technology development efforts, the strategy for TDP projects is not only to entrust the project to non-profit research institutes, which can result in the industry not knowing much about the particular technology, but also to employ a dual-participation process between the public and private sectors. Once private industry is capable of developing the technology, projects are entrusted to both private and public corporations. It is expected that more than 20% of the TDP budget will be for projects assigned to private industry. Once private industry is in full control of the new technology, an application under *the Regulation Governing Assistance in the Development of New Products* is submitted to the Industrial Development Bureau of the MOEA for the acceleration of commercialization. For crucial technology with significant influence on industrial development, the government becomes a partner for such acceleration of commercialization in order to establish a new industry if private enterprises cannot afford the needed investment.

For the purposes of applying research results to industry, the selection of research topics goes through a number of stages. The Department of Industrial Technology (DOIT) of the MOEA periodically entrusts industrial associations with investigating the needs of the industry. Research topics must be in accordance with industry policy. For each research field, DOIT invites experts from each particular industry, government and academic sectors and research institutes, to discuss long-term planning and policy formulation for industrial development. If necessary, possible plans and policies are proposed to the Strategy Review Board (SRB) of the Executive Yuan. After discussion, development directions and policies for each research field are identified. Then, based on these policies, the

research institutes submit their annual R&D proposals. During the review of the R&D proposals by DOIT, the Review Board of Industrial Technology and Planning of MOEA has the power to invite experts to undertake a review of the proposals. The evaluation is based on many considerations, including potential contributions to industry, government policy, industrial needs, and the capability of undertaking and completing projects as well as the estimated budget.

There are many effective ways to promote research results (see Wilhelm, this volume). During project execution, results are passed on to industry whenever possible. After the project is finished, every possible method is used to promote the research results. These include seminars, publications, expositions, technology transfers, patent licensing and the spinning off of new companies if possible. The research institutes provide technical consultations and other services to industries, in order to fully utilize the results of TDP projects. By performing TDP projects and promoting the project results, the capability of industries of developing advanced products is enhanced, so that the effectiveness of *the Regulation Governing Assistance in the Development of New Products* managed by the Industrial Development Bureau is maximized. The management mechanism of the TDP is shown in Fig. 4 (MOEA, 2001a).

Major Measures Undertaken to Upgrade Industrial Technologies

To achieve the goal of upgrading industry technology, DOIT adopted strategies for varying industrial sector needs (Hsu & Chiang, 2001). In addition, adequate measures were implemented in different stages according to the current and future needs of the private sector. In the final stages, the technological development was undertaken by non-profit organizations like ITRI, DCB, and III; the results from the R&D were diffused to the private sector by way of technology transfers, seminars, technical services, and spinning-off companies. Consequently, high-tech has become the main force in the Taiwan industry today.

The measures undertaken to attract cooperation from the private sector in 1994 lured the private sector to engage in other R&D activities to upgrade their technology. The industrial sector joined the TDP R&D projects in the early stages so that the projects could meet the true needs of the private sector. The industrial sector also often attended to research work during development to expedite the commercialization of products and to lessen the risk that the technology developed would have a short life cycle. To accelerate the founding of technological enterprises, resources accumulated from the project, like research capabilities, facilities, human resources, and knowledge, have been made available to the private sector since 1997 in the form of 'open laboratories'.

To meet the requirements from the private sector to upgrade and broaden the technology, DOIT sponsored TDP for the industrial sector in 1997 that entrusted various companies from industry to carry out TDP. This was in order to ride the trends of the coming knowledge-based era in which the creation of knowledge and human resources will be the essential factors. The first priority was to direct abundant R&D and human resources to universities in the private sector. For this reason, DOIT directed TDP to universities in order to assist them in carrying out technological development. The relationship of government industrial policies to various sectors from industry, government, academic and research institutes is depicted in Fig. 5 (MOEA, 2001a). The following describes the five main development strategies for industrial technology development.

The Underpinning of Non-Profit Research Institutes Performing TDP—Interactions between Government, Research Organizations and the Private Sector

In order to encourage the domestic industrial sector to invest in R&D activities the major form of government technical assistance to industry was to contract non-profit research institutes to perform generic technological development and then to transfer their research results to the domestic and private sectors. Some efforts also dealt with innovative and pioneering fields. In the meantime, to encourage research of technologies common to both civil and military use, Chung-Shan Institute of Science and Technology (CSIST), a subordinate to the MOD, actively transferred technologies applicable to civil use to the private sector. Each research institute assisted the private sector in bringing the research results into production. Depending on the needs of the manufacturers, the technology transferring methods included training of professional personnel, technical services, spinning-off new companies, or contracting out jobs for a specific product production for the use of technology testing. Most effective were the spin-off companies that systematically transferred human and technological resources to the private sector. This enabled the rapid emergence of the Taiwan semiconductor industry and the overall accelerated development of Taiwan industry. Take for example the integrated circuit industry that accounts for over half of the production of HSIP, at least half of the manufacturers have come about as the result of TDP (Chang & Hsu, 2001).

Allocating TDP Projects to the Private Sector—Interactions between the Government and the Private Sector

To encourage the private sector to contribute to R&D activities, DOIT has entrusted the private sector to the TDP since 1997 that has attracted the private sector to carry out tasks in TDP. The project has been broadened

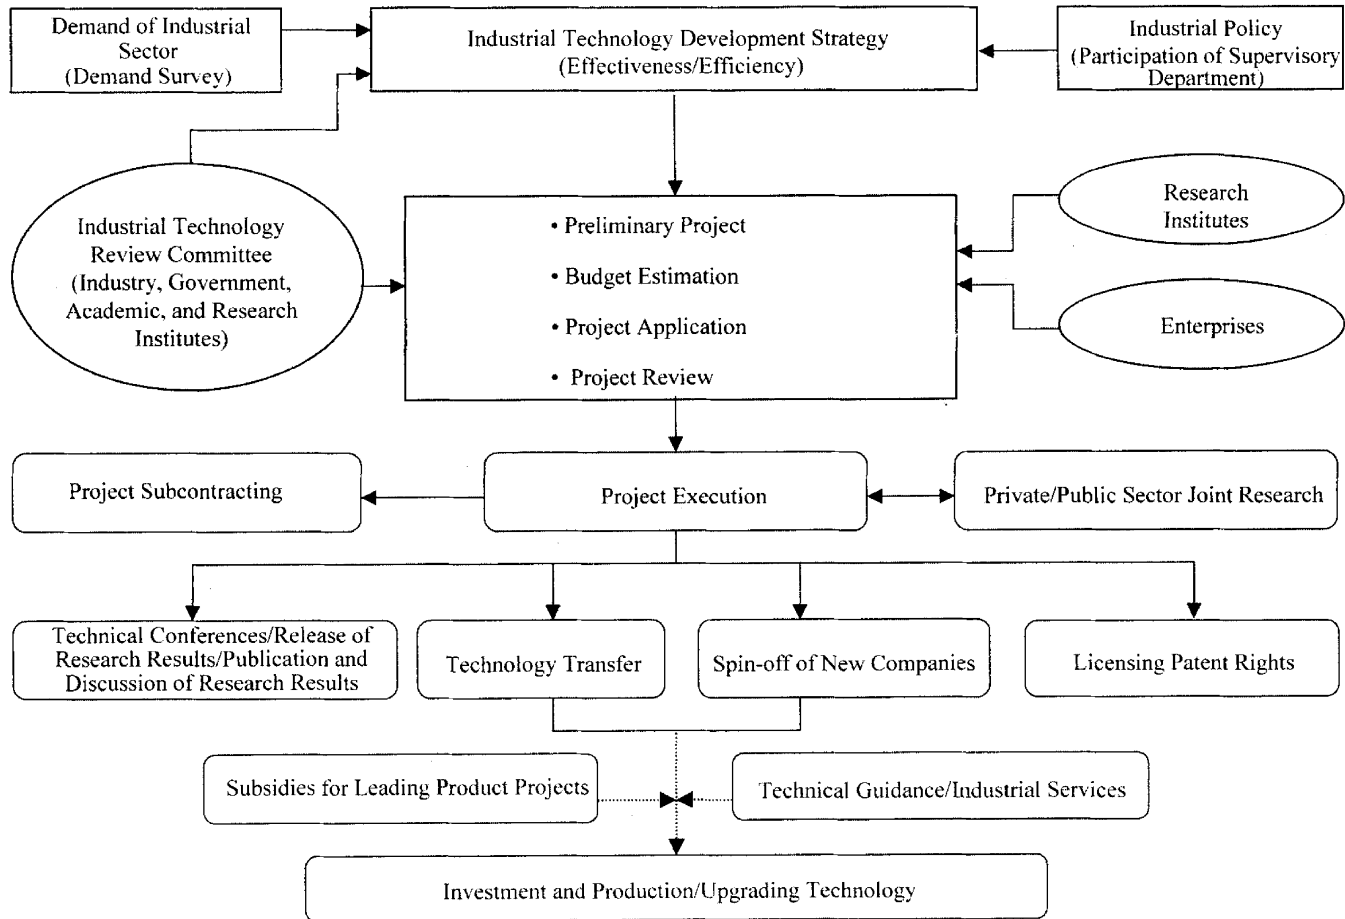

Figure 4. The management mechanism of the technology development program in Taiwan.

Source: MOEA Technology Department Program 2001.

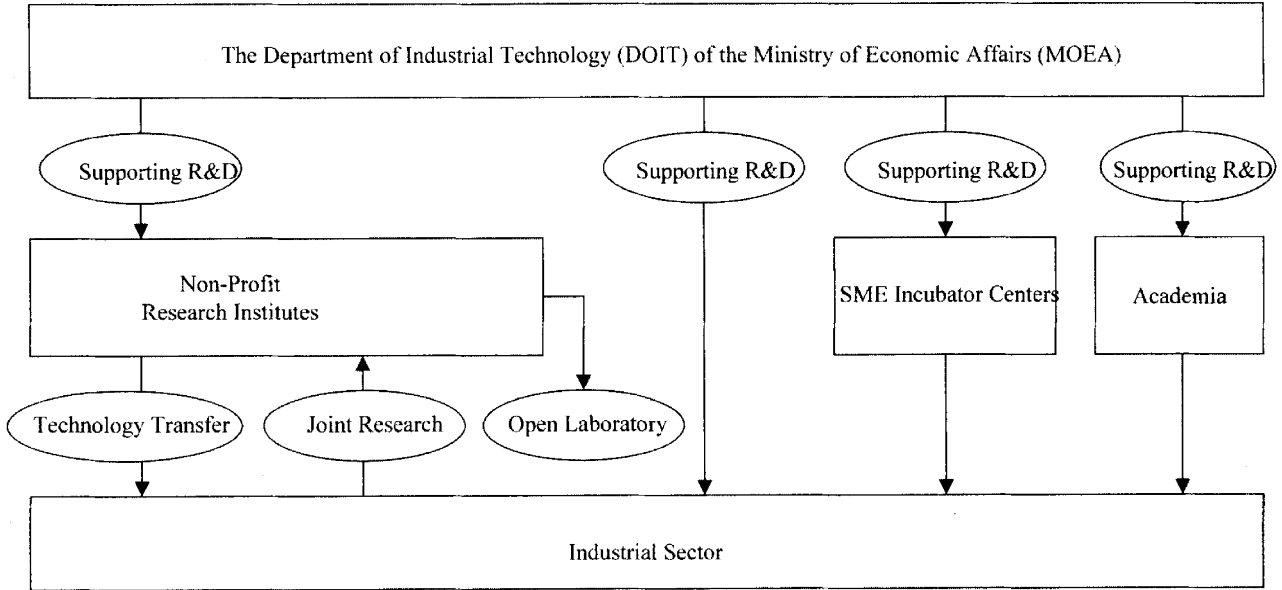

Figure 5. Industrial technology development strategy in Taiwan.

since 1999 to encourage manufacturers cooperating with R&D in industrial technology, subsidies to be limited to no more than 50% of the total expenditure of the program. The following describes the measures taken (MOEA, 2001b).

(1) *Supporting the Private Sector in Developing Industrial Technologies*

After the project to develop pioneering, critical or aggregate technologies was approved, the private sector was granted subsidies, so that it could invest in R&D and improve its stock of technical personnel. This measure resulted in the enhancement of R&D capability. Furthermore, in order to promote a sound overall R&D capability, a program for integrating technology development was formed. It was formulated in 'Notes for subsidizing of preliminary research for an Integrated Industrial Technology Development Project', in order to stimulate cooperation among manufacturers.

(2) *Encouraging SMEs to Develop New Technologies*

For the purposes of preliminary research for pioneering innovations or improving technology, or for R&D in some specific innovative techniques, subsidies were granted to those small or medium enterprises that carried out R&D. The grants also encouraged qualified professionals or experts to join innovative research or even set up their own companies. Besides luring the small to medium-sized enterprises to engage in the R&D efforts, the program also stimulated the founding of new high-tech companies.

(3) *Developing Demonstrative Information Applications*

It was decided to approve and subsidize companies developing pioneer application structures or advanced applied information systems that were innovative domestically, effective, or might stimulate interest in their applications. The goal was to improve the overall capabilities of information applications.

Granting TDP Projects to Universities—Interactions between Government and Academic Institutions

The utilization of academic resources by the government can be traced back to 1992. The MOEA, in its execution of TDP, channelled the results from basic research by the academic organizations to non-profit research institutes, which served as the medium for further applications and test productions. The results from the non-profit organizations were then transferred to manufacturers cooperating in the program.

In order to utilize the valuable R&D capabilities of academia effectively, the program began to plan for direct commissioning of research to universities in 2001. The strong capabilities of the academic teams in R&D is expected to work toward the development of

pioneering and innovative industrial technologies. Through the process of innovating high-tech industry, all sectors in the development of industrial technologies it is hoped, may be integrated.

Stimulate Cooperation between the Private Sector and Research Institutes—Interactions between the Research Institutes and the Private Sector

Starting in 1990, DOIT drew up promotional plans, which encouraged research institutes to get together with industrial entities. This joint research strategy has resulted in a better matching of TDP R&D projects with the needs of industry.

Enterprises participating in TDP projects must inject some of their R&D resources, such as manpower, to identify technology research specifications, since this also promotes national R&D investment. Furthermore, by integrating resources from industries, resource utilization efficiency is enhanced. This industrial cooperation strategy has businesses actively participating in R&D projects early-on in the technology development stages, which not only helps steer R&D projects in the right direction, but also achieves gains from the research results. Overall, industry benefits from the new technologies developed, and can discover talented staff early on, to be absorbed into the organization once the person starts his/her professional career.

To sum up, the TDP's cooperative strategy is based on the following objectives: to integrate R&D resources; to accelerate R&D efficacy; to communicate with relevant industries on their needs and requirements; and to accumulate learning experiences. These four critical objectives yield concrete resources and increase application performance for both individual firms and the whole industry.

Establishing Open Laboratories and Incubators—Incubating of High-Tech Companies

Interactions between the research institutes and the private sector will utilize the R&D resources of the research institutes more effectively. The open laboratories resulting from this will breed new technology industries in the fields of communications, optoelectronics, semiconductors, medicine, precision machinery, biotechnology, and computer software. The elements essential for R&D and the starting of new companies will be readily available, such as human resources, technology, information, communications, space, facilities, laboratory equipment, technology management, consultation facilities for starting up businesses, industrial safety, and amenities. With this supportive environment for R&D, entrepreneurs invest and create new industries. This brings about a boost for R&D capability, improves competitiveness, and creates opportunities for manufacturers.

The functions of open laboratories can be divided into two activities: (1) cooperative research; and (2)

incubating of new businesses. Cooperative research is cooperation between manufacturers and research organizations on various specific topics. Open laboratories provide necessary resources for research work. The research personnel work closely together to achieve higher levels and standards of quality. Incubating new business programs provides a sound research environment to people or enterprises wanting to create new careers or pioneer new businesses. The program also renders services for the commercialization of products, managerial training, and capital assistance. The goal is to help reduce the risks associated with the founding of new businesses or new careers so that the ventures can succeed.

The research institutes established the open laboratories and the new-business incubator centers for the private sector to effectively utilize R&D facilities and to enhance the industrialization of the technologies developed. Participating members include ITRI, DCB, the China Textile Institute, the Metal Industries Development Center, the Food Industry Research & Testing Institute, and CSIST. There were approximately 50 new-business incubator centers in 2000, spread around the country with the active promotion of the government. In addition, the program was extending to include national laboratories to help cultivate professional personnel for the private sector and to develop pioneering technologies.

R&D and the Technology Diffusion Strategy of the Research Institutions

In order to develop higher-added value and technology-intensive industry, to promote the establishment of emerging high-tech industry, and improve the present industry structure so as to reach sustainable development, government helped the establishment of research institutions in phases and also took the responsibility to improve industry technology based on the requirements of industrial development. For instance, ITRI was established in 1973, with a predominant role in innovation technology. It was to be the stimulus for starting up domestic industry technology; III was established in 1979, to promote the development of information software/hardware industry in Taiwan. In addition, in order to advance biotechnology, the government also set up DCB, with the expectation of improving the Taiwan biotechnology. Since the industrial structure of Taiwan is still dominated by SMEs, seven non-profit research institutions were set up in 1992 and 1993, including printing, plastics, shoe-making, bicycles, precision machinery, stone materials processing, and pharmaceutical technology research center.

Among them, ITRI is the largest non-profit industry technology application research institute in Taiwan, and has engaged in R&D for nearly 30 years. Starting from the establishment of TDP by MOEA, it built up its own R&D resources, then encouraged enterprises to

engage in technological development, further propelling the Taiwan industrial structure to advance toward technology-intensive development. There are around 6,000 employees in ITRI, with more than half holding Masters or Ph.D. degrees. They range over various extensive fields of technological research, and are distributed in seven research laboratories and four research centers. These are the Electronic Research & Service Organization (ERSO), the Computer & Communication Research Laboratories (CCL), the Opto-Electronic & System Laboratories (OES), the Mechanical Industry & Research Laboratories (MIRL), the Union Chemical Laboratories (UCL), the Material Research Laboratories (MRL), the Energy & Resources Laboratories (ERL), and the Center for Measurement Standards (CMS), the Center for Aviation & Space Technology (CAST), the Biomedical Engineering Center (BMEC) and the Center for Industrial Safety and Health Technology (CISH).

ITRI is actively involved in the development of industrial technology, to assist industry to improve technology, to establish new technology-based industries and upgrade existing industries. In order to improve industrial technology, the R&D departments of ITRI complies flexibly with the requirements of industries. For instance, it emphasized R&D planning from the very beginning, selecting technology sectors suitable for development in Taiwan, and focusing on introducing technology from abroad. Following urgent requests from industrial circles, it made great efforts to diffuse its R&D achievements, and to transfer experts to appropriate areas so as to equally emphasize R&D for and implementation of, emerging technology-based industries (Chang et al., 1993).

At present, it strongly encourages industry to engage in R&D activities to actively create economic benefits, and to balance industrial development. For the task of improving industrial technology, ITRI will continue to implement actively R&D projects for enterprises in the future. It will also open laboratories to accelerate the establishment of innovative enterprises. It will also engage in R&D of cutting edge advanced technology for Taiwan's domestic industries, in order to open up new technological possibilities (including cutting edge) for enterprises. It will also sustain an unending supply of technology resources to create technology required by enterprises at opportune times. At the same time, it will accelerate internationalization of R&D and combine with the development of the science-based industrial park.

The technological development strategy of ITRI is the R&D strategy stimulated by the goal of establishing core technologies, R&D construction of the appropriate environment for technological innovation, and the improvement of enterprises' R&D capability. With respect to establishing core technologies, it is to integrate technological fields and create the following benefits.

- As far as R&D environment construction is concerned, it is to build up information networks and promote exchange of specialists from different fields.
- Regarding technological innovation, it is to strengthen state of the art technology R&D, promote internationalization and also recreation of innovation culture, to enable ITRI to own an unflinching supply of motive power of technology.
- With respect to improving R&D efficiency of enterprises, it is to use active methods of putting R&D outcomes into use by enterprises such as cooperation among enterprises, technology transfer, R&D strategic alliances, and public laboratories etc., to accelerate the improvement of R&D efficiency by enterprises.

The Recruitment and Training of Talented Professionals

The recruitment and training of talent has been one of the most critical strategies in the Taiwan technology innovation program. Since 1980, the influx of returning overseas scholars has created a mushrooming effect on high-tech industry.

The Recruitment of S&T Talented Professionals

To accelerate the upgrading of domestic industries, the government has adopted a strategy to recruit overseas professionals needed by the country. These people are needed for the improvement of R&D capabilities to accelerate the increasing involvement of the private sector in the development of cutting-edge technology. Measures have been taken to enhance the effort to recruit overseas researchers in science and technology. In 1983, the government to build up technology personnel framed the 'Program for the enhancement, cultivation and recruitment of talented individuals in advanced technology'. This provided the basic human resources for domestic industries in developing high-tech industries. The government also increased its support for the graduate schools of major universities in fields of science, technology, medical science, and agriculture. Overseas scholars were recruited as university faculty members to improve research capabilities. In 1995, another program, 'Program for the enhancement in utilization of talent in advanced technology', was implemented to recruit high-tech talent from Silicon Valley in the U.S. and other overseas areas.

The Cultivation of Talented Technology Researchers

The government pushed for the cultivation and use of talented high-tech researchers to meet the needs of high-tech industry for manpower in advanced technology. After the review of effects from the 'Program for the enhancement in utilization of talent in advanced

technology', a 'Program for the cultivation and utilization of technology talent' was brought about by the Executive Yuan. The program was aimed at building up a sound foundation for the cultivation and utilization of domestic scientific talent in advanced technology. This would greatly improve the national development of science and technology. In 2001, the program was further amended to a high degree to meet the needs of the knowledge-based economy. Seven major talent enhancing strategies were proposed:

- (1) The cultivation of high-tech researchers in universities.
- (2) The training of industrial technology personnel.
- (3) The recruitment of high-tech professionals.
- (4) The recruitment of overseas experts in technology.
- (5) The recruitment of technical staff from Mainland China.
- (6) The attracting of talented graduates.
- (7) The promotion, circulation and utilization of talented scientists in the private sector, government, universities, and research organizations.

To meet the demand for high-tech engineering talent in the new technology industries, the 'Project for the cultivation of important high-tech industrial sector talented individuals' was put into effect in July 1998, for a period of three years. The 'Project for the cultivation of advanced talented researchers throughout various technology fields' was implemented in 2000. The project screened talented people with technical backgrounds in R&D or management from domestic high-tech industries and research institutes. These people were recommended by the organizations where they worked and were sent abroad for practical training or short-term workshops. The government subsidized their training abroad for a term of six to nine months of practical training in areas of investment appraisal, technology transfer, and intellectual property rights.

In addition, to meet the development trends in integrating 3C (consumer electronics, computer, and communication) technology and the government's subsidies to R&D efforts in the 3C technologies, the Ministry of Education has urged schools to open classes of 3C integrated technologies since 2000. Due to the rapid development of the electronics, information, and engineering industries, there is a severe shortage of qualified individuals, particularly in the fields of wireless communications, Internet, and software. In addition, such individuals were badly needed for businesses in the electronic sector. As a result, plans to cultivate talented researchers in electronics technology, industrial computers, and information electronics, were put into effect. The projects included on-the-job-training and preparation classes. The goal is to resolve the shortage of talent in the domestic technology industries.

The Technology Commercialization Method Utilized in HSIP

The Taiwan government has adopted a policy of establishing science-based parks to develop high-tech industries in Taiwan. Since the main conditions for developing high-tech industry are professional staff, the most advanced technology and fast acquirement and digestion of information, Hsinchu was chosen as the place to establish the first science-based park in Taiwan. The reason for this was that Tsing Hua University, Chiao Tung University and ITRI are located in Hsinchu, and provide excellent human resources, assisting manufacturers to break through technology bottlenecks. The establishment of HSIP is an important measure taken by the Taiwan government to promote the development of high-tech industries. After 20 years of such development, it is indeed an inspiring symbol for the Taiwan high-tech industry.

Since HSIP was founded in 1980, up to the end of 2000, it comprises 289 manufacturers of high-tech products, employing 102,840 workers, with an invested capital of NT\$694.5 billion. There are six major sectors: integrated circuit, computer and peripherals, communications, opto-electronics, precision machinery, and biotechnology. Since the main objective for establishing the science-based park in Taiwan is to promote the development of high technology and industry, and the government uses the necessary resources for high-tech industrial development as the means of carrying out its policies, this section explains the ways of innovation by HSIP based on different measures used by the government to promote the use of the resources to benefit manufacturers or entrepreneurs who engage in the development of high-tech industry (see Boly et al., this volume). Technology sources, human resources, funds requirements, preferential land tax and other levies, and the management structure are five important resources provided by the government for manufacturers in HSIP. There are five major factors to be discussed are:

- (1) technical resources;
- (2) human resources;
- (3) capital resources;
- (4) risk sharing of new business; and
- (5) the operating environment (Chang & Hsu, 2001).

Technical Resources

Technical sources for manufacturers in HSIP come from R&D projects by manufacturers or subsidies from the Science-based Industrial Park Administration (SIPA) for innovative projects: technology transfer or collaboration with ITRI, subsidies from the TDP sponsored by MOEA; cooperative programs with NSC or universities; import from or cooperation with, foreign sources; and national laboratories like the National Nano Device Laboratories, the Synchronous Radiation Center, and the Precision Instrument Center.

The relations between HSIP manufacturers and nearby ITRI, Tsing Hua University, and Chiao Tung University can be discussed on three technological levels: basic research, applied research, and technology development. The universities are mainly engaged in the basic research, subsidized by research grants from the NSC. ITRI and other Research Institutes mainly receive contracts from the TDP to carry out R&D of applications of advanced and generic technologies. ITRI ensures the realization of the commercialization of technology by the private sector. The industrial sector is mainly involved in the development of specific technologies and the commercialization process. Besides research work done by the private sector itself, results from the basic and applied research work of the government are also adopted by the private sector. For manufacturers in HSIP close to the universities and ITRI, effective cooperation is easy and an efficient network of operations is achieved.

There was a great need for imported technology in the early days of HSIP. ITRI served as the main source of technology. Manufacturers could also contract ITRI to develop technology for new products or to resolve technical problems. The mission for ITRI was to accelerate the development of Taiwan domestic industry by passing on its achievements in R&D to the private sector to generate maximum benefits. For this reason, ITRI utilized all available channels to diffuse technology to the private sector.

ITRI has served HSIP very well. In advanced countries, universities work very closely with the private sector in R&D, and the way HSIP has been set up also enables the practical application of research work by the universities. Back in the 1970s when Taiwan was planning to develop high-tech industries, there were only a few people experienced in R&D, even in academic circles. For this reason, ITRI was founded in 1973 with government subsidies to link basic research by universities and the development of technology by the private sector. By 1980 when HSIP was established, ITRI had become the critical and main source of technology for HSIP manufacturers. With the growth of HSIP, the main sources of technology were from abroad or from technology transfer and cooperation, or from the nearby universities.

Human Resources

Human resources are the motive power of creation. The gathering together of advanced manpower is the greatest success of the HSIP. Many university graduates went into ITRI to sharpen their professional skills before moving into the private sector. HSIP is right next to National Tsing Hua University, Chiao Tung University, and ITRI (Guan Fu Division). Another ITRI division, the Chung Hsin Division, is only ten minutes away. This has greatly assisted the exchange of talented managers and researchers among the four parties.

This occurred in the following ways:

- (1) college graduates working directly in ITRI or the factories inside HSIP;
- (2) technical training courses sponsored by ITRI;
- (3) workshops given by universities targeted for employees inside HSIP or ITRI, with emphasis on theory, advanced technology, or technical management;
- (4) employees of ITRI and HSIP manufacturers attending classes given by universities;
- (5) seminars and speeches inviting scholars or experts sponsored by HSIP, ITRI, or universities;
- (6) review boards to review master theses, doctoral dissertations, and research projects; and
- (7) research projects commissioned out to school faculties for consultation or collaboration.

The experience from HSIP showed the private sector that investment in advanced technology personnel often provides maximum returns. There were four measures taken by the government for cultivating talented people in advanced technology:

- (1) providing advanced training on the job;
- (2) providing training for career change;
- (3) recruiting overseas talents to work and train domestic personnel;
- (4) sending research personnel for training abroad.

Taiwan began its development in advanced technologies in 1980. With the shortage of domestic R&D capacity, overseas experts and scholars were recruited, especially those from Silicon Valley in the USA. Besides bringing in knowledge of advanced technology, market information, equipment procurement information, these people expanded technology transfer and cooperation using their overseas experience, some even established subsidiaries here. From their attendance at overseas seminars and conferences, information about advanced technology was at hand.

In order to meet the demand for qualified personnel, to improve the quality of manpower, and to shorten new personnel training time, SIPA sponsored training programs with ITRI and nearby universities. Workers in HSIP actively attended the programs in order to keep up with the rapid advances in the technology field and to maintain competitiveness. Furthermore, the recent policy of the Ministry of Education to acknowledge Master's degrees earned from on-the-job programs (studying during spare time for a Master's degree) should provide another incentive for personnel to undertake further qualifications.

Capital Resources

In the early stage of HSIP, the capital needed for development was insufficient. The government provided loans to the private sector or invested directly

through the Chiao Tung Bank. Development Funds from the Executive Yuan were granted by the administration to provide for investment in high-tech industries. In order to implant technology into the private sector, ITRI also set up a venture capital company. Besides assisting ITRI in technology transfer, this company helped manufacturers of promising technology to acquire the needed capital. The company also invested directly in high-risk technologies, which had strong market potential. Measures to encourage the founding of venture capital enterprises to invest in high-technology companies proved to be very effective in starting up new companies in the HSIP.

With the growth of the domestic capital market, manufacturers in HSIP issued common stocks, and distributed stocks to employees. This enabled the manufacturers to directly acquire capital from the public and employees, from entrepreneurs, venture capitalists, banks, and other related enterprises.

The government took several measures to assist manufacturers gain the necessary operating funds. Rapid depreciation measures allowed the investors of large equipment in the park to accelerate depreciation of the equipment and thus delay tax. This gave the manufacturers the advantage of gaining operating capital without paying interest. The measures were very helpful for semiconductor and opto-electronics industries that engage mainly in manufacturing. The government also provided mid-to-long term business loans to makers of important technologies for industrial development. The policy attracted manufacturers to invest in high-risk advanced products and met the manufacturers' need for expanding capital.

Diverted investing was another major source of capital. Because the electronics industry is a major manufacturer, investing in the makers of important components or products was common. With the readiness of capital, market, production, top managers, and managerial systems, shortening the preparation time to start up a business reduced the costs of innovation. Manpower, capital, technology, market, marketing, regulations, managerial systems, all these formed a tight interrelated network between existing or new manufacturers. When the timing was right, these factors generated another manufacturer. After more than twenty years of fostering new enterprises, HSIP has created a sound environment for new businesses.

New Business—Risk Sharing

To cope with the insufficient investment in high technology in 1980s, the government drew up several measures to stimulate investment. Some examples are:

- four- to five-year period of profit-seeking enterprise income tax exemption;
- accelerated depreciation;
- an extended tax-free period;
- capital gains credits; and

- broad expenditure listing.

Further measures on exports included credit and tariff free periods on commodity taxes of exported goods. These overall reductions on tax and tariffs increased manufacturers' net profits.

Two important characteristics of the investment in HSIP are that it is high risk and concentrates on high-technology. This kind of enterprise will contribute most to accelerate the upgrading of domestic industry because it stimulates the development of related technologies. Due to the need for high investment in R&D, it requires the government to share the risk and cost. The tax reduction measures encourage and help the start-up enterprises in high technology in their initial phase of development.

The Operating Environment

HSIP is a community of abundant information. Besides periodicals issued by the SIPA and information on the Internet, employee organizations and associations sponsor various gatherings, such as training courses, seminars, speeches, and cultural activities. Being alumni or alumnae, room-mates, or colleagues, generating a free flow of information brings many people in the park together through their interactions. This also influences the way business operates.

So as to provide a supportive environment for high-tech industry, the government implemented several measures, including a one-shop window service and simplified administrative procedures. Constant efforts were made to improve the basic facilities in order to achieve an appropriate environment. A system to automate customs clearance was put into effect. All these were aimed at giving advantages to manufacturers inside HSIP to increase their competitiveness in the world market.

Innovation in the Taiwan IC Industry

This section describes one important area of the Taiwan high-tech industrial scene—the integrated circuit (IC) industry. The innovation process involves four major sectors: government, research institutes, academia, and the private sector. The Taiwan IC industry in 1973 consisted of assembly plants but had then grown to comprise a complete industrial infrastructure, including design, mask, fabrication, and assembly capabilities by 1990. By 1995, Taiwan had caught up with the advanced nations and reached 0.5-micron ultra-large-sized IC technology. Taiwan has also become the world's fourth largest producing country (Chang et al., 1994).

The selection of the IC industry as a target industry by the government, the introduction of foreign technology from the Radio Corporation of America (RCA) in the USA, the assimilation and improvement of imported technology by ITRI, and the transfer of this

technology to local industry all helped in the formation of this industry. ITRI collaborated further with the private sector to develop sub-micro technology, and advanced into the independent making of memory products such as dynamic random access memory/static random access memory (DRAM/SRAM). During the evolution of these developments over more than twenty years, the government subsidized ITRI's R&D funds while ITRI played the role of stimulating technology research and diffusion. Together they have assisted the establishment of new technologies and generated the present prosperity of the Taiwan semiconductor industry.

The Taiwan IC industry, under government supervision, has developed from rough beginnings into the flourishing industry it is today. Throughout this development process, ITRI has been involved in the planning and performing of R&D activities, and the transferring of technology to the IC industry. There are mainly four stages in the development of the Taiwan semiconductor industry: medium scale IC (MSI), large scale IC (LSI), very large scale IC (VLSI), and ultra large scale IC (ULSI) technology. The following describes the measures taken by the interaction of government, ITRI, universities, and the industry in each stage of the process (Chang & Hsu, 1998).

The Initiation Stage—MSI Transfer from Abroad

The Taiwan semiconductor industry began with the founding of the U.S.-owned Kaohsiung Electronics Company assembling transistors in 1966. Not until 1973 did Taiwan-owned Wonban Electronics begin its production of transistors. In the academic world of Taiwan, only National Chiao Tung University had a semiconductor laboratory to cultivate this field.

The Taiwan government were hoping that the local electronics industry would move in the direction of technology-intensive products, and government advisors suggested that it should develop IC design and manufacturing technology in order to stimulate innovation throughout the island's electronics industry, which would also spin off related industries in the process. A task force was funded by the MOEA to discuss how to carry out the development strategy of this high-tech industry. The strategy is described below:

- (1) The Technology Advisory Committee (TAC) was established to take responsibility for planning.
- (2) The technology transfer was adopted as an initial strategy for the quick development of the industrial base in Taiwan.
- (3) ITRI was chosen to undertake the introduction, assimilation, improvement and initial feasibility studies of manufacturing ICs in Taiwan.
- (4) Over a period of four years, around NT\$410 million (this was a significantly large figure for Taiwan in the economic climate of the 1970s) was invested in purchasing the required manufacturing

technology, product designing and testing, purchasing required instruments and equipment, and building a pilot IC plant.

Since at that time advanced countries had reached the level of large scale IC technology and because there were no domestic IC manufacturers, ITRI decided to attempt to gain a leading role in medium scale IC technology. The resulting success was later transferred to the private sector.

The MSI Stage-Introduction of Foreign Technology

The strategies for introducing foreign technology mainly included decisions regarding technology specifications and technology partners, and evaluation of the progress of technology transfer and the results of its introduction. These items will be described below.

(1) *Decisions Concerning Technology Specifications*

Many types of IC technology were developed in the 1970s. The members of the TAC discussed the technologies available and then decided to obtain low power, high-density technology that would provide sub-micron development potential. The complementary metal-oxide semiconductor (CMOS) was thus selected as the technology to be developed. This decision successfully led Taiwan to the sub-micron technology level in 1992.

In the mid-1970s, the IC process technology of the USA had advanced to 3.0-micron, but only 7.0-micron technology was available for technology transfer. What made Taiwan purchase 7.0-micron technology? Different opinions on this subject are summarized as follows:

- (a) on the basis of the principles of technology transfer, it was highly unlikely that advanced countries would be willing to transfer new technologies to other countries; instead, mostly technologies with a lower comparative advantage or obsolescent technologies would be transferred. Therefore, it would either be impossible for Taiwan to purchase the most advanced technology, or Taiwan would have to pay a very high price to purchase the technology;
- (b) in advanced countries, 7.0-micron technology was a mature technology with the advantages of higher consistency, complete technical documents, many skilled technicians, and effectiveness in the operation of equipment. This technology was thus very suitable to be transferred to Taiwan and redeveloped by the inexperienced organizations there;
- (c) because products manufactured with 7.0-micron technology had already been introduced into the market, feedback was available concerning process technologies, product development or design technology, and mar-

keting channels. This meant that Taiwan would easily be able to learn about all aspects of IC technology, from R&D to commercialization of products;

- (d) Process improvements were to be achieved from technical personnel, equipment, and clean room environments. Therefore, although the technology introduced greatly lagged behind that of advanced countries, it was still possible to upgrade it through investment and R&D after introduction. Clauses stressing personnel training were thus essential in the introduction contract so that capabilities for assimilating and improving the technology could be built up.

(2) *Selecting the Technology Partners*

IC technology originated in the USA (see Gutmann, this volume), and American companies not only had experience in technology transfer but also were willing to transfer technology to developing countries. American companies were thus selected as the source of the technology transfer and requests for proposals (RFPs) were sent to more than 20 companies in the USA. The evaluation team visited more than ten IC companies who responded to the RFP, and RCA and another company (referred to here as company X) entered the final round of selection.

The budget required by RCA was twice as high as that for company X, but the technology provided by RCA was far more complete, comprising design, process, manufacturing management and cost accounting, whereas company X proposed to provide only process and design technologies. Moreover, RCA could provide training for 35–40 people for a period of six months to one year; in contrast, company X suggested that training for three to four persons for a period of three months would be enough.

The objective of establishing IC technology in Taiwan could be achieved only through extensive personnel training. The technology content and personnel training provided by company X could not be expected to meet the requirements of the plan. Although the winning-bid principle under the budget system of the Taiwan government was to select the bid with the lowest price, since company X could not offer a package with a technology content similar to that offered by RCA, RCA was finally selected as the technology partner.

(3) *Decisions Concerning Technology Specifications*

RCA would provide 7.0-micron CMOS process technology and the product specifications and design and testing technology for a 3.5 inch digital electronic clock that was to serve as the product vehicle. Assistance in building an IC pilot plant, suggestions for equipment specifications, and training of personnel were also included in the

technology transfer. In 1974, the Electronics Research and Service Organization (ERSO) was established by ITRI to implement the technology transfer. A team of young engineers was recruited and trained by ERSO for a period of time. These personnel were then sent to RCA for one year of technical training at various sites in the USA.

(4) *Successful Introduction*

The schedules for building the IC pilot plant, purchasing equipment, and training personnel were coordinated well by ERSO/ITRI, and after the engineers had completed their training and returned to Taiwan, the pilot plant and equipment were ready for pilot runs. In 1977, the first IC was produced by the pilot plant and the functions of this IC conformed to the evaluation standards, this being a criterion for the success of the technology introduction stipulated in the introduction contract signed with RCA. The following describes the four main factors affecting the success of this endeavor:

- (a) development direction: The development direction was determined and planned by the technology advisory committee composed of experts and scholars from the government, industry, and academic and research institutes. The committee made suggestions and decided on appraisals for the long-term strategy to develop IC technology;
- (b) collaboration in design, manufacturing, perfecting of products and subsequent marketing: ITRI obtained the 7.0-micron technology with the 3.5 inch digital electronic clock needed to verify the technology. The products were then exported to Southeast Asia countries. From the planning of the technology, ITRI was positioned to control all links to the making, design, perfecting of products, and marketing. ITRI also opened channels to gather related information. This helped ITRI in its planning and integrating of technology transfer and the commercialization of the products;
- (c) human resources: Recruitment from overseas and cooperation with local universities in cultivating talented professionals;
- (d) funds: Government subsidizes to support R&D.

The Transfer of Technology to the Private Sector

After the process technology introduced from RCA was verified through the output from the pilot plant of ITRI, the results were transferred from the research institute (i.e. ITRI) to local industry. As no related operation had been set up at that time, there was no receiver for this technology. Therefore, a team of personnel was transferred from ITRI to spin off a new business, the United Microelectronics Corporation (UMC).

In October 1979, UMC became the first company to apply officially to the Science-Based Industrial Park to establish a plant there. In order to assist in the upgrading of domestic industries and the development of technology-intensive industries, the Science-Based Industrial Park was established in Hsinchu by the Taiwan government in July 1979. Preferential loans, tax reductions, administration services and other incentives were granted to companies established in HSIP. UMC, with capital of NT\$500 million, commenced pilot runs in April 1982 and had reached breakeven point by November 1982. UMC's sales exceeded NT\$100 million per month in June 1983, and the company was marketing its products in Taiwan, Hong Kong, Korea and the USA.

There are five aspects to consider in understanding how this result was achieved:

- (1) the process technologies transferred from ITRI to UMC;
- (2) the transferred product technology;
- (3) the project planned by ITRI in order to establish UMC, including the transfer and training of personnel;
- (4) the coordination provided by ITRI for the competitive operation of UMC in the future; and
- (5) the successful future transfer of technologies developed by ITRI to UMC.

The Rapid Expansion Stage-Upgrade to LSI, VLSI

After UMC was spun off, Taiwan had a private enterprise capable of producing IC although compared to America and Japan, the standards were still very low. There was a growing need for higher-level semiconductor technology. A four-year project (1979–1983) was proposed by ITRI to the government. The major goal of this project was to upgrade the technology to large scale IC level, and to build up related development tools, particularly the making of masks and computer aided design (CAD) capability. The developed technology was to be transferred to the private sector, after verification by the pilot plant.

The LSI Stage-Technology Development

From 1979 to 1983, ITRI invested more than NT\$670 million to upgrade IC technology. The production capacity was raised from 7.0-micron to 3.0-micron, and the making of a bipolar metal gate was achieved. As regards IC design technology, a computer simulation program was obtained from abroad and a logic simulation program was also independently developed by ITRI. An automatic mask design system was developed to increase the speed of product design. To better the masking technology, a mask duplicating technology was obtained and improved to perform the masking locally. This enabled the domestic IC makers to control the timing of the production process, and eliminated any dependence on foreign services.

The LSI Stage-Technology Transfer

In IC design, the Syntek Semiconductor Co. Ltd. was established by staff from the Digital Circuit Design Department in ERSO/ITRI in 1982. Many other companies were also established in a similar way, such as Wel Trend Semiconductor Inc. and Silicon Integrated Systems Corp. (SIS).

ITRI planted the first seeds of the domestic IC industry by engaging in the design and fabrication of IC. ITRI also made use of every possible method of technology diffusion to transfer new technologies to industry. These methods included: spinning off new companies, offering seminars, accepting design commissions from manufacturers, technical staff training, newsletters, etc.

The VLSI Stage-Technology Development

After these achievements, there was still a great gap of technical levels between the domestic IC industry and industries in the U.S. and Japan. It was unlikely that domestic manufacturers could catch up with foreign advanced countries by their own efforts in research and development. Because of this, ITRI proposed to the government a five-year plan (1983–1988) for technology development. The major goal was to raise the IC technology to very large scale IC design and manufacturing. From 1983 to 1988 a total of NT\$245 million was invested in upgrading process technology from the 3.0-micron to the 1.0-micron level. In addition a VLSI laboratory was built. A common design center was promoted to diffuse ASIC (application-specific integrated circuit) design technology. Furthermore, optical masking capability was upgraded to incorporate electron-beam masking technology.

The VLSI Stage-Technology Transfer

(1) IC Design Technology

ITRI adopted direct training to expedite the transfer of IC technology, and to shorten the R&D time for enterprises. A joint design small scale center was set up with mature developed computer-aided design programs and circuit design methods. Engineers from various enterprises were trained to be able to utilize the computer workstations to design and develop customized IC products.

After careful evaluation, ITRI recognized the high-risk involved for domestic enterprises in applying special purpose IC products to the market. Due to the lack of IC design talent, domestic enterprises were limited to technology development, and were lukewarm in accepting technology transfers. To generate an environment for the enterprises to acquire necessary talents, ITRI turned to domestic universities to foster IC design engineers. The following describes the measures taken by ITRI to transfer technologies to

the academic and industrial sectors (Chang et al., 1993).

(a) Transfers to Academia

Because of the general scarcity of specialists in the IC design field in Taiwan at that time and the relative immaturity of ITRI's IC design technology, there was a lack of interest in such technology in the electronics industry. Therefore, ITRI looked to educational institutions for help. By joint training with academic institutions, it was expected that more specialists in this field would become available to industry. In addition, ITRI continued to perform R&D activities in order to develop more sophisticated IC design technology.

