Taking into account the foregoing ideas and arguments, it seems that the need for a new, second generation of educational multimedia is self-evident. However, before proceeding with a description of HICEMTs, it is important to discuss more precisely their importance or, in other words, why people need them.

The Importance of HICEMTs

The value of HICEMTs can be discussed from various multifaceted perspectives, but five closely related perspectives—technological, economic, societal, educational, and psychological—are particularly important. The *technological* perspective refers to the earlier-mentioned realities of the information age and its challenges for people. Thus, one of today’s realities is extremely fast development in terms of high technology; the challenges range from a huge change in individuals’ lives in business and private settings to a strong need to know and use appropriately the extraordinary quantity of developed software and applications. New breakthroughs in high technology encourage companies to rapidly introduce technological innovations related to business practices. For example, all of Bill Gates’s 12 rules for succeeding in the cyber era (Gates, 1999) are related to new technologies. But companies forget that it is, first of all, people who use today’s information and communication technologies. Unfortunately, the human mind does not improve as rapidly as new high technologies! Consequently, current realities of cybersociety reveal an exceptional need for the elaboration of special technologies whose primary goal is the development of human mental abilities (Shavinina, 2000). Therefore, there is a large and growing impetus for the development of HICEMTs.

The value of HICEMTs is clearly revealed from an *economic* standpoint. As mentioned earlier, today’s industrial competition is increasingly harsh, and firms must bring new products and services to the global market with unprecedented speed. Nevertheless, the speed of human thinking lags behind the speed of the international market. There is thus an increasing need to develop special technologies for the mind—and especially HICEMTs—so as to accelerate the speed of human intelligence and creativity and generate new ideas and solutions in accordance with the demands of the world market. Such development is one of the key purposes of HICEMTs.

The importance of HICEMTs is also evident from a *societal* perspective. Everyone knows that modern society has many unsolved problems, including demographic, medical, environmental, political, economic, moral, and social problems. Accordingly, contemporary society can be characterized by a strong need for

highly able minds that can productively solve the numerous social problems and make appropriate social decisions.

As mentioned earlier, today’s cybersociety produces many challenges to citizens, who must be exceptionally able if they are to bring innovative solutions to these challenges and, as a result, contribute to further societal progress. In short, intellectually creative citizens are guarantees of political stability, economic growth, industrial innovations, scientific and cultural enrichment, psychological health, and the general prosperity of any society in the 21st century.

HICEMTs also have value from an *educational* perspective. As discussed elsewhere (Shavinina, 1997a, 1997b), the real and the most important goal of education should be seen not as knowledge transfer but as development of people’s intellectual and creative abilities. Today’s children and adults must have at their disposal a set of productive educational and training technologies to reach this goal. The main purpose of HICEMTs is developing human mental resources, which allow people to both successfully apply existing knowledge and produce new knowledge.

At the same time, education is—by its nature—a psychological process based on underlying psychological mechanisms. The essence of HICEMTs coincides with the goals and nature of education and with the basic functioning of users’ minds. Only in the case of a maximal matching between HICEMTs and the goal of education, on the one hand, and between HICEMTs and fundamental mechanisms of the functioning of human intelligence and creativity, on the other, one can really make assertions about productive learning and training. Any society that wishes to improve the quality of education should focus attention on the actualization and development of its citizens’ intellectual and creative resources (Shavinina, 1998a).³

Finally, among many possible *psychological* arguments in favor of HICEMTs, it is necessary to mention

³ Certainly, some opponents can point out that current realities of the African continent—where large segments of the population live at extreme levels of poverty—prevent local government officials and parents from investing in educational technology. However, this is not entirely true. The success of the WorLD program testifies to this. In almost all 15 WorLD countries (e.g. Mauritania, Senegal, and Uganda), parents are so excited about the opportunities their children are gaining through the program that they have set aside parts of their meager incomes to help the school pay its monthly connectivity costs. The same is true for officials in these countries. For example, in Mauritania, when the minister of education, a former biology teacher, was introduced to various websites for use in biology, chemistry, and other sciences, he was impressed by the depth and breadth of information available. Shortly thereafter, at his request, the ministry of finance agreed to finance leased-line Internet connectivity for all secondary schools in Mauritania (Carlson & Hawkins, 2001).

(Continued overleaf)

at least two. First, the human mind is a unique phenomenon in nature, and its development must be realized by individualized means designed to be appropriate for the advanced development of mental resources. Certainly, educational multimedia applications in general provide a good opportunity for education when, where, and how users wish. However, HICEMTs allow people to advance in learning and training according to the unique characteristics of their minds (i.e. personal abilities, speed, and time). HICEMTs provide an exceptional opportunity for individualized, personalized, differentiated, and flexible learning and training because the underlying idea of these novel technologies is the following: many differing people can find in HICEMTs the individual means (i.e. the individual approach) for actualizing their own mental potential and the subsequent development of their intellectual and creative abilities (Shavinina, 2000). Second, the earlier-mentioned conclusions about the current state of educational multimedia show that there is at present no educational multimedia technology that can satisfy all the discussed features of these five perspectives as they manifest themselves in their contemporary requirements of the human mind in general and intellectual and creative resources in particular.

When the Medium is ‘Mental’

McLuhan (1964) argued that all of a culture’s technologies are extensions of the human body and nervous system. He suggested that, as culture advances, the new technology (the new medium) used to frame and convey information creates a new environment that is more influential than the content of the information it conveys. In his now famous phrase, McLuhan described this superordinance of the medium over its content as “the medium is the message”. Vandervert (1999, 2001) argued that, in the case of contemporary cybereducation in general and in the case of HICEMTs in particular, for the first time in human history “the medium (i.e. the new technology) is mental”. Current levels of advancement in multimedia technology and psychological science form a strong foundation for the development of such mental technologies.

³ (Continued)

Likewise, critics can note that in America 20% of all children are born in poverty and about the same percentage drop out of high school. There is also the sad problem of school violence. As a result, American society’s educational focus is on broader social and economic issues other than the development of new instructional technologies. However, this is not the whole story. For example, the National Science Foundation (NSF) and other government and private funding agencies provide many grants for the development of new educational technologies, which supports our assertion. For instance, in 1997 NSF provided grants to 52 of 120 universities involved in the development of Internet 2, the next-generation Internet (Lan & Gemmill, 2000).

New Scientist magazine’s November 7, 1998, issue was devoted to Silicon Valley’s phenomenal capacity to generate and nurture ideas leading to the birth of dozens of the world’s most successful high-technology companies. This issue emphasized that Silicon Valley’s companies (e.g. Hewlett-Packard) profoundly understand the need to invest in ideas. Moreover, “now, even private entrepreneurs create companies which exist solely to produce ideas with money-making potential” (‘Editorial Introduction’, 1998, p. 30). HICEMTs can be viewed as instruments that will enable individuals to generate such ideas. It is clear today that great ideas—resulting in innovative discoveries and inventions—are beginning to rule the global economy. Energy-information calculations show that the full information-processing capacity of each person’s brain is approximately 22 legacies (Vandervert, 2001). Thus, the human brain is characterized by huge creative potential. The primary purpose of HICEMTs is the actualization and development of this potential. These new technologies will help people produce innovative ideas leading to significant achievements and exceptional performance in all areas of human endeavor.

HICEMTs: General Characteristics

The nature of HICEMTs can be understood through a set of their general and specific characteristics. The general characteristics of HICEMTs are as follows: (a) general psychological basis; (b) actualization of fundamental cognitive mechanisms; (c) new targets of educational and developmental influences; (d) better adaptation to individuals’ psychological organization;⁴ and (e) ‘psycho-edutainment’ as an overall framework. Each of these five characteristics actually represents clusters of characteristics, and these within-cluster characteristics are highly interrelated.

General Psychological Basis

Their general psychological basis implies that HICEMTs are based on psychological processes and phenomena and, especially, on the mechanisms of human intellectual and creative functioning. General psychological processes and phenomena include attention, perception, short-term and long-term memory, visual thinking, knowledge base, mental space, concept formation, analytical reasoning, metacognitive abilities, cognitive and learning styles, critical thinking, motivation, and many other psychological mechanisms. One of the strong arguments to place psychological foundations at the heart of HICEMTs is the fact that the educational process is always a

⁴ Working on the development of a series of new textbooks on mathematics, which are largely based on her theory of human intelligence, Kholodnaya (1997) introduced the principles of new targets of educational influences and a need to better adapt learning and teaching materials to children’s psychological organization.

psychological process. As mentioned earlier, learning, teaching, and training are based on fundamental psychological mechanisms.

For example, a person's knowledge base is an important psychological foundation for the process of knowledge transfer, which is traditionally considered a goal of education and of any educational tool. Psychologists have demonstrated a significant role for knowledge bases in the successful functioning of human intelligence and creativity (Bjorklund & Schneider, 1996; Chi & Greeno, 1987; Chi & Koeske, 1983; Kholodnaya, 1997; Runco, in press; Runco & Albert, 1990; Schneider, 1993; Shavinina & Kholodnaya, 1996; Sternberg, 1985, 1990). The quantity and quality of specialized knowledge play an essential role in highly intellectual performance and in the process of acquiring new knowledge. For example, productive problem-solving cannot occur in the absence of relevant prior knowledge (Chi & Greeno, 1987). The knowledge base can facilitate the use of particular learning strategies, generalize strategy use to related domains, or even diminish the need for strategy activation. Moreover, a rich knowledge base can sometimes compensate for an overall lack of general cognitive abilities (Bjorklund & Schneider, 1996; Schneider, 1993). However, current educational multimedia products do not take into account this specificity of the psychological nature of the human knowledge base, particularly with respect to its optimum functioning, which distinguishes exceptional intellectual and creative performance (Rabinowitz & Glaser, 1985; Shavinina & Kholodnaya, 1996; Shore & Kanevsky, 1993; Sternberg & Lubart, 1995). Other examples of psychological processes and phenomena and their appropriateness for the development of HICEMTs have been described elsewhere (Shavinina, 1997a, 1997b, 1998a).

Fundamental Cognitive Mechanisms

HICEMTs are directed toward actualization of fundamental cognitive mechanisms, which play a significant role in an individual's intellectual and creative functioning. This is the second key characteristic of HICEMTs. The following cognitive processes and phenomena are viewed as important in contemporary accounts of human intelligence and creativity (Brown, 1978, 1984; Flavell, 1976, 1979; Kholodnaya, 1997; Mumford, in press; Runco & Albert, 1990; Shavinina & Kholodnaya, 1996; Sternberg, 1984, 1985, 1988a, 1988b, 1990): (a) conceptual structures (Case, 1995; Kholodnaya, 1983, 1997); (b) knowledge base (Chi & Greeno, 1987; Chi & Koeske, 1983); (c) mental space (Kholodnaya, 1997; Shavinina & Kholodnaya, 1996); (d) cognitive strategies (Bjorklund & Schneider, 1996; Pressley, Borkowski & Schneider, 1987); (e) metacognitive processes (Borkowski, 1992; Borkowski & Peck, 1986; Brown, 1978, 1984; Campione & Brown, 1978; Flavell, 1976, 1979; Shore & Dover, 1987;

Sternberg, 1985, 1990); (f) specific intellectual intentions (Shavinina, 1996b; Shavinina & Ferrari, in press (a), in press (b)); (g) objectivization of cognition (Kholodnaya, 1997; Shavinina, 1996a); and (h) intellectual and cognitive styles (A. E. Jones, 1997; Kholodnaya, 1997; Martinsen, 1997; Riding, 1997; Sternberg, 1985, 1987). Other processes and phenomena should also be embedded in HICEMTs. These psychological mechanisms provide a necessary foundation for the further successful development of human creative and intellectual abilities, because enhancement of an individual's mental potential must be based on already-actualized cognitive resources (Shavinina, 1998a).

The great French scientist Blaise Pascal asserted that "chance favors the prepared Mind". To rephrase Pascal's assertion with regard to HICEMTs, the prepared mind will gain much more advantage from specially elaborated psychoeducational multimedia technologies designed for the development of mental abilities. Through repeated exposure to the fundamental processes and phenomena of the human cognitive system, HICEMTs become 'know-how' learning and training multimedia technologies, and they thus provide an underlying educational basis for the subsequent development of an individual's mind.

New Targets of Educational and Developmental Influences

HICEMTs bring new targets of educational and developmental influences. The conventional wisdom of companies and developers of current educational multimedia technologies is to address their products to the abstract 'user' as a whole. Developers and experts in this field are mostly unconcerned with where their products and services are directed. There is a general user (i.e. children, adolescents, or adults), and what is needed is to specify to what age category a given CD-ROM or Internet-based program is addressed (Shavinina, 1997b). For example, in analyzing the contemporary state of educational multimedia available on the Internet, Roberts (1996) did not even raise the question as to where these learning programs are directed. Instead, the goal is seen in another issue: "How do we redesign and adapt our classroom teaching and learning approaches in ways that are effective and appropriate to distance education?" This shows that 'players' in the contemporary arena of educational multimedia do not go beyond the simple 'placing' of the content of printed learning manuals on the Internet or CDs.

From a psychological standpoint, it is unproductive to direct educational multimedia technologies to users in general, because people represent in themselves complex psychological systems with many hierarchical components, multidimensional variables, multifaceted parameters, and structural interrelations. And to direct any educational influence to such complex systems as

a whole is to decrease immediately the quality of education. As a result, the exact targets of the existing educational multimedia applications are missing, although they could be responsible for the higher productivity of the educational process. For instance, in analyzing the current educational multimedia technologies, we can always ask ourselves: “To what exactly—in the structure of users’ intelligence or personality—is the given educational multimedia technology directed?” However, it is not easy to answer this question from a psychological point of view (Shavinina, 1997a).

The main goal of current educational multimedia is ‘knowledge transfer’. But today such transfer is not fully realized, because successful knowledge transfer is a derivative of fundamental psychological mechanisms. Consequently, it is the basic mental processes and phenomena that should be viewed as the real targets of learning, teaching, and training. Therefore, the development of HICEMTs leads to a change in the traditional audience (i.e. targets) of available educational multimedia products from ‘users as a whole’ to the underlying mechanisms of human intellectual and creative functioning. The primary objective of education has also changed: from realizing simple knowledge transfer to developing intellectual and creative abilities. Such changes will result in significant increases in the quality of learning and will contribute to the advancement of educational multimedia products and services (Shavinina, 1998a, 2000).

Better Adaptation to Individuals’ Psychological Organization

The foregoing features of HICEMTs allow them to be better adapted to an individual’s psychological organization than current educational multimedia. HICEMTs can take into account numerous psychological characteristics of users, such as behavioral, developmental, emotional, motivational, personality, and social features. HICEMTs are directly built on the psychological specificity of users (Shavinina, 2000).

For example, any two CDs or Internet-based courses for learning of a foreign language are certainly different for children and adults. It is clear that this difference is mainly connected to content. And developers of educational multimedia, for the most part, are limited by content issues. Their way of thinking is the following: “Children cannot understand some educational material, so we need to present them with more simple information”. But this is not enough. Another difference between CDs for children and for adults concerns the psychological organization of the two groups of users. Adults have an internal motivation to study foreign languages, whereas children should have a strong, ongoing external motivation in addition to the internal one (or even instead of it; Shavinina, 1998a).

HICEMTs have the potential to generate the necessary conditions for the appearance and maintenance on

the appropriate level of a child’s motivation to learn, cognitive behavior, emotional involvement, and personal satisfaction with her or his gradual progress through the educational content (Shavinina, 1997a, 1997b). It does not matter by what means developers of educational multimedia can reach this goal (e.g. exciting scenarios, specific multimedia effects, user-friendly means, innovative learning methods, and so on; certainly, their combination would be desirable). The principal thesis is that educational multimedia technologies should fit the internal psychological structures of human intellectual, creative, behavioral, cognitive, developmental, emotional, motivational, and other systems. HICEMTs are developed to accomplish this goal, and contemporary achievements of information and communication technologies allow today’s developers of educational multimedia to reach it.

Psycho-Edutainment

As we have argued and predicted elsewhere (Shavinina, 1998a), the appearance of ‘psycho-edutainment’—a new area of the global educational multimedia market—is an inevitable event. This innovative multidisciplinary multimedia field that emerges at the crossroads of existing multimedia fields (i.e. education, entertainment, and edutainment) and a new area—psychology—is the only scientifically viable framework for the development of HICEMTs. Taking into consideration that: (a) education is, in its essence, a psychological process; (b) entertainment involves its own psychological mechanisms related to games; and (c) play is a preferable and leading form of children’s activity, one can conclude that HICEMTs cannot be developed other than through the synthesized regrouping of contemporary fields of multimedia (Shavinina, 2000). The nature of HICEMTs cannot be associated with one particular multimedia field; they may be created only in the space of ‘psycho-edutainment’.