Computer-aided, very large scale integration design techniques had not been introduced to academic institutions in Taiwan until July 1983, when specialists in this field were still extremely scarce. The National Science Council and Ministry of Education, together with ITRI, initiated the Multi Project Chip (MPC) project. The main objective of the project was to improve students' and professors' own practical ability in IC design. The students and professors taking part in the MPC were encouraged to participate in computer-aided design training at ITRI. A basic logic cell library and computer-aided equipment were provided to different universities, so that the universities could design their own ICs. Also, a chip foundry service was provided, so that the universities could manufacture their IC designs.

Chiao Tung University, National Taiwan University, Tsing Hua University, Cheng Kung University, National Taiwan Institute of Technology, Central University, Tatung Institute of Technology, Chung Cheng University and Tamkang University were the nine major universities participating in the MPC project. There were 12 departments involved and approximately 150–200 specialists were trained each year.

(b) Technology Transfer to the Private Sector

To achieve effective transferral of technology to industry, ITRI adopted a dissemination approach to allow firms to design their own ICs according to their needs. A joint design center was established which offered training courses and CAD tools. Thus, IC design technology could be transferred directly to industries.

The joint design center was founded in Hsinchu in March 1985. By promoting ASIC design concepts, publishing IC design handbooks, organizing conferences and training classes, and issuing newsletters about ASIC,

the center aimed to consolidate the design techniques of system engineers and familiarize them with CAD applications, so that the idea of specialists designing their own ICs could be realized. The center provided basic design methodology and CAD tools. This proved to be an effective method, because corporations were able to find out exactly what they required. At the same time, this approach reduced the time and effort which the research institute formerly might have spent learning about the client's requirements. The advantages of such a method of transferring technology were that a high degree of security in the design of an IC could be maintained and the time required for both parties to communicate was shortened considerably.

The Taiwan domestic firms' IC design technology was developed in 1976. However, the number of design companies increased rapidly to 30 only after 1987, when the Taiwan Semiconductor Manufacturing Company (TSMC) was founded. TSMC's main business was VLSI foundry and ASIC design services. TSMC allowed IC design and manufacturing to be separated. Consequently, design specialists no longer had to worry about the substantial investment needed for manufacturing. Some design specialists now come from the Joint Design Center at ITRI and some from overseas. The number of professional design companies has increased from 30 in 1987 to 55 in 1990; and marketing revenues have increased from US\$32 million to US\$236 million.

(2) *VLSI Fabrication Technology*

TSMC is a global enterprise specializing in IC foundries. This was a joint venture by the government, research institutes, domestic and foreign enterprises. Major technical and supporting staffs composed of more than 150 persons, transferred from ITRI. ITRI further assisted by leasing its VLSI plant to TSMC. As a result, TSMC achieved world class VLSI fabrication technology, and gained independent key technology for manufacturing IC products.

(3) *Masking Technology*

After the founding of TSMC, many domestic enterprises invested in the IC design, and many ASIC design companies emerged. As a result, the demand for masking services grew tremendously. The Industrial Technology Investment Corporation (established by ITRI in order to transfer ITRI's technology to local industry) invited relevant entrepreneurs to jointly found the Taiwan Mask Corporation (TMC), and transferred staff, technology, and business from ITRI to the company. TMC was established in 1988 with most masking

techniques transferred from ITRI, and signed a ten-year contract with ITRI for technology transfer and joint development.

The Growth Stage- Joining ULSI

By 1990, Taiwan had the beginnings of an industrial infrastructure for the IC industry including design, masking, fabrication, and assembly facilities. In order to upgrade the technical ability of the Taiwan IC industry, the government contracted ITRI to perform a five-year (1990–1995) project aimed at the development of sub-micron fabrication technology, with DRAM/SRAM products to be used as the primary vehicles for testing the feasibility of the fabrication technology. The success of the sub-micron project makes Taiwan only the fifth country in the world (following the U.S., Japan, Germany, and Korea) able to independently develop 16 megabit (Mb) DRAMs. This also attracted a record (1994–1997) three-year investment of over NT\$200 billion in 8-inch memory-product-wafer IC manufacturing plants.

The ULSI Stage-Technology Development

After ITRI had completed the transfer of about 150 technical personnel to the newly established TSMC the following question arose: how would ITRI be able to proceed efficiently with the development of sub-micron technology? ITRI's upper management then decided that since most of the technical personnel had been shifted to private industry, and the purpose of ITRI's technology development was to transfer it to industry, there was no reason companies should not participate in ITRI development projects in order to avoid the manpower shortage problems. At the same time, this would also facilitate and speed-up the technology transfer process.

The funds appropriated for the development of sub-micron technology, and its effect on domestic IC technology, were unprecedented. The following will describe the administration of the project.

(1) *Direction Guidance*

During the execution of the project, a 'Sub-micron Advisory Committee' was formed by MOEA and was composed of representatives from the industry itself, government, academic and research institutions. A meeting was held two to four times a year to provide guidance and consultation for the sub-micron project on targets, contents, progress, technologies, achievements, and ongoing plans.

(2) *Execution of the Project by ITRI*

The sub-micron project undertaken by ERSO/ITRI. ITRI was able to attain its goal by the expected date by recruiting capable persons as project leaders, as well as completely allocating all responsibility and authority of the ERSO director to the project leader. The following describes the main guidelines for the project.

(a) Setting up Specific and Achievable Goals

After careful analysis, the project leader aimed to raise the technique level from 1.0-micron to 0.7-micron within two years. This specific goal gave the project members a clear target to work for and in the meantime, it enabled the project leader to manage the progress of the project.

(b) Modifying Specifications According to the Needs of the Project

During the sub-micron project's planning stage the wafer size was set at 6 inches. In addition all necessary equipment was devoted to producing 6-inch wafers. Although IBM at the time, possessed 8-inch wafer production technology, the equipment used in Taiwan was modified from the original 6-inch wafer production equipment. Thus, Taiwan decided 6-inch wafers to be the target for development. By the beginning of the second year of the project, with the Japanese IC equipment manufacturers ready to accept 8-inch wafer production equipment purchase orders, the project leader applied to the committee for a change of target from 6-inch to 8-inch wafers. After reviewing the following points, the government decided to upgrade the project to making 8-inch wafers with a reapportionment of NT\$1.2 billion more and a six-month extension of the project.

- (i) Rapid progression in technology: IC equipment manufacturers had already begun making 8-inch wafers. It was estimated that by 1995, there would be limited 6-inch wafer equipment available; thus reducing the willingness of the private sector to invest.
- (ii) Lack of competitiveness: For instance, the cost of producing DRAM using 6-inch wafers would be 180% that of 8-inch wafers.
- (iii) The project leader promised to speed up the process and limit the delay to six months.
- (iv) To increase the budget at this time would be less expensive than to change to 8-inch wafers at the end of the project.

Since the primary concern was to develop fully-competitive sub-micron technology by 1995, technologies developed by ITRI would still require technology transfer and investment for production-site build-ups. Therefore, the industry might be reluctant to accept a transfer of less up-to-date technology; besides, converting a completed sub-micron lab to 8-inch wafer production would require a far greater investment than converting it at the initial stages. With these considerations in mind, the committee agreed to shift the project goal to

8-inch wafers, add an additional NT\$1.2 billion to the current budget (making the total budget NT\$7 billion in all), and extend the schedule by six months. These changes were later approved by MOEA.

(c) A Supportive Environment for R&D

ITRI gave the project director total authority in the technical area, and provided maximum assistance in administration. The project leader was able to turn all the participants' attention to the project goals, set precise milestones, and give incentives to participants to enhance the team spirit by continuous revision and timely modification of the project where necessary.

(3) *Monitoring by the Private Sector*

The firms' investments and participation in the sub-micron R&D process not only assisted the government in monitoring the implementation of the project, but also enabled the companies to obtain the newest technology developed by ITRI in the shortest possible time. Therefore, the project advanced without undue difficulty and was completed on time.

The ULSI Stage-Technology Transfer

ITRI formed a 'Sub-micron Working Consortium' to transfer the technology and products to member firms so that the domestic IC industry could catch up with the advanced countries. The 'Sub-micron Technology Application Association' was then formed to assist IC design firms in applying advanced fabrication technology and design of prototypes for the 8-inch wafer. This greatly reduced the time needed to develop highly added value novelties.

At each stage of the implementation of the sub-micron project, ITRI worked to transfer all technical data to the firms in the Sub-micron Working Consortium in the shortest amount of time possible. Therefore, even the most advanced 0.5-micron fabrication technology was immediately transferred for use by firms, enabling UMC and TSMC, for example, to make immediate use of ITRI technology transfers to develop 0.6-micron fabrication technology. ITRI also provided design rules for DRAM and SRAM logic to design companies in the Sub-micron Working Consortium for advanced product designs such as 16Mb DRAMs and 4Mb SRAMs.

Meanwhile, MOEA made use of the developed sub-micron fabrication technology and related purchase of equipment and personnel, and targeted the much-needed key component—the DRAM—as the choice for assisting local firms to raise their competitive levels through production in the domestic private sector. Thus MOEA used the sub-micron lab equipment, technology, and human resources in collaboration with private companies to form professional production companies devoted to DRAMs. This was carried out in the form of a practical plan to apply sub-micron fabrication

Table 1. The development strategy of industry.

Development Stages	Initiation	Burgeoning	Growth
Technology Selection	Technology level is far behind those of leading countries	Technology level closely follows those of most countries	Technology level is synchronous with those leading countries
R&D Activities	The research institute transfers the technology from abroad, then assimilates and progresses by in-house R&D activities	The industry participates in the research institute's R&D projects	The industry collaborates with the research institute in implementing the R&D projects
Technology Transfer	The main method used by the research institute to transfer the R&D results is to spin-off new companies after the R&D project is finished	Technology diffusion is used during the R&D implementation stage. And the new spin-off company is used after the R&D project is finished	The research institute will mainly use technology diffusion to industry during the R&D implementation stage and after the R&D project is finished
Industrial Development Result	A rough and ready industry is established	Upgrades the industrial technology ability and expands marketing areas	Increases the industry's R&D capabilities to improve competitiveness in international markets

technology, commencing with the selection of suitable private corporations to participate in the plan.

The spin-off of a new company from the sub-micron project was done in an open and fair manner, by publicly seeking investment partners. The open bidding attracted 13 local companies, headed by TSMC in September 1994. These 13 companies included suppliers, at various levels of the information and electronics industries, as well as funding institutions. The new company was named Vanguard International Semiconductor Corp. (VISC) and its primary goal was the production of DRAMs. The initial capitalization was NT\$18 billion. MOEA, possessing the sub-micron lab, equipment, and technology, took 32% of the company stock right away, making this the fastest return on investment ever among MOEA R&D projects. ITRI completed the transfer by the end of 1994, and transferred a total of 330 people to VISC.

Summary of the Taiwan IC Industry Development Strategy

To summarize, the progress of the Taiwan the semiconductor industry from the 1970s to the end of 1990s can be divided into three stages: the initiation stage, the burgeoning stage, and the growth stage. During the evolution of the Taiwan IC industry, the government made conscious choices about which industries would be targeted for technology transfer from abroad, contracted non-profit research institutes to develop interim technologies until the technology was obtained,

then transferred the technology to industry to facilitate setting up corporations for commercial purposes. Furthermore, the process assisted the firms in establishing R&D capabilities, and increased the industry's international competitiveness. In each of these three stages, e.g. the initiation stage, consisting of obtaining technology and facilitating setting up domestic companies, the burgeoning stage, consisting of the formation of manufacturers' R&D facilities, and the growth stage consisting of further raising the industry's international competitive levels, the strategies employed were rather different from one another. The following is a summary of the differences between the three stages of technology selection, R&D activities, technology transfer, and industry development results. These are also listed in Table 1.

9. Conclusions

In order to promote the development of the Taiwan high-tech industry, based on the development environment in the 1970s and considering all factors needed to develop high-tech industries, various measures were implemented, to advance the germination and development of high technology. After development lasting thirty years, these seeds have grown up to become large trees, and today's high-tech forest in Taiwan. These seeds have brought new vitality to this forest but their function has gradually been superseded.

The Taiwan innovation system is gathering strength from industry, government, academic and research

institutes. Technology-based enterprises have become the core of the whole industry. Technology-based enterprises from the industry, government, academic and research institutes have come together to form Taiwan's own industrial innovation system. This system will continue to instill competitiveness into the Taiwan technology-based enterprises, and serve as a guideline for government to consider which policies to follow. With the coming era of the knowledge-based economy, the innovation system shall play an even greater role when Taiwan is forging ahead as a knowledge-based nation.

To develop high added value knowledge-based industry, the emphasis should be on services as well as manufacturing. In addition, the academic and research organizations must become more efficient in transferring their technological innovations to the private sector. As regards the hardware structure, the Taiwan innovation system will continue the collaboration between industry, government, academic and research organizations and a knowledge management system will be introduced to increase operational efficiency. As for the software aspect, the effort will be on the synchronous diffusion of talented personnel among the private sector, academic and research circles while research work progresses.

The Taiwan attempt to develop an innovation system has resulted in a successful technology industry. With the coming of the knowledge economy era, considering the current structure of the Taiwan industry, relying on innovation to maintain economic growth is a feasible strategy. Future innovation systems based on the existing system will be developed, but will be more open, integrated, and advanced. The new measures will include government policies to utilize global resources; incentives for collaboration or alliances among industrial, academic and research sectors; and the pressure from the government for more successful innovative results. The goal now is to advance the Taiwan innovation system to a more comprehensive and efficient stage.

Innovation in the Upstream Oil and Gas Sector: A Strategic Sector of Canada's Economy

A. Jai Persaud¹, Uma Kumar² and Vinod Kumar²

¹ *Natural Resources Canada (NRCan)*

² *Sprott School of Business, Carleton University, Canada*

Abstract: The upstream oil and gas sector is a strategic part of Canada's economy and an important driving force of innovation. It relies on partnerships to develop new ideas and bring them to market, adopt new knowledge and technologies to improve productivity, gain competitive advantage, and deal with environmental problems. Significant interests exist in understanding innovation in the sector, given Canada's innovation agenda, recent Speeches From the Throne, and climate change concerns. This chapter will address the meaning of innovation, the importance of the sector, key aspects of innovation in the sector and their relationships to Canada's innovation strategy.

Keywords: Oil; Gas; Energy; Technology; Innovation Policy; Sustainable Development; Climate Change.

Introduction

Studying innovation in the sector is crucial to understanding Canada's innovation system. Innovation underlies Canada's quality of life and provides environmental, economic, and social benefits. Innovation has always been considered as a driving force in economic growth and social development but in today's knowledge-based economy, the importance of innovation has increased (IC, 2002). The Government of Canada is interested in making Canada a highly innovative economy as reflected in the launch of *Canada's Innovation Strategy* in February 2002 and the commitments made in the Speech From the Throne (SFT) in 2001 and in 2002.

The oil and gas sector is a major part of Canada's energy and resources industries and a strategic component of Canada's economy and innovation system. With \$51 billion in new capital expenditures, the oil sands is expected to be Canada's largest natural resource development opportunity over the next decade. Significant interest exists in innovation from the standpoint of reducing costs, arresting the depletion of oil and gas reserves, successfully adding to reserves, exploiting non-conventional more expensive and less

accessible sources and supplies of oil, and reducing the environmental impacts. The fields of energy and environment are inherently difficult to separate, especially because there seems to be a strong relationship between environmental awareness and energy production and use.

One of the most serious contemporary environmental problems is climate change (global warming). It is considered as one of the most important aspects of sustainable development, which calls for the integration of economic and environmental objectives. The signing, in 1997, of the Kyoto Protocol,¹ to limit greenhouse gas (GHG) emissions thereby reducing the risks of global climate change, has brought to the forefront the importance of the environment and sustainable development. The Protocol is considered

¹ In 1997, in Kyoto, Japan, 159 countries negotiated a treaty setting out legally binding reduction targets for six greenhouse gases (carbon dioxide (CO₂), methane (CH₄), nitrous oxide (N₂O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulphur hexafluoride (SF₆)) averaging 5% below 1990 levels for industrialized countries. The timetable agreed to is 2008–2012.

one of the most important international agreements of the 21st century (Grubb et al., 1999). The Kyoto Protocol is likely to have significant implications for business, industry, governments, regions, countries and all other aspects of our lives. The Government of Canada just released its *Climate Change Plan for Canada*, which underscores the importance of innovation in reducing GHGs and achieving other economic objectives, noting:

Through innovation, we will be able to maintain our strong economic growth, create additional export opportunities and reduce greenhouse gas emissions.²

For Canada, the oil and gas sector will figure prominently.

This chapter will discuss the role of innovation in the upstream oil and natural gas sector in Canada and against key aspects of Canada's innovation strategy. It will also draw on results of the recent innovation consultation exercises and the National Roundtable on Innovation and Skills in the Natural Resource Sectors and Allied Industries. The chapter is organized as follows: 'Technology and Innovation' discusses the meaning of technology and innovation; 'Canada's Innovation Strategy' highlights key aspects of Canada's innovation strategy; 'The Natural Resources Sector in Canada' discusses the strategic importance of the resource sector and innovation system; 'Overview of Upstream Sector' provides an overview of the upstream sector; 'Key Oil and Gas Innovation and Applications' addresses innovations in the sector and their impacts on several key concepts of Canada's innovation strategy. The final section provides a brief conclusion.

Technology and Innovation

Technology can be considered as an ensemble of theoretical and practical knowledge, know-how, skills and artifacts³ that are used by the firm to develop, produce and deliver its products and services (Burgelman et al., 1996; Gerwin & Kolodny, 1992). In a business firm, operating activities such as purchasing, manufacturing and distribution; support activities such as R&D; maintenance activities such as personnel; and control activities such as accounting, all have their own technologies (Gerwin & Kolodny, 1992). Technology is responsible for many of the important changes in our society and for determining corporate success, profitability and growth (Chakravarti et al., 1998). Emerging

technologies bring not only new opportunities to grasp, but also threaten to replace old ones (Burgelman et al., 1996).

The critical importance of technology is lodged in the dynamic aspect of the concept, i.e. technological change. Technological changes include small improvements in machines and the organization of labor, arising from slow processes of learning by doing, learning by using, and from major or radical changes. Incremental changes (or minor innovations) are innumerable and occur more or less continuously in any industry (Rosenberg, 1994). Major or radical changes are usually termed discontinuous events, which spawn other changes (Steele, 1989). Some major technological advances which will change the boundaries or rules of competition (Dror, 1988; Hart & Milstein, 1999; Schumpeter, 1934). Among process inventions that have greatly increased productivity was the Hall process for producing aluminum, the Bessemer process for producing steel, and automatic looms that replaced earlier hand looms (Samuelson & Nordhaus, 1989). As a result of technological progress, capital, output and real wages per worker grow over time. The importance of technology is widely acknowledged is considered critically important to the success and survival of individual companies and economic well-being and growth and one of the principal drivers of competition in industries (Burgelman et al., 1996; Porter, 1985).

The word innovation can have different meanings in different context and the one chosen will depend on the particular analysis of the measurement. The *Oslo Manual*⁴ defines innovation with respect to technological product and process innovation. The technological product and process innovating firm is one that has implemented technologically new or significantly improved products and/or processes during the period under review.⁵ The innovation system involves a number of key elements concerned with the generation, dissemination and application of new knowledge: research and development to provide new ideas; education and information services to develop the required personnel; and design engineering and marketing services to incorporate the new ideas into production and distribution systems (SC, 2001).

⁴ The *Oslo Manual* considered as a textbook on innovation and national systems of innovation, and a compendium of socio-economic questions on the nature of innovation in market oriented economies.

⁵ Holbrook & Hughes (2001) argues that the Oslo Manual uses the first two of five types of innovation presented in the classic work of Joseph Schumpeter. The five types of innovation defined by Joseph Schumpeter (1934) are: introduction of a new product or qualitative change in an existing product; process innovation new to an industry; the opening of a new market; development of new sources of supply for raw materials or other inputs; and changes in industrial organization.

² Posted on Government of Canada's Website:

http://www.climatechange.gc.ca/plan_for_Canada/index.html

³ By 1987, when Random House released its completed updated unabridged dictionary, the word technology had grown to include 'interaction with life society and the environment'.

What does innovation include?

The term 'innovation' encompasses much more than R&D or technological change. Innovation makes knowledge useful and turns it into wealth and prosperity. However, innovation does not come out of the blue. It requires investment in a variety of activities, such as bright ideas, learning systems, training, R&D, technology commercialization, corporate culture and entrepreneurial spirit.

Source: CBOC, *Investing in Innovation: 3rd Annual Innovation Report*, November 2001a.

According to IC (2002), through innovation, knowledge is applied to the development of new product and services or to new ways of designing, producing or marketing an existing product or service for private and public markets. The term 'innovation' refers to the world first, new to Canada or simply new to the organization that applies them. Innovation is seen as the process through which new economic and social benefits are extracted from knowledge. Innovation is about the means to achieve a higher standard of living, economic prosperity, international competitiveness, environmental improvement and social well-being that lower production costs, utilize less energy and minimize environmental impacts. It is also the pathway leading to sustainable development in Canada.

Research and development (R&D) is at the heart of the innovation process. R&D is defined as creative work undertaken on a systematic basis in order to increase the stock of knowledge.⁶ R&D, however, is not in itself considered as innovation. Companies that perform R&D are far more likely to report innovations. The popular approach to assess the adequacy of R&D is to quantify the amount of money spent on R&D as a percentage of sales. Roberts (2001) found a strong correlation between R&D intensity and sales from new products as well as between R&D intensity and the overall newness of a firm's technology emphasizing R&D as a vital area for company success. Also, most successful economies invest heavily in R&D. Current real incomes in Canada are 30% below those in the United States and 90% of this gap is considered due to productivity differences. The CBOC (2001a) argues that given that investment in technology boosts productivity, it is plausible to argue that the productivity gap can partially be explained by under investment in R&D in Canada's private sector. Firms can benefit by investing in R&D in two ways (Globerman et al.,

1999). First they can reduce their production costs or improve their product quality relative to other firms. Second, they can introduce new products into the market place. Although these are the economic arguments, there are also other factors involved in the decision of firms to innovate, e.g. corporate culture (see Carayannis & Gonzalez, this handbook).

Canada's Innovation Strategy

Government action is of vital importance to the technological progress and economic development of a country.⁷ On February 12, 2002, the Government of Canada launched an innovation strategy for Canada by releasing two papers—*Achieving Excellence: Investing in People, Knowledge and Opportunity* and *Knowledge Matters: Skills and Learning for Canadians*. The two papers build on the 2001 Speech from the Throne (SFT), which committed to improve our environment, create an innovative economy and share opportunities with all Canadians from coast to coast. The SFT states that the Government of Canada will:

promote innovation, growth and development in all parts of the economy, including the agriculture and resource sectors.

It commits to spurring innovation through new federal investments in strategically targeted research in natural resource management, coordinated with partners. The 2002 SFT reaffirms the government commitment to innovation.

From the launch to October 2002, the Government of Canada engaged key stakeholders from a wide range of large and small businesses; academia; governments; industry, business, and labour organizations; voluntary sector organizations and other stakeholders and partners in a series of regional, national, and sectoral meetings expert round tables and best practice events to solicit feedback and commitment to *Canada's Innovation Strategy*. *Achieving Excellence* lays four major areas (*Challenges*), which presents ideas and explores opportunities in to improve Canada's innovation system:

- new knowledge and bringing it to market;
- skills needed;
- business and regulatory environment; and
- elements at the community level.

⁷ Industrialized countries have recognized the importance of innovation. Some countries like the U.K. and Australia have launched formal strategies while others such as the U.S. and Sweden without formal strategies have vigorously supported innovation. The U.S., the most innovative country in the world, by almost all measures, has a plethora of methods such as increasing R&D, funding basic research in universities, funding government laboratories and conducting large amounts of defence research, investment in schools, the development of partnerships.

⁶ R&D is defined by the Frascati Manual, OECD as creative work undertaken on a systematic basis in order to increase the stock of knowledge, including the knowledge of man, culture and society, and the use of this stock of knowledge to devise new applications.

Table 1 also provides targets in these four main areas. Over 10,000 Canadians participated in the national engagement process on innovation and learning.⁸ These consultations led up to the National Summit on Innovation on November 18–19, 2002, which called for short term and longer commitments to improve innovation in Canada.

According to *Achieving Excellence*, the private sector needs to strengthen its ability to develop innovations for world markets and adopt leading-edge innovations from around the world. Relatively low levels of investment in R&D, too few strategic technology alliances and limited pools of capital contribute to Canada's relatively poorer innovation performance. The two major goals of the innovation strategy are to vastly increase public and private investments in knowledge to improve Canada's R&D, and to ensure that a growing number of firms benefit from commercial application of knowledge. The Government's targets by 2010 are to: at least double the Government of Canada's current investment in R&D, place Canada among the top five countries in the world in terms of R&D performance, make Canada a world leader in the share of private sector sales attributable to new innovations, and raise venture capital investments per capita to prevailing U.S. levels.

As part of the consultations, sectors within the economy including the oil and gas sector and associations provided input to the Government innovation strategy. The natural resources sector and allied industries provided input in several broad areas during the engagement process and the Round Table on

Innovation, held on October 3–4, 2002, in Vancouver. The resource sector and allied industries which included the upstream oil and gas sector commented on six broad cross-cutting areas: Investment Climate, Access to Resources, Sustainable Development, Market, R&D, and Skills (NRCan, 2002). The oil and gas and resources sector views will be highlighted in the context of the four broad challenges, including, the key roles the Government of Canada plays in promoting and fostering innovation in the oil and gas sector through several ways including partnerships with industry, providing a conducive environment to spur innovation.

The Natural Resources Sector in Canada

Canada's natural resources sector include the energy, minerals and metals and forest sectors, and are closely linked to a broad group of allied industries, including supplier and service industries. Canada's natural resources industries have long been a foundation of its economic strength. Figure 1 shows the economic contribution of the sector.

Canada has a natural advantage in its rich endowment of natural resources and state of the art—knowledge and technology base. Canada has built a strong economy and a high quality of life for all Canadians on its natural resource endowment and innovations, which improve productivity and competitiveness. The sector is part of the 'knowledge-based economy' by consuming and developing leading edge technologies such as sophisticated electronics, robotics, computers lasers and sensors. In 2001, natural resources contributed 13% of the GDP (\$129 billion), and almost \$150 billion in exports, accounting for \$73 billion to Canada's positive trade balance. It employs some 1.5 million Canadians in direct and indirect jobs

⁸ <http://www.innovationstrategy.gc.ca/>

Table 1. Building a more innovative Canada.

Knowledge Performance Challenge (new knowledge and bringing it to market)	Address key challenges for the university research environment
	Renew the Government of Canada science and technology capacity to respond to emerging public policy, stewardship and economic challenges
	Encourage innovation and the commercialization of knowledge in the private sector
Skills Challenge (skills needed)	Produce new graduates
	Modernize the Canadian immigration system
Innovation Environment Challenge (business and regulatory environment)	Ensure effective decision making for new and existing policies and regulatory priorities
	Ensure that Canada's business taxation regime is internationally competitive
	Brand Canada as a location of choice
Community Based Innovation Challenges (elements at the community level)	Support the development of globally competitive structures
	Strengthen the innovation performance of communities

Notes: 1. The figure was created with data from Natural Resources Canada, <http://www.nrcan.gc.ca/statistics/factsheet.htm>.
 2. Mining and mineral processing industries (or minerals industries) include mineral extraction and concentrating, smelting and refining, non-metals and metals-based semi-fabricating industries, and metals fabricating industries. Minerals include uranium mining; energy includes coal mining..

(well paid and highly skilled) and is the lifeblood of over 650 communities from coast to coast⁹ Canada's high quality of life and a significant portion of its economy is linked to natural resources (NRCan, 2002).

Natural Resource System of Innovation

The sector's system of innovation is unique and more complex than other sectors in the economy. The system is multidimensional with linkages along the supply and value chain (CBOC, 2001c; NRCan, 2002a). The firms often buy technologies rather than developing them with in-house R&D; innovation is usually undertaken through collaboration; the sector focuses more on improving processes than developing value added products.

Canada's natural resources sector operates in a competitive, national and international environment and must compete for investment dollars with other sectors (e.g. information and communication technologies) within Canada and internationally. In Canada and around the world, business confidence is ensured by a stable and competitive business environment that encourages investment in the natural resources sector and promotes sustainable development and wise use of resources. Investment in science is not just for technology development but also for new knowledge acquisition. New knowledge leads to informed decisions on regulations, codes and standards. More importantly, knowledge contributes to increased public and business confidence, which fuels the innovation engine.

The natural resources industry is . . . an important contributor to the economic wealth of Canada. The industry is very capital intensive, highly competitive and global in nature. The resource industry is also highly innovative. It is a world leader in 'spawning' high-technology services industries.

Conference Board of Canada: *Investing in Innovation in the Resource Sector*, February 2001b, p. 4.

Energy Sector

The energy sector is an important part of the resources sector. Canada has a secure, reliable and diverse source of energy including fossil fuels (oil and gas, and coal), hydro electricity, and nuclear power. Canada is also a leader in energy efficiency technologies and R&D of renewable and alternate energy sources, including hydraulic, solar, wind, biomass and other innovative technologies such as the fuel cell.

The primary source of energy has changed over time. In the 19th century, wood was the primary source of energy. At the turn of the 20th century, coal replaced wood as the primary source for about 50 years. With the proliferation of the automobile and the growing demand for gasoline, petroleum and its associated products have become the primary source of energy. Today, energy is produced as a mix of all energy sources. That mix changed in the past, and is changing now and will most likely change in the future. Sustainable energy development challenges us to examine the present mix of how energy development would change and how new environmental

⁹ http://www.nrcan.gc.ca/inter/innrndtbl_e.html

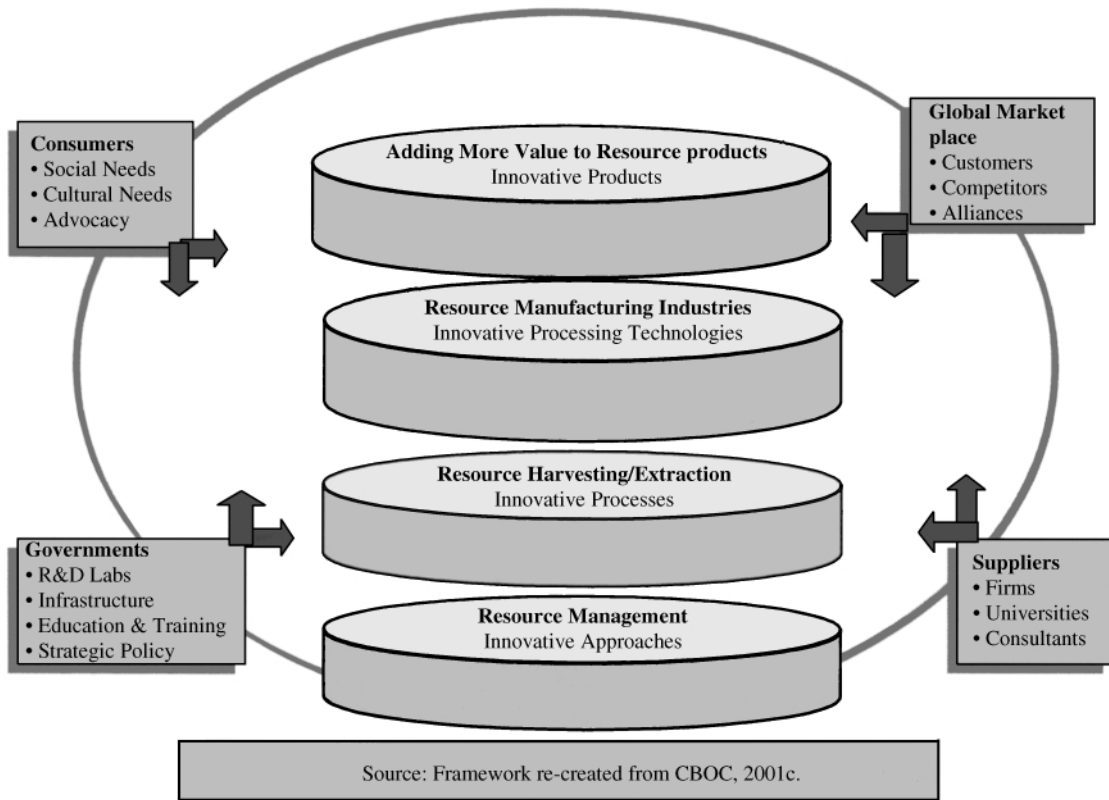

Figure 2. Natural resource system of innovation.

technologies will impact both production and energy use (NRCan, 2000).

The availability of different sources of energy at reasonable cost has been a key factor in the attainment of a high standard of living in Canada. This advantage led to the development of industries having particularly strong demands for energy. This abundance of cheap energy resources has helped Canada develop a strong industrial base and has given Canada a competitive edge over other countries. It has also helped Canada to deal with the economic disadvantages of small domestic markets, long distances, rugged geography and relatively harsh climate. In 2001, energy provided 6.5% of Canada's GDP (\$64.5 billion), direct employment of 222 jobs, \$37 new capital investments and \$57 billion in exports (NRCan, 2002).

There are three broad underlying energy policy goals in Canada (NRCan, 2000). First, is energy security—ensuring secure and reliable access for present and future generations while increasing flexibility and diversity of the Canadian energy supply system. The second policy objective is to ensure economic growth in terms of investment, regional development, and employment. The third and most recent policy objective is to reduce and manage atmospheric emissions

effluents and wastes resulting from energy development and help Canada to meet its climate change commitments and its environmental, health and safety goals. Energy policy in Canada must reflect a balance of these issues and Canada's responsibility acting within the community of nations to resolve global issues. The issue of climate change will be discussed later as it will be a major variable that firms will have to address in maintaining competitiveness. The IEA notes that the major factors that bring about energy technology innovations include:

energy security requirements, environmental concerns, economic competitiveness, the availability of finance and prevailing social values (IEA, 1997, p. 17).

Overview of Upstream Sector

The petroleum industry includes the oil and gas sectors and is usually discussed in terms of upstream and downstream operations. According to the Petroleum Communications Foundation (2001), the upstream petroleum industry finds, produces and processes oil and natural gas. Exploration and development activities refer to all the upstream activities that are required to

find new oil and natural gas resources and develop them to the point where they are ready to be processed. Exploration involves the search for petroleum including seismic surveys and drilling. Production describes the steps of getting petroleum out of the ground. The upstream sector includes more than 1,000 exploration and production companies as well as hundreds of associated businesses such as seismic and drilling contractors, service rig operators, engineering firms and various scientific, technical, service and supply companies (Canadian Petroleum Foundation, 1999).

Upstream expenditures include geological and geophysical activities (e.g. seismic, geological and geophysical), land costs (operating lease, and bonus bids costs), costs of drilling oil and gas wells and oil sands expenditures. Development wells are drilled to produce the oil and natural gas reserves and properly assess the level of reserves.¹⁰ In the case of oil sands in Canada, the reserves are known to exist and no exploration activity is required to find the resources. It should be noted that both Canada and the U.S. are the most extensively drilled areas in the world.

Economic and Strategic Importance of the Oil and Gas Sector

The oil and gas sector is an important contributor to the Canadian economy and energy security. In 2001, oil and gas production accounted for \$24.1 billion, 32% of the energy sector GDP of \$64.5, and \$36 billion trade surplus. Alberta accounted for 76% of Canada's total oil and gas production in 2001 (valued at \$49 billion; different from GDP estimates which are value added, reflecting intermediate inputs). The industry provided a secure oil and gas supply for North America. Canada produces oil and gas well in excess of its own requirements and, as a result, is a significant net oil and gas exporter. Canada is the largest oil and natural gas exporter to the U.S. In 2001, Canada exported about 1.4 million barrels of oil per day with 99% going to the U.S. Canada also exported 3.8 Tcf (valued at \$25.6 billion) of natural gas to the U.S., meeting 94% of the U.S. import requirements, and 15% of total U.S. demand. In 2001, oil and natural gas accounted for 73% of Canada's energy supply. The upstream petroleum industry has operations in seven provinces and two territories. Most Canadian oil and gas production is concentrated in the western provinces of Alberta, Saskatchewan and British Columbia.

Oil and Gas Reserves

Canada has significant oil and gas resources. However, only a small percentage is considered low-cost as established reserves (economic at today's prices).

¹⁰ The wells drilled in new virgin territories are called wildcat wells. Those in already explored areas are called step out wells.

Established conventional reserves are in the range of 3.4 billion barrels. Canada has vast high-cost non-conventional resources and oil sands (very heavy oil) and offshore supplies. Oil sands reserve is upgraded into synthetic oil at the Suncor Energy and Syncrude Canada plants, or produced and exported in the form of bitumen. Canada's oil sands reserve is the third largest oil resource basin in the world, after the Persian Gulf and Venezuela. On a world scale, Canada like the U.S., is a high-cost oil producer. Similarly, Canada has about 61 Tcf of established reserves (lower cost supplies) as opposed to higher costs gas resources, which total 630 Tcf.

Oil and Natural Gas Key reserves and production parameters

Crude Oil

- Established conventional reserves—3.4 billion barrels, oil sands 6.8 billion barrels, 1.4 billion frontier
- Oil sands ultimate recoverable potential represent over 300 billion barrels greater than Saudi Arabia's reserves
- Canada current oil production of 800 million barrels annually
- 62% exported to the US, 17% of U.S. Demand
- Canada first as crude oil exporter to the U.S. ahead of Saudi Arabia

Natural Gas

- 61 Tcf established reserves
- undiscovered potential of 301 Tcf in Western Canada
- Third largest producer in the World
- Current production of 6.1 Tcf
- 63% exported representing 15% of U.S. demand

Sources: Natural Resources Canada, U.S. EIA 2002.

Canada produced 2,200 thousand barrels per day of crude oil and 6.1 trillion cubic feet of natural gas in 2001. Canada's domestic oil supply includes various sources: conventional (light and heavy), oil sands, and offshore production. Canada's oil supply is projected to increase significantly due to production from oil sands. Most of Canada's natural gas production comes from conventional sources of the Western Sedimentary Basin (WSCB). Production has increased by 50% over the past 10 years due mainly to higher exports to the U.S. Supplies from the east coast offshore are expected to play an increasing role in the future.

The Innovation Environment Challenge

Developing Canada's resources, with due consideration for the business environment, requires an approach to decision-making that is based on sound science, Canadian values, public involvement, corporate social responsibility, and new governance models (NRCan, 2000). Finding balanced approaches that achieve economic prosperity and environmental performance will also help to maintain access to global markets. *Achieving Excellence's* target is for Canada to be recognized internationally as an innovative country in order to attract required talent and capital. The Government's goals are to address public and business confidences, Canada's stewardship regimes, incentives for innovation, and to ensure that Canada is recognized as a leading innovative country.

Drivers of the Application of Advanced Technologies

The substantial declines in real oil and gas prices since the mid-1980s and a dim prospect for the sustained recovery over the long-term, provided significant motivation for the use of advanced technology to reduce costs and to improve profit margins. Firms also turned to rationalizing their operations by downsizing, and focusing more on core their competencies. The requirement to reduce costs had to be achieved in spite of the resource depletion working in the opposite direction. As reserves are found and extracted over time, it is argued that it becomes more expensive to replace them. It is assumed that firms exploit their best resources first.

Unless technology improves to make it easier to find and produce the next generation of resources, the average cost of production will inevitably rise over time. The pressure to lower costs also underscores the need to undertake the development of new technologies. Emerson (1998) notes that investment will take place as long as prices exceed costs. Both Canada and the U.S. are price takers. If oil cannot be produced at less than the prevailing market prices, it could be imported into both countries from other producing nations. Governments have a strong interest in competitiveness because companies will relocate to lower costs producing regions.

Significant motivation in the use of more advanced technologies in the upstream sector stems largely from competitive pressures to reduce costs in the face of lower oil and natural gas prices. Most oil and gas companies today stress the importance of technology in achieving the strategic objectives of their organizations. The recent concern over the environment, in particular, climate change, is likely to provide another impetus to implement and develop new technologies in the energy sector. This is captured by the U.S. National Petroleum Council (NPC, 1995), which notes that the competitive edge of the industry will increasingly depend on the ability to manage and apply technology effectively and rapidly. This will include leadership in

technology development and environmentally acceptable hydrocarbon fuels.

Oil and Gas Prices

The behavior of oil and gas prices are key determinants of oil and gas supply (Persaud & Kumar, 2001). A well known fact of the resources sector is that commodity prices are cyclical and volatile. Prior to 1973, crude oil prices, expressed in WTI at Cushing, averaged less than US\$10/barrel (bbl). The following 29 years saw significant volatility in prices due to a number of major events. The first oil shock took place in 1973 due to the Arab oil embargo which caused oil prices to triple and brought profound economic disruption in the world for the ensuing years (Martin et al., 1996). The Arab oil embargo was followed by a number of destabilizing events in the Middle East including the Iran Revolution, Iran/Iraq War and the Gulf War, the Asian economic crisis in 1998 and 1999 and the tragic incident of September 11, 2001. The EIA (2002) notes that crude oil prices in 2002 began at roughly \$16 per barrel and were between \$25 and \$30 per barrel by the fall. The EIA is projecting a slight decline in real oil prices (\$2000) to 2005 increasing slightly thereafter to \$26.50/bbl by 2025. One of the key factors that will impact oil prices is technology.

Unlike oil prices which are determined in the world market, natural gas prices are determined in the North American market. Several factors that have affect gas prices in recent years including increased competition, improved pipeline accessibility, the commoditization of natural gas and the greater use of storage capacity. This point will serve to illustrate the gas price cyclicality. In the United States, for instance, when prices increased in 1992 and 1993, after several years of decline, industry responded by bringing additional supplies to the market thus forcing prices downwards in 1994 and 1995. Average natural gas prices in the U.S. are expected to drop from \$4.12 per thousand cubic feet (Mcf) including purchases on the spot market to \$2.75 in 2002. Prices are expected to increase to about \$3.90/Mcf in 2025 (IEA, 2002), with technology being a key determining factor in accessing and producing resources competitively in an environmentally sound manner.

Key Oil and Gas Innovation and Applications

Historically, until very recently, the technology used in the upstream sector of the petroleum industry has remained relatively unsophisticated. Only over the past 15–20 years, have there been rapid developments and applications of technology in the industry (Bohi, 1997). Significant motivation in the use of advanced technologies in the upstream sector stems largely from competitive pressures to reduce costs in the face of a declining commercial resource base, and relatively low oil and gas prices (the recent run up in prices are not expected to be sustainable according to most fore-

casters). Advanced technologies, including enhanced oil recovery techniques, are required to recover a large proportion of oil and gas in place. Only about 10–20% of oil in place from a producing reservoir is recovered. Thus, much of the oil remained in abandoned reservoirs. This is not the case for natural gas, which has a higher recovery factor. New technologies are required to further reduce the costs of frontier, Arctic, and oil sands supplies.

With the recent concern for climate change, technology is considered crucial in reducing emissions in the upstream sector. Companies may reduce their emissions per unit of production through increased efficiency of their energy use, reduced flaring and reduced non-fuel emissions of GHGs. The Upstream Oil and Gas Working Group (UOGWG)¹¹ of the NCCP argued that in the absence of technology to supply alternative energy sources or greatly increase energy efficiency, meeting Canada's Kyoto Target would put severe constraints on households and lifestyles, as well as all Canadian industry, imposing severe costs on the whole economy.

A broad range of technologies is being forecast for upstream oil and gas, such as, reservoir evaluations, reservoir engineering, and drilling techniques. These technologies span the entire value-chain of the industry—finding, development and producing oil and gas. Also, they cover a wide range of deposits including conventional, offshore, Arctic oil and heavy oil,¹² and oil sands (see Table A3, Appendix).

There are four major technologies in the industry, these are: 3-D seismic, horizontal drilling, offshore technology, and oil sands technology. Horizontal drilling and 3-D seismic may also be considered Schumpeterian changes given the number of other developments being spawned. The development of these technologies was due to a culmination of other major developments in computing and drilling. These four technologies could be considered to be the same for the oil and gas industry as the Bessemer process was perceived to be for producing steel and the Hall-process for producing aluminum. Overall, the four major technologies are fairly complementary in many respects and are adaptable to many situations. Provided in Table 2 is a summary of the description, application, and impact of these technologies.

These technologies are expected to play a key role in reducing costs of adding reserves by improving knowledge of the size of the resource base, extending

¹¹ The Upstream Oil and Gas Working Group (UOGWG) was one of the seven working groups of the Industry Table to carry out analysis to address climate change issues for the Climate Change Secretariat. The UOGWG comprised of several upstream industry organizations such as the CAPP, Canadian Gas Association, Canadian Energy Pipeline Association, Small Explorers and Producers Association of Canada.

¹² Term is used to refer to conventional heavy crude and sometimes bitumen unless explicitly stated.

the life of the reserves, improving success ratios, the targeting of drilling of oil and gas deposits, influencing project development of frontier and oil sands projects (e.g. Adelman & Lynch, 1997; Fagan, 1997; Fisher, 1994; IEA, 1997). In terms of labour productivity, IC (2002) shows that the crude petroleum and natural gas sector in Canada to exceed that of the U.S. Several papers (e.g. Saklou, 2000; Williams, 2000) presented at the 16th World Petroleum Congress (WPC), stressed the importance of technology in the petroleum industry.¹³ Emerson (1997) makes a similar point but goes even further by noting that it is time to abandon the concept of fixed stock of oil in favor of a more subtle characterization of oil reserves as a flow—a flow which is dependent on continual adaptation and innovation to keep replacement costs below price and this will lead to continued investment.