The five features just described provide the general characterization of HICEMTs. The other considerable portion of the features of HICEMTs relates to their more specialized characterization.

HICEMTs: Specific Characteristics

Among special characteristics of HICEMTs, the following can be distinguished: (a) ‘intellectual’ content; (b) ‘creative’ content; and (c) ‘intellectually creative edutainment’. The first two characteristics deal with the specific content of HICEMTs, and they demonstrate ‘*what*’ should be included in these technologies. Intellectually creative edutainment, however, represents a substantial portion of the important characteristics related to the mode of presentation of this content. Consequently, intellectually creative edutainment describes ‘*how*’ specific content might be embedded in HICEMTs.

Intellectual and creative contents cover many different, multidimensional, and interrelated aspects.

However, it is not possible to consider all of them here, because they vary significantly and depend on developers. At the current development level of psychology, there are many different theories of human intelligence and creativity (Detterman, 1994; Kholodnaya, 1997; Miller, 1996; Runco, in press; Runco & Albert, 1990; Shavinina, 1998b; Simonton, 1988; Sternberg, 1982, 1985, 1988b, 1990; Sternberg & Lubart, 1995) that predetermine developers' conceptions of creative and intellectual contents. A variety of the psychological approaches in the field of individual intelligence and creativity will strongly influence differences in the content of HICEMTs through developers' conceptions. These different approaches predetermine what is intellectual and creative in HICEMTs.

From our point of view, one of the possible approaches to developing the content of HICEMTs can be based on Kholodnaya's (1997) theory of individual intelligence. This theory is one of many theories that might underlie the development of HICEMTs. Sternberg's triarchic theory of human intelligence and Gardner's multiple intelligences theory are well-known examples of other theories that could also serve as foundations for the development of HICEMTs. Our goal is not to consider all possible theoretical approaches that may underlie HICEMTs. It is beyond the scope of one chapter to analyze the advantages and limitations of the existing theories of intelligence and creativity in their application to the design of HICEMTs. This is a topic for another chapter or even a book.

The joining of entertainment and education has led to the appearance of 'edutainment', a rapidly developing multimedia field. And, as mentioned earlier, the combining of psychology and edutainment has led to the emergence of 'psycho-edutainment', a promising new multimedia area. Equally, the combination of intelligence and creativity with edutainment leads to 'intellectually creative edutainment', a framework for the development of HICEMTs. HICEMTs will significantly transform 'edutainment'. Therefore, modern multimedia technology, educational games, and entertainment—built on the fundamental psychological processes and basic principles of human intellectual functioning and creative performance—form a type of 'intellectually creative edutainment' that provides a real opportunity to develop HICEMTs.

How Many HICEMTs?

Of course, an inevitable question arises: How many HICEMTs can be developed? The answer is quite clear: An unlimited number can be developed. There are at least three scientific reasons for this. First, as mentioned earlier, the variety of psychological approaches and theories in the areas of human intelligence and creativity—which provide a foundation for developers' conceptions of creativity and intelligence—exclude, in principle, a limited number

of HICEMTs. Second, the complex, multidimensional nature of intellectual and creative abilities (toward the actualization and development of which HICEMTs are directed) excludes only a single educational multimedia technology that would be more productive than other technologies, because the development of mental abilities can be achieved through various psychoeducational methods. Third, the transdisciplinary nature of HICEMTs (i.e. in which, in contrast to traditional interdisciplinary and multidisciplinary approaches, "the complete fundamental-level merging of 'disciplinary' sources of knowledge is the focus"; Vandervert, 2001) provides a basis for the development of a variety of new psychoeducational multimedia technologies (Vandervert, Shavinina & Cornell, 2001). Finally, technological and economic factors also result in the exclusion of a limited quantity of HICEMTs.

General and Specific HICEMTs

HICEMTs are not a simple 'placing' on CD-ROM or the Internet of already-existing creativity and intelligence training such as Osborn's brainstorming, Parnes's creative problem-solving, Feldhusen's critical thinking, Torrance's futuristic creative problem-solving, or Sternberg's (1986) intelligence program. This is a rather trivial task. More precisely, such products should be referred to as 'computer versions' of printed matters (i.e. books, manuals, tests, and so on), but not as HICEMTs, because they do not use the multiple possibilities of multimedia. HICEMTs can be developed in two main directions: (a) as derivatives of special creativity and intelligence training, but essentially changed, enriched, and presented in multimedia form; and (b) as derivatives of any knowledge domain (i.e. chemistry, biology, mathematics, history, and so on). In other words, one can distinguish general and specific HICEMTs. In the case of the latter, the aforementioned principles of HICEMTs will provide a foundation on which a special content of any domain can be built. These principles will serve as a basis for the development of an immense quantity of HICEMTs across various content domains.

HICEMTs in Action: A Practical Illustration

One of the possible examples of today's educational multimedia products that addresses many of the general characteristics of HICEMTs is Knowledge forum, a second-generation CSILE product.⁵ This Web-based educational technology can be considered, to a certain extent, as a partial practical illustration of

⁵ For more information on CSILE research, development, team members, and applications, visit the CSILE website (<http://www.csile.oise.on.ca>). For CSILE product information, contact Learning in Motion, 500 Seabright Avenue, Suite 105, Santa Cruz, California 95062 (mcappo@learn.motion.com).

HICEMTs on-line. Its authors assert that they are developing a miniature version of a knowledge-building society using CSILE software (Scardamalia & Bereiter, 1996).

Created by Marlene Scardamalia, Carl Bereiter, and the staff of educational and psychological researchers and computer scientists at the Ontario Institute for Studies in Education of the University of Toronto, Knowledge forum was born over a decade of research on 'expert learning' (Bereiter & Scardamalia, 1993; Scardamalia & Bereiter, 1994). Expert learning refers to learning that leads to the gradual acquisition of expert knowledge through continual reinvestment of students' mental resources in addressing problems at higher levels (Bereiter & Scardamalia, 1993). Scardamalia and Bereiter's cognitive research on the nature of expertise and expert learning has resulted in a knowledge society model for an educational network that engages students in constructing, using, and improving knowledge (Scardamalia & Bereiter, 1996).

The aim of Knowledge forum is to enhance students' knowledge building and understanding, with a particular emphasis on kindergarten through Grade 12. When students analyze and evaluate information and revise and reshape ideas, real knowledge building occurs. In other words, Knowledge forum supports knowledge construction. In brief, this educational technology proceeds as follows. Students initially represent and develop their ideas and questions through the production of graphics and text notes. However, as research on expertise demonstrates, often students' initial ideas and theories are based on misconceptions. As students reach a deeper understanding, their initial theories change. Students then reference other work (and can track back to the original source with a simple mouse click), identify gaps in knowledge, and ask for collaboration to increase their understanding. Referencing and 'building-on' facilities, therefore, help students create a multidimensional knowledge-building framework for their ideas. Sharing of comments helps them revise their ideas and initial theories. As students structure and connect their ideas beyond the usual 'topic titles', they improve their ability to understand and apply new concepts. Continual improvement of ideas is supported by features of CSILE software that encourage explanation-seeking, theory-building, problem-solving, argumentation, publication, and other socio-cognitive operations that help advance understanding. Through a variety of linking, searching, commenting, and visiting activities, the network encourages consideration of various ideas from different perspectives. The purpose is to enable participants to gain knowledge and understanding. In short, Knowledge forum provides an environment in which knowledge can be examined and evaluated for gaps, added to, revised, and reformulated.

Bereiter (1994) introduced the concept of *progressive discourse*, defining it as a set of innumerable

local discourses that consist of clarifications and resolutions of doubts and that generate ideas advancing the larger discourse. He asserted that meaning making and new conceptual structures arise through a dialectic process in which members of a learning community negotiate contradictions and begin to synthesize opposing standpoints into a more encompassing scheme. Progressive discourse is another label for what most educators call inquiry learning. It is especially useful in problem-based learning, wherein the field of inquiry is ill defined and there are no simple or straightforward answers. The concept of progressive discourse is also closely related to the concept of *engaged learning*, which integrates authentic tasks, interactive instruction, collaborative knowledge building, heterogeneous grouping, and co-exploration by students and teachers (Sherry, 2000).

Evaluation research shows that students using CSILE, the first generation of Knowledge forum, outperformed control groups on both standardized tests and knowledge tests (Scardamalia & Bereiter, 1996). Students working in Knowledge forum demonstrated impressive results in terms of textual and graphical literacy, theory improvement, implicit theories of learning, and comprehension of difficult concepts. The depth of their explanation and understanding was higher than that of control groups. Scardamalia and Bereiter (1996) also found that pupils working in Knowledge forum became actively involved in building and richly linking databases, pointing out discrepant information, contributing new information and ideas, considering ideas from different viewpoints, and forming important new working relationships and study groups.

As can be seen, Knowledge forum is built on general psychological processes and fundamental cognitive mechanisms associated with the successful growth of an individual's knowledge base, leading to the acquisition of expertise. Knowledge forum also brings new targets of educational influences. In other words, Knowledge forum incorporates general psychological characteristics of HICEMTs.⁶

⁶ Other possible examples of today's educational multimedia technologies that incorporate some of the general characteristics of HICEMTs are the Web-based Integrated Science Environment (WISE) and the Learning by Design (LBD) project. Developed by Marcia Linn and her laboratory in the Department of Education, University of California at Berkeley, WISE is a simple yet powerful learning environment where students examine real-world evidence and analyze current scientific controversies. WISE is a powerful tool that combines advanced educational approaches and cutting-edge multimedia technology. WISE Version 2 is a more powerful and versatile generation of the WISE software, with increased capabilities for expansion, internationalization, and customization-localization. See <http://www.wise.berkeley.edu> for more details.

Summary

The economic, technological, scientific, societal, and cultural future of human beings will apparently be synonymous with a permanent need for intellectual and creative minds, because all areas of endeavor will require an extremely high level of innovation. And only exceptionally able people can produce new ideas of such quality that lead to real innovations. Despite the evident importance of individuals with creative and intellectual abilities in the life of any societal 'organism', one should acknowledge that their development through psychoeducational methods is far from well understood. Thus, the development of HICEMTs seems to be a very timely and needed endeavor.

Therefore, by rethinking the role of education in the information era, using contemporary multimedia technology, using findings of psychological science in general and knowledge on human intelligence and creativity in particular, and elaborating 'intellectually creative entertainment', an entirely new wave of technological innovations in psychology—HICEMTs—can be developed. HICEMTs will dominate the global educational multimedia market of the 21st century.

Created by Janet Kolodner and her colleagues at the EduTech Institute, Georgia Institute of Technology, the LBD project has as its goal developing a design-based curriculum for middle school science and software to go with it. LBD takes its cues from case-based reasoning, according to which one can best learn from experience if one does a good job of interpreting one's experiences and anticipating when the lessons they teach might be useful. See <http://www.cc.gatech.edu/edutech> for more details.

Dimensions of Scientific Innovation

Gerald Holton

Jefferson Physical Laboratory, Harvard University, USA

Abstract: Research in the history of scientific innovations reveals that apart from the usual textbook presentations of how science advances, there are—especially in the early, private stages of individual scientists' work—a great number of different procedures in actual use of which the final published papers rarely give even a hint. Examples of these often essential but largely hidden mechanisms of scientific innovation are given from the study of works by Johannes Kepler, Henri Poincaré, Enrico Fermi, and the discoverers of high-temperature superconductivity.

Keywords: Innovation; Scientific innovation; Discovery; Creativity; Kepler; Poincaré; Fermi.

Introduction

One of the last physicist-philosophers, P. W. Bridgman, defined the scientific method as “doing your damndest, no holds barred”. Bridgman, a Nobel Prize winner (1946) for establishing the field of high-pressure physics, and also the father of the movement in philosophy of science known as operationalism, was venting his exasperation with the simplified, school-book view of how scientists do their work, especially when they face a really difficult problem. For he knew, as all science practitioners do, that during those early, ‘private’ stages of research, when euphoria is about to give way to despair, enlightenment may come from the most unexpected, even ‘nonscientific’ direction. In modern times, scientists have been taught to keep this fact secret; the publications of the final research results are silent about it. The great biologist Peter Medawar once confessed, “It is no use looking to scientific ‘papers’, for they not merely conceal but actively misrepresent the reasoning that goes into the work they describe”.

So let me pull away the curtain that usually covers the human drama, and discuss a few examples of the difficult struggle—not to demean but rather to celebrate it. And it makes a good story to boot.

Pursuing Cosmic Harmony, but Finding a New Law

The first example of a pioneer breaking through the boundaries of current knowledge in an unexpected way is Johannes Kepler. Since antiquity, splendid scientific ideas and results had been accumulating. But it is not unfair to characterize natural philosophy which Kepler

faced at the start of the 17th century by the work of a contemporary of his, Robert Fludd of Oxford, whose writings have been called a mixture of the “astrological, alchemical, magical, cabalistic, theosophic, mock-mystic, and pseudo-prophetic”. Kepler's main findings were quite different, and are useful to this day. He discovered the three basic laws of solar system astronomy that determine how all planets move. The most difficult to uncover was his third law, which states that for every planet, the square of its period of revolution (T) around the sun, when divided by the third power of its mean distance (R) from the sun, yields the same number. In short, T^2/R^3 is a constant, the same for all planets of our solar system.

How dull that result sounds now! But this simple law revealed to Kepler and to the entire world the commonality that binds together all the planets into one harmonic system, despite their vastly different individual orbits, speeds, and sizes. And that commonality also made more plausible Copernicus's heliocentric theory, which in Kepler's time was still widely resisted. Equally important, the third law, together with Galileo's mechanics, helped Newton to discover the dynamics of the solar system—the high point of the 17th-century Scientific Revolution.

In short, Kepler's equation was a crucial breakthrough, away from the stagnant prison of the narrow Aristotelian–Ptolemaic astronomy and into the infinitely open landscape of the modern worldview. We know the date of the climatic moment of Kepler's discovery: May 15, 1618. After years of agonizing exploration, while living in misery as a servant to city governors and the mad Emperor Rudolph II, he now

could express the feelings of an exhilarated iconoclast. He wrote: "What 25 years ago I already had a vague premonition of; what I determined 16 years ago as the whole aim of research; what I devoted the best part of my life to—that I have at last brought into the light . . . I yield freely to the sacred frenzy . . . The die is cast, I am writing the book . . . It can wait a century for a reader, as God himself has waited six thousand years for a witness".

But how did Kepler do it? With what motivation and what help did he batter his way through the wall that had stood for millennia? On first opening Kepler's voluminous published works, we see little that seems promising. His three golden laws are scattered like rare jewels in a mountain of confusing and mystical material. To some degree the cultural soil on which he stood was the same as that of Robert Fludd. Early in Kepler's first book, the *Mysterium Cosmographicum* of 1596, he searched for the causes for the numbers, dimensions, and motions of the orbits of the planets. Surely the Creator must have had in mind some secret, harmonious order when He placed the planets' orbits in what looks a seemingly accidental manner, with huge, empty spaces between the orbs. Kepler first thought he found the answer in his famous fantasy that God had arranged a set of the five regular Platonic bodies, one nestled inside the other, to define and separate the paths of the six then-known planets. The secret harmony of the solar system might thus be revealed by geometry. And it almost worked. The fit with existing observations was close, but not quite good enough, and Kepler knew he had to look elsewhere to find the secret.

So when we open his *Harmonices Mundi* of 1619 we find at last, in its fifth section, Kepler's powerful third law, which establishes that all the orbits have a simple common mathematical property. But to our astonishment, the law appears in just one sentence, in the middle of a book that is mostly concerned with harmony in music. Though earlier Kepler had been motivated by a neo-Platonic philosophy, in which he had looked to geometry for the celestial harmony, now his search turned to associating the motions of the planets to relations among musical notes.

That sounds far-fetched now. But Kepler's university training had centered on the quadrivium: the four fields of arithmetic, geometry, music, and astronomy. In addition, Kepler had rigorously studied music theory, which was then much debated among intellectuals. Kepler had read not only Ptolemy's *Harmony*, but also a book by one of the period's most interesting innovators of music theory, namely Galileo's father, Vincenzo Galilei, the author of the *Dialogo della musica antica e moderna*. In Kepler's mind, God, in the act of Creation, had made use of musical consonances in designing the world system, with the resulting harmony radiating down from heaven, to resonate within the soul of each human being.

Specifically, what Kepler attempted was to make concrete and quantitative an old dream about the harmony of the spheres that went back to Ancient Greece. He discovered that when he associated with each planet in the solar system musical notes which represented their speeds at various moments, there were 48 occasions, repeated through eternity, when the speeds of the planets happened to be equivalent to musical chords that we would regard as harmonious. For example, comparing the speed of Saturn at its two extreme points along its ellipse, the ratio of these two speeds comes to 106 divided by 135, which is close to 4 divided by 5—only a churlish person would deny that! This ratio, 4/5, corresponds musically to a major third—pleasant to the ear and to the mind.

Kepler applied such reasoning to all the planets. In this way, he found that during their orbital motions, Earth and Venus from time to time sing out a minor and a major sixth. Kepler even found a heavenly six-part chord, generated by the orbital velocities of all six planets known at the time. Now it all worked—the harmony of the world system was revealed—although to more rational scientists, including Galileo, it must have seemed like the ravings of a madman. But that real, permanent breakthrough, Kepler's third law, was simply a byproduct which Kepler had stumbled on while carefully comparing the parameters of the planetary orbits in his search for those celestial harmonies.

It is regrettable that in our schoolbooks it now all comes down to merely learning the formula of Kepler's law, and that the cultural and historic context is neglected. But that this separation is possible carries an important lesson, too. For contrary to today's fashionable relativists and constructivists of scientific history, it is precisely a strength of science that, in the long run, it can throw off the various cultural scaffoldings which, in the nascent phase, helped some individual in building part of the ever-unfinished Temple of Isis. The concepts and theories of mature science, as used in daily life and publications, work well without any residue of their various individual human origins. It is left only to the historian to record the cries of agony and ecstasy of the pioneers.

The best metaphor for the scientist working, like Kepler, at the extreme intellectual limit seems to me that of a person trapped in a narrow prison, down in a shaft where the high walls consist of what is *already known*, the knowledge that satisfies the ordinary mortal but which oppresses the extraordinary one, as with claustrophobia. He claws desperately against those walls, as Kepler did for 25 years, trying to climb up or break out, to escape from the incompleteness of the known into the world beyond, of which he has only a haunting premonition. Robert Oppenheimer once compared working on very difficult problems with trying to

crawl upward inside a mountain, not knowing when and where one will find the escape.

The Relativism of Impotency

At this point, I should recognize that a few scientists and philosophers do speak of having found epistemological limits in the science of the real world. The usual examples mentioned include Heisenberg's so-called principle of uncertainty (or, as he initially referred to it, the principle of inaccuracy (*Ungenauigkeit*)); that the speed of light is an upper limit for transmitting information; that no perpetual motion machine can exist. Fifty years ago, Sir Edmund Whittaker proposed the charming terminology that these and similar cases reveal the existence of the *Principle of Impotency*. But the feeling that these are really epistemological limits rests on a misunderstanding. The examples cited, and others like them, are only discoveries about the behavior of nature that, relative to a previous stage of science, were unexpected. Thus earlier forms of science for centuries gave false hope that a perpetuum mobile can be built. The fact that it cannot is an important, positive finding about nature, expressed in a law of thermodynamics. Similarly, the Newtonian style of science before Einstein and Heisenberg, before relativity theory and quantum mechanics, allowed one to think that positions and momenta of moving particles can both be found simultaneously to arbitrary degrees of accuracy, or that there exist Absolute Space, Absolute Time, Absolute Simultaneity, and instant propagation of information. These hopes within the old framework turned out to be false, revealing instead a more accurate picture of nature's operations.

All such cases are analogous to Galileo's discovery, by means of his telescope, that the moon has mountains like the earth, instead of being perfectly round and smooth as previous science had maintained. The impotency to find a smooth moon is an impotency only in the context of Aristotelian science. In the context of the new Galilean science, it became an unexpected fact of nature, and an important discovery.

'An Anticipatory Consonance with Nature'

The next case represents another point on the wide spectrum of those inexhaustible ingenuities and variety of means by which scientists try to transcend the limits of contemporary understanding. This one reveals a trick or tool that some scientists turn to, at least for a while. The scientist-philosopher Michael Polanyi coined for it the term "tacit knowing". Partly in rebellion against positivism, and in direct confrontation with the famous ending of Wittgenstein's *Tractatus*, Polanyi defined his concept in one sentence: "I shall start from the fact that *we can know more than we can tell*".

The concept is perfectly familiar from everyday experience (recognizing a face; or the skill displayed by an athlete, a musician, a craftsman). At first glance

it seems out of place in science, but it is not far from what Einstein called "*Fingerspitzengefühl*", a feeling at the tips of your fingers where the way out of the difficulties lies.

When struggling with a problem that cannot be solved by standard procedures such as induction from good data, some scientists, often unconsciously, seem capable of using personal intuition. To return to our earlier metaphor, they can, so to speak, look over the top of the high wall before them. It is a precious gift, for which the physicist-philosopher Hans Christian Oersted has provided the happy term, an "anticipatory consonance with Nature", not too far from Leibniz's concept of resonating with the Pre-established Harmony.

A striking example of tacit knowledge is the moment when Enrico Fermi's hand moved in a way he did not understand, but eventually helped him to unravel a mystery which led him effectively to launch the nuclear age. It happened one morning in October 1934, in the old physics laboratory at the University of Rome. Fermi, a brilliant leader of a group of scientists almost as young as he, was puzzled: fast neutrons, when sprayed at a sample of silver sitting on a wooden table, copiously produced artificial radioactivity in the silver. However, they failed miserably to do so when the experiment was repeated on a marble table in another part of the laboratory. As was realized later, on the first table some of the neutrons that reached the silver had first hit the table top and then been scattered up from its wood, having been slowed down by collisions with the nuclei of the hydrogen atoms in the wood. However, the heavy atoms in the marble could not produce this slowing effect on neutrons—and contrary to accepted theory at the time, it was *slow* neutrons, not fast ones, which strongly induced radioactivity in silver. As one would say today, the hydrogen nuclei had acted as 'moderator', a concept that later became essential for constructing nuclear reactors.

Fermi described the crucial moment where the tacit dimension of scientific understanding asserted itself in this example:

I will tell you how I came to make the discovery which I suppose is the most important one I have made. We were working very hard on the neutron-induced radioactivity and the results we were obtaining made no sense. One day, as I came to the laboratory, it occurred to me that I should examine the effect of placing a piece of lead before the incident neutrons. [I interject here that this was not going to work because lead, with its heavy atoms, would not slow down neutrons significantly] . . . (but) I was clearly dissatisfied with something: I tried every 'excuse' to postpone putting the piece of lead in its place. (Finally) . . . I said to myself: 'No, I do not want this piece of lead here; what I want is a piece of paraffin'. It was just like that: with no

advanced warning, no conscious, prior reasoning. I immediately took some odd piece of paraffin . . . and placed it where the piece of lead was to have been.

At once, the induced radioactivity presented itself abundantly, even for silver sitting on the marble table. Fermi's former student and co-worker, Emilio Segrè, called it "the miraculous effects of filtration". Within hours, Fermi understood what was happening: the hydrogen nuclei in the piece of paraffin slowed down during collisions; the material in the wooden table had done the same before. Fermi's "anticipatory consonance with Nature", long before the purely rational part of science could produce the correct theory of nucleonics, turned the research project of that whole group into a powerhouse of innovation. On coming across such events, where tacit knowing asserts itself to help leap over a barrier, I am reminded of Aristotle's observation: "The intellect approaches the object of its research while that is still opaque and obscure: but the intellect circles around it, and suddenly, thanks to its noetic light, the matter becomes visible and comprehensible".

Invoking the Personal Thematic Presupposition

Turning to more recent times, we may point to a study that shows again how the most unlikely-appearing tool, in the hands of the right persons, can be used to cut through a well-established border at the edge of known science. It is the story of the discovery of superconductivity at high temperatures. Superconductivity is the loss of electrical resistance below a critical temperature (T_c). The phenomenon of ordinary superconductivity at very low temperatures had been known since 1911, when Heike Kamerlingh Onnes discerned it in mercury cooled down to just a few degrees above absolute zero (to about 4 Kelvin). Many investigators took up the search for electrical conductors with higher critical temperatures, where it would be easier and cheaper to keep a substance resistance-free, and where the practical applications could be fabulous.

Here and there, small progress was made. But by 1973, over six decades after the original discovery, the best efforts in many research laboratories working with a great variety of materials had brought the critical temperature T_c only up to about 23 Kelvin. The general frustration of failing to break through this limit, year after year, was crystallized in a remark by Bernd Matthias, a highly respected physicist at the Bell Laboratories: in the absence of successful theories to guide one, it would be best to give up the search, for otherwise "all that is left in this field will be these scientific opium addicts, dreaming and reading one another's absurdities in a blue haze".

All this changed practically overnight, when superconductivity existing at about 30 Kelvin was discovered in 1986 by a two-man team, Karl Alex Müller and his former student Georg Bednorz, both

working at the IBM Zurich Research Laboratory. Their announcement became an instant sensation, not just because of those extra 7 degrees, but mainly because the materials used by the Swiss team were distinctly different from all previously known superconductors, and this alone opened up the promise of reaching much higher ceilings. Also, the compound they used was relatively easy to prepare and to modify. No new technology was involved; the particular ceramic they used had been available for decades but had never been considered a candidate for high-temperature superconductivity research.

The news of the discovery caused a so-called "Woodstock of Physics", an impromptu session at the meeting of the American Physical Society in 1987; over 3,500 scientists crowded into the meetings rooms to hear about the new achievement. The Nobel Prize committee awarded the 1987 Prize for Physics to Müller and Bednorz with maximum possible speed. All over the world, researchers could now look in new directions for ever-higher temperatures T_c . The present record stands at over 160 Kelvin. For some physicists, the hope has been revived that eventually a superconductor will be found that works even near room temperature. The practical applications, already substantial, would be immense.

Now, the most interesting question for me was: *What were the crucial elements* that made the scientific discovery of Müller and Bednorz possible in the first place? Their success depended not only on their own skills, but on two other factors. The first was of course the work of other scientists who had preceded them, and on whose findings or inventions they built—as is true in every advance. But the other factor was a crucially important leap of the imagination, a typical characteristic of the barrier smashers throughout the history of science. The most intriguing addition here, as so often, is the private dimension of scientific discovery, the motivation.

Because of the tradition of formality in science writing today, the personal aspect of the discovery was of course absent from the published record. But here I was lucky. Dr Müller and Dr Bednorz kindly allowed me to interview them, and what I found was revealing indeed. The two men had first spent two fruitless years trying to get to a higher T_c with the types of material that had been used by all the others. But earlier they had worked with success on quite different problems in physics, using a class of highly symmetrical (cubic) crystals. As Dr Müller said, since his student days, they had always "worked for him". Nobody had so far tried to use these perovskite-type crystals for studying high-temperature superconductivity, and there were no convincing reasons from existing theory why anyone should have. Nevertheless, the Swiss team decided to try its luck on a perovskite-type material, a copper-containing oxide, fundamentally different from the materials that had been ransacked by the pioneers in

the field. When other physicists heard about it, they called it a ‘crazy’ idea. But it worked.

Why was it not a crazy idea for Müller and Bednorz? I asked Dr Müller to share his motivation with me. It turned out that his unlikely choice of a perovskite in that search was guided not just by the force of (well rewarded) habit. As he put it: “I was always dragged back to this symbol”, the cubic crystal. He first became fascinated with the cubic crystal structure in 1952, when he was working on his doctorate. It so happened that Wolfgang Pauli was one of Müller’s professors at the Swiss Technical Institute (ETH). Just at that time, Pauli had published an essay entitled ‘The Influence of Archetypal Ideas on the Scientific Theories of Kepler’, in a book with Carl Jung. Much impressed by that essay, Müller started to read Kepler avidly, and so he encountered Kepler’s commitment to the use of three-dimensional structures of high symmetry—the cube and the other four Platonic solids—in his early work on planetary motion.

Dr Müller continued as follows: “If you are familiar with Carl Jung’s terminology, the (cubical) perovskite structure was for me, and still is, a symbol of it—it’s a bit high-fetched, but—of holiness. It’s a Mandala, a self-centric symbol which determined me . . . I dreamt about this perovskite symbol while getting my doctor’s degree. And more interesting about this, is also that (in this dream) the perovskite was not just sitting on a table, but was held in the hand of Wolfgang Pauli, my teacher”. At the time, Müller had divulged this extraordinary aspect of his inspiration, which encouraged him eventually to try a perovskite for superconductivity, only to friends and to Pauli’s last assistant. He has since discussed it in an introspective essay, illustrated with the Dharmaraja Mandala.

To the historian this is familiar ground. Some scientists, from Kepler to Francis Crick and James Watson, were guided in the early stages of their research by a visually powerful, highly symmetric geometrical design. So in faithfulness to Müller’s self-report, his personal thematic presupposition has to be added to the resources he used and was as important as any of the others. With that inclusion, we recognize the inheritance of a line of empowering conceptions, reaching in this case back first to Wolfgang Pauli and then to the works of Kepler, who gloried in his thematic preference for high symmetry four centuries earlier.

Thematic Influences in Scientific Discovery

In the cases already addressed, we have seen how preexisting commitments in culture, philosophy, and society have shaped the very process and direction of discovery. In the final, most extensive case, we turn to a scholar who was doubly influential as a scientist and as a culture carrier, directing further exploration across academic and disciplinary boundaries.

Henri Poincaré (1854–1912)—mathematician, physicist, and all-round polymath—was a very symbol of the establishment, his five professorships held simultaneously, and a member of the *Académie des Sciences* as well as the *Académie Française*—a rare combination, making him in effect doubly immortal. Nor did it hurt his standing in society that his cousin was Raymond Poincaré, the Prime Minister and eventually President of the French Republic. By temperament, Henri Poincaré was conservative, but also immensely productive, with a torrent of nearly 500 published papers on mathematics—many of them fundamental discoveries, from arithmetic to topology and probability, as well as in several frontier fields of mathematical physics, including launching in his book on celestial mechanics what is now called chaos theory. But regarding himself justly as a culture carrier, and perhaps sensitized by a then fashionable turn-of-the-century movement brandishing the slogan ‘the Bankruptcy of Science’, Poincaré also wrote with translucent rationality on the history, psychology, and philosophy of science, including his philosophy of conventionalism, in such semi-popular books as *Science and Hypothesis* of 1902. For cultured persons all over the world, these were considered required reading. And all his work was done with intense focus and at great speed, one finished right after another.

Poincaré was a mathematical genius of the order of Carl Friedrich Gauss. Before he was 30, Poincaré became world-famous for his discovery, through his ingenious use of non-Euclidian geometry, of what he called the fuchsian functions (named after the German mathematician Immanuel Lazarus Fuchs, who was publishing in the 1860s to 1880s). I shall come back to the circumstances of that discovery in a while.

Although Poincaré generally kept himself well informed of new ideas in mathematics, on this particular point his biographer, Jean Dieudonné, allows himself the schoolmasterly remark that “Poincaré’s ignorance of the mathematical literature, when he started his researches, is almost unbelievable . . . He certainly had never read Riemann” – referring to Bernard Riemann, the student of Gauss and the person first to define the n -dimensional manifold in a lecture in June 1854. That lecture, later published, and the eventual opus of Riemann’s three-volume-long series of papers, are generally recognized to be monuments in the history of mathematics, inaugurating one type of non-Euclidean geometry.

For over 2,000 years, Euclid’s *Elements of Geometry* had reigned supreme, showing that from a few axioms the properties of the most complicated figures in a plane or in three-dimensional space followed by deduction. Euclid has been the bane of most pupils in their early lessons, but to certain minds his *Geometry* was and is representative of the height of human accomplishment. To Albert Einstein, who received what he called his “holy” book of Euclidean geometry

at age 12, it was a veritable “wonder”. He wrote: “Here were assertions . . . which—though by no means evident—could nevertheless be proved with such certainty that any doubt appeared to be out of the question. This lucidity and certainty made an indescribable impression upon me . . .”.

Galileo, too, was stunned by his first encounter with Euclid. It is said that as a youngster, destined to become a physician, he happened to enter a room in which Euclidean geometry was being explained. It transfixed him, and set him on his path to find the mathematical underpinnings of natural phenomena. To Immanuel Kant, of course, Euclidean geometry was such an obvious necessity for thinking about mathematics and nature that he proposed it as an exemplar of the synthetic *a priori* that constituted the supporting girder of his philosophy.