Forecasting Upstream Oil and Gas Technology

In the oil and gas supply sector, technology progress for exploration and production activities is represented by trend-based improvement in finding rates, success rates, costs, and the size of the resource base. The view of new technologies and their impact is obtained mainly from experts in industry and government. The U.S. National Energy Modelling System (NEMS),¹⁴ which is considered a highly sophisticated and 'technology rich model', assumes the impact of technologies through the cost function based on expert opinions (U.S. DOE/EIA, 2000).

The UOGWG developed a list of a broad range of technologies to reduce GHG emissions (see Table A3). The UOGWG considered available, emerging and embryonic technologies.¹⁵ These primarily include opportunities to improve the energy efficiency of operations, reduce methane losses, and either conserve or utilize waste stream. These options were chosen through several brainstorming sessions. A key requirement was that the analysis considers only technologies or incremental penetration levels that would reasonably be excluded from a business as usual scenario (i.e. based on current forthcoming requirements).

A Paradigm for Oil and Gas Research: Collaboration and Outsourcing

The U.S. NPC (1995) found that there is a 'new paradigm' for oil and gas R&D and demonstration

¹³ The first author was a participant at the WPC which was held in Calgary, Alberta Canada, June 11–15, 2000.

¹⁴ NRCan is in the process of implementing a Canadian version of this model.

¹⁵ Each technology is classified as near term, medium term, or future option. Near term technologies are deemed practicable to implement during the period 1999–2008. Emerging technologies or high capital costs, would be more applicable during 2008–2012. Future options are embryonic technologies that are still at the conceptual stage or early stages of development.

Table 2. Four major oil and gas technologies.

Types of Technology	Description and Application	Impact
Three-dimensional seismology (3-d seismic)	Uses sound waves to provide inference on the structure and properties of sub-surface rock layers Yield higher quality images than two-dimensional 2-D but more expensive and involves processing of a significant amount of data	Improves the ability to locate new hydrocarbon deposits (success ratios) thereby reduces the amount of drilling; Allows for monitoring production of reserves; and Increases productivity and lowers costs, and energy required and thus lower emissions.
Horizontal wells (directional wells)	Intersect the reservoirs at the side rather than from above as compared to vertical wells Provides more contact with a pay zone (area containing oil and/or gas) Much more expensive, and riskier than a vertical well and needs highly trained professionals	Increases productivity, reserves, and flexibility particularly in offshore and environmentally sensitive areas; and Increasingly important in oil sands recovery, reduces energy consumption and emissions.
Deep-water Exploration	A wide variety of methods exists: including drill ships, directional drilling methods, production platforms, remote-controlled subsea wells, and subsea pipelines High cost and risky	Makes exploration and development possible in water deeper than 1000 feet; Increases flexibility in production; and Makes offshore (e.g. U.S. Gulf, U.K. and Canada important sources of production.
Oil sands Technology	Several techniques exist to undertake surface and in-situ extraction, e.g. Steam Assisted Gravity Drainage System (SAGD)—recent innovation which uses two horizontal wells (one for steam and the other for producing)	Increase recovery and lowers costs significantly (e.g. Suncor and Syncrude, and bitumen projects); lowers emissions.

(R&D) are evolving because intense competition that contributes to low oil and gas prices, and the need to re-allocate scarce funds for large investments related to environmental compliance, have forced the industry to re-evaluate every aspect of its business, including their R&D investments. In general, the U.S. Petroleum Council found that this re-evaluation brought better efficiency and cost-effectiveness to private sector (R&D) activities. The IEA (1997) argues that such a new paradigm for oil and gas R&D may also suggest significant opportunities for greater international collaboration among member countries and the oil and natural gas industry. The new paradigm suggests a greater on user-driven collaborative R&D

(including government-industry collaboration) to compensate for smaller in-house industry programs.

The NPC's (1995) survey responses indicate that only a few companies would carry out in-house research, where the outcomes of those programs are vital to their future business interests and/or their long term viability depended on. The results of the 1999 Statistics Canada Survey in the resources sector show that a high percentage of firms rely on external sources of technologies. The CBOC (2000) in its Report, *Collaborating on Innovation* noted that firms with a greater propensity of inter-organizational technological collaboration are more likely to produce innovations than those that collaborate less.

Table 3. Paradigms of resource development.

	Old paradigm	New paradigm
Source of technology	In-house	Leverage and collaborate
Project prioritization	Technology push	User needs
Motive	Own it	Use it

Source: NPC *Research Development and Demonstration Needs of the Oil and Gas Industry, Volume 1: Summary and Discussion* (1995) p. 7.

In Canada, financial pressures in the mid-1990s have led to an emphasis on collaborative R&D to reduce costs and to achieve a critical mass of funding in the energy sector. Experience has shown that the prospects for promoting and accelerating innovation are optimized when the generation of expertise, knowledge and technology and the fostering of a business environment are met concurrently—through targeted partnerships among governments, business and academia (NRCan, 2002). There are many reasons for collaborative research including: cost reduction, sharing risks, gaining expertise, internalizing economic externalities, and co-ordinating strategies. Consortia have grown in the resource sector and are likely to play an increasingly important role in the future (Globerman et al., 1999). One of the key drivers of consortia has been the globalization of world markets (Kumar & Magun, 1995).

Achieving Excellence, Canada's innovation strategy, highlights the increasing involvement of government laboratories in partnerships. NTCan's National Round Table on Innovation, October 2002, underscored the importance of national collaborative efforts in addressing innovation and sustainable development challenges.

Sustainable Development of Canada's Oil Sands

Canada's oil sands are a world class resource and considered unique to Canada. The technology to find safe and environmental sustainable ways to recovering the oil, and to create tens of thousands of jobs is continuously being improved. This is taking place in cooperation with governments, academics and industry, researchers who have helped reduce economic and environmental barriers to development this enormous and important resource. With \$51 billion in new capital expenditures, the oil sands resource is expected to be Canada's largest natural resources development in the next decade (IC, 2002; NRCan, 2002a).

Industry has undertaken R&D for innovation, technological improvement, and increased productivity in the exploration development, extraction, upgrading, distribution and sustainable management of resources. During the consultation process on the government innovation strategy, industry argued that commercialization of R&D was critical—Canada cannot afford to 'leave good ideas on the shelf'. Industry argued for improvement in government funding for pilots and prototypes, improvement in the tax system for R&D, find good international technologies that could be imported, developed and adopted in Canada, and seek out international partnerships. Industry argued for

better links with government laboratories, universities and private sector.

A substantial amount of research collaboration takes place in the upstream oil and gas industry and this has become more popular in recent years. Since the mid-1990s, two non-traditional organizations (Canadian Oil Sands Network for Research and Development (CONRAD); and the Petroleum Technology Alliance Canada (PTAC) have emerged that have catalysed innovation in the upstream oil and gas industry, while encouraging collaboration, free information exchange and shared intellectual property ownership use rights. NRCan (CANMET's Western Research Centre) is an active member and preferred research provider to these two organizations. The Government of Canada, through NRCan and other departments and agencies, play several key roles in developing and disseminating the knowledge infrastructure that is critical for innovation, sustainable development decision-making and the generation of new ideas and technologies. NRCan (2002, p. 3) notes that:

NRCan has a key role to play in the innovation system for the natural resources sector across Canada, as both a catalyst for research and development (R&D) and innovation, and a major science and technology (S&T) performer and funding organization.

Syncrude and Suncor collaborate with other companies, governments, universities and research centres. They are industry leaders and are involved in research areas that cover all parts of the value-chain of extraction, upgrading, reusing material, of energy usage. Syncrude was a key player in the formation of Canadian Oil Sands Network of Research and Development (CONRAD). Companies are involved in collaborative efforts such as the national Centre for Upgrading Technology, Alberta Research Council, the National Research Council, and the Canada Centre for Mineral and Energy Technology (CANMET).

Government research is becoming increasingly partnership focused. Through Program for Energy Research and Development (PERD), NRCan funds R&D projects in collaboration with other federal departments. One such initiative has looked at the impact of ice on offshore floating oil production and storage platforms. The outcome of this research will help companies make better informed decisions about offshore platform operations, thus increasing production, reducing expenses incurred from unnecessary shutdowns and improving the safety of personnel.

The National Centre for Upgrading Technology (NCUT) is a joint venture partnership between NRCan and the Government of Alberta. Its mission is to make oil sands bitumen and heavy oil upgrading in Canada more economically viable and environmentally responsible by conducting R&D leading to technolo-

gies that have commercial potential.¹⁶ A technique, known, as Steam Assisted Gravity Drainage (SAGD), as noted in Table 2, took a decade of successful piloting to give operators the confidence to build independent large field demonstrations, could become a technology of choice for in situ recovery of bitumen. Developing the SAGD process was a collaborative efforts in which NRCan was involved at the early stages of development. This technique holds promise for development of Canada's oil sands resources.

NRCan is involved in research in both capturing CO₂, and developing ways to use and/or store it. In Weyburn, Saskatchewan, NRCan is a partner in an International Energy Agency monitoring project where CO₂ is injected into an oil reservoir. Capturing CO₂ emissions and storing them underground is a process with significant potential environmental and economic benefits. The CO₂ helps the oil flow to the surface; the project studies the impact of storing the CO₂ underground.

Oil and gas extraction is one of the few natural resource industry sectors whose spending has been robust over the decade. Several energy companies including Imperial Oil, Syncrude, Alberta Energy rank among the top 50 research spenders in Canada (Research Infosource Inc., 2002). It can be argued that R&D expenditure may not take full account of the level of innovation in the resources sector given the links with other sectors in which it drives innovation through massive capital expenditures and high capital intensity (Persaud & Norris, 2002).

Advanced Technologies and The Resource Base

The literature is rich with discussion on the role of the resource base, the way it changes over time, and its ultimate development (e.g. Adelman & Lynch, 1997; Cleland & Kaufmann, 1997; Dasgupta & Heal, 1979; Fisher, 1994; Hotelling, 1931; Kneese & Sweeney, 1993; NEB, 1999). A key point in the literature is that resource estimates do not take adequate account of technological developments. Further, the usefulness of the estimates of ultimate reserves from an economic standpoint is frequently questioned (Emerson, 1997). Technological advances have allowed industry to find and produce more and more oil in mature regions at lower costs, and resources inaccessible 20 years ago are now routinely being developed and produced. Adelman & Lynch (1997) note that ultimate recoverable oil potential, based on Hubbert's 'bell curve' approach (Hubbert, 1967), in the U.S. was estimated at 170 billion barrels in 1974. Production to date has already exceeded this amount, proven reserves are 20

billion barrels, and discoveries continue to be made. A parallel story exists for natural gas.

To simply extrapolate supply from a given reserve base, therefore, would underestimate supply unless sufficient allowance is made for technological impact. The impact of technology is also bringing into question the theory of depletable resources. Fagan (1997) maintains that technology is mitigating resource declines and reducing costs. Cleland & Kaufmann (1991) note that much of the debate between resource economists, on one hand, and physical scientists, on the other, is with respect to the relative impact of technical change vs. depletion. Resource economists are usually more optimistic than the physical scientists. Adelman & Lynch (1997) argue that the issue of resource shortage has led to misguided policies for several years. Emerson (1997) makes a similar point but goes even further by noting that it is time to abandon Hotelling's (1931) assumption of an operator's fixed stock of oil in favor of a more subtle characterization of oil reserves as a flow—a flow which is dependent on continual adaptation and innovation to keep replacement costs below price and this will lead to continued investment.

Forecasting Oil and Gas Supply and Emissions

Forecasting oil and gas supply is a fairly complex exercise involving a large number of variables (NRCan, 1999; Persaud & Kumar, 2001). Projecting oil and gas supply cannot be done by one single approach and, unlike energy demand for which econometric techniques are available, the approach to projecting oil and gas supply is more eclectic. Available information on the geology, technology, engineering and economics of various potential sources of supply is assembled to arrive at oil and gas resource estimates. With continued impact of innovation in the sector, forecasting supply models will have to reflect the underlying change on reserves and costs.

Sustainable Development and Innovations

Canada is well endowed with natural resources and strongly subscribes to the concept of sustainable development.¹⁷ Canada subscribes to the World Commission on the Environment Sustainable Development (WCED, 1987, p. 8), which called for 'development that meets the needs of the present without compromis-

¹⁶ The extraction process currently used at Fort McMurray project produces tailings that consist of fine clays and water that are stored in tailings ponds until the fines can settle out and be discarded.

¹⁷ In Rio de Janeiro, Brazil, 10 years ago, at the United Nations Conference on Environment and Development, Canada and more than 175 other nations committed to a comprehensive plan of action for socially, economically, and environmentally sustainable development—a plan known as Agenda 21.

ing the ability of future generations to meet their own needs'. Sustainable development is not considered a fixed state but a process of change in which the exploitation of resources, investments, technological development, and institutional change are made consistent with future as well as present needs (The Brundtland Commission, 1987).

According to NRCan's Sustainable Development Strategy:

Sustainable development is absolutely essential in the resources sector to fulfil its role as a major engine of growth and job creation in this country, helping to provide the highest standard of living and quality of life to Canadians for the 21st century (NRCan, 2001, p. 3).

In the natural resources sector sustainable development is seen as a constantly evolving process of identifying and seizing new opportunities to improve the environmental and economic performance to maximize social and economic benefits.

There are several environmental problems associated with the production and consumption of energy. Exploration, production and transportation activity impact the natural environment in different ways. Tens of thousands of wells and thousands of kilometers of pipeline and roads have a large cumulative effect over a wide area of the landscape. Major industrial operation such as oil sand mines, and gas-processing plants have major effects on relatively small areas. Offshore development poses threats to marine life and birds. Cold water temperatures and frequent storms also make it difficult to clean up oil spills further.

Low water temperatures also slow down the processes of evaporation and bacterial action that eventually break down oil.

The most significant concern with regard to energy and the environment is with greenhouse gases and the impact on global warming. This issue has attracted attention for the past 25 years and intensified in recent years. The combustion of fossil fuels results in emissions of all three of the major greenhouse gases: carbon dioxide (CO₂), nitrous oxide (N₂O) and methane (CH₄). CO₂, which has received the most attention, represent the largest share of global greenhouse gas emissions and most of it comes from energy consumption. Scientists warn that continued increase in greenhouse gases concentration could cause irreversible global warming and climate change, entailing severe detrimental economic and ecological effects.

The application of new technologies is considered as an important instrument for reducing greenhouse gas emissions and dealing with other sustainable development issues across all sectors. GHG emissions in the upstream oil and gas industry have increased since 1980 (Environment Canada, 1999). In the case of conventional oil pools, emissions have increased per

unit of production due to declining pool pressure and the need for rising fuel consumption because of higher compression requirements. Advances in oil sands technologies have steadily improved the energy efficiency of the operations. However, oil sands mining and upgrading is the most emission intensive, followed by bitumen, conventional heavy, conventional light oil¹⁸ production. In addition, oil sands production has increased continuously because of improved technology.

Emissions from natural gas production account for 35% of CO₂ equivalent of total GHG emissions of the upstream oil and gas industry. The sector consists of several source categories such as wells, gathering systems, and field facilities (e.g. compressor stations, metering stations, etc.). In addition, emissions result from gas flaring. New technologies are helping to significantly reduce the flaring of solution gas (by-product of oil production).

Skills and Innovation

In order to accelerate innovation and boost R&D performance, the public and private sector research facilities will need to be able to recruit and retain world-leading scientists, researchers, engineers and technicians, and skilled trade people. *Achieving Excellence* sets several targets in terms of developing a skilled and talented workforce, including increasing graduate admissions at Canadian universities and recruiting foreign talent.

The oil and gas sector is highly capital intensive, relying on a highly skilled and educated labor force. Training can determine the difference between successes and failures in the field. It is argued that anyone could purchase 3-D data and process the data using dedicated computer workstations, but interpreting the results for oil and gas potential is a combination of art, science, and experience. The view of several companies in the oil and gas industry is that there is a significant effort to train employees in acquiring the new skills because of the high costs associated with equipment and processes. For instance, without skilled employees significant investment can be lost in using horizontal well technology.

The oil and gas sector and other parts of the natural resources sector and allied industries face an increasing number of immediate and longer-term skill challenges. There are several reasons for these shortages including the overall aging of the labor force and stiff competition from other sectors for increasingly skilled workers. The unique characteristics of the resource sectors add significantly to the challenge of recruiting, retaining and developing sufficient pools of skilled

¹⁸ Includes conventional light oil, upgraded heavy crude oil, synthetic crude and pentanes plus.

workers. The Innovation Summit, held in Toronto, November 18–19, 2002, stressed the need for lifelong learning and flexibility to Canada's formal education system. Canadian Association of Petroleum Producers (CAPP) notes that companies increasingly demand experienced workers who can be instantly productive. Therefore, more needs to be done to help new graduates overcome the job-experience hurdle, e.g. government and industry need to collaborate on a system of first-job internships. CAPP also notes that sector associations must do more to get companies involved in such programs (NRCan, 2002b).

Innovation at the Community Level

Achieving Excellence calls for cooperation at all levels of governments to unleash the full innovation potential of communities across Canada. One major target is to create at least ten internationally recognized clusters. The Competitive Institute (1998) notes that clusters are related to core capabilities within a certain group of geographically concentrated firms. Clusters are geographically proximate groups of interconnected firms, their customers, suppliers, research and training institutions, and other physical infrastructure. They are intended to stimulate competitiveness and foster strategic alliances that combine to encourage firms to constantly upgrade and innovate.

Given the regional concentration of the oil and gas industry, it offers significant opportunities for innovation at the community level. An innovation cluster to support the work and address major challenges on development of oil and gas resources on the east coast offshore was recommended by stakeholders during the consultation process on the Government innovation strategy. It was argued that cooperative efforts are required by industry, government and academics to address the challenges of this sector and focus expertise in the most promising areas of the east coast.

Conclusion

The upstream oil and gas sector makes significant economic contributions to Canada and has a high-level of productivity. Innovation in the sector have resulted in improved success rates, increased recovery of oil and gas, expansions of the commercial resource base, and reduction of costs, and reduced environmental stress. Technology is now permitting access to frontier and non-conventional sources of supply, particularly oil sands production. The outlook is for continued favorable impact of technology and further development of these sources of supplies, which will make an increasingly larger contribution to Canada's policy and economic objectives. The favorable impact of technology across the value-chain of the industry and the view for continuous improvement is bringing into question the conventional view of a fixed resource base and rising costs. At the organizational level, the application

of technologies is improving flexibility, reducing hierarchical levels and facilitating the implementation of team work and creating the recognition that the development of skill sets is very important.

Canada recognizes the importance of innovation on economic growth, productivity and well-being. Innovation leads to a higher standard of living for Canadians. Innovations in the upstream oil and gas sector can make greater contributions to sustainable development, play a crucial role in reducing greenhouse gas emissions, and un-tapping Canada's vast resources. The Government has played a key role in several ways in the industry for example through partnerships, policies, and support for R&D, as shown through Canada's innovation strategy intends to vigorously pursue making Canada a highly innovative economy. The sector recognizes that the government can play an important role in creating the appropriate environment for innovations through smart regulations, the tax system, fostering R&D, contributing to skills development, and continued partnerships with industry (NRCan, 2002b).

Given *Canada's Innovation Strategy*, it would be worthwhile undertaking further research in these areas. Of great interest, will be studies on R&D collaboration and smart regulations. Very little information is available on the organizational and individual impacts of technology probably because of the capital intensity of this industry. This is also another worthwhile area of further research. Important, and timely studies of the impact on technologies, and the forecasting of technologies to reduce CO₂ emissions will be of increasing interests, given Canada's Commitment to Climate Change.

Acknowledgments

The authors acknowledge the use of statistics, information and projections from NRCan including *Canada's Emissions Outlook: An Update*; The results of NRCan's Round Table on Innovation and Skills (NRCan's Webpage—<http://www.nrcan.gc.ca>, and drawing from the results of the 1999 Statistics Canada Survey on Innovation. Table A2. Technologies and reasons for application.

Technology	Reasons for Technology
<i>Exploration</i> <ul style="list-style-type: none"> • Geophysics • Geology • Geochemistry • Information technology 	The discovery rate is declining because the hydrocarbon traps remaining are complex, and the volume of hydrocarbons they contain will be generally smaller than in known reservoirs. R&D into new and improved techniques is necessary to mitigate this trend.
<i>Reservoir Evaluation</i> <ul style="list-style-type: none"> • Fluid/rock interactions • Structure assessment 	The goal is to preserve access to identified deposits while developing and testing technologies designed to overcome specifically problems associated with reservoir structure and potential.
<i>Reservoir Engineering</i> <ul style="list-style-type: none"> • Enhanced recovery • Artificial Lift 	Much of the oil in a reservoir is left in place when a field is abandoned. Advanced secondary recovery and enhanced oil and gas recovery make valuable contributions to the security of supply.
<i>Drilling and Well Completion</i>	Improvements in drilling technology will greatly reduce the cost of exploiting discoveries. Advances in a number of technology areas will be crucial for developing currently uneconomic reserves.
<i>Offshore Field Development</i>	R&D will reduce capital and operating costs. Significant technology progress could radically change production installations.
<i>Field Operations</i>	R&D is necessary to increase efficiency of operations. Cost increases are expected for activities related to safety or environmental impact mitigation.
<i>Transport Systems</i>	Development of marginal fields and the production of severe fluids will require the development of multi phase flow technology and the application of advanced materials. Work on natural gas conversion to liquid products for transport should be advanced.
<i>Technology for the Arctic Regions</i>	Large supplies will be obtainable from the Arctic regions with the development and deployment of appropriate technology.
<i>Extra Heavy Oils, Natural Bitumens and Shale Oils</i>	There are very large reserves of these sources of hydrocarbons. Appropriate R&D will make them accessible and competitive.

The National German Innovation System: Its Development in Different Governmental and Territorial Structures

Hariolf Grupp^{1,2}, Icíar Domingue-Lacasa¹ and Monika Friedrich-Nishio²

¹ *Fraunhofer Institute for Systems and Innovation Research (ISI), Germany*

² *Institute of Economic Policy Research (IWW), University of Karlsruhe, Germany*

Abstract: This chapter provides several long-time series of innovation indicators bridging more than 100 years of German economic history. The ups and downs are put into perspectives and compared to important events in the global innovation system. The pertinence found for the national German innovation system seems to rest in educational, cultural and language traditions rather than in governance and territorial coverage, which changed many times. The chapter represents an analysis of the national level and two long-term studies on electrical engineering and chemistry. Thereby, the path dependence of technological paradigms within such a national innovation system becomes obvious.

Keywords: Innovation; Economic history; Germany; Science system; R&D; Patents; Path-dependence; Evolution.

It is always difficult to record the history of events that have not yet run their course and whose outstanding players are all still living Events appear different, once they are concluded; different again, while they are still developing. In both instances, the aims of the reporter also differ.

Gustav Struve (1849, p. 290).

Methodological Introduction

The general appreciation of innovation corresponds with a typically European method of thinking which is not found in all cultures. “The positive evaluation of new findings, the esteem for innovation, the idolization of inventors, as well as inventions and patents, are achievements of the modern world dominated by European-American influence, which, from a historical point of view, are relatively young” (Dohrn-van Rossum, 1999, p. 39). However, even in the Christian Occident, the present predominant emphasis on innovation results from the manifold historical changes of the past centuries. Initially, inventions and discoveries were not considered as an act of creation but only

represented the re-discovery of natural phenomena created by God. This change of consciousness—which took place prior to the period investigated by this chapter (1850–2000)—should be dealt with in order to better localize innovation-critical opinions in the present; however, this cannot be done here.

A practicable way to measure innovation could be the elaboration of definitions and measurement methods by starting from a historical point of view, with the objective of recording the enormous change characterising innovation activities. However, this chapter takes the opposite point of departure: starting from today’s definitions, an investigation of the comprehensive statistical material including related indicators is carried out, followed by the attempt to trace and complete these back before the foundation of the German Empire. This means, the presently achieved level of theory and methodology serves as a point of departure for the following retrospective.

Consequently, this chapter tries to include a considerable number of quantitative variables, preferentially in the form of *time series*. Therefore, this analysis can be included in the field of *cliometrics*, the ‘new’ kind of economic history, which is based on

quantitative methods including econometrics, aimed at reconstructing and interpreting the past (Bannock et al., 1998, p. 61). This method is regularly criticized since *indicators* cannot be *facts*; however, according to some points of view, narrative historiography cannot distinguish facts from interpretation either. According to these, no fundamental difference exists between the description of facts and the interpretation of these, since every description already represents a certain interpretation, which, moreover, depends on the definitions presently available to the describing person (Lorenz, 1997, p. 32).¹

Even if there is no basic cognitive difference between the (widespread) narrative approach and the (less common) quantitative approach, the objective of the quantitative approach is the statement of a relationship between variables, based on many cases, and thus generalization (Fogel, 1994, p. 237 onwards). In contrast, the qualitative approach aims to compare case by case, i.e. this contribution has an analytical or holistic character (Lorenz, *loc cit.*, p. 238). It seems that most historians prefer an approach by case (qualitative approach), whereas most social scientists choose the variable approach, verifying hypotheses for a whole series of cases.

To be provided with variables for many cases on the aggregated level, conceptual ideas are needed which regulate inclusion and exclusion. Whereas, in general, brief experiences can be clearly delimited, the application of specific selection criteria is often difficult, especially in the case of long time series, due to the fact that the individual investigation of all relevant indications is absolutely impossible. Moreover, indicators have a *selective* rather than objective quality, so their undeniable status only applies to a specific disciplinary context: according to the present status of empirical economic research, more or less ideal indicators are available for theoretical constructs. The process of ‘*statistical adequation*’ means the ‘tailor-made adaptation’ of measurement concepts, the result of which is not entirely satisfactory in view of the theoretical constructs but which at least corresponds with the descriptive framework used as a basic structure for measurement.²

This is aggravated by the fact that the theoretical constructs of innovation research are not clearly defined. Up to the present, rival and unconciliatory innovation theories still exist in several disciplines (Grupp, 1998). In addition, linear models are widespread, presuming a sequential succession of innovation-oriented phases, the point of departure of which is an unpredictable serendipity in basic research or exogenous technical progress which falls like manna from heaven. Orthodox approaches have developed,

which try to subordinate or marginalize alternative approaches in order to find the ‘truth’ with the help of their own theory. From an empirical perspective such attempts must be considered with scepticism since modern epistemology actually tries to erase any efforts to find the real truth (Hoyningen-Huene, 1999). Therefore, the research on science and technology indicators should ideally begin from an heterogeneous level of theory and definitions in order to find historically solid indicators. Empirical standardization of theoretically heterogeneous constructs must take the individual contexts into consideration, however, it should lead to ‘adequate’ indicators; herewith, empirical statistical adaptation often remains incomplete, and, yet, only a minimum of discrepancy should be left (only refer to the discussion about real and ideal concepts, Machlup, 1960). In view of an economic-historical approach, definitions must be fixed as an orientation structure for both theoretical and empirical analyses; these definitions should stand iterative modification, they should apply on an inter-disciplinary level and be valid over time.

The standard German textbook for ‘businessmen and students’ by Roscher (1886), which was reprinted about 20 times by the second half of the 1880s, and which also shaped Schumpeter’s theory of economic development (1911), distinguishes six different economic activities, listing *Invention* and *Discovery* first (sic!)—ahead of mining, agriculture, the processing industry, the distribution of goods, and the service sector last (excluding wholesale). Based on this, the result-oriented concept by Schumpeter (1942, p. 136 cont.) defines criteria according to which innovation represents all that yields a profit for the entrepreneur by being the first (the so-called *quasi-rent* or *innovation rent*). Quasi-rents of innovation tend to be neutralized by time due to the effects of concurrent processes. Innovations can be seen as new goods or services, new methods of production or transportation, new markets or new organizations.

In Germany, the term ‘*novelty*’ was used as a definition of innovation for a long period of time. The word ‘innovation’ was unknown for a long-time: it only reached the German speaking regions after Schumpeter’s emigration to the United States, where he published English texts; here, the English word ‘innovation’ was maintained as the germanized ‘innovation’ instead of being translated back to the term ‘novelty’ originally used by Schumpeter. Probably the definition of innovation was adopted around 1960. Consequently, it is evident that the definition of innovation as it is used nowadays cannot be considered as an anchor for the investigation period since 1850. Prior to the 1960s, innovation phenomena were described using other definitions: archives, libraries, research institutions as well as documents from management, personnel departments, or from production centers show terms which are different from those

¹ See also the contributions included in Müller & Rüsen (1997).

² Cf. Machlup (1960), Grohmann (1988) and Grupp (1998).

used according to present standards (like laboratory, try establishment, experimental factory).

According to today's view, the concept of a specific research process which leads to measurable innovation and which requires personnel and financial expenditure, is based on Bernal's (1939) farsighted and clear analyzing work. Bernal distinguished the role of public research expenditure from that of civil research and—as things stood—from that of the war industry. The first statistics on expenditure for 'industrial research' by British companies are found in the annexes of his works. As reported by Freeman (1992, p. 3), the definitions used by Bernal during his lectures at the London School of Economics were brought to international committees (by Freeman himself as well as by others), which, in the 1960s, worked for another standardization of definitions, which led to a first paper about the measurement of output of research and development (Freeman, 1969).

Consequently, the empirical framework underlying this chapter will be determined using the current definitions and concepts. These may have had other meanings in the past, however, this 'anachronism' of long-living indicators' definitions must be accepted. Language is used by any historiography including the hermeneutic one; however, as language develops over time, definitions may arise, disappear, or change their meanings. Consequently and independently from the method applied, any historiography is anachronistic to a certain degree (Lorenz, 1997, p. 364). Former innovators were not masters of today's historical knowledge, and neither of information about present innovation processes—knowledge and information, which we have acquired from our observation post.

Because of this, the definitions found in the leading OECD manuals³ from the 1990s will be used. Cliometrics are also more concerned with anomalies than with constantly ongoing, inconspicuous processes. If a structural breakage is found in time series, this could point to a statistical artifact arisen by the change of used definitions and conventions. Consequently, found structural breakages⁴ must always be interpreted and categorized in a qualitative way. The problem of anachronism—if not avoided—can thus at least be moderated. Inter-temporal shifts of emphasis as an explanation of structural breakage are all the more permissible since a functional innovation model serves as an additional basis (cf. Grupp, 1998), working on the assumption that different innovation-oriented processes can be influenced by all types of research and development (R&D).

³ According to these (OECD, 1992, 1993), technological innovations comprise new products and processes and significant technological changes of products and processes.

⁴ Maddison (1982, pp. 2, 3) talks about 'system shocks'. Gerschenkron (1943) points to the pervasive institutional powers that may overcome external shocks for decades.

National Innovation System

This chapter is divided into a national (this section) and a sectorial level (see the next section; for the definitions of 'national innovation systems', see Grupp, 1998, p. 244). From a historical point of view, modifications of the territorial situation (population, etc.) may not be ignored. In this way, from an empirical point of view it is essential to consider, for example, the size of the Empire or of each federal territory. Not only is the German Democratic Republic considered here, but also Saarland, the Corridor, East Prussia, and others. Territorial changes which took place can be considered on the basis of today's statistical procedures, so that such data series, a priori, do not have to be absolutely consistent with a territory (also refer to Hoffmann, 1965, 2f). However, it must be pointed out that the omission of *smaller* districts (such as Alsace-Lorraine from 1871 to 1917) in most cases brings in its train less important errors of estimation than the *big variances* in the series of the whole territory of the German Reich (same paper, p. 3).

Public Expenditure for National Science and Technology

Traditionally, the development of science and technology is measured by the number of *scholars*. In this way, for example Gascoigne submitted a historical demography (1992) of the scientific community between 1450 and 1900, by listing the nationality and age of all the scientists. According to this study, Italy was the leading scientific country at the beginning of modern times in the late 15th century, representing about half of all the scientists in the world. This has remained almost unchanged during the entire Middle Ages before that century; then exponential growth with a doubling period of approximately 50 years took place.

Detailed and complete statistics are available about *scientific staff* in Germany since the foundation of the Empire, accessible via today's electronic means. However, generally accessible statistical material about *R&D personnel* in Germany has only been recorded since the 1960s (in the framework of the Federal Research Reports which have been published since 1965).

Another traditional access to the empirical definition of the importance of an innovation system is scientific expenditure (the sum of R&D funds and those for training, teaching, maintenance and diffusion of knowledge). Whereas the evaluation of expenditure for pure educational and R&D institutions is rather simple, this is more complicated in the case of institutions engaged in *both* research *and* teaching. Quota were adopted to cope with the individual fields of specialization as well as with the individual types of universities. However, it is questionable whether these reflect the right proportions between the percentage of research and that of teaching at all historical points in

time. In addition, not only is the historical consideration problematic but also the consideration of the present time. Nevertheless, it is common statistical practice in all OECD countries to work with such quota (Hetmeier, 1990; Irvine et al., 1990).

Pfetsch (1982) undertook adding up scientific expenditure between 1850 and 1975, so that rough estimates about the degree of R&D financing can be derived from this; however, these data records only include *public* expenditure, disregarding the private sector. Consequently, industrial innovation indicators must be researched separately (see below).

In order to avoid dealing with the difficulty of different currencies, the development of scientific expenditure can be best evaluated by its percentage of the *total expenditure* of public budgets. According to this, scientific expenditure in the German regions prior to the foundation of the Empire was approximately 1% (see Fig. 1). Linked to the foundation of the Empire, this percentage reached more than 2%, but dropped to almost 1.5% between the 1880s and the first World War. The Republic of Weimar attained a doubling of scientific financing which, however, was lost again due to the worldwide economic crisis. In West Germany, the support of science was pushed dramatically to reach a proportion of 6.5% of all public budgets by the 1970s (university expansion), in order to fall off to approximately 5% by German reunification. Finally, due to reunification, the level dropped even further. These indications are based on the numbers of Empire or Federal institutions and those of regions and states.

Besides the above-mentioned data records, and also based on an analysis of the older part of these, Pfetsch (1974) submitted an extensive analysis of German scientific policy between 1850 and 1914. For example, Pfetsch (same paper, p. 60 and p. 171) cannot confirm the thesis that the state spends more money on science and technology in times of increasing economic wealth. In spite of some references to anti-cyclical research policy, overall an *irregular economic attitude* is shown by government *policy*.

Surprisingly, the post-World War II expenditures start at around the same level as at the beginning of the last century (after World War I) which is at the same level as the endpoint of records in the 1940s war times, and increases in a similar way after World War II as after World War I. This points to quite *stable* and *persistent* institutional structures underlying the financial totals.

The financial support of *Research and Development* is typical for post-war Germany. Until 1945, the financing share for R&D only played a subordinate role in total scientific expenditure. Although the research share⁵ was between 20% to 30% during the first period after the foundation of the Empire, it dropped to less

than 20% by the beginning of World War I (cf. Fig. 2). In addition, it is important to know that a great deal of scientific expenditure by the Empire was used for defence tasks shortly after the foundation of the Reich. During the Weimar Republic and the Third Empire, the R&D share of the total of scientific expenditure continued to fluctuate around 20% (industrial research not included).

An increase in the R&D share of scientific expenditure was the case when research in certain areas was admitted again in the young Federal Republic, after the signing of the Treaty of Paris in 1955: at times it reached 70% and has only declined due to the recent reunification.

Prior to World War II, the relatively insignificant role played by R&D within the scientific world is also shown by the *distribution* of funds to the different *institutions*. During the decades preceding and following the foundation of the Empire, the lion's share of approximately 70% of the total public scientific expenditure is accounted for by all types of universities. Empire agencies and other institutions were established over time, so that the universities' share of scientific expenditure decreased to about 35% at the beginning of the 20th century. Now, between 20% to 30% goes to these institutions charged with varied tasks, and almost 10% is accounted for by pure R&D institutions.

During the entire period before and between the two World Wars, a small but significant and strongly varying amount of public expenditure went to missions other than institutional support. The non-institutional support is described as '*project-specific scientific expenditure*' by Pfetsch (1982, p. 113); this could be misunderstood, since part of it consists of public grants and support given to a wide range of projects and not only R&D projects. They range from 'Scientific efforts for opening up Central Africa', the publication of archives, international contributions to the surveying of earth, measures to combat typhoid fever or infantile mortality, and to financial support for congresses.

Until World War I, more attention is generally given to scientific support on an industrially relevant level, as well as to scientific application (Pfetsch, 1974). However, it would be incorrect to conclude that a major part of these funds were granted to private companies, as can be shown for the period following World War II. Industry was more interested in a proportional increase in public support of production-relevant branches of science (consequently, in the creation of external effects upon science-based industries, same paper, p. 107) than in the support of their own R&D.

Of course scientific expenditure was borne exclusively by the German states until the foundation of the Empire; afterwards, the central power moderately supported the total public science budget by 20%. Only during the Republic of Weimar did this share grow considerably (see Fig. 3). After the occupation of

⁵ More precisely, 'research share' means the 'R&D share' of the total expenditure for science and technology.

Figure 1. Development of scientific expenditure in proportion to the total expenditure of public budgets.

Figure 2. Government expenditure for science, divided into the publicly financed R&D share and other scientific tasks.

Figure 3. Development of the financing of scientific expenditure: the proportion of federal and state financing.

Germany at the end of World War II the Federal Government could not play its prior role again, all the more so since several research areas were prohibited (research in the fields of armament, nuclear science, chemistry and aviation). However, federal institutions systematically increased their influence on science until the level during the Third Reich was reached again. Since the recent reunification, federal administration has been slowly but surely withdrawing from scientific support.

Consequently, it must be noted that, following critical upheavals such as the foundation of the Empire, the First and the Second World Wars, the Federal states have always begun to take over important tasks of scientific support and are later relieved by the *central power*. The events following the foundation of the Empire, which were called ‘*getting empires*’ by Pfetsch (1974, p. 105), occurred in a hesitant way on complex scientific-political levels. The results were manifold forms of cooperation between private, mixed and individual government institutions and Empire authorities. The same can be observed since 1945 under completely different political circumstances: the Federal government only slowly became a dominant and central supporter and organizer of the scientific system, its scientific expenditure diminishing both on an absolute and on a relative level only after the reunification. Again this points to *persistent* basic structures in the national innovation system. The only historical exception is the reunification of 1990: whereas the Federal government played a dominant role as a central supporter and organizer during the reunification of the two scientific systems, its scientific expenditure diminished afterwards both on an absolute and on a relative level.

Regarding the R&D expenditure of the *German Democratic Republic* (cf. Fig. 4), note that the individual statistics were centrally maintained and are comprehensive. However, the conditions which were applied do not fully comply with those used by OECD countries and often show exaggerated values. Following reunification the relevant statistics were revised and adapted to Western standards; however, the conversion problem of the East German bank’s Mark persists. Due to the non-convertibility of this currency the reliable purchasing-power parity values of OECD countries cannot be applied.

Figure 4 compares the R&D expenditure of the German Democratic Republic with that of West Germany. In order to be certain, a pessimistic and an optimistic variation can be applied in order to show a range of uncertainty due to conversion. The first possibility of conversion is based on the purchasing-power parity (PPP) of so-called baskets of commodities, in the second model the subsidies included in GDR commodity prices are taken into consideration and deducted (anonymous, 1986, p. 259–268). It is shown in both estimations that the national

R&D expenditure of the German Democratic Republic could not equal the West German level (per head of the population) but the general upward trends somehow resemble each other. This may come as a surprise to those who point to the inefficiencies of the communist part of Germany, but, again, the underlying institutional structures remained basically the same as before the war requiring similar amounts of public support.

Development of Scientific Activities

It is impossible to achieve an insight into the development of non-codified and thus ‘tacit’ experienced knowledge of the scientific staff. For this reason the historical development of an innovation system is often shown by the personnel statistics, or by statistics showing monetary expenditure. However, only expenditure is measured by this method, instead of the fruit of scientific activities. Efficiency measurements are particularly impossible. Consequently, modern innovation statistics make regular use of yield measures; regarding scientific work, statistics of publications are a typical output indicator. Analyses about the degree of *publication activities* have been maintained for centuries; however, it must be noted that the publication media chosen by scientists may differ from one faculty to another, as well as over time (Wagner-Döbler & Berg, 1996, p. 289). Only during the 19th century did scientific magazines achieve the same degree of significance as books, the dominating publication media until then.

Regarding publication activities in selected areas, only a few but informative historical time series for selected areas are available (cf. below). However, in this section we consider totals first. Due to the known difficulties of aggregation, only limited sources of publication activities are available on this level of analysis. An analysis of the Catalogue of Scientific Papers for the 19th century shows that the output of scientific papers had been growing constantly since 1800; and it accelerated tremendously from 1884 onwards (anonymous, 1925, p. 129 onwards). This analysis is not limited to Germany but refers to worldwide publication output.

From 1900 onwards the availability of data improved worldwide. The growth rates of periodicals were evaluated in ‘Ulrichs’ Periodical Database’ (CD-ROM version) by Mabe & Amin (2001); if one takes the example of academic magazines from this catalogue, the contributions of which are submitted to a review procedure, a remarkable exponential growth is shown up to the end of the 20th century, which then slightly decreases (Fig. 5). A detailed statistical analysis covering the period from 1900 until 1944 shows an almost constant increase in the inventory of magazines of 3.2% per year, followed by a phase of expansion with an almost constant growth rate of 4.8% per year until 1974, ending with a lower rate of growth

Figure 4. Development of the national R&D expenditure per head in East and West Germany.

Figure 5. Accumulated number of worldwide inventory of referred scientific magazines (shown as a semi-logarithmic figure) from 1900–2000.

of 3.7% per year, similar to the first half of the century ('century standard').

This development seems to be linked with historical structural breakages on a worldwide level. Following its academization during the 19th century, *science* was characterized by constant expansion until the Second World War. This can be called the *normal development*. After the Second World War, the growth rate of scientific output increased and reached almost 5% for almost three decades (the so-called boom phase), due to the economic miracle, the armament race, reinforced industrial research and development activities, as well as an expansion of scientific activities in general. This phase was followed by a normal phase of expansion similar to pre-war conditions; it can be linked to the ending of university expansion, the consequences of a severe recession due to the oil crisis, as well as with a general decrease of economic growth rates ('limits to growth'). Using completely different time series, Maddison (1982, p. 92) found phases showing a high degree of temporary similarity (1930–1950, 1950–1973, following).

Analyzing the situation in *Germany*, the 'Bibliography of German Periodicals' Literature' represents an alternative regarding historical data. This bibliography covers the German-speaking periodicals' literature from 1896 until 1964, and the international periodicals' literature from 1965 onwards. However, no information about the author's nationality or the institute's location is found in this source; probably most of the older records come from German authors, but quota and changes of these are also unknown.

The Science Citation Index (SCI), which has been available as an online version as early as 1964 (see

below), has a printed version listing the publications from 1945 until 1974. Although no indications are found regarding the authors' nationalities or the institutes' locations, the listing of periodicals is classified by the countries editing and printing them. Since Mabe & Amin (2000) have proved a highly positive correlation between the number of periodicals and that of the journals' articles, the number of German-speaking articles listed in this data record can be counted for the period since 1945. The repeatedly written announcement by the SCI that records would be completed back to 1900 was withdrawn,⁶ so there is no hope for the soon publication of a *century's inventory*.

Taking into account that the total volume of publications has grown enormously, it is surprising to see that the share of German periodicals has been constant since 1945, i.e. that it has augmented in line with the worldwide volume. The average proportion of German periodicals, which is 8.9% of the total SCI inventory, shows only minimal fluctuation. Since 1974 an equally constant proportion of German authors is shown in the SCI online version so that it is obvious to link these two data records, all the more so since they overlap each other over a long period (from 1975 to 1984) so that the corresponding factor of extrapolation from periodicals to publications can be determined.

The SCI online version shows the *nationality*, a corresponding field being encoded where a German author or an institute located in Germany are concerned (independently from the medium's language). The strongest growth of the (extrapolated) publication

⁶ Personal communication Garfield, 14 October 2000.

numbers is stated from the middle of the 1960s, and during the 1970s (Fig. 6). This matches perfectly with the observation of a worldwide expansion of the scientific system, even though the German scientific world showed a *delay* of almost 20 years resulting from the special situation of reconstruction as well as from the Allied Forces' restrictions regarding certain research areas.

At the end of the 1980s the growth rate decreases not only in Germany but on a worldwide level; after 1989 the total number of German articles shows a dramatic decrease. It must be noted that the statistics cover both West and East Germany, and that this decrease in publication activities could principally represent the decay or dissolution of the East German scientific system. The publication level of 1987 was only reached again during the publication year 1993, which was characterized by strong growth in an anti-cyclical course to the worldwide slowdown. A comparison of research activities both on a disciplinary and on a qualitative level is suggested below. Figure 6 also shows a simulation of the course of the three constant growth rates, which point out the exponential growth.

From 1974 to 1990, SCI publications from West and East Germany can be compared electronically.⁷ This period is characterized by moderate growth of publication activities ('century standard'). In the 1970s, the share of East German publications was approximately 16% to 17%. However, if one compares East and West Germany, both the proportional shares of population and the proportion of R&D staff is almost 30%, so that scientific publications from the German Democratic Republic are less represented in the U.S.-based database. The proportion of East German publications had constantly diminished to reach 13% by the end of the 1980s; and there is no answer to the question as to whether the *representation* in the database was even worse or if the output efficiency of East German research activities continued declining until the end of this state.

Measured by its publication output, the *profile* of GDR research resembles that of the former Federal Republic. In proportion to worldwide average shares, researchers of both parts of Germany published much more than a pro rata share in the research areas of energy and nuclear technology, chemistry, solid-state physics and microbiology. A weaker level than the worldwide average was shown in information science, engineering, environmental research, the area of public health, as well as in other biomedical subjects. According to our estimation, this *structural similarity* could be the reason for such a strong diminution of

publication activities on an all-German level following reunification. Integration did not concern differently specialized East and West research systems but research systems with the same principal orientation, which led to the deplorable 'reallocation and consolidation' in East Germany. Independently from a political evaluation of the organization of GDR research institutes this structural similarity must be pointed out; obviously 40 years of division were not sufficient for a differentiated development of the basic specialization patterns of research in both parts of German. To a great extent, and in the sense of *path dependency*, research is still based on the (common) preferences which existed prior to the division. This unique historical situation could be understood as an unintended experiment: basic patterns of scientific specialization change only slowly, even in times of great political system change (Hinze & Grupp, 1995, p. 65).⁸

Another method of comparing the two *scientific systems* is to observe the frequency of citations. More frequently cited scientific studies are considered to be more significant (in some way), for example because they include either important methods to which many successive authors return, or especially important results (or errors which are repudiated later). GDR literature shows a lower rate of citations per scientific publication than West German literature; there are two possible reasons for this: on the one hand, the scientific value of GDR publications could have been minor; on the other hand, the periodicals in which these articles appeared were received to a lesser degree on an international level, in particular in the English-speaking realm. This could also be due to the lower circulation figure of the corresponding periodicals (partly of Soviet origin).

In the bibliometric statistics these two effects can be viewed separately, by referring the rate of citations either to the worldwide average or to the average of the individually selected periodicals (Grupp et al., 2001). The following analytical results emerge: GDR research publications show an almost general *lack of worldwide communication* of results (particularly in the Anglo-Saxon linguistic area). This explains the low rate of citations. However, a correlation between the frequency of citations and the publication organs (which are typically less read in the Anglo-Saxon area) selected by GDR authors shows that a favourable rate of citations is found in comparison with articles from countries other than the GDR which are also published in these periodicals. Consequently, GDR publications are considered to an above-average degree once the citation quota due to the lack of international spread is mathematically corrected. The *highest regard* (quota of

⁷ Due to the delay in appearance of scientific publications following submission, no quantitative cutback in literature production by the researchers of German Democratic Republic institutes can be perceived until the end of 1990 (Weingart et al., 1991, p. 4).

⁸ Recently, surprisingly similar results were also found using other methods.

Figure 6. Development phases of publication activities in Germany since 1945.

citations) is found in the areas of neuro science, internal medicine, as well as dietetics and agriculture. Following the correction of the quota of citations, the results of GDR environmental research were the least noticed by the professional world.

A division of science into 27 sub-sections (Hinze & Grupp, *loc. cit.*) leads to a surprising correlation between the degree of internationalization and that of attention received: it was found that those research areas which are *not* internationally spread are significantly more noticed by the professional world than the publications with a higher degree of internationalization. No such correlation can be found for West German research. It is possible that hierarchy and cadre selection mechanisms play a role regarding access to Western periodicals.

Industrial Research and Development in Germany

Since the foundation of the Empire, economic growth of industrial countries, in particular in Europe, has increasingly been based on the innovation energy of the *knowledge-based industry*. 'This is undeniably true for the impulses of growth immediately released by these industries, starting with carbon chemistry and electrical technology' (Wengenroth, 1997). There is hardly a clearer and more distinct way to describe the conducive effects of industrial research on the culture and efficiency of innovation.

It is still difficult to prove the companies' increasing R&D expenditure for such an undeniable success. In

particular, no complete data records are available about monetary expenditure or research personnel prior to the end of the Second World War, i.e. the data record established by Pfetsch (1982) regarding public scientific expenditure has no counterpart for industry. Today's statistics about R&D expenditure and personnel of the Federal Republic systematically start from the year 1962; certain presumptions allow the reconstruction of the corresponding indicators starting from 1948/1949 (Fig. 7). According to this, industry has continuously increased its R&D budgets to a higher degree than government, the share of which is presently approximately 40%.

The reconstruction of the corresponding indicators prior to World War II is only possible if one starts from the individual companies or branches. This was tried for in the areas of chemistry and electrical technology (cf. next section). The investigation of the history of R&D in leading companies of two selected industrial branches shows that the execution of case studies in order to represent time series is principally possible and, moreover, makes sense. During the whole investigation period many large and leading companies in Germany maintained archives which can be considered as complete in spite of difficult conditions at times in German history.

Presently the representativity of company-related R&D time series cannot be plausibly proved for the development of a whole branch and that of all branches for the whole national economy. A more detailed

Figure 7. Development of government and industrial R&D expenditure in relation to each other from 1948–2000.

analysis should include other important branches, in particular, the metal industry. However, the results found so far show that the existence of different ‘cultures’ of R&D is possible in the different branches, which influences not only the forms of organization but also researchers’ liberties and practical work.

Development of Invention Activity in Germany

The observation of the development of innovation activity is important in itself in order to establish R&D results, mostly on a technological or application level. Adopted methods are statistics on *patent applications* (a figure representing successful innovation activity seen from the innovators’ or applicants’ subjective perspective) on the one hand, and, on the other hand, statistics on the number of *granted patents* (as a figure representing successful innovation activity, seen from the objective perspective of patent examiners). Statistics on patents make even more sense if one takes into consideration that only fragments of industrial R&D expenditure are known prior to the Second World War. Instead of inputs, industrial R&D activities can be measured by their patent outputs, and this even more precisely from a technological perspective than by monetary indicators. This also explains our interest in both patent grants and patent applications: if no patent is granted after verification of the novelty, the inventive step and its commercial usefulness, for example due to a lack of novelty, the applying company had nevertheless invested R&D efforts—even if these led to an objectively already known result. Consequently, the ‘subjective’ perspective of a successful invention is closely linked to the R&D performance, which was in fact realized. Statistics on patent applications as a *proxy variable* for R&D expenditure may ignore whether the object of the invention was a world novelty or not. R&D expenditure also includes the costs of unsuccessful or belated inventions in comparison with competitors (imitations).

The period to be considered is fully included in the statistics of patents. In some German regions, patents were applied for as early as 1820, starting from the South, due to the influence of the Napoleonic legislation. From July 1st, 1877, a *patent act* for the German Empire standardized procedures. Thus, the creation of patent acts in Germany follows the scientific-technological innovation push of the 19th century, at the end of which Germany was one of the leading industrial nations. In about the middle of the century the local, largely secluded markets were dissolved, and the German economy was integrated into the quickly expanding world economy (North, 2000, p. 13; Ziegler, 2000, p. 198).

Since 1879, *patent statistics* have been available using *machine readable* methods. On the one hand, electronic data records since 1970 are more informative than those of former periods, leading to a largely increased importance and use of these patent data

records by modern studies in science and technology. On the other hand, if one makes the effort to bring the individually valid patent classifications together with technical know-how, and to chain together different patent data records for the appropriate historical sequences, assembled patent statistics can be established for the whole period. Moreover, regarding the assignment of priority years prior to 1969, these must be established according to the reference system of the individual patent authority.

Considering global patent activities in Germany (Fig. 8), an obvious difference is found between the dynamics of chronological inventions and that of scientific activities (publication statistics). The strongest growth on a low level takes place from 1820 to the foundation of the German Empire; the total growth rate for German regions is shown to be constant with the setback due to the war of 1870/1871. Following the introduction of the countrywide German patent act, the number of applications and grants rose rapidly within a few years, and continued growing at a constant rate, which, although on a considerably higher level, is lower compared with that of the period preceding 1870. This growth, which had lasted for almost one century, was abruptly stopped by the First World War, the annual patent production being halved. From approximately 1920 to 2000, an eventual development pattern nevertheless shows nearly zero growth. During almost a century, the number of annual patent applications is approximately 50,000 to 60,000. Nevertheless, German patent productivity per person reaches one of the highest degrees in comparison with the United States, Japan, and the European Union.

Diverging from this rough rule, growth is observed during the Weimar Republic phase until the beginning of the Third Reich, followed by an immense setback during the Second World War, which is distinctly more serious than that of the First World War, and a return to the secular quota by approximately 1960. Another boom follows until 1975 when a deep recession takes place, which is only overcome in the mid-1990s.

No investigation has yet discovered whether these growth cycles have *only* economic causes. The economic boom after the foundation of the Empire is well-known (Ziegler, 2000, p. 201); the same is true for the serious recession following the oil crisis in 1973 straight after the economic miracle. The question remains as to whether the reduction of innovation activities at the beginning of the Third Reich was only due to economic reasons or to a modified practice of patenting (for example by stronger observance of secrecy due to the early war economy, by expulsion or migration of Jewish scientists). Further, the question is asked as to why the growing R&D budgets granted after the Second World War did not lead to an increase in patent activities. Obviously this decrease of patent efficiency is due to an economic calculation, which is not exclusively driven by R&D inputs.

Figure 8. Development of patent applications from 1812 to the present.

Up to now, global indications have been made about patent documents of national and international actors. By *international actor* it is understood that either the inventors' residence or the applying company is located abroad. From 1881 to 1913, the share of foreign patent grants was extremely high showing an average of 35%: until 1933, Germany's reputation as the leading scientific country attracted many young scientists from abroad. Especially Americans who came to the German Empire in order to benefit from practice-oriented education for their degree, and possibly even to experience some years of active industrial research (Erker, 1990; Smith, 1990). After the First World War and the efforts to achieve self-sufficiency in the 1930s, the share of foreigners was reduced to almost 10% but remained a significant figure in spite of all war speculations. Since the reconstruction of the German patent administration following the Second World War, the share of foreign patent grants has constantly increased reaching more than 60% at this so-called globalization time.

Although most patent applications originate from industry, universities and other public research institutions are increasingly also involved in patent production. This can be linked to their stronger orientation towards applied research, as well as to their acceptance of outside resources from private industry. Prior to the reunification in 1990, universities attained a share of 3% of all West German patent applications, which grew to more than 4% after reunification. Similar contributions are shown by all other public research institutions and companies, above all the Helmholtz Association (big national labs) and the Fraunhofer Institutes. In view of their limited human resources the patent productivity especially of the Fraunhofer Society must be more highly evaluated than that of universities (Schmoch et al., 2000).

Compared with Western conditions, certain deviations in the patent law conditions of the *former GDR* were ruled by the socialist spirit of ownership. Consequently, the national patent applications at the former GDR Authority of Invention and Patent Administration (AfEP) can hardly be compared with those submitted in the West (Hinze & Grupp, 1995, p. 42 onwards). Therefore, another method was chosen for this analysis, which is now based on GDR patent activities in the West-European foreign countries. With the help of this method all the particularities related to patent law specifications are circumvented, enabling comparison with Western countries. GDR inventors were mostly interested in the economic market of the former Federal Republic, so that the foreign applications submitted for this target market can be referred to (independently of whether the application was submitted to the German Patent and Trademark Office, to the European Patent Office, or to the International Patent Authority WIPO designating the Federal Republic of Germany).

The basic framework conditions for GDR activities in view of industrial property rights are fixed in the *patent law* of 6 September 1950 (Albrecht et al., 1991, p. 4). Nevertheless, GDR patent activities according to Western legislation are hard to ascertain during the first years. This is linked to the various forms of recognition of the GDR as an autonomous state by different nations. Some GDR inventors operated from Federal Republic addresses. In spite of these imponderabilities, an increase in patent activities by GDR inventors is seen until approximately 1983/1984. Then the figures are characterized by stagnation, and since 1987 they have been decreasing. The same tendency is shown on a higher level by national patent applications in the German Democratic Republic, so that the *drop* of innovation activities prior to reunification is undoubtedly proved (Hinze & Grupp, same paper, p. 47). The causal and significant explanation of this development is the fact that since 1981 the share of R&D personnel in the economic sector of the GDR had continuously declined, and financial resources for R&D in the economic sector were also reduced.

A comparison of the *specialization* of GDR patent portfolios with those of West Germany is very interesting. According to a division of the whole GDR technology area into 28 fields, particular strength is found in the fields of paper and print, textiles, machine-tool manufacture, handling, optical instruments, and metrology. Distinct weakness is shown in the fields of chemistry, electrical technology and electronics, information technology, as well as traffic and transportation. This specialization profile was constant over time. In particular, the eastern regions' patent profile of the 1990s (including East Berlin) corresponds largely with that of the GDR of the 1980s (Schmoch & Saß, 2000). In addition, there is an amazing correlation with that of West Germany. In spite of completely different economic conditions (Stolper et al., 1964), large fields of technology show a *correspondence* between East and West Germany until reunification (Grupp & Schmoch, 1992, p. 118 onwards). This was also found for the area of basic research (publication statistics) and explained by path dependencies and *persistent* structures in both parts of Germany despite their different political regimes (see above). Since reunification, the new federal regions have expanded their top level technology (semi-conductors, biotechnology, surface technology) starting from a low level.

Consequently, the question is whether a similar influence of scientific development on technology can be found in both parts of Germany. An evaluation of the *scientific dependency of technology* is usually based on the fact that patent specifications include replies to former inventions in the form of citations to patent documents. If an invention is directly based on *science*, which was published but not patented, the patent examiners annotate references to the corre-

sponding scientific *literature*. It could be shown that the frequency of such scientific hints included in patent specifications is a valid measure of the dependency on science inherent in a field of technology (Grupp & Schmoch, *loc. cit.*).

Regarding the degree to which technology was based on science, the German Democratic Republic remained constantly behind the *world average*. Although the same is true for West Germany, the gap was distinctly smaller. During the 1980s, both West and East Germany significantly increased their orientation to science-based technology—the GDR on a lower level, West Germany showing a reduced growth rate. Comparison between the two countries is interesting in that the East–West distance was reduced in this concern.

When Germany was reunified in 1990, two almost identically *specialized* technology systems came together. It was not possible to integrate the strength of one side and the weakness of the other one; instead, the fields characterized by strength were the same on both sides and the weaker fields were equally neglected.

The limited use of science by GDR technology is clear in international comparison; the same is true for the Federal Republic, however, on a different level. In view of the extended scientific activities, which were most significant in proportion to the size of the GDR, it is surprising to find that technological development did not benefit there from the use of science and therefore, remained on a relatively science-poor level.

Sectorial Innovation Systems: Electrical Technology and Chemistry

So far, the *national* German innovation activities were analyzed in the varying territories. In the framework of this chapter, it is not possible to consider all the university and industrial sectors individually. Therefore, sectorial analysis of the two areas *chemistry* and *electrical technology* will be presented as representative studies. In literature, chemistry and electrical technology are considered perfect examples of the science-based industries, which came into existence in the second half of the 19th century. These industries are characterized by a rapid transfer of research results to production. Due to the intense exchange activities on both sides one can also talk of ‘industry-based science’ (König, 1995, p. 283), since science probably benefits more from industry than inversely in certain phases (e.g. in the case of the newly emerging academic electrical engineering).

Another motive for the choice of these two specific sectors is the power of innovation in German industry *today*, which, roughly speaking, is considered as contrary: chemistry with its brilliant innovation and export performance compares with international standards, and electrical technology (or its sub-sumption into information technology) is considered as a weak point in the German economy. According to our thesis,

an exemplary analysis of these two sectors within the national German innovation system should reveal essential facts to explain their different characters at the *end* of the 20th century.

Sectorial Expenditure for Science

Statistics on science expenditure until 1945 include a classification by *sectors*. However, only science and engineering are identified in totals, so that these data records cannot be used for the study of electrical technology and chemistry. The establishment of a data base with sufficient capacity from an institutional level (ministries, universities, etc.) also seems impossible. This has remained unchanged since the Second World War. However, personnel figures from universities are available for selected years in both chemistry and electrical technology.

Development of Scientific Activities

At first, the publication history of the two selected areas, electrical technology and chemistry, will be summarized. Another problem remains, the tracking of publication activities in the fields of electrical technology and chemistry prior to 1974, the period for which no online data base is available. To resolve this problem, the corresponding monographs were submitted to manual analyses, which made the period from approximately 1924 onwards accessible. Due to the existence of backup periods outlasting the year 1974, the manually obtained figures can be extrapolated to the database level. First analyses support the earlier hypothesis: during the 1960s and 1970s, the growth of publication activities of chemistry was higher than in later periods, so that a synchronism of scientific publication activities and the economic success of mass chemistry (base) could be confirmed.

An extension of the historical period shows rapid growth of publication activities in the field of electrical technology since the 1950s, reaching its peak from the middle to the end of the 1960s, then again in the mid-1970s. This development is followed by a decrease of publications to reach a relative low level in 1981, then followed by another period of growth. Consequently, the present study of data records is substantially supported and completed by manual tracking up to the Weimar Republic. The manual method probably has an even higher explanatory power, since the continuous completion of inventory data records could lead to artefacts, which cannot be recognized and erased during analysis. Although the SCI strives for transparency with the selection procedures of periodicals entering the database, quantitative conclusions for individual subjects are not always possible (Testa, 1997).

Publication activities in the fields of electrical technology and chemistry show interesting subject-specific deviations from the average trends of

German publications

Figure 9. Development of publications in the fields of electrical technology and chemistry, from 1924 to 1999 (early figures extrapolated).

publication activities in all scientific disciplines in Germany. In contrast to the upward development shown by electrical technology prior to, and following, reunification, which takes an anti-cyclical course compared with global publication activities, the growth of publication activities in chemistry is reduced synchronously with the publication activities in all scientific fields in the middle of the 1970s. Presumably the anti-cyclical development of publication activities in the area of chemistry can be linked to the division of basic material chemistry into specialized and fine chemistry which took place in the 1970s, followed by biotechnology. The anti-cyclic boom of publication activities in the area of electrical technology could be linked to the appearance of present information and communication technology, and could be interpreted as its scientific predecessor. First analyses of the development of R&D expenditure in chemistry and electrical technology industries support this thesis.

Industrial R&D Expenditure and R&D Personnel

In the scope of investigations about industrial R&D expenditure, special attention was given to the two industrial branches selected in this analysis. In the fields of chemistry and electrical technology, a small sample of large industrial companies could be personally interviewed regarding the existence of corresponding data records. Sometimes the relevant archives could be accessed. The corresponding indus-

trial federations were involved. Interesting series of figures are available to the federations, however, no figures were found regarding R&D expenditure or R&D personnel. In contrast to this, time series can be found about the status of memberships, about lectures and others.

Comprehensive archive material concerning the number of chemists and physicists is also available from the successor organizations of IG Farben such as BASF. These indications correlate strikingly with the patents held by these companies; the hypothesis according to which a lack of input figures can be substituted by patent statistics is thus supported. Besides this, employment figures of other technical professions can be constructed. A comparison between the total number of chemists employed by BASF, Hoechst and Bayer, and the chemists employed by universities and technological universities (cf. Pfetsch, 1974, p. 158), shows that, since approximately 1880, the contribution of industry can no longer be ignored. Prior to the foundation of the Empire, only a single-digit percentage of all chemists were employed by industry; equality was already reached in 1885, and in 1890 the number of industrial personnel exceeded that of the university staff. Prior to the beginning of the First World War, the three companies employed already three times as many chemists as German universities.

Seen from a quantitative point of view, it is found that even prior to the First World War industrial R&D

efforts parallel to public engagement could *not* be neglected either.

The most important German companies in the electrical technology branch were recorded on the basis of the list of patents granted in 1928, which was established by the German Empire Patent Office (in total 1,121 patents, classified by companies). According to this record, the contribution to patents in the area of electrical technology was 20% by the leading company Siemens-Schuckert-Werke, 15% by AEG, 9% by Siemens und Halske, and 5% by the subsidiary of the latter, Telefunken. However, the *large scale* to which electrical technology was embodied in the German economy during this period is shown by the fact that the ten most important patent assignees produced only little more than 60% of all patents; almost 40% is accounted for by other companies. Such a limited degree of concentration means that it would be almost hopeless to register complete R&D input figures by individually interviewing all companies of this branch. Since only 80% of all patents are attained by the total of the 50 most 'patent-active' companies so that the number of 'patent-active' companies, which were also involved in R&D, could have exceeded 100 according to a rough estimate.⁹

The number of scientists employed in research institutes by the above-mentioned large companies can also be ascertained; however, no indications about monetary expenditure for R&D are found in the business reports. Even the annuals of the research institutes were not informative. In the area of electrical technology it seems *almost impossible* to take an inventory of relevant R&D input indicators, covering both the broad industry structure and the corresponding period of time. However, as in the case of chemistry, a study based on a selection of companies could be carried out to find a possible correlation between personnel data and patent data. In any case, statistics on patents will serve as a significant method of investigation.

Development of Sectorial Invention Activities

Due to very detailed patent classifications, the inventory of patents in the area of electrical technology and chemistry can be recorded. Although partly contestable delimitations are necessary for this investigation, these can be documented; moreover, a study based on different delimitations is possible.

It is shown that high-voltage technology (electricity, electrical energy) and low-voltage technology (audio-visual technology and telecommunications or communication engineering) as parts of electrical technology can be divided for the whole time. On an

analytical level, a strong growth of high-voltage engineering is shown since approximately 1900 (the more modern subject in times of electrification), as well as its stagnation after 1950, whereas low-voltage engineering shows moderate growth until 1944, and becomes stronger after 1950 (Fig. 10).

In total, the very different development dynamics are reflected in global statistics by a 4% share of all German patents held by electrical technology until approximately the turn of the century; then the share shows an almost exponential growth to more than 20% during the Second World War (Fig. 11). In spite of an increased growth of low-voltage engineering, the sum of patent shares is reduced from almost 20% (1958) to approximately 13% (1998); this is in accordance with the internationally common image of a lack of specialization in the area of German information technology.

Already at the point of departure of the observation period, *chemistry* had achieved a patent share of 10% which remained quasi unchanged until 1945 (except for short-term cyclical fluctuations in a few years). During the period of reconstruction after World War II, the number of patents in the area of chemistry increased reaching more than 20%, but was hit by a severe crisis following 1967. Since approximately 1970—the proportion had dropped to less than 10%—the share of the total number of patents held showed moderate growth of approximately 12%. These high shares of national patent inventory reveal that the fields of electrical engineering and chemistry were and remain *leading industrial sectors*. They show above-average expansion, and their global economic importance is characterized by continuous growth (Ziegler, 2000, p. 240).

Analogous with electrical technology, chemistry can also be divided into patent-statistical classifications (for example organic chemistry, plastics, pharmaceutical substances, biochemistry, detergents and agrarian chemistry). Innovation activities in these six fields show extremely different degrees of development. Both of the first two fields show a continuous increase in the total number of chemistry patents (in spite of cyclical difference in detail), whereas the remaining category 'other fields', which was very significant from approximately 1880, started to grow from about 1970. This only points to different definitions concerning 'other fields'.

An attempt to subdivide the smaller fields of chemistry (the so-called 'other fields') shows the spectacular development of biochemistry and its high share of the total number of chemistry patent applications prior to the turn of the century. This surprising development is explained by a comparison of patent classes included in the definition of *biochemistry* in the years 1900 and 1998: according to our definition, *biochemistry* was dedicated to the food industry in 1900. Between the turn of the century and

⁹ In 1928, 358 member companies were registered in the central association of electrical technology and electrical industry (Zentralverband Elektrotechnik und Elektroindustrie ZVEI).

Figure 10. Moving average line of the first publications of national patent applications submitted to the German or European Patent Office (with destination Germany).

Figure 11. Share of the total patent publications about national patent applications held by electrical technology and chemistry (for Patent Offices and averaging cf. Fig. 10).

the First World War, the food industry based on biochemistry reached its peak: living organisms were used in the most varied ways. At that time, biotechnological procedures competed with chemical-synthetic procedures in the field of production.

According to Marschall (1999, p. 280), prior to the First World War a 'path dependency' arose in German chemistry, which supported the evolutionary choice for chemical synthesis. This path dependency was based on subsidized investments in high pressure technology, as well as on its use by the chemical industry. Therefore, inventions in biochemistry were repressed. Nevertheless, it must be noted that brewing beer accounted for almost 50% of all inventions in the area of biochemistry around 1900 (only a few percent today), whereas second place was held by the extraction, refining and conservation of fat (today, also only a few percent). In 1998, however, the dominating area includes devices for enzymology or microbiology, second place is held by microorganisms or enzymes.

The difference between electrical technology and chemistry also comes from the significance of foreign inventors. According to the same criteria as above, patents can also be classified in correspondence with their *country of origin*. The results show that more important foreign inventions were realized in the area of electrical technology than in chemistry. The proportion of foreign inventors in the area of electrical technology corresponds approximately with the average of all technical areas; i.e. it regressed from more than 35% (1902) to approximately 20% by 1928 and to 10% by 1942. In the area of chemistry, the situation is different: foreign inventors always played a minor role (1902, 20%), however, this quota was slightly reduced (1942, 13%).

Regarding the historical statistics of the selected sectors, it is concluded that, under conditions of a relatively low level of knowledge exchange with foreign countries, a branch suffers less from periods of crises and autarchy and that, on the other hand, intense knowledge exchange with foreign countries leads to correspondingly sensible change. This will certainly have important effects on the organization of innovation activities which should be analyzed on the level of individual institutions (companies as well as research institutes).

The patent statistics of the *German Democratic Republic* can also be divided both on a technical and on an institutional level. For example, studies exist showing to what extent the Humboldt university of East Berlin applied for patents in the areas of chemistry and electrical technology. According to this, chemistry had become one of the most prominent research areas of the GDR in approximately 1990, whereas, electrical technology lost significance (Albrecht et al., 1991, p. 107). Identical analyses were submitted for central institutes, other centers and companies (*loc cit.*, Hinze & Grupp, 1995, p. 59). The

function of universities in view of technological development was very important not only for West Germany but also in the GDR.

Discussion and Conclusions

The view back into historical times of innovation reveals many interesting perspectives: for instance the present globalization trends in R&D may now be interpreted as a renaissance of the times around 1900: before the autarky and war situations in national socialist Germany the innovation system was internationalized in a similar way as today but possibly not to the same quantitative extent. Yet, at present, the logistic and travel possibilities for exchange of knowledge are much better than hundred years ago.

Most astonishingly, the German innovation system was very *stable*, although it witnessed several political system changes in the past century. The total amount of government spending on science and innovation followed similar quantitative tracks after its formation in the 19th century, the First World War and after the Second World War. The respective central power was not a strong pillar in science and technology. Contrary, the science and technology operation was maintained and was always reconstructed by the German states before the central power found ways to establish itself as dominating. However, considerable differences are observed when regarding the strong role of enterprises on innovation after the Second World War, which was—in pecuniar terms—not as visible before. Only after reunification in 1990, the acting power was the federal government at a time when enterprises were largely dominating the financing of R&D. This was definitely different hundred years ago.

In terms of the basic sectorial structures in science and technology, the strong and the weak sides were almost the same whatever regime and territorial boundaries existed. This *persistence* of the innovation system points to a *resistant innovation culture* in and around Germany, which may not be influenced too much by external shocks or incentives, be it in monetary or institutional form. If technology and innovation policy intends to change the German innovation culture in its basics, one probably needs other government methods than those being used up to today. Even the isolation of the former GDR and its subjection under the communist regime could not change much.

There seems to be a specific German understanding of the opening and prosecution of technology trajectories. The industrial research system in Germany was one of the first in the world to be formed and developed. Other countries followed that pattern more or less closely. Yet the subjects of research seemed to be different between the countries and remained largely constant over long periods. Obviously the technical and scientific elites in Germany succeeded to follow their interests in any political system col-

Figure 12. A selection of patent shares of the whole field of chemistry (for sources and averaging cf. Fig. 10).

Figure 13. Breakdown of the 'other fields' in the total number of patent publications in the area of chemistry (for sources and averaging cf. Fig. 10).

Figure 14. Breakup of patent shares within biochemistry in 1900 and 1998.

lectively. For the research and education policy this means that soft factors like group identity, schools of thought and personal exchange are more reliable and more efficient government instruments than the traditionally monetary incentive systems. This sustainable culture imprint can only be analyzed and detected in historical time series.

Innovation is no 'reality' whatsoever, and it is not considered as existent 'in themselves'; instead, innovation activities are only constituted by the specific method of scientific approach. An historical object of investigation about innovation activities is not 'given', instead, it is 'imposed' on the researcher, i.e. he or she must establish a measurement concept. An operationalization considered as ideal could lead to an exorbitant cost of collection, whereas, a less adequate method could have favorable effects on both the process and the results of measurement. This applies particularly to evolutionary innovation research, where results are not always shown by a formal mathematical model. Here, the keyword of an 'appreciative' theory was created. Based on such an approach, absolutely no immediate, constituent measuring directives can be derived either. Consequently, the task of adequation is the construction of corresponding indicators for insufficient 'tailor-made' theoretical constructs. Although this procedure could be considered wearisome, there is no other option.

The suggested range of indicators on a national or sectorial level gives a detailed impression of both the extent and the contents of innovation activities during more than the past hundred years. The empirical base, which evolutionary researchers interested in innovation and economic history-related questions can rely on, was broadened to a large extent, so that there is no longer the possibility of a serious *empirical gap*. On the one hand, many of the questions raised by evolutionary theory cannot yet be studied on an empirical level. On the other hand, however, the inverse fact is equally correct: empirical findings have become available discovering structures, which could be picked up by the theoretical side for further construction of the theoretical thought.

On the future research agenda there should be many more such studies of innovation systems. The basic findings for Germany should be compared to other countries, which possibly suffered less from territorial and political changes. The data used in this chapter should exist in other countries as well, and maybe brought to the surface. Also, we need more sectoral studies in order to work out typologies of innovation development over long periods. Altogether results achieved so far should encourage more cliometric research all over the world.

Frankenstein Futures? German and British Biotechnology Compared

Rebecca Harding

The Work Foundation, U.K.

Abstract: This chapter compares and contrasts the market based biotechnology policies of the United Kingdom with the regionally engineered biotechnology policies of Germany in the light of the national and regional systems of innovation literature. It shows that innovation systems generally and regional innovation systems in particular are still useful concepts in explaining the clustering of biotechnology. It compares regional clusters in the two countries and argues that German policy has been particularly successful in stimulating rapid catch-up with U.K. and global levels of biotechnology research.

Keywords: National systems of innovation; Biotechnology policy; University-industry links; Clusters; Entrepreneurship.

Introduction

Of all the areas of innovation policy within a government's remit, the area of biotechnology may seem the least obvious as a focus for an Anglo-German comparison to a lay audience. To begin with, the whole area of biotechnology is fraught with ethical difficulties, not least because biotechnology is often seen as synonymous with 'Frankenstein' pictures of chickens without feathers, or mice with ears grotesquely sprouting from their backs. Second, although at an individual level people can clearly see the link between genetic research and their own health prospects, other areas of biotechnology, for example agricultural biotechnology, have less obvious benefits either to society or to the economy. And finally, for all the millions that have been poured into biotechnology across the world, and the fact that biotechnology accounts for 41% of all world wide patents (ZEW, 20002), there is still no long term 'cure' for cancer, no end to world poverty and hunger, and indeed, very few profitable biotechnology companies providing employment in their regional or local communities.

This chapter is an attempt to answer the question as to why governments across the world commit so many resources to biotechnology by comparing German and British policy development over the ten year period since 1992. Much of this policy has been predicated upon a belief that European countries are 'behind' the U.S. in biotechnology and that audacious measures

need to be taken to ensure that we 'catch up' with the performance of the United States economy. Policy makers across Europe have admired the strong university-industry links in the U.S. around bio-medical research, have seen the impressive biotechnology 'clusters' of entrepreneurial start-ups and research spin-outs, venture capital, specialist support services and large pharmaceutical companies around leading U.S. universities, and have tried to mimic these structures in their countries. At an EU level the whole area of biotechnology and research-led innovation and entrepreneurship was central to the Lisbon Summit's 2000 agenda.

To a large extent, much of this policy was based on evidence from the United States throughout the 1990s that research-led entrepreneurship generally would lead automatically to increases in productivity and, hence, economic growth. Europe has a productivity gap with the U.S. and studies of innovation would suggest that, by addressing the 'innovation gap' this would be closed (Fagerberg, 1987; Freeman, 1995; Lundvall et al., 1992) and, inevitably, higher employment and wealth generation would follow (Bygrave, Camp, Hay & Reynolds, 1998).

For most people, however, the interest in biotechnology may still seem perplexing. 'Why', puzzled a senior U.K. trade unionist during an interview, 'does the government want to pour money into science? How on earth can a few professors with test tubes and

microscopes create jobs?' Given the furore surrounding genetically modified foods, alongside the highly specialized and skilled types of employment that new biotechnology firms create, this question is quite justified and it is the aim of this paper to address that issue by means of an Anglo-German comparison.

The chapter is constructed as follows. It first looks at the features of a specifically Anglo-German comparison and argues that, as the countries with the most highly developed biotechnology structures in Europe, as well as quite distinctive policy structures, they are interesting cases in their own rights. The chapter goes on to examine some of the literature that has informed policy towards biotechnology. By examining the literature on national, regional and sectoral systems of innovation in particular, the specific mechanisms that policy makers in each country have employed can be evaluated. Of course, in the end the real way in which the success of any policy to stimulate or redirect the focus of a national or regional innovation system rests on the effectiveness with which the sustainability of any changes can be measured. The next section takes the discussion of innovation systems on to examine the unique characteristics of biotechnology allowing a further layer to the understanding of policy instruments. It is argued that the real reason why biotechnology has formed such a central part of government science policy in both countries is because of the intrinsic regional and 'clustered' nature of the industry that allows it to fit neatly alongside existing programmes for regional regeneration and economic growth.

The chapter then goes on to look at policy structures in the two countries in terms of basic expenditure on research and development and policies to stimulate private sector involvement, commercialization and clustering. It constructs a map of policies in the two countries and highlights the strong regional dimension to policy in both countries. The section concludes by pulling together the literature search and the overview of policy to highlight the key 'critical success framework' in each country.

The next section uses the critical success framework to examine documentary and attitudinal evidence in the two countries. It looks first at the evidence in terms of clustering effects (large companies, business angel activity, specialized consultancies and venture capital firms) and goes on to examine attitudes towards university-industry links and academic venturing in the area of biotechnology.

The chapter concludes by attempting to answer the question, 'why bother with biotech?' It argues that biotechnology is a central part of any government's science strategy. European policy makers do need to ensure that we do not fall behind the U.S. either in research or in commercialization for the simple reason that a national monopoly over one particular aspect of scientific endeavor would distort future competitive-

ness as and when commercial biotechnology products become part of everyday life in the way that computers have. Further, there is evidence from the Anglo-German comparison that jobs are created through a strong biotechnology policy and that this leads to a strong sense of regional renewal around science-based industry. However, the critical stage in a biotechnology company's development comes when it is moving from a largely public sector supported, research and prototype base to actual commercialization and sustainable growth. The issue of how to manage this process effectively both at the level of the individual firm and at the level of policy is not clearly understood and there is scope for more research in this area.

Why an Anglo-German comparison?

Britain and Germany represent interesting cases within this wider European effort to catch up with United States. They have, respectively, the largest and the second largest biotechnology sectors in Europe. Both have strong regional biotechnology clusters around world class universities and both countries invest the largest amounts in Europe of private and public sector money in biotechnology. Their biotechnology policies at a government level are strongly supportive of establishing and developing robust biotechnology research and, accordingly have the most policy and infrastructural attributes that are either supportive or strongly supportive of biotechnology (for example, risk capital, public sector support for R&D etc.) (Senker et al., 2001).

What makes the comparison especially interesting, however, is the way in which the two countries have moved towards this position during the last decade. Britain's biotechnology sector is strongly established and has emerged out of high quality research and strong commercial involvement in that research in and around the Cambridge area in particular. Awareness of the significance of biotechnology as a scientific area was first raised in the 1970s and 1980s by a government-commissioned report and subsequent policy sought to increase general awareness, particularly amongst private sector companies about its potential. Government policy has worked over the last five years to extend the cluster-based activity beyond Cambridge to other regions of the U.K. Thus, for example, policies like University Challenge and the Higher Education Innovation Fund have attempted to stimulate the flow of seed corn finance to university research-based spin-outs and encourage academic entrepreneurship generally and, as a corollary, biotechnology in particular.

In contrast, Germany's biotechnology sector was substantially less developed than U.K. or U.S. biotechnology at the beginning of the 1990s. Although the capacity to audit trends in biotechnology did exist within the Fraunhofer Society's technology foresight program, Delphi, research activity was limited to three

Gene Research Centres at Cologne, Heidelberg and Munich. Real awareness of the importance of biotechnology as an area of research and commercial activity did not really become widespread until the latter half of the 1980s (Wörner et al., 2000). Historically-based mistrust of biotechnology because of its association with genetic manipulation and legal restrictions on R&D in this area contributed significantly to its relatively backward stage of development in comparison to the U.K. in the early 1990s (Harding, 1999, 2001). With the amendment of the Genetic Engineering Act in 1993, the legal barriers to biotechnology research were removed. The subsequent government-led BioRegio program was set up in 1995 and has arguably been a central driver behind the development of a systematic and positive approach to biotechnology research and commercialization. It was supported by a strong commitment at a policy level to increasing funds for basic research in biotechnology.

The two countries provide examples of two different approaches to the development of biotechnology then. Both countries have marked similarities according to Senker et al. (2001). For example:

- both have favorable knowledge and skills regimes and strong science bases with an active emphasis on technology transfer between the research base and commercial application;
- both have strong multinationals operating in the pharmaceuticals and chemicals areas;
- in both countries the public is generally positive about biopharmaceutical research and development although more wary of the application of biotechnology techniques such as genetic modification in the agro-food areas.

Yet in the U.K. the structures are largely market led. Policy works to *facilitate* market operations where any gaps are apparent, for example in funding or in research and development. In Germany, biotechnology as a legitimate area of scientific investigation and of commercial enterprise has been developed to a significant extent by policy effort to *create* markets where none existed. This has been done through support for research network development and for biotechnology start-up finance.

There is one final way in which the different policy perspectives is interesting as an area of examination. Within the economic literature comparing and contrasting German and British economic performance there is a tendency to characterize the two economies at different ends of a management spectrum. The British economy is seen as exemplifying the 'Anglo-Saxon' model of market-based flexibility and radical innovation-led growth while the much more rigid, structured

and ponderous Rhineland-Capitalist model, of which the German economy is viewed as paradigmatic, is reported to be far less successful in creating structures that support and sustain radical innovation led development (see, for example, Soskice, 1996). Entrepreneurship generally is a test case of this polemic approach to analysis since, by definition, it would be more dominant and more widespread as an expression of labor market activity. Bio-entrepreneurship as a particular case is interesting as it combines both the requirement for radical innovation and regulatory flexibility, especially in labor markets, in order for it to be able to thrive.

Against this background, then, Germany would seem on the face of it to be at a disadvantage. Its labor market inflexibility is well documented (Funk, 2000, 2001) and, arguably manifests itself in the rigidly high levels of unemployment that the economy is currently experiencing. Further, some economists have noted that the German economy has a tendency to produce incremental innovations rather than the radical paradigm shifting innovations that characterize the U.S. or the U.K. economy (Casper et al., 2000; Hall & Soskice 2001; Soskice, 1996). Germany would apparently have a comparative disadvantage in biotechnology innovation, then because of these two structural weaknesses.

The evidence does not support this as a hypothesis, however. In 1995 German policy makers set themselves the target of overtaking the U.K. as the leading country in Europe for biotechnology start-ups. By 2001 it had achieved this with 332 Core Entrepreneurial Life Science Companies (ELISCO's) (BioM, 2002) compared to the U.K.'s 250 (www.dti.gov.uk). Also, although the U.K.'s bioscience sector, including all biotechnology companies, remains larger in terms of longer-established firms and, hence, total turnover, the absolute size of the German industry in terms of the number of firms is marginally bigger at 465 compared to the U.K.'s 450. German biotechnology now accounts for the third highest number of patents per employee in the world after the U.S. and Japan. And finally, in terms of levels of total entrepreneurial activity (TEA) and, indeed, attitudes towards entrepreneurship, Germany and the U.K. are remarkably similar (Harding, 2002; Reynolds et al., 2002; Sternberg & Bergmann, 2002).

Much of the development in Germany is still embryonic—it has a much larger number of start-up companies established for less than three years, for example, where in the U.K. the biotechnology sector is more established. However, the sheer pace with which Germany has caught up in terms of biotechnology research and entrepreneurship warrants further investigation in its own right as it arguably represents an extension of the base of the 'business system' to incorporate this type of activity and, hence, to allow its industrial structures to adapt (Casper, 2000).

Why Support Biotechnology?

The Financing Gap

Within the context of the whole European biotechnology sector and its comparison with the more advanced state of its counterpart in the U.S., the U.K. and Germany are big players with the largest and second largest number of firms respectively. However, the European market is still substantially underdeveloped, heavily reliant on independent start-up firms and with a relative under-representation of university spin-outs. The risk capital market is still weak with less than 3% of total venture capital investment across the whole of Europe going to biotechnology ventures and less than 1% going towards biotechnology in the U.K.

The financing gap for biotechnology is illustrated in Table 1. In simple terms, potential investors see biotechnology as risky. Biotechnology is research intensive and this is expensive. Thus the amounts of money required even to prove that a concept is viable (let alone commercializable) are very high. It can take anything between ten and twenty years to get to the stage clinical trials have been completed and the development of a commercially viable product at the end of this is by no means assured. Indeed, it has been estimated that for every 100 biotechnology research ideas, only one is likely to have any commercial potential at all (Harding & Lissenburgh, 2000). This means that the risks faced by potential investors are high relative to the rate of return within the 'normal' lifespan of a venture capital investment (where exit is usually planned within three to five years). This manifests itself in a clear under-representation in biotechnology financing relative to total equity financing.

Table 1 clearly shows that, as a proportion of total investment, or even of total high technology investment, biotechnology is a poor relation. Amounts invested across the whole of Europe have remained relatively static since 1996, while total investment has gone up by nearly five times, high-tech investment has nearly doubled and seed and start up investment for all sectors has almost trebled. The EVCA reports that in Germany total investment in biotechnology rose between 2000 and 2001 and in the U.K. they fell over the same period. Across the whole of Europe the trend

for biotechnology investments was downwards, although the level of investment still remains slightly higher than in 1999.

Table 2 looks at the relative structures of venture capital in Germany and Britain and compares it to the EU average.

The table shows quite clearly the different foci of the German and the British venture capital industry. In Britain, investments are heavily focused at the large scale end of the market with management buy-outs (MBOs) and management buy ins (MBIs) comprising the majority of venture capital funding irrespective of sector. In Germany the seed and early stages of start up development account for higher levels of investment than in the U.K. and are substantially higher than the European average. The industrial sectors which attract substantial investment focuses are biotechnology and ICT while in the U.K. the sectors tend to be much more general and not science based.

The reason for this difference in financing focus is arguably because of the different policy emphases in the two countries (for further discussion of this, see Harding, 2001). In Germany, enterprise and innovation policy generally has concentrated on stimulating industrial systems and networks by encouraging public-private sector partnerships, technology transfer and private finance capital at a regional level. The BioRegio program is an example of this but others include the InnoRegio program for the eastern States to develop innovation structures there. In order to ensure that private sector investment has gone into biotechnology and ICT, the government has implemented a system parallel investment through the *Kreditanstalt fuer Wiederaufbau* (KfW) and the *Deutsche Ausgleichsbank* (DtA). Under this system any risk capital investment fund prioritizing early stage technology investments can construct a 'fund of funds' (broadly, a venture capital fund consisting of more than one independently managed fund) and thereby draw down on a further, proportionate, fund of money from the KfW as leverage to 25% extra investment in a specific project. Alongside this, the KfW will also provide up to a 50% guarantee on any investment made by the main 'fund of funds', thus the risk to the investor is on just 25% of the total amount invested. Clearly this acts as a major stimulus to private sector investment in riskier

Table 1. Financing gap for biotechnology.

	1996	1997	1998	1999	2000	2001
Biotech	2.70	2.60	2.40	2.60	2.90	2.65
Hi-tech	19.60	23.90	27.80	25.60	31.40	28.00
Seed and start-up	6.50	7.40	11.40	12.90	19.00	15.00
Total VC funding (m)	6,788	9,655	14,460	25,116	34,986	24,331

sectors, and the higher numbers of investors in biotechnology start-ups.

Indeed, it is this desire to mitigate the risk faced by potential biotechnology investors relative to the returns they might get that underpins much of government policy towards the financing of biotechnology entrepreneurship. There is clearly a gap between biotechnology investments and total venture capital investments as Tables 1 and 2 show. What German policy has attempted to do through the KfW and the DtA is to leverage private sector money into riskier areas of investment by guaranteeing any losses that may be made on projects that do not deliver.