But in the early part of the nineteenth century, a long-simmering rebellion came to a boil against the hegemony of Euclidean geometry, and especially its so-called fifth axiom—the one which implies, as our schoolbooks state clumsily, that through a point next to a straight line only one line can be drawn which is parallel to it, both of them intersecting only at infinity. Here, the main rebels were Riemann, the Hungarian János Bolyai, and the Russian Nicolai Ivanovich Lobachevsky. As to Poincaré’s initial ignorance of that particular literature, ignorance can be bliss, not merely because reading Riemann’s turgid prose is no fun, but chiefly because Poincaré’s approach was original with him.

When I look at the work of scientists, I try to be alert to the role the thematic presuppositions may have motivated their discoveries. In the case of Poincaré, the most prominent thematic element, common both to his mathematics, his physics, and his philosophy, is his embrace, for better or worse, of the theme of *continuity*. Thus, as his biographer summarizes it, the “continuity methods dear to Poincaré led him to adopt continuous parameters and groups in a field that would have benefited from greater flexibility”. Poincaré’s adopted “Hermite’s method of ‘continuous reduction’ in the arithmetic theory of forms”, had a policy for looking for ‘invariance under transformations’, and proved the “existence of a whole continuum of solutions” in the three-body problem. It was Poincaré who had to inform H. A. Lorentz that Lorentz’s transformation equations in the early version of relativity theory formed a group that left invariant the quadratic expression $x^2 + y^2 + z^2 - c^2t^2$. In sum, “The main leitmotiv of Poincaré’s mathematical work is clearly the idea of continuity”.

That had a parallel predilection in Poincaré’s physics. Indeed, Poincaré may well have achieved a true special theory of relativity before Einstein, had he not clung obstinately to the old concept of that continuum in space, the ether, which Einstein was to dismiss in 1905 in one casual phrase. In fact, Poincaré

never made his peace with Einstein’s ether-free relativity. His beautiful and seductive prose often hid a tentative method of argument just where he was getting most into trouble. Thus he toyed with the idea of a uniform time, a Newtonian sensorium of God; yet on rejecting it as untestable, he put nothing else in its place. In 1912, long after Einstein’s and Minkowski’s achievements in relativity had become acknowledged by more and more excellent physicists despite the initial shock, Poincaré bared his conventionalist philosophy by writing on those radical innovations:

What shall be our position in view of these new conceptions? Shall we be obliged to modify our conclusions? Certainly not; we had adopted a convention because it seemed convenient and we had said that nothing could constrain us to abandon it. Today some physicists want to adopt a new convention. It is not that they are constrained to do so; they consider this new convention more convenient; that is all. And those who are not of this opinion can legitimately retain the old one in order not to disturb their own habits. I believe, just between us, that this is what they should do for a long time to come.

Worse still, Poincaré’s long researches in electromagnetism, including the Maxwellian theories of light which he had introduced in France, caused him to be repelled by another of Einstein’s other great discoveries of 1905, that of the quantum of light, later called the photon. The confrontation between these two different minds came to a head in 1911 at the so-called Solvay Conference in Brussels. A large fraction of the world’s best physicists were gathered for a meeting to unpuzzle the strange new quantum theory, which contradicted the centuries-long Newtonian idea that nature does not move by jumps, and instead proposed the introduction of discreteness and discontinuity into nature’s phenomena.

As the proceedings of that conference show, Poincaré and Einstein appeared to be on opposite sides, in part because Poincaré, surprisingly, had come to the conference without having seriously studied the new quantum physics publications. The British physicist J. H. Jeans came away from the Conference converted to the new physics, writing simply: “The keynote of the old mechanics was continuity, *natura non facit saltus* (as Newton had put it). The keynote of the new mechanics is discontinuity”. But Poincaré, writing in 1912 after the summit, and shortly before his unexpected death, concluded, “The old theories, which seemed until recently able to account for all known phenomena, have recently met with an unforeseen check An hypothesis (of quantization of energy) has been suggested . . . but so strange an hypothesis that every possible means was thought for escaping it. The search has revealed no escape so far Is discontinuity destined to reign over the physical

universe, and will its triumph be final?" It was a cry from the heart, the more so as the antithema of discontinuity was invading classical science from many directions, for example, in genetics ('mutations', entering in the 1890s), in radioactivity ('transmutations', a few years later), and in the experimental findings in C. T. R. Wilson's cloud chamber that showed individual collisions between an alpha-particle and an atom.

On the evidence given so far, it would be easy to judge Poincaré to be, and to regard himself as, a continuist to the core. But we have learned that especially those innovators, in both science and the arts, who are far above our own competences and sensibilities, are not so easily pinned down. They tend to have what seem to us to be contradictory elements, but which somehow nourish their creativity.

In the case of Poincaré, his readers can encounter also a *discontinuist* side. Having warned, at the very end of the Solvay Conference, that quantum physics contradicted the very basis of classical triumphs, namely the use of differential equations, he nevertheless threw himself at once into a serious study of the consequences of quantum ideas, declaring them to be potentially without doubt the greatest and most profound revolution that natural philosophy has undergone since Newton. The other main evidence for Poincaré's willingness to face the force of sudden changes emerged strikingly in his ideas about the psychology of invention and discovery.

The reference here may be widely familiar, but is so startling that it deserves nevertheless to be mentioned. I refer to the famous lecture on "L'invention mathématique", which he gave in 1908 at the *Société de Psychologie* in Paris. The fine mathematician Jacques Hadamard, in his book *The Psychology of Invention in the Mathematical Field* (New York: Dover, 1945), remarked on that lecture that it "throw(s) a resplendent light on relations between the conscious and the unconscious, between the logical and the fortuitous, which lie at the base of the problem (of invention in the mathematical field)" (p. 12). In fact, Poincaré was telling the story about his first great discovery, the theory of fuchsian functions and fuchsian groups. Poincaré had attacked the subject for two weeks with a strategy (typical in mathematics) of trying to show that there could not be any such functions. Poincaré reported in his lecture, "One evening, contrary to my custom, I drank black coffee and could not sleep. Ideas rose in crowds; I felt them collide until pairs interlocked, so to speak, making a stable combination" (p. 14). During that sleepless night he found that he could in fact build up one class of those functions, though he did not yet know how to express them in suitable mathematical form.

Poincaré explained in more detail: "Just at this time, I left Caen, where I was living, to go to a geological excursion . . . The incidence of the travel made me

forget my mathematical work. Having reached Coutance, we entered an omnibus to go someplace or other. At the moment when I put my foot on the step, the idea came to me, without anything in my former thoughts seeming to have paved the way for it, that the transformations I had used to define the fuchsian functions were identical with those of non-Euclidean geometry. I did not verify the idea; I should not have had time, as, upon taking my seat in the omnibus, I went on with a conversation already commenced, but I felt a perfect certainty. On my return to Caen, for conscience's sake, I verified the results at my leisure" (p. 13).

Perfecting his idea came unexpectedly sometime later, when he was engaged in entirely different work: "One morning, walking on the bluff (at a seaside resort), the idea came to me with just the same characteristics of brevity, suddenness and immediate certainty, that the arithmetic transformations of indefinite ternary quadratic forms were identical with those of non-Euclidian geometry". Poincaré analyzed those two events in these terms: "Most striking at first is this appearance of sudden illumination, a manifest sign of long, unconscious prior work. The role of this unconscious work in mathematical invention appears to me incontestable". "It seems, in such cases, that one is present at one's own unconscious work, made particularly perceptible to the overexcited consciousness . . ." (pp. 14–15).

Hadamard collected a number of similar reports, where out of the continuous, subterranean incubation in the subconscious, there appeared, in a discontinuous way, a rupture of startling intensity, the conscious solution. He mentioned Gauss himself who spoke of such a rupture as "a sudden flash of lightning", and similar observations by Hermann Helmholtz, Wilhelm Ostwald, and Paul Langevin—not to forget Mozart, who spoke memorably about the source of his musical thoughts as follows: "Whence and how do they come? I do not know, and I have nothing to do with it".

Poincaré himself also expressed puzzlement about the source of his sudden ideas. In the full text of Poincaré's talk of 1908, soon widely read in chapter 3 of his popular book *Science and Method* (1908), he confesses, "I am absolutely incapable even of adding without mistakes, (and) in the same way would be but a poor chess player" (p. 49). But he reported to having "the feeling, the intuition, so to speak, of this order (in which the elements of reasoning are to be placed), so as to perceive at a glance the reasoning as a whole". He celebrated "this intuition of mathematical order that makes us divine hidden harmonies and relations" (pp. 49–50). To be sure, after that intuition comes labor: "Invention is discernment, choice". But for that, priority must be granted to aesthetic sensibility in privileging unconscious phenomena, 'beauty', and 'elegance'. How congenial this must have sounded to the artists among his readers!

Poincaré had discussed the nature of discovery also earlier, especially in his book, *Science and Hypothesis*. A point he made that particularly struck home at the time was the notion that concepts and hypotheses are not given to us uniquely by nature itself, but are to a large degree conventions chosen by the specific investigator for reason of convenience, and guided by 'predilections' (p. 167). As to the principles of geometry, he announces his belief that they are only 'conventions' (p. 50). But such conventions are not arbitrary. Eventually they have to result in a mathematics that sufficiently agrees with what we can compare and measure by means of our senses. And in the specific case of physics, any convenient presupposition still would eventually have to pass the test of serving in the explanation of observable phenomena.

A significant part of *Science and Hypothesis* was Part II, consisting of three chapters, devoted to non-Euclidean and multi-dimensional geometries. In those pages there are neither equations nor illustrations; but there are great feats of trying to clarify things by analogy. To give only one widely noted example: in attempting to make the complex space of higher geometry plausible, Poincaré introduced a difference between geometric space and conceptual or 'representative' space. The latter has three manifestations: visual space, tactile space, and motor space. The last of these is the space in which we carry on our movements, leading him to write, in italics, "*Motor space would have as many dimensions as we have muscles*" (p. 55).

These and Poincaré's other attempts to popularize the higher geometries must have left the lay reader excited, but, to tell the truth, not really adequately informed. Happily, at just about that time help came from a few popularizations by others which further enhanced the glamour of higher mathematics in the imagination of the young artists in Paris. One of these aids was a book that plays an important role in our story. In 1903, a year after *Science and Hypothesis*, there was published in Paris a volume entitled *Elementary Treatise on the Geometry of Four Dimensions: An Introduction to the Geometry of n-Dimensions*. In it, Poincaré's ideas and publications are repeatedly invoked, from the second page on. The author was a now almost forgotten figure, E. Jouffret (the letter E. hiding his wonderful first names, Esprit Pascal). He identified himself on the title page as a retired Lieutenant Colonel in the Artillery, former student at the Ecole Polytechnique, officer of la Légion d'honneur, officer of public instruction, and member of the Mathematical Society of France. In 1906 he added a more stringent treatment, in his volume *Mélanges de Géométrie à Quatre Dimensions*.

There is also a good deal of evidence that a friend of the circle of artists in Paris, an insurance actuary

named Maurice Princet, was well informed about the new mathematics, and acted as an intermediary between the painters and such books as Jouffret's.

Of course non-Euclidean geometry had been around for many decades, Lobachevsky writing in 1829 and Bolyai in 1832. But both were little read even by mathematicians until the 1860s. Then, for two decades to either side of 1900, a growing flood of literature, professional and popular, fanned the enthusiasm about that unseem fourth spatial dimension.

This cultural phenomenon can have a variety of possible explanations. First, one must not forget that this branch of mathematics was still at the forefront of lively debate among mathematicians themselves. There were about 50 significant professionals in Europe and in the United States working in that area. Second, to lay persons, the new geometry could be a liberating concept, by hinting at an imaginative sphere of thought not necessarily connected to the materialistic physical world that had been presented by 19th-century science—which in any case was itself in upheaval thanks to a stunning series of new discoveries. And above all, the new geometries lent themselves to wonderful and even mystical excesses of the imagination, not least by literary and figurative artists and musicians. They included Dostoyevsky; H. G. Wells; the science fiction writer Gaston de Pawlowski; Alfred Jarry of pataphysics; Marcel Proust; the poet Paul Valéry; Gertrude Stein; Edgar Varèse; George Antheil; the influential Cubists Albert Gleizes and Jean Metzinger, and so on—not to speak of Ouspensky and the Theosophists. Some artists were explicit about their interest. For example, Marcel Duchamp, in his private notes, wrote about his innovating encounter with Jouffret's book, and explained to friends that part of his masterwork, the "Large Glass", incorporated representation of four-dimensional objects. Kazimir Malevich gave the subtitle "Color masses in the Fourth Dimension" to a work in 1915; and as late as 1947, the surrealist Max Ernst produced a painting he called "L'homme intrigué par le vol d'une mouche non-euclidienne".

The scientific imagination at times avails itself of the most unexpected, 'extra-scientific' conceptions, while 'doing their damndest', be it through music, tacit knowledge, thematic presuppositions, aesthetic (or philosophical) preferences. We now know of the influence of *Naturphilosophie* and the philosophy of Immanuel Kant on Hans Christian Oersted's discovery of the magnetic field around electric currents; of Niels Bohr's debt to the psychology of William James, in proposing the Complementarity Principle; and of the encouragement Einstein found for his whole unification program, from the special theory of relativity on, in the literary works of Johann Wolfgang von Goethe, which Einstein studied from his school days on. The examples are endless.

But here one must avoid a careless extrapolation. The work of major composers, artists and authors bears forever their sacred individual authority, as well as the stamp of the cultural context of their time. But the products of research which eventually become absorbed into the *scientific* canon, into the corpus of mature and rational science, have left behind those extra-scientific, often ‘non-rational’ influences which, in the nascent phases, may have led individual scientists to their major discoveries. No matter what tools they used, or what the momentary social context of their labors was, the lasting results are only revelations of Nature’s own regularities; and those are in principle open to anyone—as is proved by the fact that not infrequently the same law, such as the Conservation of Energy, was discovered more or less simultaneously by several researchers in different countries, approaching it in their unique ways. When the building is finished, the scaffolding falls away.

Albert Einstein put it this way: “Science as something coming-into-being, as a goal, is just as subjectively, psychologically conditioned as all other human endeavors”. But at the same time he warned: “Science as something already in existence, already completed, is the most objective, impersonal thing that we humans know”.

The second lesson from our case histories is that the imagined epistemological limits of natural science have turned out to be porous or illusory. I have seen no solid evidence that it will ever be otherwise. On the contrary, nature has constantly revealed ever more startling surprises—and mankind’s comprehensibility to deal with them has been ever more agile.

This leaves me less with satisfaction than with a sense of wonderment, of awe. Another insight of Einstein contains, for me, the final word on this topic, especially because it shows in his last sentence where human beings do encounter a real, insuperable mystery—although not one of reason but one of the spirit.

In a letter of 1952 to his old friend Maurice Solovine, Einstein wrote: “You find it strange that I consider the comprehensibility of the world . . . as a wonder or as an eternal secret. Well, *a priori* one should expect a chaotic world which cannot be grasped by the mind in any way. One *should* expect the world

to be subject to law only to the extent that we order it through our intelligence. Ordering of this kind would be like the alphabetical ordering of the words of a language. By contrast, the kind of order created by Newton’s theory of gravitation, for instance, is of a wholly different character. Even if the axioms of the theory are proposed by a human being, the success of such a project (finding order in nature through science) presupposes that a high degree of ordering exists in the objective world; and this could not be expected *a priori*. That is the ‘wonder’—which is being constantly reinforced, precisely as our knowledge expands”.

Do Radical Discoveries Require Ontological Shifts?

Micheline T. H. Chi and Robert G. M. Hausmann

Learning Research and Development Center, University of Pittsburgh, USA

Abstract: The theoretical stance explicated in this chapter assumes that scientific discoveries often require that the problem-solver (either the scientist or the inventor) re-conceptualizes the problem in a way that crosses ontological categories. Examples of the highest level of ontological categories are ENTITIES, PROCESSES, and MENTAL STATES. Discoveries might be explained as the outcome of the process of switching the problem representation to a different ontological category. Examples from contemporary and the history of science will be presented to support this radical ontological change hypothesis.

Keywords: Scientific discovery; Ontological shift; Emergent systems; Contemporary science; History of science; Representation.

Introduction

This chapter entertains a simple claim. The claim is that many great revolutionary discoveries in science may have occurred because the scientists have undertaken an ontological shift. That is, the scientists had re-conceptualized or re-represented the problem (i.e. the phenomenon to which she/he is seeking an explanation) from the perspective of one ontology or ontological category to another ontology. The remaining chapter explains what this re-representation or shifting across ontological categories entails, and why it is unusual to undertake, thereby explaining the low frequency of revolutionary scientific discoveries. Examples from contemporary and the history of science are cited to exemplify this claim.

The Nature of Ontological Categories

All concepts and ideas (or concepts within ideas and theories) belong to a category. Psychologists define concepts in the context of their category membership. The term concept is used here broadly to refer to a category instance (such as a cat, as an instance of the category Animal, a thunderstorm as an instance of a Process category, and an idea as an instance of a MENTAL STATES category). To assume that all concepts belong to a category is quite standard. For instance, White (1975) also assumed that a concept signifies a way of classifying something. The advan-

tage of categorization is that it allows people to assign the same label to a new instance of the category, and to make inductive and deductive inferences about a new category member (Chi, Hutchinson & Robin, 1989; Collins & Quillian, 1969; Medin & Smith, 1984). Thus, there is clearly a cognitive advantage of having a categorical representation.

What structure does a categorical representation take? Psychologists have by and large addressed the hierarchical (subset–superset) nature of categorical representation. Questions of interests have been: Within such a hierarchy, which categories are the basic level (Rosch, Mervis, Gray, Johnson & Boyes-Braem, 1976)? How are super-ordinate categories coalesced and subordinate categories differentiated (Smith, Carey & Wiser, 1985)? But most of the attention has been paid to the nature of the features that coheres category members, such as whether they are defining features, characteristic features, core features, explanation-based or theory-based features. In our work, we are concerned primarily with lateral (rather than hierarchical) relationship among the categories. We define the lateral relationship to be an ontological one (Chi, 1997).

Ontology refers to the categorical structure of reality. It has long been assumed, since the times of Aristotle, that things belong to *fundamentally different* ontological categories. What is in dispute, to some extent, is the structure of the ontological categories. Categorical structure is typically hierarchical, with

'being' as the topmost category, subsuming everything that exists (Lowe, 1995). Deciding on the structure of ontological categories is a metaphysical question. Our concern, however, is to propose that *psychologically*, people represent categories with ontological boundaries as well. We are not focusing, at the moment, on the exact structure of such psychological ontological categories, but merely to propose the influence of such ontological categories on discoveries.

We can begin by assuming a few major ontological categories as psychologically real and distinct, as our working definition. Consistent with theories provided by Sommers (1971) and Keil (1979), there is likely no dispute that ENTITIES (or material kinds), PROCESSES, and MENTAL STATES are three basic ontological categories, both metaphysically and psychologically. These major categories (or sometimes we will refer to them as trees)¹, with subcategories that they subsume, are shown in Fig. 1. Thus, Fig. 1 shows a plausible ontological categorical structure. Other major ontological categories that are not shown may be TIME, SPACE, and so forth. Another issue that we are

not dealing with is whether metaphysical ontological categories map directly onto psychological ontological categories. We suspect the mapping is not perfect; however, we will sidestep this issue for now.

The psychological reality of ontological categories can be determined by their ontological attributes, which is a set of constraints or properties governing the behavior of members of a given ontological category. For example, objects in the ENTITIES category must have a certain set of constraints that dictate their behavior and the kinds of properties they can have. ENTITIES (such as sand, paint, or men) can have ontological attributes such as being containable, storable, have volume and mass, can be colored, and so forth. In contrast, Events such as war (belonging to the PROCESS ontological tree) do not have these ontological attributes and obey a different set of constraints. Therefore, members of two ontological categories that occupy different trees have mutually exclusive ontological attributes.

Notice that the definition of an ontological attribute is quite different from all the other kinds of categoral features that psychologists have studied. It is not a defining feature, which is an essential feature that a member of a category must have; nor is it a

¹ Trees will be referred to in capital letters, and ontological categories will have the first letter capitalized.

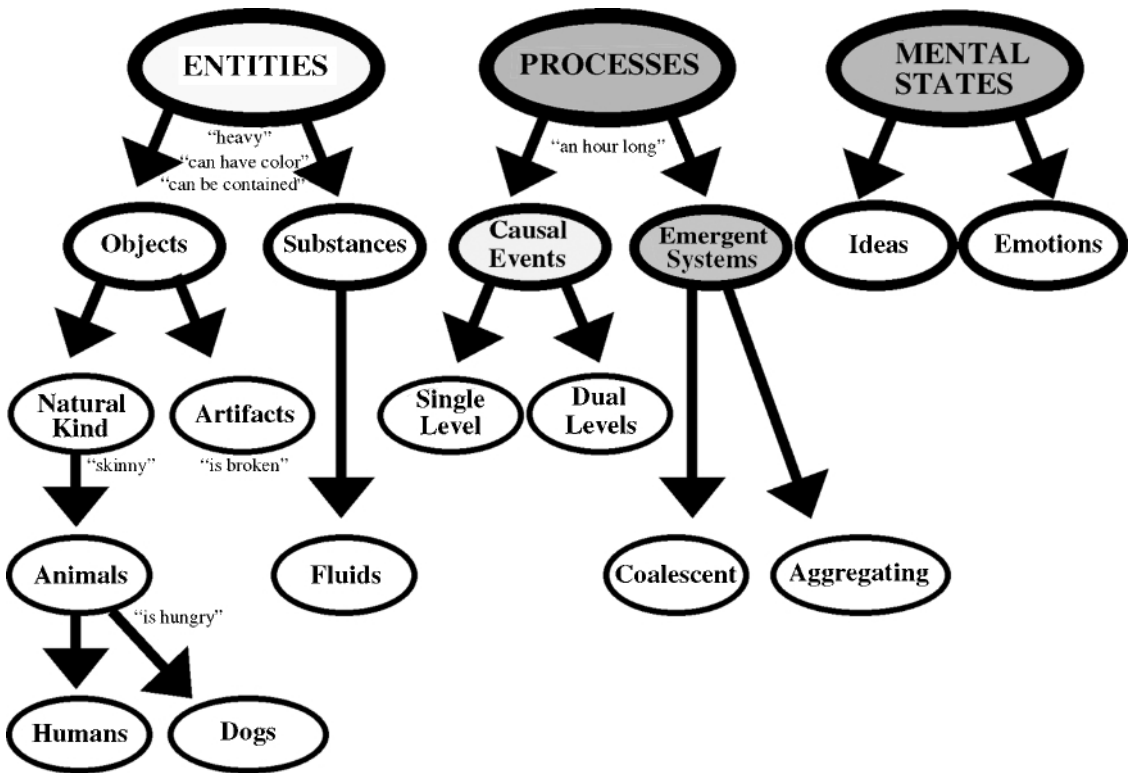

Figure 1. A plausible structure of ontological categories.

characteristic feature, in which the members of a category frequently or typically have (Chi, 1997). Instead, an ontological attribute is defined by Sommers (1971) as a feature that an entity has the potential to have, such as being colored, even though it does not necessarily have it. War or pain, for instance, does not have the ontological attribute of 'being red', whereas squirrels can have such an ontological attribute even though squirrels are commonly not red. Thus, ontological attributes are distinct from other kinds of categorial features in that they are constraints that govern a member of an ontological category, without that member necessarily having that feature.

The psychological reality of ontological categories can be determined by a linguistic test commonly used by philosophers—the predicate sensibility test. As illustrated in Fig. 1, each of the major trees (ENTITIES, PROCESSES and MENTAL STATES) generates a hierarchy of subcategories. A predicate (indicated in quotes), which modifies one concept, will sensibly modify all other concepts below it on the same (branch of a) tree (commonly known as 'dominates', e.g. Sommers, 1963; or 'spans' Wall, 1972), even if it is false. For example, 'hungry' can be applied to the category of Animals and all of its subcategories, such as 'humans' and 'dogs'. Therefore, Animals and Humans are not ontologically distinct. Thus, a bee, an Animal on the ENTITIES tree, has the potential to be 'heavy' even though it is false, whereas a bee cannot be 'an hour long', a predicate of the PROCESS tree. Conversely, an event can be 'an hour long' but not 'skinny'. The point is that predicates on the same tree can modify concepts below it sensibly even if it is false because it is plausible that a specific concept possesses that attribute, and moreover, the truth or falsity of the sentence can be checked.

When an attribute of one category cannot span members of another category, then the two categories are ontologically distinct, and they will be referred to here as 'lateral' or 'parallel' categories. For example, 'is broken' (an attribute of the Artifact category) cannot be used sensibly to modify an entity from a parallel category such as a dog (a member of the Animal category). That is, 'dogs' and 'Artifacts' do not involve a direct hierarchical relationship. Similarly, it makes no sense to say, 'the thunderstorm is broken'. Such statements are called category mistakes. 'The thunderstorm is broken' is not merely a falsehood, for otherwise 'the thunderstorm is unbroken' would be true. 'The thunderstorm is broken' is a category mistake because 'broken' is a predicate used to modify physical objects made by humans, whereas a thunderstorm is a type of PROCESS of the Emergent Systems kind. By this definition then, categories on parallel branches of the same tree (such as Natural Kind and Artifacts, see Fig. 1), as well as on branches of different trees (such as Natural Kinds in the ENTITIES tree and Events in the PROCESS tree), are onto-

logically distinct. However, parallel categories on the same tree do share some attributes. For example, both an Artifact such as a teapot and a Natural Kind, such as a dog, can have color. Nevertheless, they will be considered to be ontologically distinct, as the evidence to be cited below shows, because they have mutually exclusive sets of ontological attributes. In contrast, the attributes of the trees are totally, mutually exclusive.

Gelman (1988) and Keil (1979, 1989) tested the psychological reality of a few ontological categories depicted in Fig. 1. Besides the sensibility judgment task, Keil (1989) has also used a physical transformation task such as surgical operations to show that even young 5-year-old children deny the possibility that a toy bird could ever be made into a real bird. Thus, they adamantly honor the distinction between Natural Kinds and Artifacts even at such a young age.

In general, categories are ontologically distinct if one is not super-ordinate of the other. Thus, branches on the same tree can presumably form distinct ontological categories as well, as in the case of the distinction between Natural Kinds and Artifacts. For purposes of our discussion, we will consider the categories on the three major ontological trees in Fig. 1 to be ontologically distinct, as well as 'branches' on the same tree that do not occupy a subordinate/super-ordinate relationship. Whether or not there are degrees of ontological distinctiveness (e.g. are humans and dogs less ontologically distinct than Natural Kinds and Artifacts?) remains an epistemological and psychological issue that is not addressed here.

Are Processes of Ontological Shifts Difficult?

What is an ontological shift? By our definition, an ontological shift is merely the re-assignment or re-categorizing of an instance from one ontological category to another. Suppose we acknowledge that Fish and Mammals are distinct ontological categories. Children often mistake 'whales' to be a kind of Fish rather than Mammals. However, when children are told that a whale is a mammal, they do not seem to have difficulty reassigning whales to the Mammals category. So it seems that the process of shifting itself may be straightforward, and perhaps it is analogous to a routine learning process of linking or integrating new ideas with old, provided that the old ideas already exist. That is, children already know about the category of Mammals, so that transferring the category membership of whales is not difficult.

The apparent ease of shifting across ontological categories, as demonstrated with the whales example, can be further seen in the ease with which adults shift across ontological boundaries when they use and understand metaphors. That is, metaphors often take the form of combining a predicate from one ontology to modify an entity from another ontology. Take Lakoff's example of anger, which is a MENTAL STATE. In metaphors, anger is conceptualized as a

mass Substance, and takes the grammar of mass nouns, as opposed to count nouns. Thus, one would say *How much anger has he got in him?* but not *How many angers does he have in him?* Because anger is treated as a mass Substance, it can occupy space, can be contained, and can come out, such as *He 'let out' his anger* or *I could barely 'contain' my rage*. This anger Substance is sometimes conceived of as a kind of heated Fluid, such as *She got all 'steamed up'* or *His pent-up anger 'welled up' inside him*. The quoted terms can all be understood as predicates from the Substance category.

Thus, it seems as if shifting across ontological categories is fluid and easily undertaken. However, there is a class of situations in which an ontological shift is necessary, but people find it extremely difficult to do. This is the case when students misunderstand concepts such as heat transfer, electricity, natural selection (Chi, 1997; Ferrari & Chi, 1998). Thousands of studies have documented the misconceptions students hold and the failure of innovative instruction to remove their misconceptions. This difficulty in correcting their misconception may have arisen, we proposed, from the possibility that correcting their misconceptions requires an ontological shift (Chi, in press; Chi & Roscoe, 2002). For example, students tend to conceive of concepts such as heat transfer as a kind of a non-emergent Causal Event, whereas they are in fact a kind of an Emergent System (see Fig. 1). Causal Events are processes with activities that occur with temporal and spatial contiguity, often with an identifiable agent that directly or indirectly produces an effect. Emergent Systems, however, are similar to complex dynamic systems (Casti, 1994; Holland, 1998), in which numerous individual agents or elements independently interact in some uniform way to give rise to complex behavior at the macro level that is not exhibited at the level of the individual elements. For example, each element can follow a simple rule simultaneously and independently along with all the other elements, without any explicit goal to achieve. Yet, a macro pattern will emerge that looks as if the system is intending to achieve a certain goal, and that the process of achieving this goal is orchestrated by some director/agent in some sequential way.

Besides this special case of misconceptions in the context of learning and understanding, shifting ontologically may be difficult (if not directly told to do so) for three basic reasons. The first is a lack of the alternative category. The second is the lack of awareness of the need to shift. Finally, the third is that it is resource-intensive. We discuss the first reason briefly since it does not apply to scientific discoveries and elaborate on the latter two reasons more extensively.

Lack of the Alternative Categories

This reason may not be a relevant one for discovery, but in learning science concepts, students often fail to

successfully re-conceptualize a phenomenon or concept with respect to the right ontological category because they may lack knowledge about the target ontological category. In particular, as mentioned above, we have identified a class of science concepts that entail an Emergent System kind rather than a non-emergent Causal Event kind of process (see Fig. 1 under PROCESSES). Students are unfamiliar with this Emergent kind of PROCESSES; therefore, one could assume that they cannot shift their representation of processes from a Causal to an Emergent kind when that category does not yet exist in their knowledge (Chi, in press).

Lack of Awareness

Even if people do have the alternative ontological categories, they may still not shift spontaneously because they may not be aware that they have to shift their representation of an entity or phenomenon from one ontological category to another. This lack of awareness may arise from four sources. First, it is a low-frequency phenomenon. That is, we do not routinely need to re-classify a phenomenon from being of one kind to another kind. We generally categorize an entity correctly on the basis of its outward appearance. How we represent an everyday entity or phenomenon usually corresponding to its true identity. For instance, when we identify an animal that is furry with a wagging tail as a Dog, our categorization is usually accurate. Thus, it is seldom the case that the core features of an entity or phenomenon are in fact different from its surface features, so that we have misclassified it and have to shift. There are a few exceptions. For example, children often classify whales as a kind of Fish because it has many of the characteristic features of a fish, such as swimming in water, shaped like a fish and so on. This is one of the few instances in which the surface features belie the true core feature. Occasionally, we must shift in the context of reading stories and watching films. For example, in the popular children's novel *Indian in the Cupboard*, the central theme of the book is that a toy Indian comes alive. A great deal of suspense usually surrounds such a kind of conversion and the main character is clearly surprised. A similar ploy is used in *Velveteen Rabbit*. Similarly, in the film *The Crying Game*, a male character is disguised as a female. The viewers are surprised when the disguise is revealed. Notice that these kinds of revelations in stories and movies are much more dramatic than mistaken identity. Misidentifying one person (e.g. an undercover agent) for another (a preacher), as often occurs in mysteries, is suspenseful, but not as dramatic because no ontological categories had to be crossed: both an undercover agent and a preacher are Males, whereas, discovering that a character is really a Male rather than a Female requires shifting that person's categorical membership laterally. The drama, in the case of crossing ontological

categories, arises because the viewers or readers must revisit and revise all the previous assumptions and implications about the character when he was a male because a new set of properties and features has to be inherited when an instance changes membership. Thus, since we are not accustomed to re-represent or re-classify a phenomenon or entity from one ontological category to another, we are not aware that such a shift is sometimes necessary.

However, mistaken classification based on the perceptual features is precisely the source of misconceptions in science (Chi & Roscoe, 2002; Chi, Slotta & de Leeuw, 1994). For example, we perceive and feel heat flow from one location to another. Therefore, when heat flow is conceptualized as a Causal Event, it appears as if the hot molecules move from one location to another location, when in fact the flow sensation derives from the collective random bombardment of all the moving molecules moving at different speeds (Chi, in press).