That the financing gap is more acute in the U.K. is also apparent from the data presented here. The reasons for this are complex, rooted in the nature of the private equity market in the U.K. (which tends to favor larger investments) and extend beyond the scope of this chapter (for further detail, see Harding, 2000, 2002a). Suffice it to say that successive research has shown U.K. investors to be averse to technology investments both in terms of the amounts of money they put in (Murray & Lott, 1995; Murray et al., 2002) and in terms of their attitudes towards technology investments (Harding, 2000).

The Knowledge Gap

Governments support biotechnology for reasons other than the finance gap, however. Biotechnology concepts are complex and heavily reliant on multi-disciplinary research teams. The research is itself expensive and need to build 'critical mass' in terms of research quantity before any of the concepts are likely to become commercializable. Once an idea with commercial potential is developed, there is still a very long time to full commercialization and many points along the route to market that might end in failure. For example, the public outcry around GM foods has presented many very large biotechnology companies

such as Monsanto with problems in terms of share price and, hence, access to further research funding. Huntingdon Life Sciences is an example of another company that, even when it appeared to be relatively successful, found difficulties in gaining further funding once public opinion swung against it.

This points to the importance of the basic research function within the 'typical' biotechnology firm. Until a product is developed, and this can take some time, the company is organized around a concept or a set of concepts that have commercial potential but that require further research in order to progress them further. This requires a strong research base and highly qualified personnel. It also means that a biotechnology company is high reliant on the research institutions (in particular universities) operating in related fields of research in close proximity.

It is this 'networked' nature of the biotechnology firm that makes it unique and that makes it an attractive vehicle for delivering government policy. The true value of the firm lies in the quality of the research team that 'own' the initial concept and their national and, critically, international research networks. Often these are groups of scientists from related disciplines who have worked together on research and often they do not have any developed knowledge of management, or even of presenting their ideas to a lay audience in an approachable manner. They will always require access to sophisticated research base (including laboratory facilities) and often require access to specialist legal, administrative and financial support as well (OECD, 2001; Sohet & Prevezer, 1996).

Biotechnology as a Policy Focus

There are clearly some factors associated with biotechnology that warrant public sector support. In particular, the above section has highlighted a financing gap and a knowledge gap (the 'personal networked' nature of activity) that mean that it cannot survive

alone. This in itself, however, may not justify the large policy emphasis that is being put on biotechnology research in all industrialized economies. In order to examine this, it is necessary to see biotechnology in the context of competitiveness in wider, science-based industries.

Biotechnology is an area of research and commercial activity is derived from the public sector research base in life sciences on the one hand and the research activities of the chemical and pharmaceutical sectors on the other. Increasingly the pharmaceutical industry is the core sector underpinning R&D in biotechnology. These pharmaceutical companies spend very high proportions of their total turnover on R&D as this is where the competitive advantage in that sector originates (Sharp, 1996).

The research intensity of the sector has increased with combinatorial chemistry (inter-disciplinary chemistry) and molecular biology now working together to develop new diagnostic and drug delivery mechanisms as well as long term gene-based solutions to diseases or, in the case of agri-environmental biotechnology, crop development. These tools and techniques are developed in-house in large company research laboratories but the risks associated with the research are high since the 'critical mass' in research effort discussed above applies equally to large companies as it does to small. As a result, brand new areas of biotechnology research, which are not likely to lead to new products or processes in the immediate future, but which may have commercial potential in the future are often strategically 'outsourced' to smaller research-based companies with strong links to research institutions in the public sector science base (Gambaradella et al., 2001; Sharp, 1996; Walsh 1997). In order that the pharmaceutical industry within a country remains competitive, it is essential that structures to support this type of activity exist.

Gambaradella et al. (2001) point to the declining competitiveness of the European pharmaceutical sector and argue that one of the core reasons for this is the underdevelopment of its networks and support infrastructures in the science-based relative to the United States. Germany and the United Kingdom are leaders in the European market, but there is still a competitive gap between them and the U.S. which is potentially extremely damaging to the future competitiveness of the whole sector. They point to the global mobility of researchers in this area since all belong to international networks of scientists and experts. Increasingly, they argue, that local 'innovation clusters' are globally competitive with one another as locations for science-based businesses and it is here that the scale of the U.S. science system as well as its links with the commercial base far exceeds that of Europe (Gambaradella et al., 2001; see also Cooke, 2001).

Biotechnology is core to the competitive success in pharmaceuticals because of this reliance on research

outsourcing and excellence in the science base. It is no one clearly defined area (Webber, 1995) and instead appeals to three major policy areas.

University-Industry Links

The first area is science policy generally and university-industry links in particular. Biotechnology requires a strong basic science research base in the life sciences if concepts or ideas with any commercial potential at all are to be developed. This means that firms tend to cluster in 'knowledge sources' (Cooke, 2002). And, since the research and commercial effort in biotechnology is so internationalized, these 'knowledge sources' compete *and* collaborate with one another nationally and globally.

This 'symbiotic tension' where research and industry compete for and collaborate in research projects but are ultimately mutually interdependent in the transfer of technology from the science base through to industrial application is well documented for the German system and regarded as a source of competitive advantage for German innovators (Harding, 2000, 2001). Gambaradella et al measure the extent and scope of networks between the public and the private sector science base for pharmaceuticals in the U.S. and Europe and argue that the concepts of competition and collaboration in technology transfer are important in understanding competitive advantage in the pharmaceutical industry (see also Cooke, 2001; Kaufmann & Todtling, 2001; Love & Roper, 2001; Senker et al., 2001). Further, the transfer of knowledge in biotechnology is tacit in nature and relies substantially on the relationships between scientists in research institutions and private sector laboratories making the spatial concentration in technology transfer at a regional level especially significant in driving the propensity to innovate (Todtling & Kaufmann, 2001; Zeller, 2001).

What policy makers in Europe generally and in Germany and Britain in particular should be aiming to stimulate in the biotechnology sector, therefore, is the development of strong university-industry research networks in the interests of enhancing their attractiveness as locations for global R&D, either by large companies or as the home of international research-based firms. This is the source of national comparative advantage in technology transfer. 'Symbiotic tension', from studies of biotechnology clusters and university-industry links, is key to understanding the viability, sustainability and competitiveness of the biotechnology sector. It is this processes that enhances the development of vibrant university-industry links nationally and, hence, that facilitates the location of international R&D in one country as opposed to another. It is no longer possible to regard the national and the global innovation system or network as independent of one another (Archibugi et al., 1999) since research is internationally mobile and will locate

around specialized centres of excellence. Policy has to ensure that research specialization is enhanced by strong university-industry networks and linkages if it is to create attractive locations for global biotechnology R&D.

Regional Policy

There is a substantial body of literature to suggest that, in a world where R&D is mobile internationally, competitive innovation advantage is generated at the regional rather than at the national level (Cantwell & Iammarino, 2000; Cooke et al., 2000; Edquist, 1997; Harding, 1999; Sachsenian, 1997). This is because technological specialization that is so critical to the symbiotic tension relationship within technology transfer is best developed at a regional level. Regional universities have scientific specialization within specific areas and resources to support that focus, any spin-out companies from university research are likely to be within the areas of scientific excellence developed within the university and large companies are more likely to locate and, hence, to transfer knowledge where such excellence exists. Learning and adaptation to changing market and technological conditions is more likely to be effective and sustainable at a regional level since tacit knowledge transfers more easily between actors in close spatial proximity with clear links to the cumulative skills and attributes of the regional labor market (Cooke et al., 2000; Dodgson, 2001; Michie & Oughton, 2001; Porter, 2000). As expertise starts to build, specialist financiers, accountants and lawyers are established to support the science base and any start-up businesses are provided with appropriate and readily accessible advice and consultancy. The evolution of this type of regional 'industrial system' is argued to go some way to explaining the development of Silicon Valley and Route 128 in the U.S. (Sachsenian, 1997).

The attractiveness of the 'cluster' approach (Porter, 1998) to policy makers is clear, especially for biotechnology. Since biotechnology research and commercial activity is interdependent with scientific and commercial networks, since tacit knowledge transfer is behind the symbiotic tension at the heart of competitive success in this industry and since firms cluster close to knowledge sources, it makes sense to operationalize biotechnology policy at a regional level. Universities, as identified above, are 'magnets' of biotechnology activity, but a true innovation system at a regional level is created for biotechnology through the combination of research hospitals and 'chains of transactions between scientists, entrepreneurs and various intermediaries including inventors and lawyers' (Cooke, 2002). Only by systematizing this set of interactions will regionally generated knowledge add value through the cumulative learning process to create the specialization that is so important to international

competitive advantage in research led sectors such as biotechnology.

Evidence suggests that such regional 'centers of excellence' or 'clusters' and their intra-regional links (both within a country and globally) are necessary preconditions for creating attractive locations for global biotechnology R&D. Interestingly, the national, regional and sectoral systems of innovation are peculiarly interdependent for biotechnology because of its knowledge intensive and research-led nature (Freeman, 2002; Gambaradella et al., 2001; Malerba, 2002; Owen-Smith et al., 2002; Senker et al., 2001). For policy makers this is a complex message—that regions are important as the point of delivery but that the sources of learning and added value actually rest in the networks that individual researchers have nationally and internationally. In other words, national science policy and regional cluster policy should be mutually reinforcing and formulated to 'promote network building among firms and other actors of a regional innovation system and to interlink these intra-regional networks with national and international knowledge sources (Koschatsky & Sternberg, 2001).

Finance Policy

Technology-based firms are both more suited to venture capital investment *and* more likely to seek venture capital investment. They require significant amounts of capital but, because their business is based on an innovation rather than a proven business concept, investments in them are inherently more risky. In theory, at least, this ought to be the domain of risk-takers and, hence, also the domain of venture capitalists. Yet the figures presented in Tables 1 and 2 above suggest that both Germany and the U.K. are behind the U.S. in terms of venture capital investments, particularly in biotechnology and this is a clear challenge for policy.

Linking venture capital with bio-innovation through policy is, at best, complicated. Yet, as one German venture capitalist argued, "Venture capital investments are for technology-based companies. I am a financier, but I have had to learn about (bio)technology—quite simply, this is where the money is". The reasons for this are as follows:

- *Returns to technology investments are high.* The Bank of England estimates average returns on technology investments to be around 23% (Bank of England, 2000). But one technology investor claimed return rates of 45% in the U.K. and rates in the U.S. are certainly higher at 33.7% (www.nvca.com). This return rate is evidence of the high growth and wealth creation potential of technology-based firms as much as evidence of their suitability for venture capital funding. Yet venture capitalists themselves will not be able to take advantage of these potential returns

unless they can be encouraged into riskier, technology-based investments.

- *The growth potential that these companies have is embedded in the value that they add to their initial concept.* All technology-based companies start with a commercially unproven innovative idea at the seed stage—this is the risk. The growth process is the cumulative ‘proof’ of the idea or concept’s commercial viability. The value at the end is the return. But, especially in science-based industries like biotechnology, this growth process requires substantial development funding. This funding can be necessary over a long period of time—as long as ten years. This is significantly longer than most venture capitalists will invest without a clearly defined exit route, thus there is a clear role for government support at the seed stage and even at the start-up stage to leverage in informal and formal venture capital.
- *The acquisition of substantial capital investments allows the technology-based firms to attract key scientists and innovators into their business.* The value of the company is embodied in the personnel that are employed within the organization. As one Dutch biotechnology fund manager said, “We don’t invest in profit, we invest in value. Biotechnology companies never make a profit but their ideas can be worth millions. One company came to us suggesting that the size of the workforce should be reduced in order to show a working profit. This would have been a disaster as we were investing in the high potential value of their scientists. That’s what we can sell on”.
- *It is important therefore that such companies can access easily the high net worth individuals that add value to an innovative concept.* This is primarily a function of the supply of such people from universities, colleges and industry. In turn, this is a function of the capacity of the education and training

system, the higher education system and the industrial system to create, develop and, critically, keep, these individuals. The role for policy here is in creating an infrastructure that creates such high value ‘human capital’ in which venture capital can invest.

- *Finally, in order that the rate of return is fully realized and venture capitalists continue to invest in technology projects, there has to be a good supply of investment opportunities for venture capitalists.* This deal flow stems from universities and colleges through academic entrepreneurs and from indigenous and overseas hi-tech companies with research capacity. Governments can do much to stimulate a culture of science and technology-based entrepreneurship through funding for basic science, significant funding for university-business partnerships, science parks, incubators and programs to stimulate high technology investments. Yet there is evidence that there is a weakness in the commercialization of science from the research base across Europe (DG-Enterprise, 2000), but in the U.K. in particular (Bank of England, 2002).

The biotechnology financing life-cycle is presented in Fig. 1.

At the seed stage of concept development, relatively small amounts of money, since much of the activity is research-based rather than commercially-driven. At this stage, the role of public sector funding of the science base is clear in order to provide adequate resources for centres of research excellence to develop.

The second, early stage, of development is where the commercial potential of a concept has been proved and a patent registered. Here there is far greater potential for private sector investors to participate. In the U.K., for example, business angels are particularly important

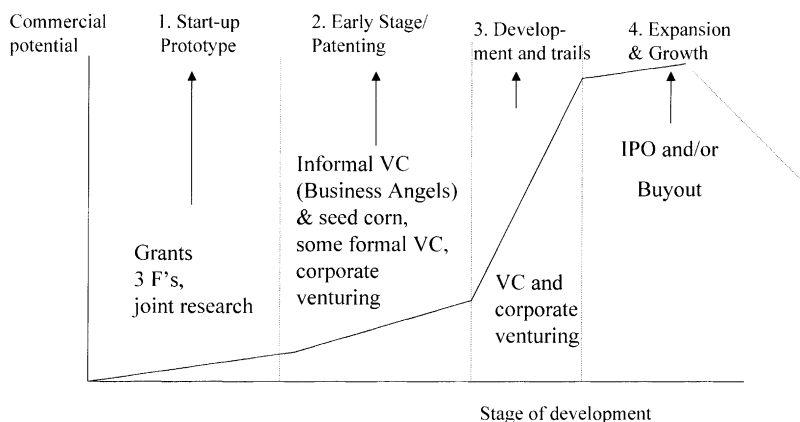

Figure 1. A biotechnology finance life cycle.

in funding biotechnology companies at this stage, while in Germany, corporate venturing (where firms fund research in return for an equity stake in the emerging business) is more common. Government guarantees for private sector investments at this stage can be used to encourage investors to take risks with biotechnology based businesses.

Corporate venturing and private equity are most important at the third, development and trials, stage of development. Here the potential for the value of the company to grow is substantial—not least because the networks and research expertise of the personnel within the company become valuable assets in their own right.

The final stage to initial public offering (IPO) or trade sale (sale to a large pharmaceutical business, for example) is the point at which the venture capitalist or private investor will exit and realize their investment.

Each stage is fraught with risks for the private investor. Biotechnology projects can fail at each stage either because insufficient research has been conducted or because the concept is not viable. Even after clinical trials (a process which can take up to ten years), there is still a risk that the route to market will be blocked by adverse or inconclusive results. And, as the example of the agri-environmental biotechnology firm Monsanto showed, if a public outcry threatens the acceptability of the product, then investments are not secure even once the company is floated on a stock exchange.

This perceived risk goes some way to explaining the reluctance of the venture capital industry to make investments in biotechnology (Murray, 1999). However, biotechnology is unique, not just in its *modus operandi* but also in the source of value in the business. This value, as stated above, rests in the people in the business. Their research and their networks are assets to potential investors, especially large pharmaceutical companies seeking to spread the risk of financing non-core but strategically important R&D. Policy has to have two strands to its approach to biotechnology financing therefore—first, to mitigate risks of private sector investors, either by providing support at the seed and early stages of development or by providing parallel investments for riskier projects, and second, to increase awareness of the inherent value in the intangible assets of the bio-business.

Implications for Analysis

The difficulty of assessing the benefits of biotechnology in its own right and of assessing the effectiveness of policy to alter national systems of innovation to stimulate developments in a particular technology or a particular area of scientific entrepreneurship rests in the ‘intangible’ nature of many of the ‘third stream’ activities that are so dominant within biotechnology. In the broadest terms these ‘third stream’ activities are the relationships between the science base and the industrial base. As such, they are extraordinarily difficult to

measure within the conventional toolbox of national systems of innovation theory.

The relationship between the science and engineering base (knowledge generation) and the institutions involved in the commercialization of science (knowledge transfer) can be co-ordinated through policy to produce an innovation system which is capable of adapting to new competitive and technological pressures. However, measuring the effectiveness of policies to develop the commercialization of science remains a challenge for academics and policy makers alike.

The role of nation state generally and of governments in particular is, as it always has been, to ensure that the institutions of industrial society and economy adapt to the pressures of any new ‘global’ or technological paradigm. It is not the change in itself that is new or, even, interesting. Thus the interesting question is not whether nation states should adapt but how.

It is the means by which institutions adapt that is key to understanding the nature of innovation generally and technology and knowledge transfer in particular (Harding, 2001). The evidence of history suggests that it is not change in itself that is interesting in the context of the path-dependent nature of innovation (Duysters & Hagedoorn, 1995). Change in itself is endemic. What is interesting, however, is the extent to which policy can influence the way and the rate at which a national system of innovation can itself change in response to the exogenous imperatives of global competitiveness. In the U.S., this has taken the form of the interdependent development of the institutions of innovation to create scientific structures that are, “less and less a matter of the independent unfolding of knowledge and more a response to technological progress in the development of a practical means to produce goods and services” (Mowery & Rosenberg, 1999). The key, then, is to establish the source of this adaptiveness within a particular system of innovation.

Within the national systems of innovation literature there are three broad categories of writers. The first largely take as their starting point the importance of relationships between institutions in the science base and indigenous industry, which, they argue can be measured and evaluated using economic/econometric methodologies. Researchers use, for example patenting statistics (Patel & Pavitt, 1994) or citation indices (Hicks et al., 1996) or industry-based matched sampling to establish both the existence and effectiveness of national systems (Mason & Wagner, 1998). The methodological approach of these authors is to narrow the ‘institutional linkages’ to quantifiable relationships between two variables. The results tend to be biased towards large firms because of the techniques used. Nevertheless this approach can:

- identify distinct national systems which, arguably, are the reason why ‘growth rates differ’ (Fagerberg, 1987);

- establish the tendency of firms in a particular country to utilize their own, domestic, science base as a source of blue sky research.

A broader methodological approach looks at national systems of innovation through the perspective of corporate governance (Casper et al., 1999; Freeman, 1995; Lundvall et al., 1992; Prajs, 1981; Soskice, 1996; Tylecote & Conessa, 1999; Vittols, 1997). This approach identifies key institutional features of national systems of innovation, for example, incentive structures, education and training, industrial relations, finance or government policies. Authors seek to establish the influences that particular aspects of the system have on the capacity of an economy to innovate often using qualitative and historical techniques. Using this approach, it is possible to isolate the key features of a 'national system' which make countries different. Thus, for example, the U.S. has particular structural strengths which mean it has advantages in radical innovation, while Germany and Japan have institutional strengths which favor incremental innovations (Soskice, 1994; Tylecote & Conesa, 1999).

A third school of writers can also be identified who take a socio-historical perspective on the reaction of national structures generally to major exogenous changes (see for example Albert, 1993; Giddens, 1998; Sorge, 1999; Zysman, 1996). Some of these authors take the change itself as the determining variable and attempt to define the features of the 'global' system, while others take as their perspective the need to understand the institutional adaptiveness of national systems of innovation. What is common amongst these authors, however, is the critique of the neo-classical economic approach to globalization—that national economic and business structures will inevitably be subsumed in a 'global' market order. Instead, these authors point to the intrinsic adaptiveness of systems. Their views on the eventual sustainability of systems are different—they range from theories of systemic convergence under the supremacy of the Anglo-Saxon model (Streek, 1997) to hybridization whereby national systems adopt and adapt eclectically aspects of models from elsewhere to suit their own structures (Lane, 1999).

The contributions made by all of these authors cannot, indeed should not, be under-played. Whatever approach is taken, unique national systems of innovation can be defined. All view NSIs from a macro institutional level and derive specific national strengths and weaknesses accordingly. This has an obvious appeal for policy makers seeking to strengthen the science base of an economy and, accordingly, 'maximize national returns for public and private investments in R&D in terms of efficiency and competitiveness' (Patel & Pavitt, 1999, p. 20). Intriguing, however, is the quite different standpoints on the sustainability of national systems that the different

methodological approaches derive. The more quantitative perspective leads to the conclusion that national systems are 'under strain' (Patel & Pavitt, 1999, p. 23). This conclusion derives from the fact that large company R&D is itself internationalizing and there is thus a discernible weakening in the links between corporate R&D and the national science base. Corporate governance and socio-historical writers, however, are often (although by no means uniformly) more optimistic about the sustainability of national or even regional systems. They regard change in itself as inevitable and see the interesting question as being how national systems are adapting (Duysters & Hagedoorn, 1996; Lane, 1999; Whitely, 1999).

That the jury is still out on the sustainability of national systems is largely a question of methodology. Arguably, the burden of proof rests with the institutional writers who stress the importance of historical processes in understanding institutional (and hence national) adaptiveness. But conversely, econometric techniques are criticized by institutional and socio-historical writers on the grounds that the narrowing down to measurable variables mitigates against a full understanding of how national systems work and, hence, adapt.

While accepting that quantitative techniques can underpin qualitative research by providing trend indicators, in order to understand the process of adaptation, it is necessary also to take as broad an institutional perspective as possible. All of the approaches summarized above tend to view national systems and institutional linkages at a macro-level. But this mitigates against a full understanding of the social mechanisms and practices by which these linkages are effected generally and by which technology transfers in particular. In order fully to comprehend this it is necessary also to examine national systems from two perspectives:

- first, a 'bottom up' approach: in other words, to examine the source of innovation within research institutes, within universities and within industry. The aim here is to establish the means by which technology transfers and, hence, to find the mechanisms through which the innovation system adapts;
- second, using a policy-interface approach: in other words, to establish the interface between policy mechanisms and the institutions of the innovation system. The aim here is to establish the role of policy in altering the rate at which the system adapts.

The research for this chapter has taken the 'bottom up' perspective to establish the innovation dynamic that creates both the resilience and the adaptiveness of technology transfer systems. It supplements this by arguing that it is the policy-interface between national policies to stimulate 'leading edge' technologies and the institutions within the system of innovation that are key to ensuring that this adaptiveness is a permanent

and dynamic feature of any technology transfer system.

German and U.K. Policy Compared

The previous section identified three areas around which biotechnology policy is built: university–industry links (particularly support for basic research and for technology transfer), regional development (‘clusters’ or ‘centres of excellence’) and finance. None of these areas are mutually exclusive, however and, given the multi-disciplinary and networked nature of biotechnology itself, it would not be appropriate to construct a single policy towards this sector. Further, since the whole area biotechnology is interwoven with the Public Understanding of Science as well as with strong ethical considerations, any policies tend to cross-departmental and legislative boundaries.

To this end, this section compares policy formulation and policy implementation and delivery in terms of three areas:

The legislative, regulatory and policy system: this, broadly, includes departmental responsibilities to construct legislation, regulate biotechnology R&D and commercialization and increase awareness and understanding of biotechnology (and ethical considerations around biotechnology) in the wider public. It also includes an analysis of the policy initiatives towards biotechnology in both countries.

The support for university-industry links: including the funding of the science base and technology transfer, as

well as the institutional structure of the science system that delivers biotechnology research and commercial activity.

‘Cluster’ or ‘Centres of Excellence’ at a regional level: both German and U.K. policy makers have been strongly influenced by the ‘regional systems of innovation’ and ‘cluster’ literature surveyed above that suggests a link between innovation at a regional level and strong national biotechnology performance.

Finance policy in both countries is woven into policies towards support for technology transfer and regional cluster development. Thus this area of policy is not examined in its own right but is instead integrated into the wider discussion and analysis (for further reference, see Harding, 2000, 2002).

The Legislative, Regulatory and Policy Framework

Nowhere is the complexity of biotechnology more obvious than in the legislative and regulatory framework that underpins policy formulation and delivery. This complexity is apparent in both countries and is illustrated in Table 3.

Table 3 breaks the framework for biotechnology policy into five areas, legislative responsibility, guidance and advice (including on ethical matters), monitoring (including regulation, intellectual property and technology/impact assessment), access to funding (for R&D and commercialization) and research and expert services.

Table 3. *The biotechnology legislative and regulatory framework in Germany and Britain.*

	Legislation	Guidance and advice	Monitoring	Access to funding	Research and expert services
Germany	BMU BML BMG	BMU BML BMBF BMG RKI	RKI ZKBS	BMBF BMW BML BMG Länder DFG	Dedicated govt institutes RKI DFG funded institutes Universities MPG HGF FhG WGL
United Kingdom	DTI Culture HSE DETR MAFF DoH Home Office European Standards	DTI Culture HSE DETR MAFF DoH Home Office Research Councils Trade Associations	HSE MAFF DoH	DTI DoH Home Office Research Councils Wellcome Trust	Culture DETR DoH Home Office Research Councils Universities

Germany and the U.K. have one central department broadly responsible for the research and training agendas—the Bundesministerium fuer Bildung und Forschung (BMBF) and the Department of Trade and Industry (DTI) respectively. In both countries the remit of these departments is extensive and covers the guidance and advice, access to funding and general policy formulation (see Table 4). In addition to this, the

Table 4. The biotechnology policy framework in Germany and Britain.

	Germany	U.K.
Basic Research	<p><i>Deutsche Forschungsgemeinschaft</i>: research council funding prioritizing biotechnology research (14% increase in funding) <i>Max-Planck Gesellschaft</i>: national networks of basic research institutes. Research specialisms at regional level <i>Blaue Liste Institutes</i>: regional research institutes with Länder funding</p> <p><i>Gene Centers</i></p> <p><i>National initiatives</i> include specific funding for Nanotechnology, proteomics, bioinformatics, German Human Genome project and sustainable bioproduction <i>BioFuture</i>: competition to provide young scientists with resource-base to develop high powered research and commercial careers in applied biotech research</p>	<p><i>Biotechnology and Biological Sciences Research Council, Medical Research Council and the Natural and Environmental Research Council</i> provide funding for basic science in universities</p>
Applied Research	<p><i>BioFuture</i>: also provides support for commercialization and incentivization to stay in Germany <i>Fraunhofer Institutes</i> work with companies on applying biotechnology research</p>	<p><i>Biotechnology Exploitation Platform Challenge</i> <i>DTI funding for partnership research</i></p>
Technology Transfer	<p><i>INSTITI</i>: national network of patenting search organizations linked with technology transfer structures like AN-Institutes and Fraunhofer <i>Kompetenzzentren</i>: tech transfer centers within the BioRegio structures to facilitate university industry links Various other programs including <i>Innovation-Market, Innovationspartner & Deutsche Wirtschaft</i></p>	<p><i>Biotechnology Exploitation Platform Challenge</i>: to encourage universities and businesses to work together <i>University Challenge</i>: not specific to biotech but a seed fund for university technology spin outs</p>
Commercialization	<p><i>BioChance</i>: competitive access to development finance for established start-up biotech firms conducting high-risk R&D</p>	<p><i>Bioscience Unit</i> (DTI) champions commercial exploitation including IPR agreements, regulation and tech transfer <i>Biotechnology Mentoring and Incubator Challenge Fund</i> to create high quality sustainable biotech companies <i>Trade Partners U.K.</i>: to encourage exports in biotechnology</p>
Cluster Development	<p><i>BioRegio</i>: Competition between Länder to develop clusters around biotechnology generally <i>BioProfile</i>: Competition-based extension finance for BioRegio Regions to develop focus/specialization in dedicated area of research. Designed to give new drive to BioRegio initiative</p>	<p><i>Public-private sector partnerships</i> to stimulate biotechnology R&D and commercialization in the regions following report by Minister for Science in 1999 <i>University Challenge</i> to stimulate science and commercial networks through universities</p>

Table 4. Continued.

	Germany	U.K.
Regulatory Framework	Regulation falls under three categories: <i>national environmental policy</i> (BMU), <i>agricultural biotechnology</i> (BML) (including animal testing and research) and <i>health</i> (BMG) that governs Genetic Engineering. The <i>Robert Koch Institute and the Central Advisory Committee for Biological Safety</i> monitor health and safety issues and develops guidelines	Responsibility spread across a number of different government departments and guidance notes are prepared accordingly. Advisory Committees provide health and safety and ethical advice. Department of Health has responsibility for medicine licensing
Public Understanding	<i>Science Live</i> : 'science touring truck' equipped with research facilities to allow scientists to run experiments where resources might otherwise not exist + trained personnel to raise profile and understanding of biotechnology. Web-based reference center for bioethics <i>Safety research and Monitoring</i>	BIO-WISE: explaining the commercial potential of biotechnology to businesses <i>Department of culture</i> provides information courses <i>Public understanding of science</i> (e.g. through Science Museum)

DTI is also responsible for biotechnology legislation since the biotechnology directorate and the Office of Science and Technology sit within that department.

Germany's legislative and regulatory framework is far more embedded within a wider departmental structure than in the U.K. There are 17 different departments or organizations involved with biotechnology at a national level (compared to 11 in the U.K.). The Environment Ministry (Bundesministerium fuer Umwelt—BMU), the Federal Ministry of Food, Agriculture and Forestry (BML) and the Federal Ministry of Health (BMG) control legislation, for example, while the BMBF is responsible for policies that enable researchers and small businesses to get guidance and advice on ethical, regulatory and research matters. The Federal Economics Ministry (BMWi) also provides funding for biotechnology. The State governments also provided research and commercialization funding, as does the KfW/DtA while research and consultancy is provided by a plethora of establishments within the science base of the German economy including the Max Planck Institutes (MPG), the Fraunhofer Institutes (FhG) and public and private sector research laboratories, universities and research establishments (some of which are dedicated to biotechnology—for example the Gene Centres in Cologne, Heidelberg and Munich). Monitoring and ethical guidance is a clear responsibility of the Robert Koch Institute and the Central Advisory Committee for Biological Safety (ZKBS) and forms part of Germany's wider policy to ensure that Technology Assessment is fully integrated into any R&D activity (Harding & Harding, 2001a).

Departmental responsibility for biotechnology within the U.K. rests with the DTI, the Department of Culture, the Ministry for Agriculture, Fisheries and Food, the Department of Health (DoH), the Depart-

ment for the Environment, Transport and the Regions (DETR—now the Deputy Prime Minister's office) and the Home Office. It is only the DTI that has an explicit role towards biotechnology in the form of legislation, funding or regulation—for the other departments biotechnology is integrated into wider policy frameworks. The Health and Safety Executive (HSE) and the European Standards Office play a strong role in monitoring and regulation while the General Medical Council (GMC) has a bioethics committee which assesses the ethical implications of any biotechnology research. R&D is funded by the DTI and the DoH. By far the largest budget is with the DTI since it controls the research council budgets as well. Interestingly, charity funding for research (for example the Wellcome Trust) forms an important, if small, part of the total funding for biotechnology R&D.

There are three marked differences between the German and the U.K. legislative and regulatory structures. First, the German framework is to a large extent embedded within its wider science and technology system. This means that the responsibilities for pure (basic or blue sky) research as opposed to applied or commercial research and development are clearly delineated at the point of delivery (Harding, 2001). Thus, for example, a Max Planck Institute would not be involved in the front line of commercialization research since this extends beyond its remit although the Fraunhofer Institutes may well be. There is a strong 'blue sky' element within the dedicated 'Blau Liste' research institutes like the Hermann von Helmholtz Gemeinschaften (HGF) and its post-1995 successor in the eastern States, the Wissenschaftsgemeinschaft Gottfried Wilhelm Leibnitz (WPL). All this institutes are predominantly supported by the federal government, but a token 10% of funding comes from the regional

States to ensure that long term public interest projects are fully investigated.

This regional role in the biotechnology framework is a second key difference between the U.K. and Germany. The role for regional level governance and funding for research is not clearly defined in the U.K. while in Germany a critical part of the remit of State (Laender) governments is to formulate regionally based science policy based on regionally defined interests and needs.

Finally, the third key difference is in the financing of biotechnology. Again, in Germany, this is embedded within the existing institutional framework of the social market economy which means a clear delineation between national, regional and local responsibilities in the funding of both of public interest research and of commercial activity. Pure research is largely funded by the Deutsche Forschungsgemeinschaft which had in 1999 a total research budget of DM 2,278 billion, 36% of which was dedicated to life science research. Alongside this, the KfW and the Deutsche Ausgleichsbank (now a merged organization) have responsibility for facilitating loans, mezzanine and equity type finance and work with regional and local banks and venture capital firms to operationalize this. The U.K. funding system, as it is depicted in Table 3 is largely for basic research in biotechnology and comes predominantly from the research councils, charitable trusts (around 7%) or from government departments. Where research is applied and likely to lead to commercial exploitation of the science base, finance is through policy initiatives like University Challenge and has a strong private sector dimension to it.

The spread of biotechnology across so many departments and non-governmental organizations (like for example the GMC) is illustrative of a wide dissemination of biotechnology awareness at a policy level. It is interesting to note, however, that, although both governments do pay some attention to the importance of raising public awareness and understanding of biotechnology, the extent to which this is explicit within the above framework is limited.

The policy framework to support biotechnology policy in the two countries is described in Table 4.

There are three things that are immediately obvious from Table 4. The first is the sheer size of the German effort in the area of biotechnology policy in relation to the U.K. Policy has sought to raise the profile of the technology amongst scientists and businesses alike and, simultaneously has put in place a framework for informed public debate about the issues in biotechnology research. The second feature of the German system is its heavy reliance on competitions as a way of providing funding to research (basic, applied and technology transfer) as well as to network building at a local, regional and national level. Applicants for funding through these routes have to demonstrate a clear and established track record and evidence that

they are already following the strategies they propose in their bid for funding. In other words, the structures and systems for delivery have to be in place and some progress has already to have been made if a bid is to be successful. The final feature of the system is its embeddedness within the overall framework of the German science system. That is, the clear delineation between basic scientific and applied research, the integration of technology transfer and commercialization and, as a logical extension, the capacity to build clusters relatively easily on the back of existing institutional structures that support competition and collaboration in R&D.

The U.K. system similarly reflects the intrinsic nature of its science system. It relies heavily on a competitive process for funding of any kind and, similarly, has sought to engage private sector money on a matched basis at all stages of research and commercialization beyond pure, or 'basic' research. This is especially the case for any product development work as well as for cluster development. Collaboration in the system comes from specific policies to support partnership (for example the biotechnology exploitation platform) and from broader policies to support university-industry partnership. These latter policies, such as University Challenge, The Higher Education Innovation Fund and the Science Enterprise Challenge are not purely for biotechnology however. Public understanding is facilitated through BIO-WISE (although this is technically to explain the commercial potential of biotechnology and not to widen public understanding).

Support for University-Industry links

Biotechnology relies heavily on the efficiency and effectiveness of the science base to develop products with any commercial potential at all. And, similarly, the process of biotechnology development which transfers pure science know-how into industrial application (the technology transfer process) is dependent upon collaborative and communication channels with business. So, if government is to be successful in promoting the industry, it has both to ensure the adequate funding of the science base and, critically, develop support structures to facilitate the effective transfer of knowledge from basic scientific research into product development.

The first thing to examine, then, is the overall level of science funding in Germany and the U.K. in order to understand the scale of differences between the two countries. Funding for the science base as a percentage of GDP is given in Table 5. For comparative purposes, the U.S. is included in the next two tables.

Germany spends more as a percentage of GDP than the U.K., although does not spend as much as the U.S. However, Germany has a much larger GDP than the U.K. and this translates into a higher level of overall expenditure on Science, Engineering and Technology

Table 5. Overall levels of science spending in Germany and the U.K. as a percentage of GDP (U.S. as comparator).

	1993	1994	1995	1996	1997	1998	1999	2000
Germany	2.42	2.32	2.31	2.3	2.31	2.32	2.44	2.46
U.K.	2.15	2.11	2.02	1.95	1.87	1.83	1.87	—
U.S.	2.62	2.52	2.61	2.66	2.7	2.77	2.64	—

(SET). For example, the U.K. SET budget expanded by 7.5% to £6,734 million between 1999 and 2000, but Germany still spends more than twice the amount in real terms on its science base than the U.K. and expanded its funding by 14% over the same period. This is shown in Table 6 which shows government budget allocations for R&D (GBAORD) in current dollar prices for comparative purposes.

Another point is worthy of note here. German reliance on the private and governmental sectors for funding of R&D in comparison to the U.K. This is illustrated in Table 7 which shows the sources and modes of funding in the two countries.

Germany's funding for R&D is largely from government or business. The U.K. in contrast has a lower level of private expenditure on R&D and lower levels of public expenditure on R&D. Funding from abroad as

well as funding from other U.K. organizations, often charities, is a sizeable proportion of total funding. This is particularly important for biotechnology since much of the 'other national sources' category is accounted for by large national medical charities such as the Wellcome Trust.

Actual expenditure on biotechnology is hard to derive on a comparative basis (see also Senker, 2001). The reason for this is that, as can be seen from Tables 3 and 4 above, the reach of biotechnology research and application extends far beyond one government department and is interwoven with the structure of the science system itself. However, the German government claimed to spend something in the region of £750m on biotechnology in 2001 across all government departments. In the U.K. the three research councils with the most explicit remit for funding

biotechnology are the Biotechnology and Biological Sciences Research Council, the Natural and Environmental Research Council and the Medical Research Council. Their combined budget is £567.1m, although this is a general budget allocation and is not for biotechnology specifically.

Since it is so difficult to establish exactly how much is being put into biotechnology in the two countries, and since much of the effectiveness of biotechnology as a vehicle for commercial application and, hence, innovation-led growth, rests in the relationship between universities and industry, it makes sense to dwell on this area a little longer. This is broadly 'technology transfer', although the relationships between universities and industry at a local or regional level is core to specialist cluster development too.

Table 8 examines policy priorities in Germany and the U.K. in this area.

There are a number of points that can be drawn out from this table.

- (1) In Germany, funding for teaching and research in Higher Education establishments comes from regional and national level governments. Thus teaching, for example, is broadly funded by regional governments beyond a token 'core' funding from the national government. However, research is funded by both the regional and the national governments (through the DFG and Blaue Liste Institutes in the case of national interest research). This means that regional governments can set research funding priorities to reflect regional economic priorities and that cluster development policies can build on this to develop sectoral specialisms and networks;
- (2) The U.K. government has prioritized funding for the science base generally and for biotechnology in

particular and there are more resources available for research in this area. The commercialization strategies are reliant on the engagement of private sector businesses through 'matched funding';

- (3) Both countries have mechanisms for anticipating technological changes and formulating policies and strategies accordingly, In Germany the mechanism for evaluating biotechnology developments through the Delphi program is based in the Fraunhofer Society. The U.K.'s Foresight Program is run through the Office of Science and Technology and is based on committees of scientists and business people who evaluate the commercial potential of technological change as they occur;
- (4) At the point of implementation, the German policy mechanism reflects the institutional structure and responsibilities of the science system generally. The U.K. in contrast has a much more decentralized delivery system alongside a centralized funding system and is reliant on private sector partner involvement.

The highly contested research market in the U.K. makes collaboration, even in an area where it is essential to collaborate, more difficult. In contrast, the strongly collaborative nature of German science system means that collaborative science is easier—this may go some way to explaining the speed with which Germany has caught up in terms of patents.

University–Industry Links and Academic Entrepreneurship

Both governments have put a large effort in to raising the profile of academic entrepreneurship as a driver for technology transfer and commercialization. Policies are similar in both countries and include strategies to stimulate incubators, science parks, venture capital

Table 8. University–industry policy priorities in Germany and the U.K.

	Policy Priority (2001/2)	Formulation Mechanism	Implementation Mechanism
Germany	Enhancing efficiency of science system; ICT, biotechnology; health research, sustainable development, physics chemistry and materials sciences, nanotechnology, energy, transport and mobility, space, marine technology	Federal Government, BLK ¹ and Science Council <i>Delphi program to advise on future scientific trends (through Fraunhofer but also in conjunction with MITI)</i>	Federal and regional funding initiatives and programs; foundations and institutional structure VC Innoregio and Bioregio programs
U.K.	Increased infrastructure funding, research in key technologies, boost to science budget to build on university research; commercialization of public sector research	DTI, POST, OST, Chief Scientist, Foresight Program and Foresight fund	Government departments, research councils, universities, research and technology organizations in private sector, Faraday Partnerships Programs and initiatives; VC through University challenge and HEIF, R&D tax credits

Source: Harding & Harding, 2001.

and, critically, to streamline intellectual property agreements so that both universities, researchers and businesses can profit from research. Evaluating the effectiveness of these types of policy in any rigorous sense is extremely difficult since there are a multitude of different ways in which the relationships between academics, academic entrepreneurs and business are built.

Within the context of this research it was neither necessary nor appropriate to attempt such an evaluation. However the Global Entrepreneurship Monitor study interviews entrepreneurial experts across a number of countries of which Germany and the U.K. are two. This study uses an identical methodology to speak to these experts, and asks them questions around 'entrepreneurial framework conditions', including R&D transfer, education and training, culture, policy, government programs and finance. For the purposes of this paper, the German and the U.K. expert surveys have been used to draw out any general messages on university-industry links generally and biotechnology in particular. The results are shown in Table 9.

What is clear from this table is that problems in the relationship between universities and business exist in both countries. Specifically:

- there is too much regulation. In Germany the experts focused specifically on patenting requirements and technology assessment regulations in biotechnology while in the U.K. the regulation was seen in the broader context of labor market regulations and taxation;
- the support structures that help R&D to commercialize are seen as too expensive in both countries. This includes patent searches and access to professional business support (for example accountancy firms and legal practices);
- the R&D transfer system doesn't always work as effectively as it might—there is still mistrust between industry and the science base in both countries;
- the patenting and IPR systems in both countries are viewed as unwieldy or ineffective.

There are a number of stark differences between the two however.

- *Government Programs*: In Germany interviewees were very positive while in the U.K. University Challenge was seen to have excluded non-university bio-innovators. It was also pointed out that U.K. policies are not focused explicitly on biotechnology and that this might restrict the potential for biotechnology exploitation;
- *Finance*: Seed and early stage funding for biotechnology in Germany was seen as good. Respondents in the U.K. argued that there is still a shortfall in equity-based funding for biotechnology;

- *Universities*: these were seen in the U.K. as still have real problems in dealing with spin outs as well as with small and medium sized businesses in their local communities. In Germany the attitudes were generally more positive—that universities were developing along the right lines but that there is still under-utilized potential;
- *Physical infrastructure*: This was seen by experts as 'awful' in the U.K. but excellent in Germany.

The Regions

The U.K.'s market-based policy contrasts with Germany's 'engineered' cluster development policy through BioRegio. BioRegio rests on an analysis by the German government in the early 1990s that concluded first, that biotechnology was likely to be central to future economic growth (prompted by the Delphi program) and second that mechanisms had to be established to facilitate a quick and effective catch up. The best way of doing this, was seen as being through the regions.

Regions with established biotechnology sectors (through the Gene Centers) along with other regions with strong biological or biomedical research universities competed for funding in a competition launched in 1995. The BioRegio program assessed proposals against four criteria:

- that the networks would create a motor for biotechnology 'catch up';
- that the proposal would stimulate biotechnology start-ups;
- that the proposal would grow existing biotechnology R&D;
- that venture capital provision would be an integral part of the cluster design.

The overall aim of the program in 1997 was to make Germany 'number one' in Europe by the year 2000 (for further reference on BioRegio, see Dohse, 2000). Seventeen projects were approved, although three were selected as 'models': Munich, Rhineland and Rhine-Neckar. These model regions received more public money and priority access to future competitions. None of the regions received more than a maximum of 50% of public sector funding, however being a model region provided greater leverage to private resources.

Dohse (2000) argues that cluster development in Germany was strongly influenced at a policy level by the literature on regional innovation systems as drivers for national technological specialism and competitiveness. Similarly, U.K. policy has been influenced by the literature and by policy and practice in other countries—especially the U.S. and Germany (DTI, 1999). The theory behind cluster development in the two countries is very similar, therefore, and, as shown in Table 8, this translates into a very similar set of critical success factors against which the policies can be assessed.

Table 9. Attitudes towards university–industry links in Germany and the U.K.

Entrepreneurial Framework Condition	Germany	U.K.
Finance	<ul style="list-style-type: none"> • Banks seen as not having skills to evaluate research-based business proposals • Neuer Markt was important in getting culture of technology-based businesses going • Access to venture capital for university projects good but this is less the case in the eastern States and there is a perception that the money is ‘public’ money and therefore not commercial • Development finance for university projects is good 	<ul style="list-style-type: none"> • Persistent risk aversion on behalf of U.K. investors towards university start-ups • Equity gap for university projects because financiers do not have the skills to evaluate, especially in biotech • Finance is hard to come by unless it matches with a priority area
Government Policy	<ul style="list-style-type: none"> • Too many regulations from government. This is particularly severe for biotechnology businesses 	<ul style="list-style-type: none"> • Regulation, especially in areas of employment law, make growth very hard, especially for science start ups
Government Programs	<ul style="list-style-type: none"> • Programs effective and logical • Incubators work well to transfer technology • Finance measures are used well • Programs have increased awareness of science venturing • Regional policies excellent—especially BioRegion 	<ul style="list-style-type: none"> • Programs tend to favor entrepreneurs within universities and not those from outside the university sector • Incubators work well
Education and Training	<ul style="list-style-type: none"> • Lack of business education in schools, especially for the life sciences • There is a strong supply of well qualified people • Germans prefer not to work across scientific disciplines which is an issue for biotechnology 	<ul style="list-style-type: none"> • ‘Anti-science’ culture in schools • Lack of business education throughout the system • Major skills gap in critical scientific areas
R&D Transfer	<ul style="list-style-type: none"> • Patent protection is not always effective and is over-complex especially for biotechnology • It is not easy to find the best support for patenting searches as there are so many of them • Underutilized potential in research base • Entrepreneurship in universities is increasing but more is necessary 	<ul style="list-style-type: none"> • Universities have real problems with SMEs • There is more entrepreneurship at universities but there is still too little • University scientists have no concept of what it means to set up a business
Commercial Professional Infrastructure	<ul style="list-style-type: none"> • There is a tight network of support agencies • Commercial support is expensive 	<ul style="list-style-type: none"> • Variable quality across the company • Duplication is an issue • Commercial support expensive
Physical Infrastructure	<ul style="list-style-type: none"> • Excellent 	<ul style="list-style-type: none"> • Major source of competitive disadvantage—‘world class scientists need a world class infrastructure. We can’t offer them this’
Market Openness	<ul style="list-style-type: none"> • When big pharmaceutical companies are involved they are strongly supportive of start-up biotech companies 	<ul style="list-style-type: none"> • Flexibility in labour market • Strong support from large pharma companies
Culture	<ul style="list-style-type: none"> • Scientific entrepreneurship is a popular career choice increasingly because of the intellectual freedom it gives researchers • Negative attitude to failure • Working hours culture is changing in Germany and this will be positive • Public understanding of science could be improved • Heavy reliance on government programs 	<ul style="list-style-type: none"> • Persistent ‘anti-science’ culture in the general population made worse by media coverage • University–industry links still generally weak and not based on mutual understanding

Source: Bergmann & Sternberg, 2002; Harding, 2002.

Table 9, then, looks at biotechnology clusters in four regions—two in Germany and two in the U.K. Cambridge and Munich are compared as models of ‘best practice’ in the two countries. Alongside this Jena and Manchester are compared as examples of regions with a strong historical research base but weaker economic and infrastructural support at the outset. The material in these tables is based on publicly available material and further research would be necessary to assess or evaluate the actual performance of these biotechnology clusters.

In all regions, the biotechnology cluster strategy appears to have created jobs, attracted private capital, stimulated HEI spin-outs and created research specialisms.

Critical Success Factor—Assessment of Regional Cluster Initiatives

Regional level delivery especially has been an especially important policy instrument in both countries. The evidence of dynamic development is clear from Table 10 in both countries.

Combining the ‘critical success factors’ outlined in Table 8 alongside a number of conditions for successful regeneration provides some initial analysis of the success of the strategies in the two countries against five criteria:

Actual research and patents: this gives an indication of the strength of science base and its potential for production of the critical mass of research necessary for developing commercial products in the future. All four of the regions have strong research universities and specialisms with active patenting activity in core biotechnology areas. Cambridge, Manchester and

Munich have attracted R&D capacity from large multinational firms, while Jena has developed its own commercial R&D strength though Jenoptik.

Numbers of large companies: This gives an idea of the private sector networks and investment that has been leveraged through an initial public sector investment. The market is most developed in Cambridge, although Munich also has a strong track record in recent years for attracting private investment. Manchester and Jena have also been successful in attracting some large company investment, especially in related technological areas.

Private finance raised and numbers of VC firms: Venture capital is seen by policy makers as a means of stimulating start-ups and science based entrepreneurship and, although it is by itself, not enough to guarantee this, evidence from the U.S. suggests that it is a necessary if not sufficient condition. All regions have been successful in attracting large amounts of venture capital funds. The key difference between Germany and the U.K. however, is that these funds have been leveraged by strong policy efforts through the KfW and DtA while in the U.K. the government has played a minimal role.

Numbers of start-ups and SMEs: this gives an idea of the ‘lead generation’ of growth businesses in the cluster. All regions have been successful in creating spin-outs and start-ups. Cambridge is the most established region and has the largest number of publicly listed biotech businesses. The other regions are still in the ‘catch-up’ phase and have more embryonic life science businesses (ELISCOS). Evidence on the sustainability of these tiny businesses is sparse.

Jobs created: All regions record job creation through life science and biotechnology based businesses. Cambridge, where the cluster is arguably most developed, attributes 10,000 jobs to the biotechnology sector and Munich has a similar number. Jena is slightly different to Manchester in that it already had a large and established life-science based business before BioRegio and hence claims that 6,000 jobs have been created as a direct consequence of growth in biotechnology.

Is there a Frankenstein Future?

Is there a Frankenstein future? The short answer to this is no—whether we like it or not, Europe (and in this case, Germany and U.K.) have to have a biotechnology industry because this underpins the competitiveness of the pharmaceutical industry as well as the long term viability of the life-science sector. The analysis of the above sections is arguably only scratching at the surface of what is actually happening on the ground, but it nevertheless points to the potential of the sector to provide jobs, create innovation and, hence, to stimulate economic growth.

Table 10. Critical success factors in regional policy.

Germany	U.K.
Strong research base	Strong science base
Entrepreneurial Culture	Entrepreneurial Culture
Role Models	Increasing corporate base
Integrating management culture with scientific research	Capacity to attract key staff
Incubation	Premises and infrastructure
Supported up start-phase	Business support services and related international large companies
Guidance to market	Skilled Work Force
Access to finance and investment	Effective Networks
Corporate involvement	Supportive policy

Source: Rebecca Harding fieldwork, 2002.

We can learn a lot from the analysis here. First, the market based strategy in the U.K. and the more ‘engineered’ strategy in Germany cannot be compared directly in terms of their effectiveness or suitability outside their national context. Germany has a networked science system that is characterized by the ‘symbiotic tension’ under which firms and research institutions compete for and collaborate in research projects. The BioRegio contest and the spread of other related initiatives through the institutional system of German R&D and technology transfer has produced a rapid catch up in biotechnology. This in itself has been impressive to watch—especially for those who judged the German system incapable of rapid change!

In contrast the U.K.’s more market based system would not be effective in Germany but has merits within the context of the U.K. economy. Universities are used to competition in research and this ensures that the quality of research conducted remains high. There are issues around the extent to which the system can be adapted to further technology transfer and maybe some of the reduction in the competitiveness of the U.K. biotechnology sector relative to Germany in the last couple of years stems from the difficulties that U.K. scientists and businesses have in collaboration—there is ‘tension’ but no ‘symbiosis’ between the users and the producers of science.

The issue of sustainability is key, especially for Germany where criticisms of its strongly public sector approach center around the small size of many of the biotechnology start-ups. Where the U.K.’s structures are more established, for example in Cambridge, the sustainability of the sector can be taken much more for granted.

However we can learn three key points from the speed with which Germany has caught up. Specifically these are:

- regions are important as vehicles for appropriate policy formulation and delivery;
- substantial funding is critical;
- funding is key—needs a lot of money because biotech is expensive and networked.

In conclusion, then, there is no Frankenstein Future as such, but there is a role for strong and careful regulation and monitoring of the technology. Along the way, in order to ensure that the public keeps abreast of the pace of change in this sector, it is also critical that the public understanding of the science itself is increased.

Finally, there is scope for understanding much more about the way biotechnology works from the standpoint of a more detailed Anglo-German comparison and further research should concentrate on addressing the following issues:

- first, policy has been a ‘leap of faith’ and measuring effectiveness has been hard. We need new measure-

ments that incorporate the role of the tacit knowledge transfer and network development intrinsic to biotechnology research. In short, we need to be able to measure ‘symbiotic tension’ and its effect on the development of biotechnology;

- second, Germany has a higher number of ‘platform technologies’—i.e. equipment and supplies or drug delivery systems that have clear commercial potential as opposed to U.K. which is still more research oriented. This may be because of differences in the applied research funding structure and in particular the use of equity-based finance in the early stages of biotechnology start ups. The area of biotechnology finance warrants further investigation since it may well be that the form this takes fundamentally alters the trajectory along which biotechnology research develops;
- finally, the management of small biotechnology firms is an interesting area for further comparative research. This has been conducted for Germany in some detail (ISI, 2001) but there is scope for expanding this on to a much more extensive level in order to examine the impact of networks on the trajectories along which biotech develops.

Future Innovations in Science and Technology

Joseph F. Coates

Washington, D.C., USA

Abstract: This chapter describes future innovations in genetics, brain science, information technology, nanotechnology, materials science, space technology, energy, and transportation. This 25 year look into the future in Part I considers scientific developments and in Part II their practical technological applications. The work depends upon two assumptions: first, that we have the capability to see the future to an extent that is useful; second, we can take action to promote the desirable and to discourage and even prevent the undesirable. We of course have the moral obligation to use these abilities to anticipate and to influence.

Keywords: Innovation; Future; Genetics; Brain science; Information technology; Medicine; Ecology; Environment.

Introduction

Over the next quarter century there will be an indeterminately large number of advances in science and technology, which will affect our personal, family, group, work, organizational and governmental lives and behavior. Most of these effects will be good, but others will adversely affect us. The purpose of this chapter is to lay out that broad range of developments, using as the guiding term 'innovation'.

That, however, creates a problem: innovation has two quite distinct meanings. The first meaning is that of invention, creation, or discovery, to bring forth something truly new and useful. The other meaning is adoption of what is new to you, whether 'you' are an individual or an organization. For example, somebody invented the word processor (innovation, meaning no. 1) and that having been invented in different forms, it was then adopted (innovation, meaning no. 2) by literally millions of people and organizations. This chapter concentrates on the creative sense of innovation, and only lightly touches on applications. Sometimes the movement of uses or applications from institution to institution or person to person is referred to as 'technology transfer'. The reason for discussing both of these meanings of innovation is that each is essential to our future prosperity and well-being. A great invention that doesn't propagate might as well not exist, while the capability to propagate something not

worth propagating is just an empty game. See for background, the U.S. Dept. of Energy (1984).

The two meanings of innovation are growing more intimate. Corporations, nonprofit groups, and government are getting more integrated in their perspective on the two meanings. For example, common in corporate research these days is the question of what the market is. In other words, if something does come forth from research and development (R&D), how extensively is it likely to be adopted?

The government is increasingly engaged in programs to support basic research that will later develop into practical applications. Clear examples of that are the programs of The National Institutes of Health and the broad sweep of basic research sponsored by The National Science Foundation. On the other hand the government is increasingly attempting to anticipate how the basic research it supports will be used, that is, what its applications will be. A recent example is by Roco (2002). The government is also lifting the antimonopoly constraints on organizations, allowing them to come together and engage in 'pre-competitive' joint research—that is, research that is of such broad generic value that any organization could use it without necessarily revealing what the organization's detailed proprietary developments or plans are.

New inventions bring new capabilities. The capabilities can be in any dimension: color, size, shape, material, stability, durability, physical or biological

properties, or scope of effectiveness. Capabilities determine the future applications or uses and hence determine how likely the new development is to be important.

Time Horizon

The study of the future is now a well-established procedure in business, government, and other large organizations. Though short-term, one to three year forecasts, are usually dependent on mathematical models and masses of data, they deal with business concerns about commodities, markets, and production. Other forecasts, such as this present one, are more strategic in purpose, by helping the reader or user to understand the forces at play which may substantially alter his or her enterprise over a longer period, usually ten to thirty years. These strategic forecasts are based on three assumptions. First is that we can see the future to an extent that is useful. Second is that we have the capability to intervene, to promote desirable and reduce the likelihood of undesirable outcomes. Third, we have the moral obligation to use the capabilities to anticipate and to influence. While forecasting does describe future outcomes, its primary purpose is to draw the user into an awareness and examination of his or her assumptions about the future. After all, it is the case that most organizational failure results from faulty assumptions about the future.

In a study of the future more detailed than this chapter can be, one would define the system under consideration, and then for each component of the system, identify trends and forces at play. With this in hand, one would define a variety of alternative futures from which one would then draw implications for managing the future. This chapter can only sample from a wide range of such studies conducted by the author (Coates, 1997b) and others.

In anticipations of big change, it is almost useless to look out only five years or so. Such a short term finds many technologies frozen because of long planning cycles and long R&D requirements. The exceptions include minor innovations that have to do with eye appeal or the combinations of features that are frequent in electronics and in food. To go out 25 years provides an opportunity to look at today's seminal and emerging developments and anticipate how they may mature over the next generation. Empirical research shows that seminal developments take about fifteen to forty years to enter the market or come into use, and to reach a point where they are of any significance. See the U.S. Dept. of Energy (1984). We strike a middle ground here by looking out about a quarter of a century.

Seven fields are discussed below as the most important ones for innovation in the sense of new inventions, discoveries, and devices. The emphasis is on physical and biological sciences. Relatively little attention is given to the social sciences, although they will be increasingly important as they move from being

advisory to being more definitive. Each of the seven areas covers basic developments and some of their implications. Part II of this chapter pulls together practical applications in some exemplary areas to illustrate the complexity of innovations affecting complex systems.

Part I: Innovations in Science and Technology

This part discusses seven areas of scientific and technological developments likely to have broad practical applications. They are genetics, brain science, information technology, materials science, energy, space and ecology and the environment. While information technology is the most widespread and dynamic in bringing about successive waves of innovation and change, two biological sciences are discussed first, genetics and the brain, because each are at the seminal stage. Each will in the next quarter century blossom into hundreds, if not thousands, of practical applications, delivering unheralded and until recently, unanticipated capabilities to humankind. As a rough analogy, they are each at the stage of information technology in 1950.

Genetics

In the last 50 years, research has established the following:

- all heritable characteristics of living things are carried by a class of chemicals called deoxyribonucleic acid (DNA);
- this is a long chain made up of basically four components, which one can consider as A, B, C, and D;
- those components comprise a code;
- the code forms units that are called genes, which represent the heritable characteristics of the organism;
- that code has been deciphered. It leads, in the egg, to the production of proteins. Those special proteins are catalysts, or more properly, enzymes, which working with the material in the immediate environment proceed to restructure those materials into the organism that the DNA is programmed to produce;
- we have learned to synthesize DNA;
- we have developed means for taking DNA apart, for putting it back together, and for combining synthetic DNA with natural DNA;
- we have learned that we can take DNA from any organism and put it into any other organism, and if circumstances permit the resulting organism will manifest the newly transferred characteristics.

In brief, we have developed a technology of DNA. A good basic reference is Atherly (1999). For a brief view of the future of genetics, see Coates (1997a).

The Human Genome Project, which is the most important biological project now under way, had its origins in medical concerns and has consequently been

primarily focused on diseases and disorders. See Shapiro (1991). We should soon be in a better position to identify and relate the structure of DNA to specific diseases and susceptibilities. It is virtually daily news that a connection has been made between some disease and its genetic base. All of the thousands of diseases and disorders fall somewhere on a spectrum from absolute certainty of occurrence to probable occurrence to unlikely occurrence. Hawley (2001) has written a useful introduction to the human genome, as has Tudge (2000).

What are the consequences of this new knowledge? First and most obviously, will be easier and earlier diagnosis. If a disease is known to be genetic and is in your family, it is now fairly straightforward to determine whether or not you carry the gene, for those diseases whose gene locus on the DNA has been identified. Following diagnosis, but not close behind, will be attempts at prevention; that is, to intervene in some way or another to prevent the genetically programmed disorder from manifesting itself. Following that will be therapy.

Therapy will come in two primary forms: gene therapy and pharmacology. First, strategies involving replacing, neutralizing, or eliminating the defective gene, generically called gene therapy, will undoubtedly dominate the future of the treatment of disorders of genetic origin. Today, there have been no outstanding, unequivocal, complete successes, but this is the earliest stage of a true biomedical revolution. One has to be able to see the longer-term future, not just focus on the partial successes and failures of short-term basic research and experimentation.

Gene therapy might work by several different mechanisms. The easiest one to understand would use an organism, such as the influenza virus, which attacks a specific tissue—e.g. the lungs. If the genetic defect were one that affected the lungs, such as cystic fibrosis, one would remove the disease-causing portion of the influenza virus and attach to the remaining, now benign, virus the gene that was absent or defective in the lungs. Then, one would literally attempt to infect the person with that benign new virus, and thereby deliver to the somatic cells—the body cells—the genes necessary to effect correction in the specific biological target, the lungs. Many variations on this, as well as other strategies, are under extensive investigation as explained by Howard Hughes Medical Institute (1999).

The second strategy is less obvious, but in the short run—the next 10 or 15 years—may have bigger consequences. There are many relatively unexplored opportunities to intervene pharmacologically to prevent, arrest, or reduce the potential intensity of a disorder. Historically, most diseases have been treated at their beginning or their end points. For example, we give vaccines to prevent diseases. We dose with antibiotics when pneumonia occurs, Pharmacology

will expand over the next one or two decades, as it searches for and finds remedies at the intermediate biochemical stages in genetically based conditions. Again, see Howard Hughes Medical Institute (1999).

The most interesting long-term consequence of genetics research is human enhancement. The genetic knowledge that will permit us to identify diseases and disorders will also allow us to identify the means and mechanisms for enhancing human capabilities. Unfortunately, this is an area that has tended to receive thoughtless, automatic, knee jerk, negative responses, as if the capability to enhance people's function must lead to that genetic horror movie, 'The Boys from Brazil', or to the rise of fascistic armies of clones prepared over a generation to sweep the world with their great strength and power.

Almost all of the ethical and conjectural discussion fails to address the single most important and obvious factor in the development of new genetic capabilities—what ordinary people will do when confronted with the opportunity to use specific genetics technologies.

Let me illustrate the kind of problem that might apply to. When Banting and Best discovered the role of insulin in preventing diabetes, that led to the survival of a large number of people who otherwise would have died before they procreated. Now those people survive and they reproduce, and continue to add their defective genes in larger and larger numbers to the human genome, i.e. our collective gene pool. That having happened over the last 70 years, makes the defective insulin gene or genes attractive candidates for genomic correction. We will be able to prevent the defective gene from passing from one generation to the next by replacing it in diabetic's germinal cells with a sound gene.

Inevitably, there will be some group of people who will reject the emerging capabilities to virtually eliminate disease and disorders and to enhance the human condition. It will be for a variety of reasons—fear, resistance to novelty, ideological indisposition and religious beliefs. In the long pull, there will be new genetically-based differentiation among people, but not necessarily in the sense of Aldous Huxley's Alphas, Betas, and Gammas (which were roughly the super intelligent, the intelligent and the dullards). It could come along a variety of different dimensions. We already have people who are genetically differentiated into what, if we were thinking of dogs, chickens and cattle, we would call varieties. We have tall, thin, dark-skinned people from East Africa. We have short-legged, squat, stout people in the Arctic. We have light-skinned, mesomorphic people in Northern Europe. We have shorter, dark-skinned people in the Mediterranean region. We have people with characteristic Asian features throughout the largest continent. We have a variety of distinctly different people among the Amerindians. Those genetic differences came about in response to natural forces shaping the preferential

survival of the most environmentally appropriate people. The reality must be faced squarely, that we are the first species to be able to directly intervene in shaping its own evolution. That Lamarckian capability will be uniquely ours, and it will effectively be irrepressible. Our choice is not yes or no. Our choice is whether we intelligently or stupidly manage that capability.

The stages of application of medical genetics will first be diagnosis. Next will be correction or prevention of a disorder. Following that will be human improvement to help some people reach a common norm. Then there will be enhancement to raise people to competencies and capabilities far above the norm.

Let me suggest a plausible, hypothetical calendar of events on the immediate genetic horizon.

Human Genetics Development 2000 to 2040 (Primarily the United States)

2000 to 2015	Expanding knowledge of multiple gene interactions and the associated disorders.	
2000	Human genome fully sequenced; genomics gives way to proteomics—protein mapping.	2023
2000 to 2020	Upper middle class people primarily interested in genetic diagnosis and therapy.	2025
2005 to 2025	Declining costs of genetic interventions.	
2005 to 2035	Pharmacological and genetic therapy compete vigorously to treat genetically based disorders.	2028
2005 → 2006	Expanding market. Exponential growth in the practice of genetic enhancement.	
2007	Two percent of children in the United States are genetically serviced perinatally, 3% more before age twelve.	
2007 to 2025	Upper middle class people are first into genetic enhancement, that is, elimination of nonmedical or nuisance conditions such as overweight, short stature, etc.	2030
2009 to 2016	Public policymakers set genetic enhancement goals in five countries and provide incentives for meeting them. They are North Korea, China, Finland, Israel, and Singapore.	
2010	Genetic testing and interventions to influence outcomes become routine for 175 diseases and disorders	2030
2011, 2013, 2022	Law defines parameters of genetic intervention.	2035
2012	First legal genetic intervention to alter	

the germ line instigated by the pressure to correct the epidemic of Type 1 diabetics resulting from Banting and Best's discovery in 1922 that the antidiabetic hormone (insulin) was produced in the islets of the pancreas.

The Nobel Prize goes to the largest number of individuals (12) ever, all engaged in a multinational, highly integrated neurogenetics research program. The team established that between 67% and 84% of mental characteristics could be attributed to genes, and the rest largely to environmental circumstances ranging from intrauterine environments to home and school life. This triggers widespread public demand for genetic interventions to deal with mental characteristics. The resulting demand for interventions causes a quintupling of the federal research budget in mental genetics.

Mandatory premarital genetic counseling required in 14 states. Growth in genetic servicing doubles every three years in the United States. By 2022, 65% of children are genetically serviced, 95% of them for diseases or disorders and 5% for enhancement. Twelve percent of interventions alter the germ line. Enhanced people are starting to form social groups and affinity groups on the electronic networks. MENSA has a rapidly growing subgroup called MENSA-E for those with IQs above 160.

The International Olympics Committee is discussing a special Olympics for the physically enhanced. Tryouts in three countries show a consistent 2% to 7% improvement by enhanced contenders.

Decades of experience with hundreds of thousands of people define risks and previously unanticipated side effects of genetic interventions, leading to codified intervention strategies and higher safety and confidence in outcomes.

Forty-three percent of American adults and 84% of children have at least a partial genetic profile.

The anti-genetics movement (Americans for God's Way) has 16 million registered members and

- 2035 enjoys support by 27% of adults. Surveys show that 83% of members of Congress have had a genetic intervention in the immediate family.
- 2036 The American Medical Association Committee on Medical Genetics reports that since 1998 there has been a 35% decrease in genetically based disorders that manifest themselves in the first three years of life. Epidemiological studies have shown that genetically based disorders and conditions in adults 18 to 45 have declined 22%. The studies attribute 26% of this to premarital genetics counseling and the rest to interventions through pharmacological or gene therapeutic routes.
- 2038 Under the Olsen Act, passed by the U.S. Congress, citizens refusing to have a genetic inventory of their minor children will have their taxes raised by 30%, and will be double-billed for the treatment of their children's genetically-based disorders.

Recent treatments of the future of human genetics are by Stock (2002) and Dawkins (2002). Frankel (2000) deals with issues of inheritable genetic modifications.

Animal Genetics

The genetics of animals other than human beings is extremely important for commercial, scientific, biomedical, environmental and other reasons. We are able to do things with animals which are unacceptable with people, from a research, experimental and applications point of view, but which will have pay-off in understanding human biology, in the prevention of human diseases and disorders, and in human enhancement.

With rapidly reproducing animals like mice, it is now routine to identify a gene that has a function in people as well as in the mouse and 'knock out' that gene, that is, eliminate it from the organism. One can then observe what the effects are, and in turn observe what the consequences are of various interventions or treatments. It is also practical to go in the other direction, that is, add a gene to the mouse so that its effects and consequences can be studied. Obviously these techniques have profound implications for the identification, treatment, and understanding the sources of diseases and disorders, by revealing details of the complex interaction among genes. Few or no genes do a single thing. Many of them interact at several stages in the development of the individual organism to regulate the scope and penetration of different functions or structures. See Howard Hughes Medical Institute (1999).

Modern genetics is widespread in animal husbandry. If one has a highly productive or valuable bovine, horse, pig, or other cultivated animal, it is extremely desirable to conserve those characteristics and reproduce them in progeny with high fidelity. This goal amounts in many cases to preferring cloning. The cloning of agricultural animals has high economic value, leading to continuous herd improvement. That will provide important carry over of techniques to people.

Cloning research is going apace in animal husbandry. Cloning techniques form an elaborate process both biologically and technically. The individual steps and stages in that process will have direct transfer value to understanding every step and stage in human reproduction, in particular the use of stem cells for the reproduction of tissue and whole organs, and ultimately to the safe and successful cloning of people.

The preservation of endangered species can be enormously assisted by contemporary genetics. As a species becomes scarce, one problem is the tendency in zoos to inbreed them. That brings out genetic defects and thereby weakens the whole surviving strain. Modern genetics will now allow more effective cross-breeding and reduces the genetic weakening of survivors.

Not far down the road will be the resurrection of extinct species. Mammoths, dodos, passenger pigeons, and scores of other extinct animals will walk the earth and fly the air again, in the next decades. Museums are vast repositories of tissue to provide the DNA for those resurrections. No Jurassic Park, but revival of recently-made-extinct species from which we have any tissue containing DNA, e.g. dodos, passenger pigeons, and mammoths. See Coates (1992a).

Genetic research on animals is by no means limited to mammals. The whole phylogenetic scale is under investigation in order to understand not only the characteristics of individual groups of animals, but also the parallel functions that genes perform as they appear in different genera. Gene maps of exemplar species are being prepared in the same way the human genome was recently mapped. As we better understand the genome of insects we will be in a better position to deal with them if they are pests or to enhance or promote them if they are, as are our bees and butterflies, economically or socially desirable. A fine description of how genes shape animal design is given by Lawrence (1992).

Another genetically important use of mammals will be as factories for the production of valuable biomedical or health-promoting materials. By transferring the appropriate genes into a cow or a goat or another relatively large animal, one can produce complex materials, often too difficult in terms of present knowledge of manufacturing, too expensive to manufacture, or too difficult to produce even in the laboratory.

Plant Genetics

In the same way that all of the animal kingdom is being explored and mapped genetically, similar mappings are going on in the plant kingdom. Objectives are to improve food and other commercial crops, build into plants better resistance to pests, and allow plants to grow in hostile or inadequate environments such as arid zones and saline water. The crossbreeding of plants genetically, that is, the introduction of genetic material from one plant into another, will expand the human diet enormously, improve foods nutritionally, and make new, better-tasting, and more-attractive foods with longer shelf-life. For example, in the Mexican diet rice and beans are critical. Each provides essential proteins, but neither supplies the full complement. Together they do. Genetic manipulation will make it practical for transgenic rice and beans each to be a fully balanced protein source. Mauseth (1998) in his textbook, *Botany*, provides an excellent extended discussion of plant genetics.

At the gustatory level we can anticipate the restoration of taste and improved flavor to many plant crops and fruits. More exciting is the mixing of genes from different plants to create new transgenic varieties of foods that are unknown today. We may have potatoes with the taste of bananas, or strawberries that have the taste of a fruit salad.

In forestry similar genetic developments are leading to pest-resistant trees and to trees that have better commercial characteristics. Genetics will offer better remedies and better preventatives for tree crops threatened by diseases and pests.

Microorganisms

Moving down to microorganisms, there is the great potential for them becoming little factories producing all kinds of commercially valuable materials. The genes introduced into a microorganism representing any characteristic or product of a donor organism will show up, that is, be expressed, unless something specific in the environment precludes it. Consequently microorganisms will continue to expand in their use for the production of exotic and expensive chemicals. Eventually they may produce commodity chemicals with unprecedented degrees of purity, because the microorganism can only produce what its genes instruct it to produce. If temperatures are too hot or too cold, rather than produce flawed products or undesirable byproducts as occurs in a conventional factory, the microorganism will just stop producing. Microorganisms will also be used to produce enzymes, that is, chemical catalysts that can be harvested and used in chemical processing or to treat diseases and disorders.

There is recent awareness of an extensive number of extremophiles among microorganisms and larger organisms, which thrive in very cold environments, very hot environments, in saline environments, or

under high pressure. Those characteristics transferred into commercially useful species will enhance their capabilities as small factories. We are well aware of what microorganisms can do in industrial production: they are the basis of beer and wine productions and the backbone of the cheese industry. The industrialization of microorganisms is not new, but the expansion into new domains via genetic manipulation could be revolutionary.

Brain Science and Technology

Scientific developments over the past decade portend effective, reliable, safe, technologies for altering the brain and all its mental and physical functions. Prozac has enjoyed wide enthusiasm. It is the closest drug ever to Aldous Huxley's Soma—a make-you-feel-good, make-you-perform-better pill. Prozac is just the opening wedge for families of new drugs achieving the same or related objectives.

Genetics, particularly developments in molecular biology and the understanding of the human genome, will for the first time give our species direct control over its own mental evolution. Genetic research is establishing beyond any reasonable doubt that mental abilities, mental disorders, and cognitive short-falls and deficiencies are genetically-based if not fully genetically-determined. Genes set potential boundaries on performance, and the person's total environment at all ages adjusts how fully the potential is met, or diminished. A good introduction to the brain is by Restak (1995).

Psychologists have known for many years that there are numerous independent mental functions. Gardner (2000) is a current leading exponent of multiple intelligences. Genetics will tease out the loci or pattern of loci of those abilities in ever-more-refined degrees of detail. Tools for looking at the brain include imaging and tools for seeing the brain's structure and biochemistry, genetic and molecular probes, electrodes, and electromagnetic field detectors. We will be able to see the brain at work in real time and in three dimensions. The consequences of discovered linkages, whether to mental abilities or to disorders, will stimulate research on mechanisms of intervention to prevent, correct, cure, or enhance them.

We are already witnessing physical interventions in some of the outer reaches of the brain. Eyeglasses have been around for so long that we rarely think of them as brain technology, but we are moving to the point where it is becoming plausible that people will have truly artificial eyes; that is, at least light sensors that will directly affect the brain. We already have such technology for hearing—the artificial cochlea—that is steadily improving.

Neurosurgery is better able than ever to identify sites of mental pathology and to intervene positively. We have known of the brain's pleasure center for decades. It is manipulable in rats. It has also been stimulated in

people, although that ability has not yet been converted into any practical use. The earliest developments in brain technology will be directed at the relief of diseases and disorders such as depression, schizophrenia, phobias, compulsions, addictions, and destructive stress responses. But the long-term avenues of development point to human enhancement by acoustic, photonic, electronic, biochemical, genetic, and other means of intervention, as well as through improved modes of training in the technologies of meditation and thought. Vandervert in this volume illustrates the rapid pace of brain research and how it is upsetting very long held beliefs. His work is breaking new ground in the relationship of memory to the cerebellum and how that relationship he is exploring stimulates and implements innovative thinking and action.

Hypnosis, as its psychophysiological basis becomes better understood, could go well beyond stage acts and become a powerful route to influencing our behavior. We know little or nothing about the biochemical and neurological bases of hypnosis, which has within its established boundaries demonstrated repeated capability to enhance human performance.

Research Promises in the Coming Decades

- A complete structural, functional and biochemical map of the brain—a ‘geographic information system’—of the brain. Overlaid 3-D coordinated, computerized databases will correlate structure, connectivity, neurochemistry, metabolic, and electromagnetic activity to thinking, feeling and all brain activities.
 - A genetic map for all brain disorders, along with a guide to the type and extent of environmental and psychosocial influences, which interact with that genetic template.
 - The ability to scan and visualize any portion of the brain from outside the head in real time, simulate it and model brain activity and function on a computer, to test the effects of biochemical or behavioral, physical, or surgical therapies.
 - The ability to grow neurons in culture, biochemically alter their development potential or function, and genetically engineer them.
 - Much more discriminating, objective, accurate diagnosis of mental and neurological conditions based on biochemical and imaging signatures for each mental health state.
 - Prevention and successful treatment of many more disorders and conditions—aggression, learning problems, depression, degenerative disease, dementia, and other conditions associated with the physical and social environment, such as aging, stress, eating disorders, and pain.
 - Treatment through the brain of conditions not considered primarily neurological, such as infertility, diabetes, asthma, obesity, and hypertension.
- Treatments to enhance cognition, learning and other brain activities.
 - Possibly, control of cognitive ability, mood and memory.
 - Also possible: direct control of equipment and computers through actuation by brain signals.
 - Understanding the genetic and biological bases of cell death and the consequences for brain functions, which could alter the results of injury and aging.

An excellent review of brain science is by Carter (1998).

Information Technology

Information technology has the highest probability of having the most dramatic effects over the next 25 years. While one can see continuous changes over the past 50 years, the outcomes in the next century will be even more dramatic. Information technology will affect personal life, business life, social life, government activities, international commerce and foreign relations. (For convenience, we include under information technology: telecommunications, computers, virtual reality and technologies promoting smartness, that is, intelligence in devices and systems, including robots.)

Among the principal effects of the widespread use of these technologies are the following. First, every business is now primarily an information machine, irrespective of what a company thinks its business is. It may sell shoes, food, or clothing, or manufacture gadgets, but the reality is that information technology has come to dominate every aspect of the business enterprise, to the extent that businesses are more alike than different by being information machines. Accommodating to that will be important, as businesses reset their priorities to keep that information machine humming and exploit its capabilities. They will recognize the tremendous power of the information machine by reaching out to customers, suppliers, public interest groups, government, competitors, and other organizations. Information technology will also affect the traditional internal elements of the firm.

Second, information technology first allows and now demands a total systems orientation in all institutional enterprises. All enterprises for the indefinite past have recognized that they are a part of a larger system, but the practicalities of life in business or government allowed only limited attention to most of the elements in the system. The failure to take the total system into account has left many organizations at a tremendous disadvantage when they find that the world has changed while they were not watching. Information technology now makes it practical to have a truly holistic approach to all information and knowledge relevant to the enterprise.

Third, information technology fundamentally contracts time, moving things at a faster pace. By contracting time, it also in many regards eliminates

distance. Aside from any trivial inconvenience in the fraction of a second it takes to transmit an electronic message or image one can now communicate visually, verbally or with data, from any place to any place at any time.

Fourth, the consequences of all of these capabilities lie in two distinct domains, with a fuzzy interface. Almost all of information technology is introduced because it promises to deliver greater effectiveness and efficiency. It is the second level of effects, the transformational ones, that cause fundamental changes in the organization, its functions and operation. One can see a transformation in institutions in the recent enthusiasm for knowledge-management, which is intended to cast over the whole organization a new network of communication that allows the organization to know what is known inside the organization and have timely access to it. That point and that need was nicely put by Lew Platt, a former CEO of Hewlett-Packard: "If HP knew what HP knows, we would be three times more profitable". Similarly electronic commerce is radically changing companies as they try to come to grips with the use of information networks to substitute and replace or augment traditional marketing and sales.

Fifth, the formation of networks is an absolutely central characteristic of information technology. Networks may be inside of organizations, to facilitate communication and the flow of work. They may be outside of organizations, in public interest group or in affinity groups to share concerns about a disease, environmental problems, films, car and travel or anything else. Those networks widen people's awareness and give them more satisfying and rich communications, with regard to their specific interests and concerns.

Sixth, information technology can often substitute for materials and for human resources and create new enterprises. Information technology creates new businesses, not necessarily big ones. Every innovation creates new needs. Those new needs create niche markets and opportunities. The globalization of every commercial enterprise is now well underway. Global networking makes it first attractive and later necessary to be sure that one has a full grasp of what is going on around the world. Going along with globalization and pushing it hard is the need for standardization. Standardization has the general effect of making parts more compatible with each other, systems more interchangeable, and linkages cheaper and more effective. Illustrations throughout this chapter highlight these and other capabilities coming about from information technology.

Seventh, technologies can coalesce to create striking new capabilities. To illustrate, telecommunications and computation have now come together to create a capability called virtual reality. One can create images, scenes, and interactions that do not exist in any place

except in cyberspace. The computational capabilities bring reality to the images of devices and scenes, while telecommunications carry them wherever they need to go.

Virtual reality and associated experiences will drastically alter education by making it tailored to what one knows, what one need to learn, and one's particular preferred learning strategies. Virtual reality will optimize and accelerate remote learning. Virtual reality will also allow all kinds of simulation, so much so that no devices, whether as simple as a new wine bottle opener or as complex as a new housing development or cruise ship, will even begin to be built until it is completely planned, designed, built, tested, evaluated, and modified in cyberspace.

Even today, with relatively primitive virtual reality, one can walk through the offices of a not yet built building, test it for comfort and size, and even begin to place furniture in it and decorate it to one's taste. Virtual reality will have great effects on the modeling of social, economic, political, physical, and infrastructural systems. The model can then be tried out to test modifications, intrusions, inventions, innovations, and habitability.

Jacky Swann and her associates have in this volume been exploring and codifying the connections between knowledge, networking, and innovation. This triadic relationship is crucial to new developments and their applications. The model they are developing linking and comparing invention, diffusion, and implementation promises to shed beneficial light on behavior of all kinds of institutions.

Materials

The science of materials is one of the most dynamic, complex, and important areas of emerging developments. After all, our whole world is made up of materials. All products of industry, all the things that we have as food, clothing, and shelter, are materials. The physical instruments that control devices and regulate and operate the artifacts of our world are made of materials.

Information technology is ubiquitous in its effects on materials. It allows us now through computer programs to picture individual molecules and the molecular structure of materials, including surfaces. We are beginning to understand more deeply, at atomic and molecular levels, interactions among materials and the design changes that influence those interactions. For example, catalysts, which are extremely important in so many sectors, are chemicals that remain unchanged themselves but bring about changes in other chemicals that pass by them or over them or interact with them. Now it is routine to study the structure of a catalytic surface on a computer screen and design and redesign that structure to interact with molecules to be catalyzed. This is an enormous advantage in subsequent

laboratory work because it provides clear guidance to research goals.

The ultimate uses of the materials are having a dramatic effect on quality control and the production of more uniform, reliable, and longer-life artifacts. Computers are leading to smartness in artifacts and devices. By smartness, we mean that any device will be able to sense and respond to three things. First, is it operating well internally? Second, is it performing its tasks effectively and efficiently? Third, if the answer to either of the first two questions is no, the device will initiate repair or call for help.

Smartness is often accomplished by the introduction of microsensors, microcomputers, and actuators, but increasingly materials themselves are becoming smart. Examples are materials that have a built in memory, and under certain conditions of temperature, pressure or stress will revert to a previous shape or condition. This property opens up a potential for many kinds of applications, including but by no means limited to alarms. Just imagine the consequences when a surface finish or paint can announce that it has holes in it, or when the beams in a building or bridge can announce that they are weakening. Smartness will ultimately become universal. For a good overview of materials, see Forester (1988) and the U.S. Congress Office of Technology Assessment (1988), as well as Ball (1997). For an authoritative account of some leading edge developments, see Thompson (2001). Psaras (1987) has edited an authoritative volume for the National Academy of Sciences on materials research.

Biomimetics

Plants and animals do marvelous things, not all of which are fully understood. Increasing understanding of the chemistry, biology, dynamics and physiology of plants and animals is opening up opportunities to mimic their characteristics with man-made materials. The incredible strength of some kinds of seashells, the dynamic characteristics of animal flight, and insect communication by chemical receptors suggest new materials and new designs. The responses of plants to degrees of sunlight by their own movement create possibilities for imitation, duplication, and even enhancement in terms of material science. Understanding the special things living things do and how they do it is leading to great new things done with materials. See Benyus (1997).

Composites

Historically, most of the materials in the world, while sometimes complex—such as concrete or alloys—have been relatively simple scientifically. Now, through better understanding of fundamental characteristics some material can be given unprecedented strength and resistance to environmental factors, such as heat. For example, the new materials generally referred to as composites often have very high strength and a great

deal of environmental resistance so that they become competitive with more traditional materials for special applications. They promise to be able to allow structures of equivalent strength but much lower total weight than those from traditional materials, steel and concrete.

Composites are not limited to use in new super effective golf club and tennis racquets but are likely to become preferred structural material for automobiles, aircraft, other vehicles, and for containers. They are likely to become more durable parts in the structure of buildings too, and could lead to structures that can be assembled, modified or dismantled much more conveniently and cheaply than is practical today.

Traditional Materials

By no means are all of the developments in material science directed at the new. Familiar materials like glass, concrete, and wood are all subjects of a substantial infusion of scientific research to improve their characteristics. One of the wonders of glass technology is optical fibers, so pure that light waves can travel for hundreds of miles through fibers before they have to be amplified. The technology of wood has developed so much in terms of its manipulation that the current theme through the industry is ‘Anything can be made from any part of the tree’. All of the wood is useable in various forms to make almost any kind of useful product. In addition, genetics—as already discussed—will improve the quality and durability of wood, enhance the productivity of commercial forests, and lead to better resistance to pests.

Concrete is one of the most widely researched materials in the world as everywhere people search for concrete made out of local material. The U.S. Chemical Industry (1996) has offered its technology vision for 2020.

Surface Science

As devices get smaller the important factors influencing their behavior are less their bulk characteristics and more their surface characteristics. There is a surge of R&D to understand surfaces of materials. Much of that is that directed at microelectromechanical systems (MEMS) and nanoscale devices, but it is not limited to that. As we understand surfaces better, it will also influence the structure of objects of normal scale, add new characteristics to them, improve their finishes, and give them greater durability.

A long term trend in the use of all kinds of materials is the shrinkage in size of devices. The microchip is probably the most widely recognized example of this, in which literally hundreds of thousands, even a million and soon a billion or more transistors are built into a chip no bigger than the surface of a small fingernail. But, that is not the only area of development in shrinking devices.

MEMS (microelectromechanical) involve devices nominally at the size of a cross section of the hair, that can be used to sense, to respond, and to activate and or to act themselves. For example, MEMS are now the smart device that operates the safety bags in an automobile.

MEMS technology is only part way down the scale where a great deal more exciting research is going on. That is at the so-called nanoscale, which has devices and things built at the level of a billionth of a meter (approximately a billionth of a yard), or on the scale of molecules. Nanoscale devices do not now exist in any practical form, but this is a dynamic area of research and it holds the promise of being able in an ordered systematic way to plan, design, structure, and build up to useful macro-scale devices. Nature already does through genes and their interaction with the micro-environment. The goal of nanoscale research is to do with a wider range of materials what their genes are already doing with organic materials—to build-up of atoms and molecules to human scale devices. There is of course a substantial potential for the interaction of genetics technology with nanoscale technology, but the significance of that remains in the future because the research is at such an early stage. Malanowski (2001) has done a comprehensive brief review of nanotechnology.

In terms of more traditional chemistry, manipulation at the nanoscale also goes on. Current speculation sees nanoscale devices that could be swallowed or injected into the body and would have the capability to treat sick cells, or attack foreign bodies such as bacteria and neutralize them. The anticipated medical applications are developed in great detail by Freitas (2002) as part of an ongoing trilogy. Taking advantage of scare tactics, Crichton (2002) has written a novel on how nanoparticles attack us.

Energy

Greenhouse warming and the significance of its effects will primarily determine the future sources and use of energy. If one accepts the current scientific consensus that greenhouse warming is real the primary open question is the extent and severity of its consequences. The forecasts anticipate continued global warming from the accumulated carbon dioxide and some other industrial gases in the atmosphere, the earth will continue to retain more of the sun's heat than in the past with less heat and energy reradiated into space. That is the basis of the term greenhouse warming. See Watson (2001).

The critical consequences of greenhouse warming are anticipated to be, first, a smearing out of the seasons. The boundaries between winter and spring, spring and summer, will become more fuzzy. Second, overlaying the smearing out will be much more spiky weather—deeper snow falls, heavier rains, and longer droughts. Warming ecological and agricultural zones

will move toward each pole. That has big implications because agricultural productivity in the last seven or eight decades has been determined by a balance between plant type, soil type, water availability, and other additives in the forms of fertilizers and pesticides. Consequently, worldwide food production will have to be geographically rebalanced in terms of those four variables.

An important factor accelerating that accommodation will be genetics technology as discussed above. A further consequence will be ocean rise, initially the order of a couple of inches or a few centimeters. The net effect of that will be to make hurricanes, tornadoes and other ocean storms more severe by carrying the damaging water farther inland. Lying a few decades further in the future, but perhaps already accelerating at a greater than anticipated pace, will be the melting of the Antarctic ice cap, which will cause ocean rise on the order of meters or yards. This will wipe out a large number of island republics and wreak havoc on low level mainlands such as coastal Bangladesh and southern Florida. O'Neill (2001) discusses climate change and population. Also see U.S. Global Change Research Program (2000).

The implication for energy is the need for massive energy conservation through the use of less carbon-based fuel, but also more energy-efficient and effective devices such as automobiles, improved insulation against both heat and cold, and energy conservation in manufacturing. Those measures will not be enough in the terms of the most scientifically sound forecasts. There must also be a push for non-carbon energy alternatives.