A second reason for a lack of awareness for the need of ontological shift is that our mis-representation is often adequate for everyday functioning. This is especially true in the case of our science misconceptions. It is perfectly adequate for us to close the window in order not to let the heat escape, thereby treating heat as a kind of Substance that can flow from one space to another space, when in fact heat is a kind of Emergent Systems PROCESS. Thus, our mistaken classification provides an adequate explanation for the phenomena that we encounter everyday, so that we are not aware of our misconceptions.

Finally, we have a tendency to pursue endeavors in a rigid and routine manner, analogous to functional fixedness (Ohlsson, 1992). For example, consider Duncker's famous candle problem. The participant is presented with three objects on a table: a book of matches, a box of tacks, and a candle. The goal is to attach the candle to the wall so it will burn normally. The solution requires the solver to reclassify the box, not as a *container*, but as a *platform*. Subjects solve the problem correctly 86–100% of the time when the problem is presented with the box of tacks empty, vs. a solution rate of 41–43% when the box is full (Weisberg & Suls, 1973). That is, there is no reason for us to think about re-classifying the box when it is full since we can continue to think of it as a container. Thus, even reclassifying within the same ontology is uncommon.

Resource Intensiveness

Although we have assumed in a preceding section that shifting itself may not be difficult in the context of using and understanding metaphors, shifting across ontological categories may be resource-intensive in other contexts. That is, the shifting itself may not be effortful, but once undertaken, efforts and cognitive resources have to be allocated for the process of re-inheriting a new set of features. Although there is no

direct evidence on this point, there is some suggestive evidence that even shifting perspectives takes extra effort. Black, Turner & Bower (1979) have found, for example, that people prefer to maintain the same point of view when processing a narrative text. (This implies that changing perspective or one's representation may require extra cognitive resources, even though changing perspectives is not the same as shifting across ontological categories. See discussion below.)

In sum, our assumption is that shifting per se is not difficult. The ease of shifting per se can be supported by two kinds of anecdotal evidence mentioned above. In the first case, the ease of shifting can be seen in children when they are told that whales are a kind of mammal. Similarly, in novels and movies, children and adults have no difficulty in shifting their representation of a stuffed toy to a live person, or from a man to a woman, and so forth. A second example of ease of crossing ontological categories comes from adults' comfortable use and understanding of metaphors. However, in both of these cases, shifting occurs when we are explicitly told to shift, or we are presented with a metaphorical usage that includes a combination of two ontological categories. Shifting on our own, without being told, may be more uncommon, largely because we are not aware of the necessity to shift. Finally, the shifting itself may not be the bottleneck (assuming one knows about the category to which one is shifting), what is difficult may be the resource intensiveness of re-inheriting all the attributes of the alternative category. For example, it is difficult for some cognitive psychologists to consider cognition not as knowledge (a Substance) in the head but as a PROCESS of interaction; the difficulty arises not because we cannot undertake such a shift, but because we cannot easily understand all the ramifications for our views on memory, learning, and problem-solving (see the debate between Anderson, Reder & Simon, 1996 & Clancey, 1996).

Re-representation and Ontological Shifts

An ontological shift is a kind of re-representation. However, it is distinctly different from other kinds of re-representation. We discuss five other kinds of re-representation. But before discussing them, a few remarks should be made about general issues regarding representation. First, there is no dispute that certain representations of a problem may make a problem easier or harder to solve. For example, in order to give commands to the programming tool 'turtle graphics' (Papert, 1980) for the turtle to draw lines across the graphics screen, some problems are easier to solve by taking the turtle's point of view, and other problems are easier to solve by taking a more global point of view. Similarly, Hayes & Simon (1977) found differences in solution times for isomorphic representations of the classic Tower of Hanoi problem. Solution times were twice as fast if the problem was represented as

Monsters exchanging Globes, rather than Monsters changing the size of the Globes. One of the reasons that a problem can be solved more easily in one representation than another has to do with the constraints of the problem. Sometimes the constraints become more obvious in one representation vs. another. At other times the constraints become an integral part of the representation (being built in in some sense). And yet at other times the constraints can be released. Thus, whether a specific representation is more or less beneficial to arriving at the problem solution is a different issue from the issue that concerns us here: namely, whether or not shifting between representations (or re-representing) is beneficial, and if so, why it is not undertaken more frequently, as may be necessary in scientific discoveries.

Changing Perspectives

The most often discussed notion of changing representation is in the context of development. Piaget & Inhelder (1956), for example, discuss the way younger children cannot (but older children can) see things from another physical perspective besides their own. Similarly, younger children cannot (but older children can) acknowledge the listener's point of view. For example, Shatz & Gelman (1973) showed that young 2-year-olds did not adjust their speech to the age (and knowledge) of the listener, whereas 4-year-olds did adjust their speech depending on whether they were speaking to another peer or an adult. Thus these developmental studies implicate that children are capable of shifting their perspectives as they get older.

In the adult literature, besides Papert's (1980) work cited above, Hutchins & Levine (1981) have shown that problem-solvers do change perspectives as they solve the Missionaries and Cannibals problem. They used deictic verbs such as 'come', 'go', 'take', 'send', 'bring', and place adverbs such as 'here', 'there', 'across' to determine the solver's point of view, such as viewing the river that the Missionaries and Cannibals have to cross, from either the left bank or the right bank. One of their interesting findings was that when solvers were 'blocked' in their solution, in the sense that they have made two non-progressive moves out of a problem-solving state (in the problem space), then they were successful in becoming unblocked when they changed their point of view. So clearly, being able to shift one's point of view is beneficial for problem-solving, and it is a form of re-representation.

Re-representing at Different Levels

Instead of changing perspectives, representational shifts can also be considered in the context of levels. There are four ways to think about levels.

Shallow and Deep Levels

One way to think about levels is in the context of shallow surface features (such as the entities mentioned

in a problem statement) and deeper semantic features (such as the principles that govern the solution procedure). So for example, Chi, Feltovich & Glaser (1981) showed that expert physicists represented routine physics problems at a conceptually deeper level (in terms of the principles that guide the solution), whereas physics novices (those who have taken one course in college with an A grade), tended to represent the same problems according to their literal components (such as the pulleys and the inclined planes). Obviously the underlying principles of the problems determine their problem solution and not the literal components. The implication of this work is that as one acquires expertise, one's representation changes so that it is organized according to the principles of physics rather than the physical components.

Subset–superset Hierarchical Levels

Besides re-representation between levels in the sense of from a shallow more surface-oriented level to a deeper more conceptually oriented level, a second form of re-representation occurs between hierarchical (subset–superset) levels of categories. Suppose we ask students to solve the following two 'insight' problems:

- (1) A man who lived in a small town married 20 different women in that town. All are still living and he never divorced a single one of them. Yet, he broke no laws. How can you explain this?
- (2) Two strings hang from a ceiling. They are hung far enough apart that a person cannot reach both strings at the same time. The goal is to tie the strings together. Lying on a nearby table are a hammer and a saw.

These problems are typically considered to be difficult (thereby called 'insight' problems). To solve them requires that one re-represents an entity within the problem. In the first problem, the solution is to re-represent the man not as a 'bachelor', but as a 'clergyman' (a specific type of 'bachelor'). Similarly, in order to solve the second problem, one must re-represent hammer not as a 'tool', but as a 'heavy tool'. This heavy tool can then act as a weight to be tied to one of the strings to create a pendulum. One simply swings the pendulum, grabs the first string, and then catches the other string on its return. In both cases, the entities in the problems are re-represented as an instance of a subcategory. This is an example of re-representation within hierarchical levels. Hierarchical levels satisfy the relationship of 'kind of'. That is, a clergyman is a kind of 'bachelor', and a 'hammer' is a kind of 'heavy tool'.

Component Levels

A third way to think about levels is in terms of decomposition. For example, if we were asked to explain how the human circulatory system works in terms of its function of delivering oxygen to body

parts, we would explain it by appealing to the components of the circulatory system, such as the heart, the lungs, blood, and blood vessels, and that it is the contraction of the heart that sends blood to different parts of the body. One can then further ask how the heart contracts. To answer this question, we would have to discuss the components of the heart, such as the role of the rise of ventricular pressure and so on. Basically, each question and its accompanying explanation must reduce each component into its finer and finer constituent parts. Miyake (1986) collected protocol data that illustrated representational shifts in terms of a reduction-decomposition approach to levels. She showed that dyads, in attempting to understand how a sewing machine works, would move to progressively lower levels when they recognized that they had not understood the mechanism. For example, in figuring out how a stitch is made, one can understand it by explaining that the needle pushes a loop of the upper thread through the material to the underside, so that the upper thread loops entirely around the lower thread. However, in order to understand how this looping mechanism works, one has to explain the mechanism at a lower level, of how the bottom thread is able to go through the loop of the upper thread.

Component levels satisfy a 'part of' relationship, rather than a 'kind of' relationship. In these examples, ventricular pressure is part of the cardiovascular system, and looping is part of the mechanism of making a stitch.

Emergent Levels

A fourth way to think about levels is one in which the relationship between them is an 'emergent' one (Chi, in press; Resnick & Wilensky, 1998). (See the discussion about Emergent Systems above.) In this conception of levels, the (often) observable 'macro' level behaves independently of the 'micro' level objects. Moreover, the macro observable level arises from local interactions of the micro level individuals. The most commonsensical example is a traffic jam. A traffic jam is a gridlock of cars, in which cars can no longer move at the same speed before the jam. This is the macro-level phenomenon. The behavior of the individual cars in a jam is independent of the jam. Each individual car may be following the same simple rule, which is to accelerate if there was no car in front within a certain distance, and slow down when a car comes within a given distance. The independence of the macro and micro levels can be seen in that the jam itself can move backward even though the individual cars move forward. However, the jam arises or emerges from the interaction of the cars.

For another example, changes in a moth's pigmentation, due to the smoky industrialization in England in the middle of the 19th century, can be understood in terms of emergent levels as well. That is, the emergent pattern, that moths were getting darker

over generations, occurred because individual moths were independently being eaten or not eaten by birds. It so happened that lighter moths, which perched on tree trunks that were getting increasingly sooty, became more apparent and visible to hungry birds. Thus, it was more likely that the lighter moths were more visible and thereby were eaten while darker moths tended to survive. Even though one cannot specify on an absolute basis whether a given dark or light moth (on a relative scale) would survive or not (since it depended on a number of local conditions, such as whether a moth happens to land on a darkly sooted tree trunk, and whether a hungry bird happens to be nearby and can see the moth), nevertheless, over generations, the probability is such that the darker ones tended to survive and reproduce, thus producing the changing pattern of moths getting darker over generations. Thus, this overall pattern is an emergent one. It is not caused by any specific actions on the part of any specific moth or groups of moths. This is not a case of re-representation from one level to another lower level, as in the example of the sewing machine. Rather, this is a re-representation from a macro level to a representation of the relationship between the micro and the macro level, in order to understand the macro level pattern. Representing the inter-level emergent relationship is extremely difficult for students (Chi, in press).

In sum, two different kinds of re-representation are described above, one involving changing spatial perspectives and one involving four kinds of changing levels. Among these five examples of re-representation, only the last one constitutes an ontological shift. In that case, the shift is between the ontologies of 'Causal Events' and 'Emergent Systems' (see Fig. 1 again). The fact that only one kind of re-representation involves an ontological shift (or sometimes referred to as radical conceptual change, Chi, 1992) may explain why it occurs infrequently. In the next section, we revisit whether or not we have evidence that ontological shifts are possible.

Evidence of Ontological Shifts

Besides the anecdotal evidence that people can shift across ontological categories readily, as in the case of children re-representing *whale as a mammal* or the case of understanding stories about an *Indian in the Cupboard*, is there evidence that ontological shifts actually occur? There are two kinds of evidence. In this section, we suggest evidence of ontological shifts between novices and experts. In one study, we compared the explanations of ninth grade students with those of graduate physics students on simple conceptual problems, such as *Explain which coffee cup is a better insulator; a styrofoam cup or a ceramic cup?* We coded their explanations not for accuracy (which would not be fair to the high school students), but for the kind of predicates they used in their explanations. The predicates they use would indicate which onto-

logical category they represent the concept/phenomenon. Ninth graders (the novices) would explain their choice of the coffee cup with justifications such as *The coffee in the ceramic mug is hotter because the heat in the styrofoam cup is 'gonna escape'*. In contrast, the graduate students' (the experts) answers might say something to the effect that *The energy loss in the ceramic cup is through transfer of heat from a hotter source to a cooler source, due to the movement or 'motion of electrons'*. The basic difference in their explanations is that novices use Substance-based predicates. That is, viewing heat as a kind of Substance that can be contained, stored, or escaped; whereas experts use PROCESS-based predicates such as motion of electrons (Slotta, Chi & Joram, 1995). Thus, experts appeared to have undertaken an ontological shift whereas novices have not.

A better example that is not contaminated by knowledge of the domain jargon comes from our study with expert swimming coaches. Two experts with a minimum of 12 years as full-time head coach and who have produced from 20 to 100 top national caliber swimmers were compared with two novice coaches with a maximum of two years' of full-time coaching experience. Their task was to diagnose underwater films of four swimmers performing the freestyle stroke. The general diagnoses rendered by the novices focused on specific body parts, such as *the elbow was bent on extension, or the right arm was not underneath the body*. In contrast, experts tended to diagnosis more holistically, referring to processes, such as *Little and unequal body roll, or stroke unbalanced*. Basically, the more novice coaches diagnosed swimming deficiencies by attending to individual body parts (Concrete Entities), whereas the experts focused on aspects of the swimming PROCESSES, such as body roll (Leas & Chi, 1993). According to the aforementioned studies (Leas & Chi, 1993; Slotta et al., 1995), one undergoes an ontological shift in the process of acquiring expertise.

Does Ontological Shift Underlie Discoveries?

As in the case of resistance to ontological shifts in learning about many science concepts (i.e. the robustness of misconceptions), it may be the case that scientists are also resistant to change and choose to persist in generating explanations or hypotheses within the same ontology. The thesis of this chapter is to explore the claim that major scientific discoveries may have arisen because the scientist underwent an ontological shift, in terms of the nature of the novel, revolutionary explanations. Few empirical studies directly support this claim; however, Hutchins & Levine (1981) found that subjects who were blocked in their problem-solving became unblocked when they shifted their perspective.² However, as we said earlier,

shifting perspective is not exactly the same thing as shifting across ontological categories. Below, we review two domains of scientific discovery and/or scientific revolution: one in contemporary (20th century) science, and the other in the history of science, to show that these discoveries did require an ontological shift. By scientific revolution, we mean changes that are more extensive than at the level of individual theories, but rather changes that involve the research tradition or paradigm under which specific theories are constructed. We use the term 'paradigm' in the same sense as Kuhn (1996), Lakatos (1970), and Laudan (1977), who considered research paradigms as world-views that encompass a set of theories with similar assumptions and similar concepts. 'Similar' can be conceptualized, in our opinion, as those belonging to the same ontology. So, for instance, 'evolutionary theory' really refers to a family of doctrines that all assume that organic species have common lines of descent. All variants of evolutionary theories would implicitly make that assumption. Thus, theories within the same paradigm basically are modifications and extensions of one another, since they adopt the same assumptions and concepts, scrutinize the same set of problems, and use the same sort of methodologies and instruments to do their science.

Some Examples of Ontological Shifts in Contemporary 20th Century Theories

In this section, we briefly describe what may be considered major breakthroughs in the 20th century, drawing on examples from the treatment of diseases as well as theories for natural or scientific phenomena. This treatment is very superficial, and captures merely the highlights of the changes in the scientific explanations, as rendered by other scientists.

Peptic Ulcers

Thagard (1998a, 1998b) detailed the historical shifts in the causal explanation for peptic ulcers. The prevailing hypothesis prior to 1979 for the cause of stomach ulcers was an excess acidity in the stomach. The increased production of gastric acid was thought to be caused by elevated levels of stress experienced by an individual. The causal sequence of events that eventually lead to an ulcerated stomach lining was: increase in stress levels, which lead to the increased production of stomach acidity, which then leads to erosion of the stomach lining. There was a general agreement and satisfaction with the stress leading to excess acidity model, although treatment was only successful at reducing acidity (the symptom), not stress (the cause).