The most attractive general alternative will be nuclear energy, that is, the wider use of fission technology. Fusion technology, while holding great theoretical promise, seems to be continually 50 years in the future. Fission technology may achieve a broader acceptance in Europe and the United States than it has recently had as a new generation of adult citizens comes along who do not make the strong association between nuclear energy for power and nuclear energy for war.

A second, extremely attractive new energy choice is photovoltaics, the direct conversion of sunlight into electricity. That is a well-developed technology, based upon silicon, that can be used wherever the sun shines. The patterns of insolation are well worked out. One can anticipate therefore the total amount of solar electrical energy that would be available in most areas. Because of nighttime and bad weather, photovoltaics would have to be backed up by some forms of energy storage. That could be done in a dozen different ways, most obviously with batteries, but also by pumped water storage, pumping water uphill to operate a hydro-electric facility downhill.

At the moment photovoltaics in many parts of the world is not quite competitive with central power

station electrically. As technological improvements continue it will have a great appeal everywhere for the operation of remote machinery, in rural villages for the operation of water pumps and television sets and electric lights that are essential to small communities. Recent scientific developments in making organically based photovoltaic materials suggest great promise for further reducing price of photovoltaic energy.

Other widely discussed energy sources such as biomass have intrinsic limitations. In order to grow enough biomass (beyond harvesting waste left over from crop production) would itself require energy, chemicals, and other treatments. Biomass is not likely to meet more than 3%–5% of total energy production. Geothermal energy has enormous potential prospects wherever there is geothermal activity. It is well developed in Iceland and Italy. The difficulty with it is not technological. High investments for long lifetime facilities do not make economic sense against a volatile price for fossil fuels which could force a geothermal facility into bankruptcy.

Ocean energy coming from tides, or more likely from the thermal gradient where the warm Gulf Stream passes through colder water, can be used to make fantastically large amounts of electrical energy, at least based on scientific principles and detailed analyses. While studies show the great appeal in using ocean energy, one again runs up against unwillingness to give it a try. No government and no corporate consortium have been willing to even pay for a field demonstration.

An attractive and growing possibility for broad scale energy generation is wind. The technology has continually improved, particularly over the last seven or eight years, and will undoubtedly find widespread use either in wind farm generation or in a more distributed way similar to the historic generation of energy in the Netherlands. There are limitations on wind energy. It calls for backup storage. There also is the matter of noise—the thump, thump, thump associated with windmill blades.

Hydrogen is a widely discussed fuel, but in reality hydrogen is not a fuel but a mean of transmitting energy created in some other place. The parallel to hydrogen is electricity. While electricity powers many things it is not a prime energy resource but comes from energy produced in hydroelectric plants, coal-based power plants, and so on. Similarly hydrogen will not be the basic fuel, but will be produced in a variety of different ways.

Hydrogen, while extremely attractive because it produces no undesirable wastes, creates fundamentally new technical demands. It often attacks and embrittles metals; this calls for new high-tech pipe, storage and use. It also has very low density and therefore requires larger and stronger facilities to contain it, for an energy amount equal to a liquid fuel. Hydrogen of course is

particularly attractive in the long pull for powering automobiles, using fuel cells to produce electricity to drive motors on each wheel. See Hoffman (2001).

Fuel cells ideally would use hydrogen as fuel, but they get by using methane or methyl alcohol, while efficiencies are lower and byproducts are not simply water. Fuel cells in automobiles will be getting a basic test over the next decades. One general advantage of fuel cells is that they can be used at almost any scale from something as small as a hand-held flashlight or the activation of a digital camera, to a size approaching backup for a central power station.

On the other hand, assuming the unlikely—that greenhouse warming is not the key driver of the future of energy—then the central driver will be the price structure of petroleum. The limiting factor on the use of fossil fuels will then become environmental effects, particularly associated with sulfur-containing components and the production of nitrogen oxides. Here there will be strong pressures again for more efficient and effective use of fossil fuels. As it stands now the supply of fossil fuels are surprisingly generous around the world, and are growing. The known petroleum reserves are matched by known natural gas reserves of equivalent size. Natural gas of course has a great deal of appeal in that it is more simple and straightforward in fuel processing and has fewer troublesome components to it. It also is a much more effective base for petrochemical production. The rich and complex studies of petroleum and energy in the future are highly conflicted. Three solid studies, for orientation, are by Chen (2001), Deffeyes (2001), and Nakicenovic (1998).

Beyond these two portable fuels lies coal, which is available in the United States for 500 years at the present rate of fossil fuel consumption. Coal has many environmental difficulties, not only associated with its harvesting but also with undesirable impurities and byproducts.

Lying further in the background are methane hydrates. These are weak chemical complexes formed under proper conditions of pressure and cool environment. The complexes consist of a central core molecule of methane and a cage of water molecules surrounding it. The methane can be easily released by injecting heat into a deposit and methane will come forward much like natural gas. Not all deposits are pure; many have other materials that have to be sorted out. The critical factor is that the estimated reserves of methane hydrates are several times the total combined oil and natural gas reserves. If we can continue to use fossil fuels without environmental injury, we have as many as seven or eight decades in which to develop sources of energy not dependent upon fossil fuels. The move from oil to gas to gas hydrates implies a steady increase in the cost of fossil fuel energy. That in turn will be a

powerful incentive for conservation and for developing alternatives.

Space

The scientific and technological developments likely with regard to space fall into two categories. One looks to earth itself. The other looks out to space beyond the earth to explore and understand the physical dynamics of the universe, to establish whether there is intelligent life elsewhere in the universe, and to begin plans for active human exploration and perhaps even the habitable development of our or other planetary systems.

Telecommunications depend upon scores of earth-orbiting satellites. They will become more numerous, more sophisticated and more specialized. A low cost, dense, worldwide net for communications of voice, data and any other kind of information will soon girdle the earth. Closely linked to communication satellites is the development of global positioning technology, which will allow the identification of a spot on the ground with increasingly greater accuracy, first down to 100 meters, then down to 10 meters, then to a half-meter and ultimately even closer. As militarily classified technology is civilianized, unprecedented geographical detail will become available to aid the movements of ships, trucks and automobiles. It will have effects on exploration; on outdoor recreation and tourism, making it almost impossible for anyone to become truly lost, that is, without human contact, anywhere on the face of the earth.

An established technology that is flourishing and becoming more commercially as well as governmentally important is remote sensing. The most obvious form of that is photography that can create terrestrial images from space. Less obvious are other forms of scanning in other bands of the spectrum to pick up specialized information, such as temperature. Today it is possible in most of the inhabited world to find a photograph of your dwelling. The images will become more available as souvenirs of what remote sensing can do.

Remote sensing, linked to ground based information will benefit commerce, research, and government with integrated information on virtually any spot on earth. Consider what geographic information systems can do in linking the number of people living in an apartment house: their social economic data, their mobility and movement in and out of the building, the environmental pollutants coming out of the building, the amounts of the goods going in. Those linkages will be a powerful factor in future planning and the management of the environment. Use of remote sensing will also grow in archeological exploration, seeing through ground cover to identify otherwise obscure traces of previous human occupation. Remote sensing and GPS will trace the formation and movement of pollutants and contraband material and other things, which the global community finds unacceptable to transport. Rees (1996) gives an

excellent overview of remote sensing. Current developments are covered on a Web site (U.S. Geological Survey).

War and violent conflict must not be ignored as a factor that will involve space, but that is outside the scope of this chapter. As the technologies of war are refined, whether they involve remote sensing, the use of lasers for communications or as destructive weapons, or the use of explosives for various kinds of space combat, they are all likely ultimately to transfer specific positive capabilities into the civilian sector.

Cosmology has gotten a tremendous shot in the arm in the last decades as new means of exploring space across the full range of the electromagnetic spectrum are coupled to telescopes outside the earth's atmosphere giving greater depth of field and clarity to images distant in space and time. Space-based telescopes are continually revealing wonders about the universe. There has never been a period when cosmological theory has progressed at a more comprehensive and rapid pace.

We know now that there are at least 70 planets outside our solar system. All of them are large like Jupiter and Saturn, but that in part is because of the limitations of observational technology. The fact that those planets exist and the ability to sort them into different kinds of motions and relationships to their parent star is strong evidence that some stars have solar-like planetary systems. The next stage in galactic astronomy will cost enormous amounts of money, but will allow us to search for Earth-, Venus-, and Mars-sized planets. The fact that other solar systems exist is one of the triumphs of knowledge, wiping out any sense of uniqueness to our solar system and questioning any belief about our uniqueness as intelligent beings in the universe.

Other more tangible advantages of both active and passive space exploration will be better understanding of the dynamics of the sun and the comparable dynamics of stars like the sun. The sun goes through cycles that influence weather, communication, and other factors of both short and long-term consequences to earth.

The scanning of space for signals or signs of extraterrestrial life will continue to a large extent as an informal activity. One of the most interesting aspects of that is SETI (Search for Extra-Terrestrial Intelligence) which links together thousands of small business- and home-based computers during their slack hours to process information. The fact that one can have tens of thousands of people voluntarily linked in that way suggests the potential for future cooperation when more serious or urgent issues arise.

The active exploration of space by sending people, robots or other automated devices into space will continue. The early American space program put men in space largely as a propaganda measure to outshine the Russians and to show that we could play the game

better than they could. The technological and economic logic of space exploration is to send out robotic equipment first. It is relatively cheap and can be sent in greater numbers, also it is more resistant to adverse conditions and less likely to fail. We can anticipate robotic exploration of our solar system will expand in the next decades. We may send people in interesting numbers to the moon, Mars, and elsewhere, and begin intragalactic exploration by robots. It is difficult to see that happening in less than a quarter of a century, but by no means is it impossible to see that schedule either accelerated or deferred.

On the outer edge of the next quarter century we may give serious consideration to terraforming, that is, a long-term program to alter the atmosphere of Venus, which is rich in carbon dioxide, to make it habitable for people or plant life. That is the kind of plan that would operate on a hundred to thousands of years schedule. There should be no rush to do it.

Bases on the backside of the moon are attractive for many uses. They could be the launching platform for exploration. The space station that is now being assembled is a first step to more elaborate stations. The space station is the first stage of manned and unmanned long-term activities in space. It is a learning exercise. We can anticipate that in the next quarter century newer and larger space stations will be built in the region of the earth or on the moon.

Ecology and the Environment

Ecology is likely to continue its emergence as the central science of national and global environmentalism. The strength of ecology will depend heavily on massive daily data collection through both direct ground-based operations and remote sensing. Mathematical modeling and other quantitative tools are increasingly part of the ecologist's toolkit. The concept of ecology is no longer limited to the so-called natural environment. Close attention is being given to agro-ecology, that is, making the concept central to farms and managed forests.

Genetic manipulation is entering into ecology in interesting ways. As the ability to create transgenic species increases and managed environments in the ocean or on the land become more important, the survivability of species of fish, mammals, and other animals and plants will depend on direct genetic intervention.

Within the environmental movement, particularly as reflected in government, there has been a steady shift from a focus on individual species to biomes—large complex biological units such as forests. Rather than care for a particular tree or animals species, the unit of care will be ecologically broader, sounder, and more complex.

Sustainability is a now worldwide concept shaping the conduct of public and private policy toward the environment. Ecology has to become the core science

underlining any practical sustainability. Remote sensing will provide close to real-time monitoring of the quality of the environment. Crops in Russia, China and elsewhere will be monitored, allowing for better world planning against food shortages or surpluses. On the other hand remote sensing will be a better way to identify effluent from factories producing excessive amounts of CO₂. Pollution patterns in oceanic or fresh water when coupled with more traditional ground-based information will enhance the control and management of the environment.

Ecology has such broad sweep that it has spun off sub-areas and related concepts, not all of which are scientifically or technically solid. Among the more solid are urban ecology, ecological risk management, restorative ecology, and conservation ecology. Of less clear scientific merit, but strongly ideologically based, are deep ecology, radical ecology and spiritual ecology. The capstone of sub-areas is human ecology. The general concept of ecology is the total system as the unit of discourse. Human ecology emphasizes the total human enterprise as the unit of discourse.

It is a central point of all ecology that one can never do just one thing. Side effects are universal and are often more important than the primary effect of any action or intervention. Ecology will become more important as a public policy focus as greenhouse warming causes the unstoppable migration of agriculture and forest zones throughout the world. Ayres (2002) has edited a comprehensive review of industrial ecology.

Environmentalism and public interest groups have not come to grips with greenhouse warming, the concept of sustainability, or with a total systems approach, but over the next decade they will, because they must.

Historically environmental issues in the United States have been framed around three core concerns: carcinogenesis, mutagenesis and aesthetic effects. There may be future issues of equivalent importance, among them effects of environmental pollutants on brain function, on the human reproductive apparatus, and on human and animal immune systems.

Part II: Special Application Areas

This section draws together ideas developed in the scientific areas mentioned above to indicate how they may introduce innovations into our lives and our society. Obviously some technologies such as information technology will be universal in their effects. Others such as genetics will be more directly connected to the biology and ecology of plants, animals and agriculture. New materials technology will be very pervasive. The point of this section is to sample some of the most important applications of the scientific and technical innovations already discussed. The extent to which these applications are fulfilled depends less on scientific developments than on other factors determin-

ing the speed and extent to which adaptations occur in business and personal life. This section deals with what the author judges to be high probability outcomes.

The seven exemplary topics are transportation, civil engineering and construction, health and medicine, manufacturing, residences, retail marketing, and education.

Forecasts on all of the topics in this Part II are made by Coates (1997b).

Transportation

Transportation involves both people and goods. While they both use the same modes of travel they do not use them the same way or to the same extent. With regard to the movement of goods one of the most important trends is the integration of different modes of transportation to facilitate the hands-off transportation of things from the time that they leave the factory assembly line until the time they reach the hands of the consumer. Information technology affecting logistics is making this continually more practical. One can anticipate for example, that an item manufactured in Silicon Valley, California might be delivered to Bangladesh or to Poland, without ever being touched by the human hand until it reaches its destination. More standardization of packaging sizes will facilitate this. The rapid development of RFID (Radio Frequency Identification) tags will allow the item in transit to literally speak for itself as to what it is and where it is headed.

Coupled to logistics will be global information systems. Global positioning will allow goods in transit to be identified down to a rail car and even the physical location within the car. This will tighten scheduling.

In the movement of people, the role of the automobile throughout the world will continue to increase into the next decades. One can take as a baseline consideration that as economies grow and people prosper they have three generally increasing social goals. One is more meat in their diet. Second is more automotive transportation and third is more recreational travel. Automotive transportation may be as simple as a motorcycle or a motor scooter all the way through light trucks and automobiles. The reality is that the appeal of personal transportation is independent of location and culture.

Greenhouse warming and the cost of fossil fuels will effect the development of automotive transportation. There will be a broader fanning out of vehicle sizes simultaneously with the greater increase in efficiency of all engines and, as discussed above, shifts to new and improved fuels. Overlaying the appeal of the car itself is the strong trend toward more automation. The ordinary item that today is the most information-technology dense is the automobile. The typical automobile may contain as many as fifty to two hundred electronic devices and the associated communication links.

The movement toward automated driving of vehicles will continue. In its initial stages communications will be from off the road sources to the vehicle or to the driver, and interrogation by the vehicle or the driver for information from off the road sources. The direct control of the highway over the movement of the vehicle is three or four decades into the future, but more information technology introduced into the vehicle will improve traffic efficiency and effectiveness, as well as the density of travel. Short distance radar, for example, will allow cars to communicate with each other about speed and distance. More importantly, automation's shorter response time will reduce the likelihood of multiple car accidents so common in a chain of vehicles in dense traffic. Cars will be able to receive information from other vehicles and sense the conditions of other vehicles and in many regards respond more efficiently, effectively, and faster than the human driver.

Autonomous automobiles will find their first mark in wide-open spaces on relatively lightly trafficked roads. As experience evolves this will move into dense suburbs, then into even more dense cities. Overlaying the technology will be geo-positioning and global information systems, allowing the more effective transmission of information to the vehicle and information from the vehicle. In the latter case information will be about breakdowns, accidents, help needed, disasters, criminal activity and so on.

The movement towards smaller vehicles will not eliminate the need or the use of larger vehicles, but it is likely to accelerate an already existing trend in the United States—about 25% of new cars are not purchased by individuals but are purchased by fleets. Those fleets operate by criteria different from that of individual owners. Fleet owners want high resale value, low maintenance and repair costs and high efficiencies. That pattern will gradually effect all car production and accelerate the trend to longer and longer car life.

Also affecting the vehicle will be design for demolition or dismantlement. Environmental pressure will not push for merely a higher percentage of reuse of high value-added components, since the car is already 90% or more recycled. Rather, a different trend affecting vehicles will be the three Rs—recycling, reclamation, and remanufacturing. Recycling is now familiar. Reclamation is the recovery of vehicle parts to be reintroduced into manufacturing. More important in the next decade or so will be remanufacturing, in which the vehicle is returned to the manufacture for refurbishment—into basically new condition at only a fraction of the cost of a new car. That will not come about spontaneously from the operation of the market, but will call for governmental incentives or mandating.

Rail travel by people will undergo some enhancements. It will be increasingly important in developing countries. In the advanced nations it will also continue to play an important role. In North America, where

distances are greater than within most other countries, competition from airlines and automobiles will be significant. Current data suggests that Americans prefer to drive up to about 300–325 miles rather than take either a plane or railroad. Economic, social, and environmental regulatory factors may shift that balance. Light rail systems are becoming popular for moving people from the far suburbs into central business districts. The pattern of cities is changing evolving from a present pattern of expanding rings of activities, occupations, and residencies around the central business district, to a much more complex network pattern called a polycentric city. The metropolitan area will have a number of business centers with only one of them retaining the government and the arts functions.

Air travel will continue to grow as global prosperity increases. More people will be engaged in both business and tourism travel, while some of the business travel for economic reasons may be effectively taken over by information technology, i.e. video conferencing. Tourism will continue to boom and sustain the airline industry, after a slowdown associated with recession and the multinational ‘war’ on terrorism. Information media are delivering information to more and more people about places in the world. The natural desire to be fulfilled is to visit those places that one has learned about from the media.

How big aircraft will get is an open question, particularly in view of two factors. First is the potential risk of large number of lives from accidents, although it is clear that we are ready to accept one to two hundred deaths from aircraft accidents without the industry going into paralysis. More important will be the question of loading and unloading time. Already the arrival and departure times from airports consume an increasing portion of the total travel time from start to destination. That may prove to be a severe limiting factor on very large aircraft. However, for long distance trips such as transpacific travel, very larger aircraft may offer a great reduction in price and faster travel.

The technologies of balloons, both soft and rigid, are improving. Whether they again become modes of human transportation is open to question. The availability of helium rather than combustible hydrogen relieves one big anxiety. In any case, balloons will play an increasing part in construction, movements of heavy goods and loads, the harvesting of trees and anything requiring access to remote places.

Seagoing transport technologies will continue to evolve. Ocean ships are a big time activity in terms of logistics. As global populations and economics become more tightly knit those goods that do not require immediate delivery or are bulky or heavy will not be shipped by air but by sea. More manufacturing processing may occur at sea. For example, the movement of logs across the Pacific may involve some trimming and cutting or final finishing along the way.

The central technologies influencing transportation are information technologies for control, regulation and automation, energy technology to cope with greenhouse warming, the high cost of long distance travel and the new materials which may offer cheaper, lighter, better, faster, and more durable vehicles and vessels.

Civil Engineering and Construction

Civil engineering gives us society’s infrastructure, sewers, highways, waterways, rail, etc.. Changes in construction are driven technologically primarily by information technology and new materials. On the other hand, social concerns will have dramatic effects. The events in New York City on September 11th have raised worldwide questions about structures which become symbols to attack or through accidents or natural disasters, death traps for thousands of people. Another driver of change is the continuing and probably unstoppable trend toward worldwide metropolitanization. The USA today is about 81% metropolitan. In the next quarter century there will be 15 to 20 megacities with 20 million or more people, many of them in what are now considered developing countries. The scale alone will raise issues of health and safety in terms of water and sewage, and economic issues in terms of mobility and transportation in prosaic matters such as getting to and from work.

Smartness

The ability to link microprocessors, that is, computer capabilities, sensors, and actuators into devices to move or change or start something, is becoming universal. Microprocessors are in all kinds of physical equipment like cars, trucks, trains, and, building equipment. The opportunity to operate more devices remotely, safely and reliably allows doing things that would be unacceptable if people were put in that same environment. For example, automated mining can now replace numbers of people in a mine and go further and deeper, and even remove more of the valuable ore, where one would not dare do it with people present.

Smartness is a tool in the administrative and organizational aspects of building and construction, which means that it is moving to unprecedented degrees of coordination of labor and supplies at the work site. Today all large construction firms, dealing with hundreds of million-dollar projects are rapidly moving towards becoming totally smart in all their internal and external operations. All of this means that the smart devices and the smart organization will allow us to do things more rapidly and more effectively and make more durable and higher quality products and structures than we have been able to do in the past.

Smartness will allow us to build infrastructures that are self-diagnostic and self-announcing. If this bridge is overstressed, if this concrete weakens, if there is too much paint flaking off of these surfaces, or if tremors

having an adverse effect on joints and linkages occur, this will be announced. We will have new tools to maintain structures more reliably, effectively, and cheaply.

Heavy rain often floods sewers. They overflow, simply because the excess run-off can not be accommodated. Millions of tons of beautifully fresh clean water may be dropped on the landscape, thoroughly polluted by overflowing sewers. In part this results from the fact that sewers are dumb. Information technology now makes it possible to develop smart sewers, with the ability to respond to surges and to shut down if necessary to reduce the likelihood of mass scale pollution.

Infrastructure may of course take on new burdens in the future with regard to scarce resources. Infrastructure may have to automatically account for rationing of water, rationing of electricity, rationing of natural gas or other fuels. The ability to do this automatically lends a degree of reliability and fairness to the process and is a net benefit to both those who are inconvenienced by and those who administer the rationing. Infrastructure, housing, and the city are discussed by Coates (1992b, 1992c, 1994, 1995, 1997b, 1999, 2001).

Macroengineering

More grandiose than the mere improvement of present-day infrastructure is the opening up of the concept of macroengineering. Macroengineering has to do with the kinds of projects which are so large that they will run over the boundaries of individual countries either in their structures or in their effects, and will often outstrip the budget of any individual country to accomplish them. The key feature of macroengineering is that it does not improve something by 10%, 15%, or 20%. Instead it fundamentally changes the situation.

The Suez and Panama Canals and their effects are historically well-known and establish beyond question the global effects of macroengineering. There are 70 or so plausible macroengineering projects that have been shown in varying degrees of detail to be practical. Talked about in recent years (but nothing has been done about it) is the movement of fresh water in the form of giant icebergs from Antarctica to the west coast of Latin America, to Baja California, to Saudi Arabia, or to the Australian Outback.

More macroengineering projects will be considered in the next 25 years, and hopefully several will be undertaken. A possible one mentioned earlier in this chapter is harvesting of energy by tapping into the thermal gradient between the Gulf Stream and the surrounding colder water. Another interesting water project would take surplus water from Southern France and pipe it under the Mediterranean Ocean to supply agricultural water to North Africa. Other North Africa projects would include laying down black top, perhaps 300 yards wide, to begin to change the microclimate

along the coast and induce rainfall; then take advantage of that rainfall by plantings to change soil composition.

Mega Cities

Dealing with the problems of mega cities is high on everyone's list of world public health problems—for example, the contamination of water supply by sewage. The high cost of providing modern fresh water and sewage facilities may be inevitable, but the scope and size of these impending problems raise an alternative possibility. What is now routine in large parts of the rural world may be taken advantage of in cities: collecting human waste as a valuable resource for urban gardening. This could convert a serious health problem to a benefit in large cities and at the same time relieve the visual tedium of the vegetation-free urban environment.

The infrastructure also calls for other changes. If you consider a city of 20 million people the places to work should be located closer to the places where people live. Will we have to get away from the concept of a central business district and surrounding rings of other economic functions which have marked the classical cities of North America, Europe, and Asia, in order to deal with the mass populations of mega-cities and the problems of ground transportation?

Smartness will offer many benefits, and materials science will offer additional ones. One of the long-term trends in civil engineering and construction is the recyclability of materials. For example in road building in the United States it is customary to replace highways with a newer wider highway, or replace the road surface periodically with a new surface. In doing that one removes the old surface and throws it onto the scrap heap. The black top and perhaps even the concrete disposed of this way are resources that have economic value. In the future, there will be more recycling of highways, buildings, and structures. That in turn will call for new road designs for easier dismantlement and recycling.

Construction's new objective is in building information technology into structures. In the United States some housing developers are striving to build that capability into their new homes. The advantage as with most other built-in construction is that it is substantially cheaper than retrofit. Soon all construction will be wired or cabled for information technology or it will be channeled with hollow tubes that can receive fiber optics for cable over the lifetime of the building.

Consider the kind of housing needed by the poorest 20% of the world population. For four people that construction would involve an average total cash allocation of \$300 or \$400 per person, along with large amounts of sweat equity, that is, the human labor the owners put in. This situation is about as remote a building model as one can get from models familiar in North America and Europe. But suppose one could

allocate a quarter of that \$300 or \$400 to a high tech package to create an enormous jump in the quality of lives of people living there. Would it be solar cells? Would it be a bicycle electricity generator? a TV set? or some kind of piping for sewage? These types of questions have been barely asked, much less answered, but the technological contributions from the advanced nations to the lowest level of housing in the rest of the world offers the potential for great enhancement for quality of life, health and safety for literally billions of people. A thoughtful collection of Manuel Castells' writings on the city has been compiled by Susser (2002).

Health and Medicine

Aging

The process of aging will undergo even more dramatic changes than occurred in the last century. Every species has an average set point for death. In people, it is about 85–90 years. Of course there are people who will live much longer or die much sooner, but that is the average set point for our species. In the short run, a quarter century, the most likely benefits of health and medicine is to 'square off the death curve', meaning that people will die prematurely less frequently from accidents, injuries, disease and the other conventional things. Therefore more and more people will live to the biological set point. We already see strong evidence of this in the rapid growth of the aging population and the forecast of a boom in centenarians.

The crucial question is, will that increased survival to old age be accompanied by vigor and good health? The answer is uncertain, but three things will help reshape the death curve. First, is giving up smoking. Second, is getting more exercise. Third, is having a well-balanced diet to avoid overweight. Medicine may help in promoting each of the objectives but the decision ultimately lies with people. We have made far less progress than we could simply because people tend to choose short-term gratification of smoking, eating, and being a couch potato over the vague, uncertain and distant promise of longer life. Hayflick (1994) outlines implicitly the limitations on moderating aging and life expectancy over the next quarter century.

Over the long-term medicine will be less intrusive in diagnosis and therapy. Early interventions of all sorts will enhance the quality of life of aging people. A big concern is mental health and freedom from dementia. While mental deterioration still threatens the aging, research now underway is likely to develop technologies to arrest mental decline and offer ways to prevent or correct the most important mental disorders.

Life extension by moving the biological set point is not likely to be of much significance to most people living today, because it will most likely involve genetic intervention. The earlier that intervention is made, the

greater will be the likelihood of set-point extension. There are several specific avenues for life extension. First is better understanding of cell death or apoptosis. The second depends on the fact that there is a tail on the DNA called a telomere that shortens with each cell division. The shortening is associated with cell death. Third, is the introduction of genes that lead to life extension, most likely by generating endogenous antioxidants.

Substantial progress has made in research along these lines with lower forms of life, and eventually we may reach the point where these findings will be established and proven in primates including ourselves. The long-term implications of a genetic intervention and the limited understanding of side effects make it most unlikely that human experiments in life extension by gene intervention will even begin on a significant scale in the next quarter century. However, along the way large numbers of people will undertake informal experimentation of their own to shift the set point, using growing knowledge of the role of antioxidants in biological systems and improved techniques for their delivery.

Human Enhancement

Human enhancement lies in our future. Normal people are on a distribution of talent and skills, whether of vision, neuromuscular control, fine motor control, stamina, strength, or mental abilities. Most biological and genetic research on people has been directed at diseases and disorders. The same knowledge, however which reveals the sources and leads to the treatments of diseases and disorders usually will carry with it the capabilities for human enhancement. It is unlikely that much of that will occur on a broad scale in the next quarter century by direct genetic interventions. But as knowledge accrues and work with other species proceeds the genetic approach will become widely accepted for enhancement as we will have seen in the treatment of diseases and disorders.

The technologies of life extension and human enhancement both raise substantial issues of public policy. Are they in the public interest? Will they benefit the overall society? How will the choices be made? What will happen to people who suffer adverse effects? What will be the effects on society of life extension and human enhancement in whatever forms they take. Those issues can only be clarified as scientific research and clinical practice unfolds. See Stock (2002).

New Techniques

The quite different line of development in health and medicine is toward more nonintrusive techniques. The use of information technology and the associated rapid development of the ability to detect all kinds of phenomenon electromagnetically, chemically, and genetically from samples of bodily waste, saliva, fingernails, skin, hair and so on, will allow each person

to have a more complete inventory of his or her biological capabilities and potentials. A genetic map will show people the likelihood for them of various diseases and disorders and the possibilities of various interventions or compensatory activities. All of this will go a long way in enhancing our overall health and becoming an important factor in squaring off the death curve.

Accompanying new information technology and techniques will be life long records of one's genetics, diseases, disorders, treatments, and their effects. The problems of balancing the benefits of record keeping with the need for privacy are not insuperable. No significant attention has been given to this issue in a positive way because the unfolding of those records has not yet begun on a broad scale, but it soon will. It is quite conceivable that the individual person will by law have exclusive rights to his or her total health records, perhaps on a portable chip with a duplicate in a safe deposit box. None of these records will be in the hands of physician or hospitals unless one voluntarily chooses to have them deposited there. Life-long record keeping will soon begin, started by one's parents and carried on through one's life. For a brief look at the treatment of disease in the present century, see Coates (2000a).

Manufacturing

The making of things in factories is being transformed by information technology as more processes are automated and markets globalized. This in turn is leading to more of the soft form of customization that is so familiar in ordering an automobile, or a hamburger at a fast food place. You have a limited number of choices from which you select, to create the product that you want. Technology however has become more sophisticated in the manipulation of materials and we may move in manufacturing to a deeper, harder form of customization in which the manufacturing processes themselves will change to meet the individual needs of a customer.

Most of the manufacturing tools, whether now automated or not, are sophisticated versions of the tools that were available at the end of eighteenth and the beginning of the nineteenth centuries. New scientific developments are opening up new capabilities for manipulating materials. For example, the automated sculpture of material in a factory rather than molded casts may come about.

Also affecting manufacturing will be the pressures on energy use coming from greenhouse warming. This will lead to higher efficiency in manufacturing and to a shift to materials that will have a net energy saving in the manufacture and use of products. Manufacturing will also have to expand to take other environmental situations into account, including for example manufacturing for refurbishment and manufacturing for dismantlement.

Information technology will provide new levels of feedback from customers. That will be unstoppable as customers are able to develop websites to attack or to applaud various manufacturers and their products. That pressure will eventually have bad effects on companies laggard in responding to the consumer.

Smartness in manufacturing will lead to further declines in the manufacturing labor force. Ultimately some factories will be unmanned except for maintenance and repair crews. Manufacturing in the 21st century is discussed by Coates (2000b).

Residences

Whether one lives in a private house or in an apartment, emerging technology will make that residence safer and more secure. It will be able to announce its own condition and call for help or repairs. The residence will be secure against interlopers and will be effectively smart in all regards. Smart kitchens will allow the householder to make a 15 second transit through the kitchen, announce who will be coming to dinner, scan the menu with the smart appliances and pick out a desirable menu from what is in the pantry and freezer. In 20 to 30 minutes a full four-course meal for four will be ready followed by 7 minutes of clean up.

The most important effects on residences will be invisible in that they will be behind the walls and in infrastructure, giving greater security against environmental mishaps, better containment of heat, a better buffer against cold, and more control of utilities flow into the home by tying utilities to the various forms of price scheduling. It may be preferable to do laundry or showering at certain times of the day or to have a house partially or totally heated or cooled at different times of day.

Throughout the home there will be extensive large or small flat screens, much like television, ranging in size from 3×3 inches to 6×3 feet. The central feature of the home will be the 'electronic home or study center' where mom and dad do some of their work if not all of it, where junior and his sister carry out their school assignments, and where the whole family seeks entertainment, recreation and a large part of socialization through information technology. 'Center' is only a convenient term, since the information tools will be everywhere throughout the residence.

Work at home of course will call for at least one additional room in every house or apartment to accommodate that work. That in turn will have ripple effects on how people dress, where they eat and how they socialize.

New materials' effects on housing will be more diversity on the one hand and more durability on the other. The ability to change the decorations on the wall or windows electronically lies in the future. Smart appliances have already been discussed.

Schooling at home for many will merely be an augmentation of what is going on in traditional

schools, but for others it will be a preferred mode. Entertainment at home will not just be with electronic games, although they will become very popular and more sophisticated, but often real time interaction with people through wall-sized screens will become common. Being able to attend a wedding, funeral, or anniversary remotely and slap hands together on each wall and see each other and share the joys or sorrows of the occasion, will be common.

Furniture will be smart. You will announce who you are and it will adjust itself to fit you. Central lighting, rather than the more expensive and wasteful defuse lighting we now have, will use light pipes to carry bright sunshine throughout the home or use a 2,000 watt lamp at night or on cloudy days.

Retail Marketing

Retail marketing is already experiencing big changes in competition among local shops, chain stores, catalogs, and the Internet. E-commerce affects what we choose to buy, when we choose to buy it, who we choose to buy it from, under what conditions, and with what modes of payment. Travel, convenience, safety, reliability, economic and financial security and ease of returns will all shape the balance among those four retailers. Many people still love to shop in the old fashioned way, to feel the goods, to march through the store and to see thousands of items. Others will see the shops only as a place to go to test out or try something and see if they like it, and then order it either through a catalog or over the Internet. Others will limit themselves mostly to remote purchases because of the high value of their own time and the increased reliability of service. See Westland (1999) for a global perspective on electronic commerce.

Right now catalogs have an edge in that they can show things in full color in many choices. But the electronic systems will gradually catch up. Then one or both systems will have full data about your choices, your preferences, your body dimensions, and your previous purchases. They will not merely respond when you call on them, but will alert you to what might especially satisfy your needs, whether those needs are for home furnishing, books, clothing, drugs, medicine, or any of the hundreds of thousands of other things in commerce for daily life hobbies, entertainment, and recreation.

As mentioned earlier under transportation, logistics systems working with radio frequency identification (RFID) will more quickly and reliably bring things to you. Electronic marketing systems will show more things to you and give you wider choices. For example, looking at an electronic catalog you might see fifty different outfits that you like, and you will be able to see yourself in outfits No. 6, 17, 24, and 39, because when a picture of you and your electronic data are deposited with the vendor you will be able to see yourself from every side in any outfit and make

appropriate changes. Try the hat from 11 with the dress from 24 along with the shoes from 27. Similar things will apply to home furnishings. You will have sent a diagram, a picture, a photograph, of where you live and the furniture vendor will work with you to remodel, or to just to select a particular new piece—an armchair, table, or lamp or a full redecoration.

Clothing

Clothing is difficult to forecast in the long term because it is so intimately linked to vagaries in the state of the economy and fashion. Nevertheless clothing will become more weather sensitive, sensitive to body temperature, humidity, specific conditions of diseases and disorders. Comfort in any environment and adjustment to your preferences will be common. A second big effect in clothing will be smartness. Clothing will be able to electronically respond to you and record or deliver messages as appropriate about your health and alert you to treatments or therapy you need to take. Clothing will also be able to interact with electronics embedded in your arm, your leg or chest to satisfactorily balance your internal condition with your environment. Chameleon-like clothing will be variable in color and changeable in texture as you wear it. Material science will allow these changes to be built in at acceptable cost to further aesthetic choices.

Clothing will also become a part of our overall health regimen, shoes being designed and made to fit electronically, garments tailored to fit the body to enhance or compensate for whatever one's wishes or dysfunctions may be. For example, if you have a tendency toward poor posture, clothing may sense that and alert you to stand straighter, to draw back your shoulders. In extreme cases it will even force back shoulders to treat poor posture or scoliosis.

Education

Education is undergoing competitive pricing with standard classroom education, from kindergarten through graduate school, at odds with education offered remotely, off-site and ad lib. As it stands now, remote or distance learning is to a large extent being driven by business and corporate needs for effective broad scale training of adults. It is also increasing in universities and extension programs. Electronic and remote graduate programs are steadily moving down into undergraduate education because they offer unique advantages in cost and quality. For example, in a sophomore composition course in English the professor can now review papers electronically and give a degree of criticism that was literally impossible face to face or with hand notations alone.

College soon will become the place to go, with the operative word being 'go', for only two reasons—to take those courses that absolutely require some hands-on work like choreography or engineering, or to find a spouse. The rest of the educational programs will be a

trade-off between those who choose to go and those who choose to get an equivalently effective education remotely at greatly lower cost. A star system of the best professors in each field from the universities across the country and later across the world will develop. Questions of credentials and student evaluation present obstacles, but by no means are they insuperable. The technologies of groupware will allow students to engage remotely in collective activities, to do homework, to discuss assignments and to exchange information and opinions.

Beginning at the other end, the dissatisfaction with the terrible state of K-12 is leading many families to augment and even to replace classroom learning with home-based learning. Many children are now adept with computers by ages three to six. For them computer-associated technology will not be appliances, but prosthesis, intimate parts of their being, in the same way that for massive numbers of people eyeglasses are no longer appliances but prosthesis.

An emerging child generation will drive expectations higher and higher in K-12 and into college for ever more sophisticated learning tools. If they are not there, they will be available at home. The most important development at home will be the electronic home-work study center.

Education of course will be increasingly tailored to the individual. Automated learning aids will allow one to achieve things currently unattainable, by evaluating first what the student exactly knows, second what needs to be poured into his or her head, then what the student's preferred learning strategies—acoustic, visual, or tactile—are. Optimization of learning will occur and the ability to learn more and better will be striking.

Related to that, we will see for the first time complete learning. No longer will 85% to 95% in a course be enough, because it means that you have not learned everything. Teaching technologies will make a complete grasp possible. After all the technology can be infinity patient and generous in stimulating rewards.

Further effects of information technology through education will not merely improve thinking but introduce new modes of thinking, as information technology becomes dynamic, with screens automatically changing and moving, as it becomes interactive, and as it becomes multidimensional. These new aspects of learning are so unfamiliar that as they become familiar they will alter the very ways that we think.

In Summary

What lies ahead is continuing enhancement of the quality of human life on a worldwide scale in unprecedented richness. The damage so common in the early phases of the industrial-scientific era will find their analogs in the future. But the expanding capabilities of science are better able to look for earlier

indicators of most problems and to propose and effect resolutions. However, science and technology are not autonomous forces, but they and their benefits are most likely to flourish in democratic societies.

The Future of Innovation Research

Tudor Rickards

Manchester Business School, U.K.

Abstract: Innovation research will increasingly be oriented towards the challenges presented by environmental complexity and turbulence. More progress may be expected in understanding the relationships between creativity and innovation. Innovation will inform, and be informed by, related fields of theory-informed practice such as knowledge management. The speed of product turnover (the velocity issue) will strengthen the case for practitioner-researcher coalitions. The relationships between the roles of the innovation players, team factors, and outputs will receive more attention. The theoretical stance advocated by critical theorists may also make a contribution in challenging more conventional organizational views of innovation.

Keywords: Creativity; Innovation; Complexity; Diffusion of innovation; Multi-level models.

Introduction

Someone once ironically said that any attempt to predict is foolish, particularly if the predictions are about the future. There is a more serious point to be made if we consider that to predict the future of a research field is to attempt to identify continuities and shifts in highly abstract mental constructions or paradigms. Nevertheless, there is a case for offering some thoughts, particularly if they are buttressed by ideas of the many diligent and distinguished researchers and practitioners. For this, I have relied primarily on an updating of a survey which I carried out recently (Rickards, 1999).

This treatment gives us some slight impression of the contours of the vast and sprawling territory of innovation. In my own survey, I reached the conclusion that since the time of Schumpeter (1912), innovation has attracted an eclectic set of researchers, policy makers and practitioners. Yet they seemed to fit into two reasonably coherent categories, namely those operating from an economics perspective, and those taking an organizational perspective. I will be concentrating more on the organizational perspective (which again is the more dominant in this handbook). We should not ignore, however, the debt that is owed to work from the so-called Austrian school of innovation theorists, later incorporated into the influential historical analysis of the capitalist system by Friedrich von Hayek (see Peters, 1992, for an introduction to Hayek's contributions to contemporary innovation practice).

Innovation retains its fascination as a process through which change may be purposively influenced. The notion that individuals and social groups may influence their world is a legacy of the enlightenment in Western thought. As a concept it grew along with the belief that rational (scientific) methods permit knowledge gains and human dominion over the forces of the natural world. This provides a platform of understanding of innovation at a philosophical level. At a different level of enquiry, we may be interested in the manner in which innovation occurs in the school-room, the artist's studio, or the entrepreneur's fledgling business empire. We need hardly be surprised that innovation, a word forced to stand for activities across such a rich set of categories, resists a unified yet coherent treatment. We are nevertheless forced to ask whether unifying principles and themes are to be detected—either within this handbook or beyond its pages? A negative answer implies that innovation researchers have begun the 21st century embarrassed by intellectual riches in the field, and impoverished with regard to sound integrative principles of their subject matter.

Linearity and Multi-Dimensionality

There remains a gulf between the instant answers offered in popular managerial texts on innovation, and the caution exercised by scholars. The informed view over the last decade has been one of realistic acknowledgement of the distance to go before the quest for

integrating theory can be considered a success (Drazin & Schoonhoven, 1996; Rogers, 1995; Van de Ven, 1986; Van de Ven & Poole, 1995). In one of the most influential textbooks, Tidd et al. (1997) made it a central theme that innovation has suffered from perspectives that have been inadequately multi-dimensional. A special edition of the *Academy of Management Journal*, a few years ago, called for more efforts at developing innovation models that span levels (e.g. individual, organizational, and market/environmental levels). The editors noted "... we were disappointed to discover that no dominant theoretical perspective had emerged to integrate the multiple streams of innovation research" (Drazin & Schoonhoven, 1996, p. 1065).

The trend in innovation research, and one which seems likely to continue, is a shift in attention away from relatively simple, linear, and universalistic models to more complex multi-level multi-dimensional ones. It is a trend well exemplified in this handbook: the more focused research contributions are deepened and extended to acknowledge complex environments, and innovation trajectories.

Historically, innovation was for several decades regarded as primarily a technological phenomenon. Later studies were to replace the centrality of technology with the centrality of market forces. That is to say, technology push was replaced by market pull. This 'either-or' swing misses the point that innovation incorporates both technology and market influences. As is also well-known, contingency theories gain in completeness at the expense of simplicity and clarity. This may also occur the expense of failing to provide any convincing normative principles for practitioners ('It all depends' is not the most comforting advice that might be offered to an executive in search of innovation guidelines).

This is not to reject the utility of limited range linear models grounded in empirical and theoretical evidence. Cooper (1988, 1992) has been among the most influential of the normative analysts of success factors for innovation (See also Cooper & Kleinschmidt, 1987). His celebrated stage gate model illustrates the power for innovation practitioners of a simplifying linear treatment as a means of exemplifying and surmounting institutional barriers to effective innovation (Drazin & Schoonhoven, 1996). It offers a means of controlling the risks of innovation and has found widespread acceptance, for example in complex technologically oriented projects as found in pharmaceuticals and engineering industry sectors. Nevertheless, an important issue returns to haunt the practitioner. Success factors are presented for innovation which has been notoriously regarded as having instability of success factors both at the level of comparing specific innovations, and across studies (Downs & Mohr, 1976). In some ways Cooper's methodology typifies the limitations of a linear

approach: it offers general factors with scope for specific project managers to change that which needs to be changed (*mutatis mutandis*) in order to adopt the general template for specific conditions. The linearity, as Mintzberg (1994) warns us, also conceals various practical and conceptual difficulties. Consider, for example the issue of novelty. Cooper, as has other researchers, resorted to modeling creativity as residing primarily at the 'fuzzy front end' of the linear process (Khurana & Rosenthal, 1988, 1997).

An evolutionary path for research models can be traced. Early innovation models as well as later versions such as Cooper's, placed the generation of novelty at the start of a simple set of stages. As Rothwell (1992) points out, research into innovation refined the basic linear model, until today we seek to incorporate more uncertainties, (Gleick, 1987; Stacey, 1992, 1996), and indeed seek to address multiple levels (individual, organizational, and market context).

The implications of this for innovation research are, I believe, profound. I suggest that at present, and in the near future, simple linear models of innovation will increasingly be found theoretically inadequate and empirically inconsistent across studies in different contexts. At present we can only regret the lack of solid longitudinal studies, and multi-level contextually rich studies. In the future, this will be increasingly acknowledged, and researchers will be encouraged to address this difficult challenge. The globalizing context will encourage efforts to understand innovation in more complex and contextual ways, in what has been described as the new competitive landscape (Bettis & Hitt, 1995). New institutional forms contribute to the increasingly information-rich innovation context (Child & McGrath, 2001).