Evidence against the prevailing explanation came from a source not initially designed to explain the etiology of ulcers. In 1979, while Warren (a pathologist) was performing an autopsy on a patient, who was diagnosed with nonulcer dyspepsia and gastritis, he

² See also (Andersen, 2002) for historical evidence.

observed an unusually high count of bacteria in his stomach. Warren's observation went against conventional wisdom because the medical community believed the stomach was too hostile an environment for the survival of microorganisms. Warren began collaborating with Marshall (a gastroenterologist), and they noted a correlation between gastritis and bacterial infection, as well as duodenal ulcer and bacteria. To strengthen their hypothesis, Warren and Marshall successfully treated 90% of their patients, who were diagnosed with duodenal ulcers, with antibiotics. After several different types of experimental studies, Warren and Marshall finally proposed the hypothesis that the bacteria, *Helicobacter pylori*, were responsible for peptic ulcers.

Today, the bacteria hypothesis remains the most viable explanation for peptic ulcers because it succeeds in treating patients at the level of the hypothesized causal mechanism, instead of merely controlling the symptoms. Instead of using antacids to control the increased stomach acidity, physicians now also prescribe a regimen of antibiotics to eradicate the infection (Graham, 1993). Notice that a breakthrough in finding a better causal explanation of peptic ulcer consisted of shifting the ontological categories of the explanations, from one of MENTAL STATES (stress) or Substance (acid) to one of Animate Concrete Entities (bacteria).

Dinosaur Extinction

Clearly, one of the most intriguing scientific issues of the modern era has been to provide a coherent explanation for the massive extinction of dinosaurs, nearly 65 million years ago. Several interesting ideas, ranging from infertility due to rising climatic temperature, ill reactions to newly evolved flowering plants, cataclysmic events (such as massive meteors or massive volcanic activity), attempted to explain why dinosaurs became extinct (Gould, 1985). However, several of these theories are not viable because they are not consistent with other empirical observations. For example, because the extinction was on a global scale, an acceptable theory must also explain why oceanic life (such as plankton) also died at the same time, and it must be consistent with the fossil record. Therefore, the first two explanations (infertility and increased toxicity in flowering plants) must be ruled out because neither hypothesis can explain why plant and oceanic life also died out (Gould, 1985).

The prevailing dogma, which finds its intellectual roots in the gradualist ideas put forth by geologist Charles Lyell, was that the Earth was modified over millions of years (W. Alvarez, 1997). The Earth has undergone long periods of climatic changes (the 'ice age' of the Quaternary Period, for example), as well as changes in sea level. To explain dinosaur extinction, gradualists assumed that, like every other species, dinosaurs became extinct because they could not adapt to the climatic changes. Scientists of the day argued

that an incomplete fossil record is evidence that dinosaurs died out over a protracted period (W. Alvarez, 1997). At this point, iridium did not play a role in the development of a theory of dinosaur extinction. According to the gradualist perspective, if iridium existed on Earth, then it would have had an Earth-bound origin (volcanic activity, for example).

Although the gradualist explanation seemed congruent with the available evidence, Walter & Luis Alvarez proposed a different theory (L. W. Alvarez, Alvarez, Asaro & Michel, 1980). They proposed that an enormous meteor struck the earth, which created enough dust to block the sun around the planet. They reasoned that the obstruction of sunlight would cause the process of photosynthesis to stop, thereby causing the entire food chain to suffer. The impact hypothesis satisfies the two aforementioned constraints. First, the impact hypothesis explains why there is global extinction (not just animals, but plants and oceanic life as well). Second, the hypothesis is consistent with the fossil record because the amount of iridium embedded within the Crustaceous-Tertiary boundary is several orders of magnitude higher than the amount found on Earth during any other time period. High concentrations of iridium are mainly found on asteroids or comets, as well as the core of the Earth. To rule out the alternative hypothesis that volcanic activity caused the extinction of the dinosaurs, the Alvarez team turned to a different strand of evidence. They demonstrated that a specific type of rock, called 'shock quartz', was also observed at the same time period. Shock quartz is formed by a violent strike to a layer of quartz. Because of the overlapping evidence, the meteor hypothesis gained popularity.

These two hypotheses have maintained the scientists' interest perhaps because they are ontologically distinct. The impact theory is based on the notion of a one-time discrete Causal Event, involving a Concrete Entity such as a meteorite, whereas the gradualist explanation can be considered a continuous PROCESS of climatic and sea-level changes, perhaps likened to an Emergent System.

Coronary Heart Disease

Discovering the cause for coronary heart disease (such as acute myocardial infarction) represents one of the most significant challenges to the medical community because an estimated 7,500,000 Americans die each year from myocardial infarction (American Heart Association, 2002). The direct explanation for the cause of heart attacks has been atherosclerosis, which is the thickening of the coronary arteries, thereby restricting the flow of blood. The question is what caused such thickening to occur. The prevailing explanation is that arteries are thickened by cholesterol deposits into the artery walls and production of atherosclerotic plaques. The plaques cause a narrowing

of the vessels. In the last two decades, Americans have been obsessed with diets that can reduce their cholesterol level to an acceptable healthy level.

More recently, however, two alternative theories have been proposed. One is the hypothesis that, instead of cholesterol, it is iron overload that causes heart attacks. This hypothesis is consistent with a number of pieces of evidence. For instance, men who regularly donate blood have a lower risk of heart disease, and pre-menopausal women who regularly lose blood, and thus iron, also have a lower risk of heart disease. Tuomainen, Kari, Nyssonen and Salonen (1998), using a case-control study of Finnish men, found that individuals with high iron levels were more likely to have suffered an acute myocardial infarction in the past 6–7 years. Presumably, iron can increase ‘oxidative stress’ on the lining of the blood vessels. That is, iron can somehow interfere with nitric oxide, a chemical that relaxes blood vessel walls, allowing the blood to flow more freely.

A second promising new hypothesis is currently being proposed, that coronary heart disease is caused by inflammation in the bloodstream. This hypothesis is compatible with the finding that many people (in fact, over 50%) with no known risk factors (such as high cholesterol levels) nevertheless do have heart attacks. Moreover, an enzyme called myeloperoxidase (MPO) and a substance called interleukin 6 were both elevated among people who had heart attacks and narrowed coronary arteries (Zhang et al., 2001). Both substances are associated with inflammation. For example, MPO is normally found in infection-fighting white blood cells, so that their elevation indicates the body’s attempt to fight inflammation. Using a cross-sectional survey, Meier, Derby, Jick, Vasilakis and Jick (1999) found that adults who had taken tetracyclines and quinolones (antibiotics) showed a reduced likelihood of experiencing an acute myocardial infarction. The exact mechanism that mediates atherosclerosis through inflammation is not completely clear. One possibility is that bacteria and other infections (such as gum infection) can cause clot-forming cells (or platelets) to clump together, thereby causing arteriole blockage.

It seems that there is a rapidly growing body of evidence that inflammation in the bloodstream can cause heart attacks. Moreover, there is a growing consensus among scientists that other disorders, such as colon cancer, Alzheimer’s disease, may also be caused by chronic inflammation. Hence, inflammation seems to be the hypothesis that is favored at the moment (in the sense that an increasing number of studies are testing this hypothesis and trying to understand its mechanism). The excitement, we believe, arises from the fact that a hypothesis based on inflammation (a PROCESS) is ontologically distinct from a hypothesis based on both cholesterol deposits and iron overload (both cholesterol and iron are a kind of Substance). Thus, an ontological shift in hypothesiz-

ing implies that the new hypothesis has inherited many other ontological attributes that require scientists to further investigate its ramifications.

Some Examples from the History of Science

In this section, a few examples of major scientific discoveries are cited that may be thought of as having undergone ontological shifts.

Epilepsy and Other Diseases

Between 430 and 330 BC, the approach to diseases was a religious one. For example, epilepsy was caused by divine visitation (Thagard, 1996). Divine beliefs fit the ontology of a kind of MENTAL STATES. Consequently, treatment of diseases was consistent with the explanation at the time, such as by appealing to the gods for mercy or other magic.

After 330 BC, Hippocrates rejected the religious approach by postulating that epilepsy is caused by an excess of phlegm, one of the four fluids (or humors) that were thought to constitute the human body. Healthy bodies supposedly had the correct proportion of each of the four fluids (blood, phlegm, yellow bile, and black bile). Imbalances in these fluids were thought to produce diseases, and different kinds of imbalances produced different diseases. Treatment of course, was again compatible with the prevailing explanation. To redress humeral imbalance, one would change one’s diet, or rid the body of excess phlegm by inducing vomiting or evacuation of the bowels, and/or letting blood from the veins.

One can say that Hippocrates’ humeral theory is radically different from the divine visitation theory because the explanation of epilepsy had undergone a major ontological shift, from a kind of a MENTAL STATE to a kind of Substance. In the 19th century, another major conceptual shift occurred, this time to postulate that diseases were caused by bacteria and other microorganisms. This breakthrough occurred from, presumably, the analogy that Pasteur made in the late 19th century between fermentation and disease. Since fermentation was caused by yeast and bacteria, so too can diseases be caused by microorganisms. Thus, another ontological shift had occurred, from one of Inanimate Substance (imbalance of phlegm) to Animate ENTITIES (micro-organisms).

Notice that before Pasteur, Fracastoro had posed another theory, the notion of ‘contagion’, which can be thought of as ‘seeds’ that can be passed from one person to another. Treatment would therefore consist of expelling and destroying these seeds, rather than restoring humeral imbalance. Although the contagion theory and the humeral theory appear to be rather different, they were not ontologically distinct. They are both a kind of Substance. Thus, Fracastoro’s theory was not a breakthrough and had little influence after 1650 (Thagard, 1996).

Theory of Evolution Through Natural Selection

In the 18th century, Lamarck postulated that environmental forces modified an organism's morphology. The classic example is the giraffe's long neck. To explain why the giraffe has a long neck, Lamarck hypothesized that reaching for leaves on tall trees gave the giraffe a longer neck. These changes in animal physiology could then be passed onto the organism's offspring. The central idea in Lamarck's theory of evolution was that traits could be acquired from intentional use. If there were a change in the animal's environment, the animal would then be able to respond (i.e. adapt) by changing its traits. Thus, the Lamarckian theory proposed that evolution is a kind of a Causal Event, in that the agent (the giraffe in this case) can directly cause and manipulate (by using and stretching his neck, for example) his own traits to suit the environment.

In the 19th century, Darwin rejected the idea that animals have the capacity to actively change their heritable traits (Gould, 1985). Instead, he postulated a radically different mechanism: natural selection. Darwin's theory can be stated in the following way. Basically, each giraffe is different from every other giraffe, from variability in the inherited genes. So some giraffes have longer necks and others shorter necks. Those with longer necks can reach their food source, so they are more likely to survive and reproduce, although some of the shorter neck giraffes may also survive if some short trees happen to be around. But in general, the taller giraffes have an advantage, given that trees tend to be tall. Because offspring inherit such a trait (of long necks), then the taller giraffes, having had more opportunities to survive and reproduce, tend to produce offspring with longer necks. Over generations, the entire population of giraffes tends to have increasingly longer necks.

The shift from intentional modification of heritable traits to probabilistic survival and reproduction due to random variation in a trait represents a radical ontological shift. Evolution via intentional adaptation might be categorized as a kind of Causal Event, whereas Darwin's theory might be best understood as a kind of Emergent System. (See Chi, in press, for more details.)

Electricity

Another ontological shift can be found in the theoretical development surrounding the topic of electricity. Among the very first documented cases of static electricity (i.e. ancient Greece) included the observation that amber attracted small pieces of straw after it was rubbed (Meyer, 1971). These early experiments are now considered demonstrations in electrostatics. The explanations generated by early theorists and experimenters were targeted at explaining why two objects are attracted to one-another after being rubbed with a cloth or fur. The first explanation for the electromotive forces began with a type of Material

Substance called 'effluvium'. In 1600, William Gilbert proposed that the effluvium stretched out across space to hold two objects together. The larger the space, the thinner the effluvium became, and the weaker the felt attraction. The experimental data confirming the existence of the effluvium as a Substance was the observation that the interposition of any object would break the attraction between two objects (Home, 1981). This was taken as evidence as a Material Substance because one property of material objects is that they are unable to occupy the same space. Home (1981) provides a description of the antiquated construct:

The effluvia are described at one point as 'fine', at another as 'subtle'; however, it is emphasized that they are material, and as such are subject to ordinary physical laws. The presence of moisture and other impurities in the atmosphere can hinder the action for the effluvia in two ways: the moisture will condense on the surface of the glass or other substance to be electrified, and in doing so may block the pores from which the effluvia are normally emitted; alternatively, the mere presence of impurities in the atmosphere should increase its density and hence the resistance it offers to the motion of the effluvia (p. 5).

Although initially successful, the effluvium theory was unable to account for a few enigmatic observations. For example, the theory required some medium for the action at a distance. It was hypothesized that the effluvium stretched out across the air, from one object to the other. However, experiments conducted after the introduction of the vacuum demonstrated that a medium was unnecessary to observe the same results. Another difficulty was the observation that some charges attract while others repel. Therefore, it became increasingly apparent that the effluvium theory was incomplete.

The effluvium theory was eventually replaced by Benjamin Franklin's single fluid theory of electricity (Meyer, 1971). Objects were considered positive if they contained more fluid, and negative if they had less fluid. The flow of electricity, according to Franklin, was from positive (objects with more fluid) to negative (objects with less fluid). Franklin also made the assertion that the electrostatic demonstrations in the lab also applied to natural phenomena, such as lightning (Holyoak & Thagard, 1995). Franklin did, however, express some doubt as to the fluid theory. He stated, "The electrical matter consists of particles extremely subtle since it can permeate common matter, even the densest, with such freedom and ease as not to receive any appreciable resistance" (quoted in Hecht, 1994). It seems reasonable for Franklin and his contemporaries to conceptualize electricity as a fluid, given the popularity of 'fluid-like' explanations for other physical phenomena (e.g. the caloric theory of heat and the impetus theory of motion).

Electricity, however, did not remain in the flow of a fluid. First, in a series of experiments, Faraday provided empirical support for the claim that different ‘forms’ of electricity were actually manifestations of a common origin. That is, electricity generated by a rotating magnet was derived from the same cause as a voltaic pile or frictional (i.e. static) electricity (Harre, 1981). Second, Faraday went on to propose a field theory of electricity, which stated that electricity was induced in a current-carrying wire when moved relative to a magnetic field. The movement of the wire thereby ‘cut’ the lines of forces surrounding the magnet, causing the induction of an electric current (Nersessian, 1992; Tweney, 1989). James Clerk Maxwell, a contemporary of Faraday, went on to formalize these ideas with his famous field equations.

A unified, mechanistic explanation for the various forms of electricity was provided by the discovery of the electron in 1899 (Harre, 1981). Sir Joseph John Thomson, who was credited with the discovery, attempted to measure both the mass and charge on the electron (Hecht, 1994). Although not everyone at the time subscribed to the atomic theory of matter, Thomson made the argument that there were subatomic particles, which could be observed experimentally. Given Thomson’s discovery, electricity could now be understood as net movement of free electrons through a closed circuit. Thus, the flow of electricity is a kind of Emergent System.

The history of electricity thus demonstrates a non-radical shift from the progression of the effluvium to the fluid theory, in that both theories involved substances moving from one place to another, as a kind of Causal Event. The breakthrough did not occur until Thomson’s ideas were established, that current flow is the net movement of subatomic particles. This revolutionary idea required an ontological shift by considering electrical current to be a kind of an Emergent System rather than a kind of a Causal Event.

The Caloric Theory of Heat

Fluid-type models of physical phenomena were used to explain not only electricity, but also heat transfer. The caloric theory of heat, proposed largely by Lavoisier, was the dominant theory of the day (Spielberg & Anderson, 1995). The theory held two basic tenets. First, heat transfer was the result of two bodies, of unequal temperature, coming into contact with one another. The caloric was understood to flow from the relatively ‘hot’ object to the ‘cold’ object. The second tenet stated that the caloric was conserved (i.e. it can neither be created, nor destroyed). Although the theory was useful in understanding new developments, such as the steam engine, it became apparent that the theory was not totally correct.

One anomaly, which could not be explained by the two tenets, was the explanation of heat generated

during friction (Spielberg & Anderson, 1995). Because the caloric was always conserved, it was hard to explain why two objects, which start in thermo-equilibrium, could produce heat when rubbed together. This observation violated the second tenet. To investigate this anomaly more systematically, Joule designed a method for precisely measuring the heat generated from friction. His apparatus included a container, with several compartments. The compartments were filled with fluid, and a paddle agitated the fluid contained within. Joule measured the temperature of the liquid with a thermometer. He found that the temperature of the liquid increased slightly when the paddle was turned. Because the system was in thermo-equilibrium at the beginning of the experiment, the only source of the heat generated was the agitated fluid. Therefore, Joule concluded that the caloric theory of heat must be incorrect, and the motion of the fluid led him to postulate a new theory of heat. The kinetic theory of heat dispensed with the concept of a separate fluid; instead, it treated heat as a property of matter. Joule reframed heat as the motion of the molecules that made up the fluid in his apparatus.