Researching Creativity's Role in Innovation

I have observed a growing tendency for the concept of creativity to be assimilated into the innovation process, often at the 'fuzzy front end' of the process. I predict that this will become a focal point for researchers, and that the research will help clarify the relationships between the two constructs.

Conventional economic models of innovation have little to offer regarding the origins of unexpected ideas that challenge rational expectations. We are better seeking insights into creativity from the social scientists, (de Bono, 1971; Gardner, 1983/1993; Koestler, 1964; Perkins, 1983; Sternberg, 1988; Sternberg & Lubart, 1991; Walberg, 1988) and the information theorists (e.g. Boden, 1994; Nonaka & Teguchi, 1995; Price & Shaw, 1988; Simon, 1996; Stacy, 1996).

An early influential model was that of Campbell (1960), a pioneer of an evolutionary theory of creativity. The core idea is that of blind variation and selective retention leading to persistence of unique new innovations. Thus, once again, we have a perspective which seeks to explain the origination of novelty

within innovation processes. Campbell offers a way of dealing with the unpredictable aspects of innovation. These have been addressed in other ways: emergence (Mintzberg, 1994, writing from the perspective of strategic planning); unintended consequences (Argyris, 1990); and ‘wicked’ problem-solving (Rickards, 1990; Rittel & Webber, 1974).

In an earlier commentary, I noted that the two terms (and therefore the concepts) are often conflated (Rickards, 1991). This observation is strongly supported by contributors to this handbook, in which the term individual innovation has been used as an integrative and organising construct. A similar decision was made in an earlier text by West & Farr (1990). In such a treatment, individual innovation has been applied rather interchangeably with the term creativity. Conflation may also diminish the attention paid to the transcendental and psychological aspects now emerging in the domain of creativity research (Andreasen & Canter, 1974; Eysenck, 1994a, 1994b; Jamison, 1993; Sass, 2000–2001; Sass & Schulberg, 2000–2001). I select the contributions by Sternberg and Kaufman to illustrate the point, and to suggest that this is a shift from the vocabulary of their own earlier work.

Sternberg and coworkers have made many distinguished contributions to our understanding of the ‘creative’ part of the innovation process (e.g. Sternberg, 1988; Sternberg & Davidson, 1995; Sternberg & Lubert, 1990). Kaufmann has offered a European perspective, (for example, through his authoritative chapter in Gronhaug & Kaufmann, 1988). It is perhaps significant that each of these authorities writing for this handbook seem prepared to depart from the vocabulary they have found more congenial in other publications (namely the vocabulary of creativity) and espouse the vocabulary of individual innovation. We may conclude that the authors do not feel there to be a significant loss in such a shift. In the past I have welcomed the support provided to the creativity field by these distinguished figures. They have been inspiring companions as the journeys of creative exploration have suffered pretty stormy seas of criticism whipped up by others of a more mainstream psychological orientation. Now it appears that they have ‘jumped ship’, (or changed horse in mid-stream, to offer another aquatic metaphor).

We may perhaps be seeing a possible future trend in innovation research in which creativity is assimilated. This would have some advantages as for many researchers and practitioners in economic fields, creativity seems to be a less credible and operationalizable construct (Rickards, 1999a; Stein, 1987). In contrast, innovation perhaps receives an over-positive bias or halo effect (Abrahamson, 1990).

Yet we should ask whether there a valuable distinction to be drawn between a creative poem and an innovative poem? I believe the answer to be a clear yes. Is there a distinction to be drawn between a creative

novel and an innovative novel? Again, I believe the answer to be in the affirmative. But what about the distinction between a creative design and an innovative design? Or a creative product and an innovative product? My suspicion is that we have some way yet to go to deal with this question.

The issue may begin to resolve itself, if we return to the idea of creativity as mediated by environment (or ‘press’, as the creativity researchers refer to it). For the initial stages of design and innovation, the novel and ‘blockbusting’ idea has a greater chance of succeeding. As the innovation proceeds, there are inevitably more constraints, and the creativity required is more of a marginal or incremental kind. In other words, there is need for creativity as long as there are uncertainties (which persist throughout the innovation process). But the creativity needed at the finish line is creativity is not so much blockbusting, as developmental. The issue will overlap with considerations of composition and competences required in innovation teams.

Emerging Fields Impacting on Innovation Research

This handbook signals the exciting new fields that are impacting on innovation research. Writing from the home base of a Graduate School of Business, I am particularly interested in the emerging themes that have enriched management theory over the last few decades, and which are the candidates for influencing innovation research into the 21st century. In general, the boundaries of proximal fields are particularly rich in innovation opportunities (Gryskiewicz, 1999). The trend towards emergence of fresh innovation interfaces will continue, I suspect.

One such interface is that between the producer and consumer of meaning (e.g. Goldsmith & Foxall, 1994; using the innovation style model of Kirton, 1976, 1994) The work has implications for models assuming diffusion process of innovations (Rogers, 1995).

Knowledge management is another area of research which is clearly muscling in on the innovation domain (see, for example, Bierly & Chakrabarti, 1996, and Spender & Grant, 1996 for a strategic treatment). It is hardly surprising, and indeed the intractable complexities (all too apparent in this work) in the field of innovation may encourage more researchers to look to knowledge management to provide a new perspective. The links are clear. Innovation requires the generation of new insights, and the actualization of innovative outputs (‘products’). Knowledge management is also concerned deeply about the origin, retention and management of ideas (Helfat, 1997). My suspicion is that some of the old innovation wine will be reappearing in new vintage knowledge management bottles. It is unclear whether the conceptual underpinnings of knowledge management will be any more secure than those underpinning the great edifice of innovation studies.

Other hot interface issues referred to in this work, and also to be found elsewhere in contemporary management theory generally, are network theory (e.g. Nohria & Eccles, 1992); constructivism (Weick, 1995); cultural variations in economic form (Whitley, 1999) and stakeholder theory (Donaldson & Preston, 1995; Jones, 1995). We may see how such fields may contribute to research development of understanding of innovation in a range of areas. One such would be National Systems of Innovation (Dodgson & Bessant, 1996; Lundvall, 1992; Pavitt, 1999). Another would be a revisiting of the extensive literature on innovation diffusion (Rogers, 1995), and the management of complex innovation projects, e.g. through alliances (Gulati, 1999).

The 'Increasing Turbulence' Theme

It has become a commonplace to point to technological forces contributing to ever-increasing environmental turbulence in which rapid technological change and knowledge turnover are critical features (Bettis & Hitt, 1995; Hamel & Prahalad, 1994). This theme seems to be one that will be enriched through studies of high velocity environments, (Eisenhardt, 1989; Gersick, 1989, 1991; Lawless & Anderson, 1996). The themes seem to be contributing to interest in more complex innovation models (Drazin & Schoonhoven, 1996). It accords with the trends in innovation research indicated in this handbook. The shift is towards interest in complex turbulent and even chaotic environments.

There may well be a more considered view in which turbulence may be of a more cyclic nature, as it plays out in competitive survival rates of innovative firms. Whatever, the details, turbulence remains an emerging and important theme.

The nature of complexity has consequences for the old question of diffusion of innovation, which may become revitalized by a generation of neo-Darwinists taking ideas of social genetics from the likes of Dawkins (1976, 1989), Price & Shaw (1998), and Dennett (1995). In this we may detect another consequence of the electronic innovation revolution. Emerging theoretical ideas seem to be assisted through the speed and ease of electronic publishing. The researchers into memetics typify countless and fragmented 'research factories'. Debate is vibrant, and largely uncensored (one from many recent examples would be Edmonds, 2001). The turbulence may be further linked with increasing interest in managing turbulence e.g. Gryskiewicz, 1999). The knowledge industries will bring their own challenges of ethical management.

This matters for example, in competition for resources across possible research fields, and policy decisions for allocating those resources. These competing fields are seeking to accommodate growing interest in ethical dimensions of corporate life, sustainability, leadership, and new institutional forms. Even such

innocent terms as modernization are opening up the debate into work/leisure issues as never before. Much of relevance to these and other contemporary vital topics may be found, often hidden away, within the current and potential boundaries of innovation research. Innovation researchers will find many more points of contact with these fields in the future.

Power to the People: Roles of Players in Innovation Research

The role of the corporate entrepreneur as innovator dates to Schumpeter (1912). Pinchott's intrapreneur (1986) has attracted some attention, and may yet have more life in it (e.g. Barringer & Bluedorn, 1999; Birkinshaw, 1997). Other innovation roles have been attributed to product champions (Schon, 1965; Markham, 1999); and a confusing number of inter-related terms (Roberts & Fusfeld, 1981).

Interestingly, leadership *per se* has not been given a great deal of attention in innovation studies. I expect that to change. (Incidentally, leadership has attracted far more attention within the creativity and problem-solving literature, where a special process-orientated facilitator is frequently described and studied).

Within management studies, leadership remains a topic as confusing and multi-faceted as innovation itself. Currently, attempts to integrate the two fields have been limited. It was good to see one contribution here from Deschamps in this work). However, it is the slightest of signals in such a comprehensive collection of work. I suspect that there will be more interest in the next decades. I base my belief on several converging themes. First, the demand for more authoritative understanding of leadership processes from executives and MBA students is being reflected in more courses on offer (as a web search quickly reveals). Our own recent research in this area suggests that links between leadership, team factors and innovative outcomes exist, and have yet to be examined in a satisfactory fashion (see Rickards, Chen & Moger, 2001). The emerging theme may throw light on the role of transformational leadership in innovation, and organizational productivity.

Towards a More Critical Theory of Innovation

Technology advances have in the past been given primacy in the variables relevant to innovation. The handbook shows that such a view is now far too simplistic. Technology matters, yet is not regarded as one among many variables of interest. Taken with other consequences of uncertainties and risks associated with innovation, we should also remind ourselves of unintended consequences of technology, and the increasing social suspicion of a technically-driven change agenda. Some writers have suggested (e.g. Abrahamson, 1991) that innovation is far too widely investigated from a perspective that innovation is of itself a good thing (the economic driver argument). My electronic experience

left me wondering what had been gained, and what lost when we fall prey to new technological innovations. To what degree are we benefitting individually and collectively from it? The technological eutopia/dystopia debate will rumble on, as innovation researchers investigate the latest turns in the story. Hard core technophiles should consider the cases in the amusing book by Tenner (1996) on 'why things bite back'.

The study of innovation, despite its various influences, has tended to locate itself towards the more conventional organizational perspective (premised on economic theory of the firm and a unity of purpose or mission (Alvesson, 1993; Willmot & Knight, 1982; Linstead, Small & Jeffcutt, 1996). Critical theory and post-modern analyses represent two emerging approaches that may have new perspectives to offer.

Critical theorists may be seen as scholars seeking to challenge the very core beliefs of prevailing knowledge systems. For example, they are more inclined to regard organizations as battle-grounds. Innovation missions are studied as expressions of rhetoric. Such approaches are being introduced into conferences as interest turns towards the creative industries (conservatively estimated as 10% of GNP in a recent U.K. government survey). The approach seems particularly appropriate for taking a fresh look at the conflicts between creative individuals seeking to gain acceptance for their ideas, and the organizational executives seeking to commercialize the ideas ('the suits').

Another possible trend comes from workers taking a post-modern approach in some business courses (Boje et al., 1996). The post-modernist argues that innovation studies reflects a dominant belief that has successfully silenced the alternative voices. A post-modern approach is believed to be particularly relevant for examining the nature of the virtual, which is of increasing interest (virtual innovation teams, intellectual property, invisible networks of interest). In short, critical and post-modern thinkers may be well placed to offer alternative critiques of the innovation phenomenon in its 21st century guises.

Research on Innovation at the Beginning of the 21st Century: What Do We Know About It?

Larry R. Vandervert

American Nonlinear Systems, USA

The Nature and Development of Innovation: An Arrow of Innovation?

Abstract: Innovation is about producing new and useful ideas and products. In this handbook the nature and development of innovation center on the mental mechanisms that propel it. To provide a framework for conclusions about the broad spectrum of ideas and applications of parts II through VII, an evolutionary 'arrow' of innovation is developed.

Keywords: Evolution and innovation; Innovation; Innovation management; National innovation systems; Social context of innovation.

The Meaning of Innovation

Innovation is about producing new and useful ideas and products. This may seem like a simple, ho-hum description of innovation, but scientists and business scholars interpret this statement in different ways. What exactly is involved in producing something 'new'? What does 'useful' mean?

Sternberg, Pretz & Kaufman (Part II) propose that, 'Innovation is the channeling of creativity so as to produce a creative idea and/or product that people can and wish to use'. For these authors, this notion of innovation inherently includes a social dynamics (forces) ingredient—innovation invariably 'propels' a field in some way. On the other hand, however, for Weisberg (Part II), while innovation is synonymous with a creative product, this product does not necessarily carry value beyond the individual who creates it. Further, Weisberg does not feel that innovation goes beyond the processes of ordinary thinking—for him innovation is 'ordinary thinking writ large'. In other words, creative and innovative people use ordinary thinking in extraordinary ways. This is analogous to saying that Olympic champions, for example, use the same muscles ordinary people use; they simply excel in their use. In my own work on the neurophysiology of innovation (Vandervert, Part II), I agree with Weisberg that innovation involves no special processes beyond elaborated ordinary thinking.

However, Root-Bernstein (Part II) proposes the idea that creativity and technology consist of effective *problem raising*. In other words, creativity and innovation are based first on the adequate formulation of problems. It can easily be shown that the process of evolutionary natural selection supports Root-Bernstein's approach. That is, if an organism does not have the mental machinery to recognize and formulate a problem as a problem, it is not likely to survive. Each niche is all about the organism's special capacities to first recognize what might be problems, and, then, second to solve those problems. But this leads us to a rather deep theoretical question: *How and why would organisms generate hypothetical problems?*

Standing at the end of a long evolutionary trend in survival strategies, human beings don't just respond to problems, they generate countless hypothetical problems. Each person, ordinary or extraordinary, has an immense capacity for generating hypothetical problems—many that they may never be able to solve. People spontaneously wonder about all sorts of things. Why would mental functions have evolved that create such 'surplus' problems, the solutions to some of which could lead to an ever-expanding knowledge of their surroundings?

The answer to this question seems to be based on the fact that, from the organism's point of view, survival is most often based on what will happen in the next few

moments. And, these next few moments will probably not consist of a simple, straightforward extrapolation of past problem situations, or even the immediate past moments. As Fox (1988) pointed out, ‘the dynamics of organism movements and their interactions with the dynamics of other organisms and with the environment are usually nonlinear phenomena’ (pp. 160–161). This nonlinear moment-to-moment problem situation makes predicting the next moves of a prey or predator very difficult, if not impossible. In order to deal with the problem of predicting the outcome of real-world survival-dependent situations, organisms would have to be selected to generate predictive rapid *simulations*¹ of such problem situations. These simulations are experienced as various series of constantly updated hypothetical moves a prey or predator might make. This is the basis, I think, of the generation of ‘surplus problems’, and, at the human level, it seems it is literally the basis of wide-eyed ‘wonderment’. Simon-ton (in press) has developed arguments that parallel this idea in what he calls *constrained stochastic processes* of creativity. Such quasi-random processes would be the perceptual-cognitive counterparts of the nonlinear survival situation described by Fox.

The fact of the matter, of course, is that all three of the above approaches to innovation are on the right track. There are strong social, mental and behavioral dynamics associated with innovation, and these dynamics exist in everyone. Innovations are characterized by most as new and useful solutions. But, at the same time, innovation must begin with new problems. And, in the large sense, innovation is about some sort of forward movement or anticipation of change. To more clearly understand this fundamental forward-looking dynamic of innovation, we can look briefly at some of the most exotic innovative ideas humans have ever produced.

Innovation and the Arrow of Time

Creativity and innovation are probably the most powerful engines of the human intellect. It is only through them that all new worlds of art, science, and

technology are conceived and ultimately realized—and this includes, of course, the rarified mental/technological world in which the theoretical physicist works. In perhaps the most rarified of worlds, Stephen Hawking (1988) described three arrows that give a direction to time, namely, the thermodynamic arrow of time, the psychological arrow of time, and the cosmological arrow of time.² For the physicist, it is fundamental that the evolution of virtually everything in the physical universe has some rule of *directionality* associated with it. Hawking points out that that in everyday, real world affairs, and this would include the phenomenon of human innovation, all three of the arrows of time point in the same direction.

Does the developmental course of innovation have an ‘arrow’, and, if so, does this arrow have an identifiable underlying mechanism? While the contributors of various chapters of the two landmark volumes of this handbook may use differing terminologies, these are the two most basic questions that are addressed. Therefore, I will probe these two questions to develop general conclusions for the volume that will encourage an open interpretation of the great collection of ideas and applications presented, and, at the same time, hopefully create new questions and problems. In keeping with Root-Bernstein’s sentiments on the importance of ‘problem raising’, perhaps the creation of new questions and problems is the best way to further the extraordinary work of the many contributors of this volume.

² Briefly, Hawking (1988) described the three arrows of time as follows:

There are at least three different arrows of time. First, there is the thermodynamic arrow of time, the direction of time in which disorder or entropy increases. Then, there is the psychological arrow of time. This is the direction in which we feel time passes, the direction in which we remember the past but not the future. Finally, there is the cosmological arrow of time. This is the direction of time in which the universe is expanding rather than contracting (p. 145).

The only term in the above quote the reader may be unfamiliar with is *entropy*. Entropy refers to the tendency of things to become disordered or to ‘deteriorate’ over time if left to themselves. That is, as time passes things will tend to ‘fall apart’, unless they are maintained. But even the energy used in maintenance reduces the available ordered energy, thus resulting in a net disorder in accordance with the entropy principle (see Hawking’s classic and easy-to-understand explanation of how your brain increases entropy by reading this book, pp. 152–153).

To better understand the broader context and fundamental significance of these three time arrows for innovation and how the arrow of all mental processes is conceived to be embedded in matter/energy/information, it is recommended that the reader be familiar with Hawking’s entire chapter, ‘The Arrow of Time’. As most know, Hawking wrote *A Brief History of Time* for the layperson, and the chapter on the arrows of time is quite understandable for that reader.

¹ Mathematically, prediction can be accomplished for linear and simple nonlinear situations using formulae which provide immediate closed-end solutions. However, for maximally complex nonlinear situations like those involved in Fox’s prey-predator scenario, prediction of families of future potential trajectories can only be accomplished by stepping through iterative *simulations* that run faster than the real-time events are unfolding. Behaviorally, such rapid simulations can be thought of as translating into vicarious trial and error behavior (rapidly running- or looking-back-and-forth in the face of problem situations) which can be observed in a broad variety of ‘organisms’ from rats in ‘T’ mazes to NBA basketball players in the heat of a game. Mentally, rapid simulations in vicarious trial and error, going back to even Tolman (1926) have been interpreted as oscillatory representations in imagination.

Restarting From Older Times

Sometimes in order to formulate a new view and new questions, we need to revisit older knowledge and re-evaluate its promise in terms of more recent thinking (see *Reconstruction/Redirection* type of innovation (Sternberg, Pretz & Kaufman, Part II)). Either explicitly or implicitly, Darwinian evolution is a common backdrop running through most of the chapters of Part II (especially, Bailey & Ford; Georgsdottir, Lubart & Getz; Marinova & Phillimore; Nickles; Vandervert). Nickles (Part II) points out that Darwin's evolutionary natural selection of biological and technological forms is uninformed as to outcome. However, like the directional arrows that Hawking described for the physical universe, both biological and technological evolution do appear to follow an 'arrow' or direction of development. To understand how such an uninformed, evolutionary arrow could work, we must go back to the evolutionary ideas of Ludwig Boltzmann, who without knowing it, provided the initial key. Boltzmann (1905) brought evolutionary processes into the *energy* realm in his classic statement on what natural selection is really all about: '(the) struggle for existence is the struggle for free energy available for work' (p. 23). In other words, selective 'fitness' refers to energy-capturing fitness. When the fox captures the rabbit, the only real, selective payoff is fur-covered *energy*. Later, further elaborating Boltzmann's conception, Alfred Lotka, a brilliant mathematical biologist, gave evolution the following arrow of *direction*: 'Evolution proceeds in such direction as to make the total energy flux (flow) through the system a maximum' (1922, p. 147).

The Arrow of Artistic, Scientific, and Technological Innovation

Lotka subsequently described how the evolutionary arrow of increasing energy flow has made its appearance in the overall history of innovation:

Man, one of the latest, and in his own judgment the highest product of evolution, has hitherto signally conformed with the principle of increasing energy flux (flow). By ingenious contrivances he has immensely refined and multiplied the operation of his receptor-effector apparatus. The excess of energy /information captured, over the energy /information barely sufficient for mere maintenance, has in his case grown to a wholly unparalleled magnitude. Normally this leaves him with a large balance available for 'play' activities and luxuries. And some of his play activities have turned out to be a most profitable reinvestment. For among them must be classed scientific research (and all forms of artistic endeavor) indulged in primarily out of curiosity, but resulting among other things in that complete recasting of methods of production which is known as the industrial and agricultural revolution. Aside from its direct benefits this has made it possible to

spend relatively large amounts on sanitary improvements, on medical education and research, and, above all, on better living among the masses of the people (1945, p. 188).

Lotka's scenario is a handy way to get an aerial view of how the uniquely human explosion of innovation is embedded within evolution. In the above portrayal of the mechanism and arrow of innovation, Lotka describes how the increasing efficiency of the energy flows provided by innovative contrivances magnifies all human tendencies. It is seen in the many chapters of this volume that there is not a cognitive capacity, field or domain of knowledge that the nervous system does not, as Lotka says, immensely refine and multiply through its contrivances of innovation (compare, Carayannis, Gonzalez & Wetter, Part II). Below, I will link this idea to several of the domains described in Part VII.

Thus, the arrow of innovation adds a needed 'directional content' to the abstract processes of natural selection that many chapters of this volume skillfully describe as underlying innovation.

Innovation in Different Domains

What is it that propels the innovative work of human beings in the various domains of technology, ideas, and art? The answer to this question has at least two appearances. First, how does the mind (or the receptor-effector apparatus in Lotka's terminology) develop innovations in the various domains of human activity, and how does it generate domain-relevant problems? (See Root-Bernstein, Part II.) Second, how might the various domains be related to the types of contributions of innovation that have been identified by, for example, Sternberg, Pretz & Kaufman (Part II)?

The First Question (The Development of Innovations in Various Domains)

It is through innovation, and only innovation, that the human mind connects the structure of its internal world (see the detailed synthesis by Shavinina, Part VII), with that of the external physical world of technological, and scientific and artistic creations. It appears that innovation, arguably the most complex of all mental operations, is orchestrated in every domain through the guiding structure of the mental models that comprise the domains (Chi & Hausmann; Dasgupta; Scripp & Subotnik; Shavinina, Part VII; Shavinina & Ponomarev, Part VI; Shavinina & Seeratan; Vandervert, Part II). The personal and social collections of mental models of a domain 'are' the domain, and an infinite variety of such domain-specific mental models can be constructed from experience.

Many, including myself, have argued that the mental models of each domain *propel* (in the sense proposed by Sternberg, Pretz & Kaufman, Part II) searches for new levels of efficiency (for example, Vandervert,

Part II). How, exactly, mental models guide problem searches for new and useful variations in the models is not yet clearly understood (compare the categories of problem-generation proposed by Root-Bernstein, Part II). However, David Ingvar has offered a very promising explanation based on both experimental and clinical evidence that centers on how the prefrontal cortex of the brain handles action programs or plans for future behavior and cognition:

It is concluded that the prefrontal cortex is responsible for the temporal organization of behaviour and cognition due to its seemingly specific capacity to handle serial information and to extract causal relations from such information. Possibly the serial action programs which are stored in the prefrontal cortex are also used by the brain as templates for extracting meaningful (serial) information from the enormous, mainly non-serial, random sensory noise to which the brain is constantly exposed (1985, abstract, p. 127).

The serial action programs that Ingvar describes may be viewed as search programs that are used in planning, simulating (imagining) new states of affairs, and gathering information that potentially can lead to the generation new conceptions within the various domains. Thus, serial action programs are the means by which mental models construct future states. Action programs do this, in concert with other brain functions, by guiding the extraction of new patterns of causally linked information. Since this newly extracted serial information may or may not be fully understood by the person, the new patterns would occasionally be experienced as the recognition of new problems in the pertinent domains. The recognition of these new problems could then potentially lead to various types of innovations.

In accordance with Ingvar's findings, then, when mental models are acquired through education and experience, one thing that happens is that new categories of problem searches are established. For example, the mental models inherent in a particular type of curriculum set in motion in the student's mind the extraction of certain categories of serial information from the environment. Consequently, the student begins to generate new (new to the student) kinds of questions (Compare with Scripp & Subotnik, Part VII).

The Second Question (How Different Domains are Related to Types of Innovation)

William Ogburn, a sociologist, proposed that the basic determinants of social change were invention and innovation. Ogburn believed that material innovation generally became part of the fabric of society more rapidly than new ideas. He referred to this idea as *cultural lag*. Is there a cultural lag effect across

different domains of innovation, in that, certain domains tend to be related to certain types of innovative contributions (à la Sternberg, Pretz & Kaufman, Part II) and not others? For example, following in the vein of Ogburn's theory, are rapidly diffusing technological innovations more likely to be of Sternberg et al.'s 'smoother' *replication*, *forward incrementation*, and *integration* types of innovative contributions? And, are the more slowly diffusing idea-related innovations more likely to be of the 'idea/value-weighted' *redefinition*, *advanced forward incrementation*, *redirection*, *reconstruction/redirection*, and *reinitiation* types?

To help illustrate this very tentative idea, each of the chapters appearing in, for example, Part VII can be examined with this question in mind. Although each of these chapters involves several types of innovation, here are what appear to be the two dominant types of innovation for each of the nine chapters of Part VII:

- Chapter 1. Replication; Redefinition
- Chapter 2. Redefinition; Redirection
- Chapter 3. Redefinition; Integration
- Chapter 4. Redirection; Integration
- Chapter 5. Replication; Forward Incrementation
- Chapter 6. Redefinition; Forward Incrementation
- Chapter 7. Reinitiation; Integration
- Chapter 8. Replication; Forward Incrementation
- Chapter 9. Replication; Integration.

An interesting issue that this sort of an examination brings to mind is that innovators (including, of course, those who write about and research innovation) might consider casting and tweaking the 'packaging' of new gadgets and ideas with an eye on their probable rates of diffusion. How quickly will this product or idea be become disseminated among target consumers? (Compare in this regard Goldsmith & Foxall, especially, their section on 'Why Measure Inventiveness?' Part V).

The Development of Innovation

About half of the chapters on the development of innovation appearing in this volume address the mental and emotional mechanisms that are involved in the development of innovation (Root-Bernstein & Root-Bernstein, Part VI; Simonton, Part IV). The other half describes how innovation can be encouraged through structured learning environments. Largely due to the applied nature of their subject matter, these latter chapters are, themselves, well-structured learning environments (see Kostoff; Reis & Renzulli; Shavinina & Ponomarev, Part VI). This situation presents the reader with a special opportunity. By bringing together the mental/emotion mechanism chapters on the one hand with the chapters on structured learning environments on the other, the reader will form a powerful literature-based/workshop-based approach to innovation of the

type described by Kostoff (Part VI). In this manner, the reader can experience a real world approach to encouraging thinking about the topics of innovation.

Following this idea, Root-Bernstein and Root-Bernstein's (Part VI) 'tool kit' of pre-logical and pre-verbal skills for innovative thinking (namely: (1) observing; (2) imaging; (3) abstracting; (4) pattern recognizing; (5) pattern forming; (6) analogizing; (7) bodily-kinesthetic thinking; (8) empathizing; (9) dimensional thinking; (10) modeling; (11) playing;

(12) transforming; and (13) synthesizing) seems to connect itself to David Ingvar's above description of how the prefrontal lobe extracts meaningful patterns from the largely non-serial sensory environment. The thirteen skills of the tool kit may be looked upon as the critical skills for building robust mental models (in any domain). Such mental models will enhance the search for new categories of serial information that will in turn be most likely lead to new questions and problems and thus to innovation.

Innovation and the Social Context Integrated: Where We Are and Where We Are Headed

Abstract: The great diversity of ideas and issues appearing in Parts VIII through XIV are presented in three integrative mappings. From these mappings a bright thread appears that shows a unity among all of the chapters. This bright thread reveals that a common social matrix resides behind all innovation.

The great diversity of ideas and studies of innovation and the social context present a particularly difficult problem for presenting a succinct, conceptually integrated conclusion. Therefore, in this concluding chapter, I provide three simple mappings for the larger parts of the volume. Mappings have the advantage of providing a graspable snapshot of complex issues. The mappings will be discussed in a manner that will both capture the components of the diverse territory of all of the chapters and reveal many of the dynamics that interrelate them.

The three mappings depict overall chapter-to-chapter integrations and help to promote the following interdisciplinary and international goals.

- (1) The continuing investigation of the relationships among concepts and models in various approaches to innovation, and to help in useful transfers of information from one discipline and nation to another.
- (2) The continuing encouragement of the development of adequate theory in areas which lack them.
- (3) The continuing elimination of the duplication of theoretical efforts in different disciplinary approaches to the study of innovation.
- (4) The continuing promotion of a unity of understandings of innovation by improving communication among specialists.

How the Mappings Were Constructed and How To Interpret Them

To construct a mapping of the various chapters in Parts VIII through XIII, concepts and issues had to be identified and then prioritized as to what seemed to be most fundamental. Certainly, these processes of identification and, especially the prioritizing, are difficult and somewhat subjective ordering tasks that I am aware are fraught with casus belli for the community of innovation scholars and practitioners. However, the purpose of the mappings should be looked upon as a first draft of an evolutionary tool that, while perhaps being a source of controversy itself, will help guide the general thinking of both individuals and teams interested in the topics of innovation.

Once the fundamental concepts and issues had been identified, the actual mapping procedure is quite simple and quite intuitive. For each of the three mappings, a central idea or concept was chosen that seemed to typify all of the rest of the concepts and issues for a particular mapping. This central idea was placed in the center of the mapping. Then the *relative* conceptual distance of each sub-concept or issue was indicated in the mapping by the length of the line from the central idea. It is extremely important to recognize that conceptual distance from the central idea does not in any way indicate the relative importance or value of a particular sub-concept. On the contrary, it may turn out in certain circumstances that a 'remotely associated'

concept will prove to be the spark that redirects thinking about the central idea of the mapping.

A Mapping of the Basic Approaches To Understanding Innovation in the Social Context

The organizing theme of the chapters in Part VIII of this volume is the impact of social psychological issues on innovation. This issue has been placed in the center of Fig. 1. Each of the 'spokes' represents one of the chapters appearing in Part VIII.

The overall message of these chapters can be captured in the following general principle: The more the social aspects of a person's or group's 'mind' are directly influenced by innovation, the more this mind will, in turn, influence innovation. Figure 1 shows that the chapters on the effects of managers' creativity schemas (Zhou & Woodman), and innovation/identity (King) seem closest to this idea. But, keep in mind the earlier caution about assuming from the mapping that these issues have the greatest potential impact.

The principle that innovation influences innovation may sound a little like a no-brainer, but it reveals at least three things. First, it means that innovation is socially constructed (e.g. Hadjimanolis). Second, it means that innovation is a learnable enterprise (e.g. Carayannis & Gonzalez). Finally, we can conclude that

the many processes involved in the social construction of innovation are subject to manipulation (e.g. Callahan & Muegge; Hadjimanolis; Nag, Corley & Gioia).

A Mapping of Innovations in Social Institutions

The chapters devoted to Innovations in Social Institutions constitute a nice continuation of the social psychological issues discussed above in Part VIII of this volume. The central idea in Part IX is *social synthesis*. This idea has been placed in the large circle at the bottom of Fig. 2. Each of the additional circles represents one of the other chapters in Part IX or X.

It can be seen from the patterns of the arrows in Fig. 2 that the seven chapters of Part IX are aimed at ideas and issues that are tightly knitted together, with many threads interconnecting them. Social synthesis in these chapters is most reliant upon the human *networking* of ideas and activities (Swan, Scarbrough & Robertson). Extremely close to these issues are the chapters on 'promoters' (Hauschildt, Part X) and knowledge translation (Major & Cordey-Hayes, Part IX). It was of great personal interest to me that the fundamental processes of social synthesis described in all of these chapters are quite analogous to the synthesis toward innovation produced by the collaboration of *brain functions* that I have described in Part II

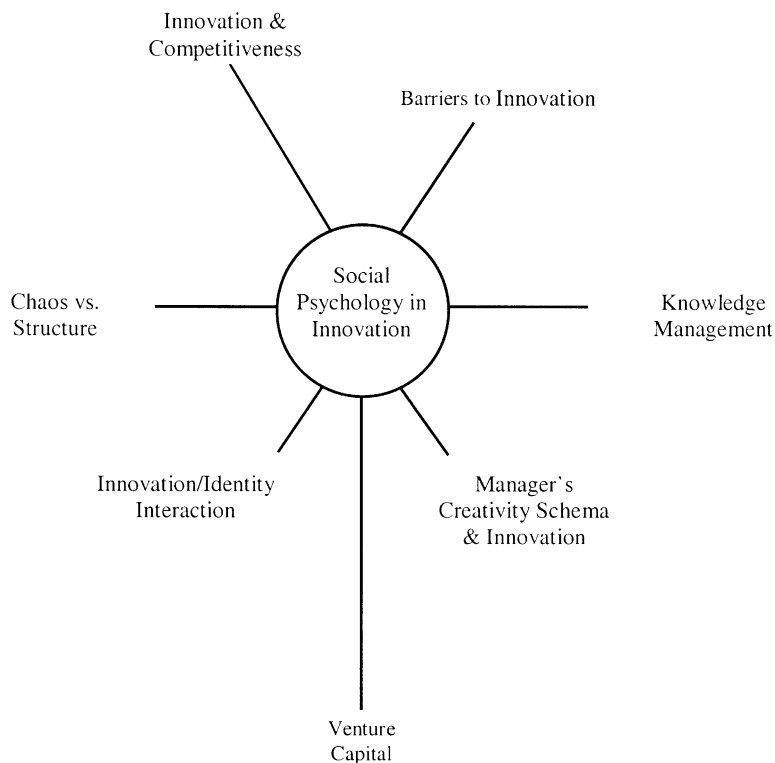

Figure 1. Basic approaches to the understanding of innovation in the social context.

of this Handbook (Vandervert, Part II). For example, Swan, Scarbrough and Robertsons' (Part IX) process model incorporating *invention*, *diffusion*, and *implementation* (see their Fig. 1) has rough counterparts in working memory/cerebellar interaction. And, the neurophysiological model, like theirs, is recursive and nonlinear.

Innovation Management

The main conceptual feature of Part X's four chapters on the management of innovation is the problem of dealing with the contradictory challenges of dualism, that is, 'functioning efficiently today while innovating effectively for tomorrow' (Katz). It seems that the management of innovation must be by nature deeply invested in this dualism, because simultaneous stability and growth are two necessary features of all systems

that survive. For example, in the life development of each human being, stages of consolidation are regularly erected while, at the same time, whole new capacities are coming into being.

This 'dualism' that faces innovation management most certainly has the most fundamental of origins. Odum & Odum (1981) laid out the core simultaneous processes that must be taken into account if a system is to survive, and, I think, to *innovate* competitively. These processes comprise the maximum-power principle of *evolution*, and I have restated them very slightly here to help capture their *informational* significance for innovation:

Those organizations that survive in the competition among *alternative choices* are those that develop more energy-information inflow and use it to meet the needs of survival. They do this by:

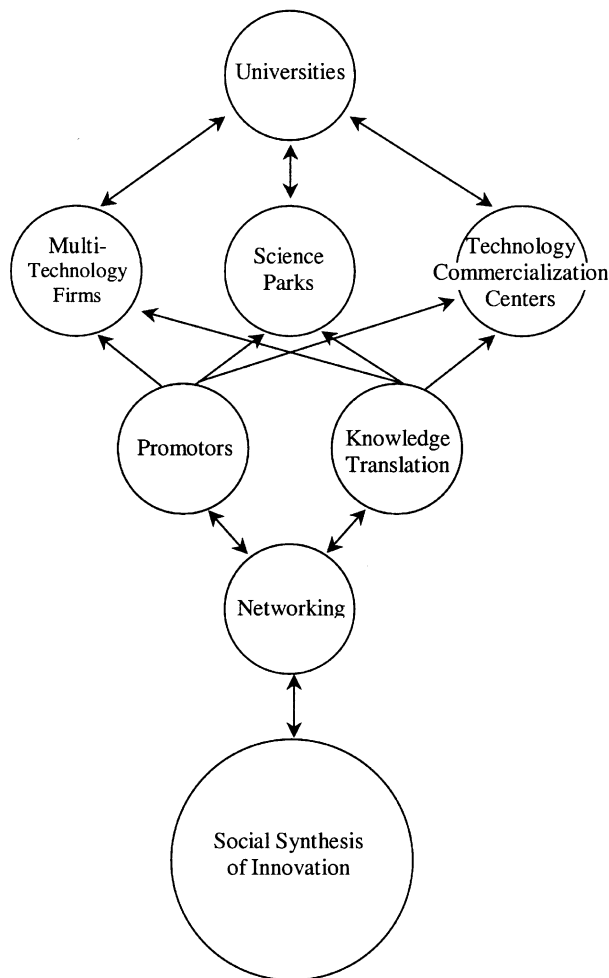

Figure 2. Innovations in social institutions.

- (1) developing storages of high-quality information (see Odum, 1988);
- (2) feeding forward and feeding back information from the storages to increase inflows;
- (3) recycling information as needed;
- (4) organizing control mechanisms that keep their systems adapted and stable;
- (5) setting up exchanges with other organizations to supply special information needs; and
- (6) contributing useful information to surrounding environmental systems that help maintain favorable conditions.

(see Odum, 1988; Odum, 1996; Odum & Odum, 1981)

This, I believe, is the underlying infrastructure for innovation management, and these processes are taken into account by management that squarely confronts the dualism discussed in these chapters. In other words, innovation management requires doing all of these things at once. Seattle-based Amazon.com seems to be surviving well, by doing all of these things right! The maximum-power principle is truly an elaborated constructivist vision of innovation management, where 'The future is not written; it is to be constructed though the interactions between individuals and groups of people' (Boly, Morel & Renaud, Part X).

Innovation and Leadership

Deschamps' Part XI chapter on innovation leadership lists the common traits of leader in terms of personal profile. The reader is urged to connect this leader profile with the story of Taiwan's innovation system that will appear below in the mapping of the 'national vigor of innovation'. It seems that the innovation leader and the national innovation system must be cut from the same cloth.

Although neither Deschamps nor Hsu & Chen (Part XIII) come close to saying it, when innovation leadership is coupled with the *survival mandate* of the maximum-power principle that is stated in the last section, another simple principle emerges: *From an evolutionary standpoint, the vision and energy in innovation is all about kicking some competitor's butt!* Innovation is the selective advantage among alternative choices, and those that don't adequately manage innovation don't survive—period! Jeff Bezos's Amazon.com is a sterling, living demonstration of the features of the maximum-power principle described above in the preceding section.

Innovation and Marketing

The two chapters on innovation and marketing in Part XII somehow remind one of Murphy's Law. That is, if anything can go wrong in the marketing of an innovative product, it will. Of course Murphy's Law comes into play only because the model of reality that planners, researchers and marketers have in their heads doesn't adequately match the details and dynamics that

are out there in the real, physical and social world. Both of the chapters in Part XII offer valuable information that would help bring into alignment the mental models of marketers on the one hand, and the actual dynamics of consumer worlds on the other (see Trott; Veryzer).

Trott offers a model of the interactions of marketing, R&D, and business planning. He proposes that, 'it is the interactions of these internal functions and the flow of knowledge between them that needs to be facilitated'. Why would this be so? It seems that if an organization doesn't do this, it's model of social reality will be off the mark, and some other organization will do precisely what Trott proposes. Then, reflecting back to the evolutionary principle in the above Part XI on Innovation Leadership, it will be your butt that will get kicked.

A Mapping of Innovation Around the World: Examples of Country Efforts, Policies, Practices and Issues

The general question of 'national innovative vigor' is the central theme of the eleven chapters of Part XIII of this Volume. It is the national imperative for the future. The most significant mapping feature in Fig. 3 is how six of the national innovation systems huddle closely around this central theme. Another interesting feature of this mapping is how the 'dynamics analysis' of Germany/United Kingdom (Harding) can be seen to bear on India's regional innovation (Mehra).

The nations tightly huddled around the center of the mapping give a strong sense that, ultimately, innovation has a great deal to do with why societies are formed in the first place. That is, social re-structuring toward higher efficiencies (innovation) bestows greater advantage than any alternative re-structuring. And, as national programs aimed at innovation become more articulated in terms of information flows, as in those clustered around the center of the mapping, the more successful they tend to become in the world marketplace. This general idea has been mentioned many times in this concluding chapter, and is, of course, part and parcel to the messages of all of the chapters of Parts VIII through XIII.

It seems that innovation in the human mind on the one hand and the many information flows necessary to social interaction on the other exist in a dynamic relationship of reciprocal modeling. Thus, ideally, the creativity of the innovative person is embedded in the organization, and the organization is embedded in that person. Sigmund Freud, certainly one of the greatest psychologists who ever lived, noticed this 'inter-embeddedness' in a way that suggested to him a general direction for the future of technological innovation:

With every tool man is perfecting his own organs, whether motor or sensory, or is removing the limits

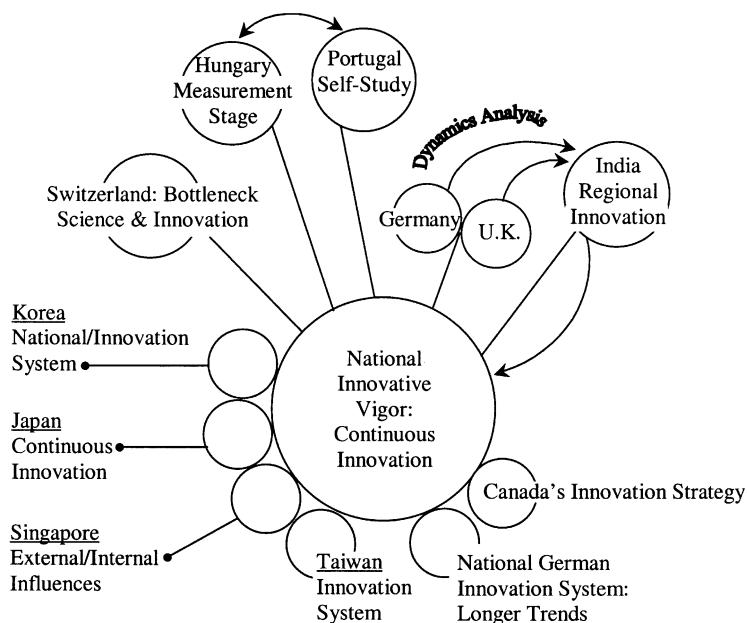

Figure 3. Innovation around the world: examples of country efforts, policies, practices and issues.

to their functioning. Motor power places gigantic forces at his disposal, which, like his muscles, he can employ in any direction; thanks to ships and aircraft neither water nor air can hinder his movements; by means of spectacles he corrects defects in the lens of his own eye; by means of the telescope he sees into the far distance; and by means of the microscope he overcomes the limits of visibility set by the structure of his retina. In the photographic camera he has created an instrument which retains the fleeting visual impressions, just as a gramophone disc retains the equally fleeting auditory ones; both are at bottom materializations of the power he possesses of recollection, his memory. With the help of the telephone he can hear at distances which would be respected as unattainable even in a fairy tale. Writing was in its origin the voice of an absent person (1930/1961, pp. 37–38)

Because distance, time and effort were being reduced essentially to zero, Freud derived from this progression toward 'perfection' that humans had become 'prosthetic Gods'. He expected the trend to continue on into the future.

Future Innovations in Science and Technology

In Part XIV of this volume Joseph Coates provides us with a far-reaching analysis and vision of the future that extends out 25 years.

While the unfolding of the future is no doubt nonlinear in its detail, there are large-scale discernable dynamics that can provide us with more 'linear' arrows

for the future development of innovation (see Rickards concerning the trend toward nonlinear models of innovation). Freud provided us with one important arrow, namely, that future innovations would involve the further refinement and extension of the qualities and capacities of the human senses, mind, and body. Continuing this theme in far more detail, Coates describes how biotechnology and information technology will lead to the greatest predictable changes. The fact that information is far easier to amplify than energy³ (this fact provides another predictable arrow for innovation) bolsters the soundness of the forecasting judgments Coates makes.

In the second section of his chapter Coates talks about future applications of scientific and technological advances. In his portion on education he mentions that, for children, computers are already not 'equipment', but prostheses. Coates is dead right about this. Although Rickards rightly cautions us on attempting to predict too far down the road, perhaps we should take Coates' idea and run with it a little. Perhaps, along with Freud (and Lotka), we should think of the future of all innovation as a seemingly inescapable tendency toward an increasingly enriched and powerful 'prosthetic' augmentation of ourselves. This can give us one very strong sense of what is likely to come next.

³ For both text discussion and simple calculations of this idea, see Tribus & McIrvine (1971). This article is aimed at a broad audience.