The switch from the caloric theory to the kinetic theory of heat is hailed as “among the greatest intellectual achievements of the nineteenth century” (Hecht, 1994, p. 565). The kinetic theory can be considered a major ontological shift in two ways. First, the caloric was considered a material Substance, which can ‘flow’ from one object to the next. However, the kinetic theory conceived of temperature as the average speed with which molecules move, so that heat energy is not a kind of Substance, rather it refers to a PROCESS, such as speed of molecules. Moreover, heat energy is transferred from one object to the next by changing the velocity of the molecules that comprise the object. Thus, heat transfer is a kind of Emergent Process.

Alternative Mechanisms Leading to Scientific Discoveries and Theory Change

What this chapter proposes is a mechanism for inducing a radically new hypothesis or theory, to explain a set of phenomena or data. The idea is that it may be the case that novel theories are often noticed, focused upon, explored, and sometimes succeeded in explaining the phenomena better, when the novel theories are ontologically distinct from the former theories. We are not suggesting that a novel theory, in order to be successful, must be ontologically distinct. Rather, we are suggesting that when a given theory, and its related family of theories, are inadequate for explaining a phenomenon or a disease for many years, perhaps an ontological shift in hypothesizing can allow a major breakthrough to occur. We illustrated this possibility with a few examples.

What other mechanisms have been proposed for scientific discoveries? The crux of understanding

scientific discovery is to understand how a new hypothesis is induced, especially a radically new one. The new hypothesis presumably can explain a pattern of observations that other existing hypotheses have failed to explain successfully. Psychological research attempting to understand how new discoveries are made often focuses on the generation of experiments to test the hypothesis, as well as evaluation of the resulting evidence. Far less work has been done on the processes of inducing a new hypothesis. However, Klahr & Dunbar's (1988) research does address the issue of inducing new hypotheses. Their task involved discovering the function of a mystery key, labeled 'RPT', on a robotic toy. The participants tested their hypotheses by writing small programs that included the mystery key. Most participants used their semantic knowledge of 'repeat' to induce their initial hypothesis. As they received feedback from the device, it became evident that the repeat function had violated some participants' initial hypotheses. However, a new hypothesis, in this task, is not ontologically distinct from earlier hypothesis. So the findings learned from this task cannot generalize to revolutionary discoveries that did involve ontological shifts.

Similarly, computational research on the process of inducing a new hypothesis took a few directions that also differed from those involving ontological shifts. Langley, Simon, Bradshaw & Zytkow's (1987) work, for example, addressed the problem of discovering laws given a set of empirical observations. For instance, BACON.5 can look for a linear relation among a set of variables by using a standard linear regression technique. If the variables and their values fit a monotonically increasing relation, then the ratio between the two terms is found, given the signs of the values of the two terms are the same. If a monotonically decreasing trend occurs, then a product is defined, and so on. BACON.5's discovery is restricted to finding an appropriate fit of a mathematical expression to the empirical values that correspond to a pre-specified set of variables. This process corresponds to the formulation of a new theory or principle (in the form of a mathematical expression) on the basis of experimental results. This is essentially a curve-fitting process, which seems to be quite different from the process of inducing a radically new hypothesis.

Another computational approach was Thagard's (1992) model, ECHO. ECHO basically describes the mechanism by which a specific hypothesis is accepted or rejected, on the basis of the number of pieces of evidence that support or contradict the hypothesis. In this sense, ECHO is not a model of hypothesis generation per se, but rather, it is a model that evaluates which of several hypotheses better fit the evidence.

Thagard (1992) mentioned two other mechanisms that characterize scientific discoveries. One is replacement of an old theory by a new theory. Replacement does accurately portray the *result* of ontological shift,

but it does not refer to the ontological shift per se. Thagard (1992) and others (e.g. Hampton, 1997) also proposed conceptual combination, in arriving at new ideas and concepts. However, it is difficult to imagine how two concepts from different ontologies can be combined, or how combining two concepts from the same ontology can derive a radically (i.e. ontologically) different concept. A third mechanism that is often proposed is analogical reasoning (Gentner et al., 1997; Holyoak & Thagard, 1995). However, by our assumption, analogy can only produce similar accounts since, by definition, analogies have similar structures. For example, it was mentioned that diseases caused by bacteria were discovered by analogizing to the process of fermentation caused by yeast. Thus, yeast and bacteria are analogous. The ontological shift (from phlegm to bacteria) occurred when the scientist noticed the similarity between yeast and bacteria. That was the insight. The analogical mapping between yeast causing fermentation and bacteria causing diseases was straightforward. Thus, we would argue that the analogical mechanism per se, mapping yeast to fermentation and bacteria to disease, did not create the discovery. Perhaps some prior ontological shift (from phlegm to bacteria) was the mechanism that caused the scientist to notice the similarity between yeast and bacteria in the first place.

Hence, in general, scientific discoveries, in the form of generating or inducing a radically novel hypothesis that explains the observed pattern of findings, have not been explored extensively. What has been explored extensively is scientific thinking more broadly, such as skills of weighing all the available evidence, ways of experimenting that are systematic, such as holding some variables constant while varying others (Klahr & Dunbar, 1988; D. Kuhn, Amsel & O'Loughlin, 1988). However, few of these research findings bear directly on the mechanism of inducing a radically novel hypothesis. This chapter proposes one such mechanism: the possible role of ontological shifts in representation as required for the generation of a truly new hypothesis, one that can be considered a major scientific discovery.

Acknowledgments

Understanding Scientific Innovation: The Case of Nobel Laureates

Larisa V. Shavinina

Département des Sciences Administratives, Université du Québec en Outaouais, Canada

Abstract: Why are Nobel laureates so innovative? Although the capacity of Nobel laureates for scientific innovation has attracted researchers' attention for decades, the phenomenon is far from understood. This chapter argues that scientific innovation of Nobel laureates is determined in part by specific preferences, feelings, beliefs, and intuitive processes, which constitute a whole field of unexplored or poorly understood scientific phenomena. Based on autobiographical and biographical accounts of Nobel laureates, the chapter explores these phenomena, demonstrating that they predict scientific productivity of the highest level that results in innovations and, consequently, outstanding scientific talent of Nobel caliber.

Keywords: Innovation; Scientific innovation; Creativity; Nobel laureates; Preferences; Feelings; Intuition; Giftedness.

Introduction

The capacity of Nobel laureates for scientific innovation has been an attractive research topic for decades. However, it is not known why Nobel laureates are so capable of innovation. This chapter discusses some hidden psychological mechanisms, which significantly contribute to the innovative capacity of Nobel laureates.

Autobiographical and biographical findings on distinguished scientific geniuses demonstrate that their mental functioning is determined in part by *specific feelings, preferences, beliefs* and other similar phenomena. But researchers rarely study these phenomena, which can be referred to as 'extracognitive phenomena'. One of the greatest minds of the 20th century, Albert Einstein, in discussions with Max Wertheimer (1959) about the development of the theory of relativity and the way of thinking, which led to it, emphasized that:

... during all those years there was the *feeling of direction*, of going straight toward something concrete. It is, of course, very hard to express that feeling in words; but it was decidedly the case, and clearly to be distinguished from later considerations about the rational form of the solution (p. 228; italics added).

Similarly, Jacques Hadamard (1954) in his study on the psychology of invention in the mathematical field cited Henri Poincaré, a famous French scientist, who asserted that:

it may be surprising to see emotional sensibility invoked à propos of mathematical demonstrations which, it would seem, can interest only the intellect. This would be to forget the *feeling of mathematical beauty*, of the *harmony of numbers and forms*, of *geometric elegance*. This is a true esthetic feeling that all real mathematicians know, and surely it belongs to emotional sensibility (p. 31; italics added).

Poincaré (1913) also insisted that "pure logic would never lead us to anything but tautologies. It is by logic that we prove. It is by *intuition* that we discover" (p. 208; italics added). In a similar way, Rosenblueth and Wiener (1945) emphasized that:

An *intuitive flair* for what will turn out to be the most important general question gives a basis for selecting some of the significant among the indefinite number of trivial experiments which could be carried out at that stage. Quite vague and tacit generalizations thus influence the selection of data at the start (p. 317).

Even such a brief account shows the extremely significant role which ‘feeling of direction’, ‘sense of beauty’, those processes usually referred to as ‘intuition’, and other similar phenomena played and play in the appearance of some of the most celebrated creative scientific discoveries.

In the context of this chapter, the phenomenon of the extracognitive refers to four interrelated—and at the same time obviously different—components. These are:

- (1) specific intellectual feelings (e.g. feelings of direction, harmony, beauty, and style);
- (2) specific intellectual beliefs (e.g. belief in elevated standards of performance);
- (3) specific preferences and intellectual values (e.g. the ‘inevitable’ choice of the field of endeavor by certain geniuses and internally developed standards of intellectual working); and
- (4) intuitive processes.

The word ‘specific’ embodies the uniqueness of these components in the intellectual functioning of gifted, creative, and talented individuals. It is interesting to note that other psychologists also use the word ‘specific’ in their accounts of the intellectually creative processes at the highest level. For example, Marton, Fensham & Chaiklin (1994) wrote about a ‘specific form’ of the feeling of being right and made reference to other ‘specifics’ in their study of scientific intuition in Nobel Prize winners.

The chapter consists of four parts. The first part deals with methodological issues related to the use of biographical and autobiographical literature as well as case-study approaches as a means of investigating the psychological underpinnings of Nobel laureates. The second part of this chapter presents findings regarding the extracognitive phenomena of Nobel laureates. The third part, a discussion, considers the relationship between the components of the extracognitive, its link to metacognition, and its functions. Finally, the fourth part concludes that the extracognitive should be viewed as the highest level of the manifestation of the intellectual and creative potentials of an individual—that is exactly the case of Nobel laureates—and, consequently, as an important predictor of scientific innovation.

Methodological Issues

Two main data sources were used in my studies: (1) biographical and autobiographical accounts on Nobel laureates; and (2) the analysis and amalgamation of research literature presenting the psychological investigations as well as other related studies pertaining to Nobel laureates. The use of the biographical and autobiographical accounts and the case-study method can be, and has been to a certain extent, a controversial matter. However, any attempt at a comprehensive

review of the research on Nobel laureates and other distinguishing individuals is unfeasible without some reliance on such accounts. These accounts and the case-study method are perfectly suited for capturing the special characteristics of highly creative and intellectual individuals and their discoveries or inventions. Autobiographical and biographical literature is essential for the research and description of persons or events distinguished by their rarity as is the case with Nobel laureates. Using this literature, researchers can describe the idiosyncratic features of gifted, creative, and talented individuals including a focus on the characteristics of their extracognitive phenomena. Often biographical and autobiographical accounts provide a holistic view of the subject (Foster, 1986; Frey, 1978) allowing researchers to develop and validate theories grounded in a more direct ‘observation’ of the individuals (Gross, 1994; Merriam, 1988). The analysis of subjective phenomena such as the individual’s feelings, preferences, beliefs, and views enables a more comprehensive ‘picture’ of the individual than that which is possible with only objective methods.

The use of autobiographical and biographical literature for the study of outstanding individuals—for example, Nobel scientists—presents, however, certain limitations, such as:

- (1) The possible subjectivity of biographers resulting from their individual interpretations of events, thoughts, and states. These interpretations may be influenced by their personal attitudes towards the person about whom they write, an attitude potentially swayed in part by whether the latter is living or not. Autobiographers can also be very subjective and contradictory in their accounts of their own thinking processes, psychological states, and the surrounding events, which lead up to and follow their particular innovative breakthroughs in science;
- (2) Time of writing the biography or autobiography, normally after an individual has already become a brilliant personality—often relies on vague memories of one’s thinking processes which may have likely been weakened or altered over time. Hence, the conclusions and reports of autobiographers and especially of biographers are not always very reliable. It certainly raises the issue surrounding the validity and reliability of subjective reports when they are used as data. This problem has been addressed extensively in the literature (Brown, 1978, 1987; Ericsson & Simon, 1980). However, despite such critiques, scholars in the field of creativity view the use of self-reports as an “effective means of learning about scientific thinking” (John-Steiner, 1985, p. 181).

It should be noted that Nobel laureates and other distinguishing personalities—who are themselves the

subjects of biographies and autobiographies—grasped the above-mentioned problems very well. For example, Einstein himself realized this clearly when he wrote at the beginning of his *Autobiographical Notes*:

The exposition of that which is worthy of communication does nonetheless not come easy; today's person of 67 is by no means the same as was the one of 50, of 30, or of 20. Every reminiscence is colored by today's being what it is, and therefore by a deceptive point of view . . . (Einstein, 1949, p. 47).

Holton (1973) further pointed out that it is not only growth or change that colours one's interpretations—it is also the difference between experience lived and experience reported.

In this case it is well possible that such an individual in retrospect sees a uniformly systematic development, whereas the actual experience takes place in kaleidoscopic particular situations (Einstein, 1949, p. 47).

However, even with these limitations in mind, the use of biographical and autobiographical literature is probably the single best source available for the investigation of the extracognitive phenomenon in Nobel laureates since such accounts are enriched with information pertaining to an individual's specific feelings, preferences, beliefs, and intuitive processes.

The Extracognitive Phenomena in Nobel Laureates

As it is well known from the history of science, any new field or topic—being at the initial stages of its development—starts with a descriptive stage. Since the research on Nobel laureates is not a well-developed topic and the study of the extracognitive is a relatively new one, the findings presented below are descriptive in nature. That is, they describe the different components of the extracognitive phenomenon in Nobel laureates and, as such, act to provide an introduction to this new concept.

The purpose of this section is to draw at least an approximate picture of the extracognitive in Nobel laureates. In order to do so, I primarily examine autobiographical and biographical accounts of Nobel laureates and existing psychological studies on these outstanding scientists. However, taking into account the fact that psychological publications on this topic are not numerous, I also refer to appropriate sociological investigations—for example, a famous study of Nobel laureates in the United States of America carried out by Harriet Zuckerman (1977). Below I present the findings regarding each of the four above-mentioned components of the extracognitive phenomenon.

Specific Intellectual Feelings

Specific Scientific Taste, Including Sense of 'Important Problems', 'Good' Ideas, 'Correct' Theories, and Elegant Solutions, and Feeling of Being Right

Zuckerman (1977, 1983) showed that a *specific scientific taste* is an extremely important virtue of Nobel Prize winners. Its primary criteria include a *sense* for distinguishing the 'important problem' and an appreciation of stylish solutions. For them, "deep problems and *elegant solutions* distinguish excellent science from the merely competent or commonplace" (Zuckerman, 1983, p. 249; italics added). For example, discussing his own feelings in the process of scientific creativity, Stanley Cohen, Nobel laureate in medicine, 1986, noted:

. . . to me it is a *feeling of . . . 'Well, I really don't believe this result', or 'This is a trivial result', and 'This is an important result', and 'Let us follow this path'. I am not always right, but I do have feelings about what is an important observation and what is probably trivial* (quoted in Marton et al., 1994, p. 463; italics added).

Analyzing Nobel laureates' replies to the question "In the absence of rational, logical support for scientific intuitions, what makes the scientist follow them?", Marton et al. (1994) found that nine out of 72 laureates said that it was a 'feeling' that made them persevere. Marton et al. (1994) pointed out that the feeling could be "a *feeling of being right, being wrong, or having come across something important . . .* The feeling is often an immediate, intense feeling of certitude, of being right, especially when an answer to a problem one has been struggling with appears suddenly, without any preceding steps whatsoever" (p. 463). It is interesting to note that Marton et al. (1994) perceived a '*feeling of great certitude*' in Nobel laureates.

Marton et al. (1994) also found that the "feeling of being right often seems to originate from artistic and/or—in the metaphoric sense—sensory or quasi-sensory qualities. You sense, see, recognize, feel in your fingers or produce certain qualities" (p. 463). As Paul Berg, Nobel laureate in chemistry, 1980, highlighted:

There is another aspect that I would add to it, and that is, I think, *taste. Taste in almost the artistic sense.* Certain individuals see art in some undefinable way, can put together something which has a *certain style*, or a certain class to it. A certain rightness to it (quoted in Marton et al., 1994, p. 463; italics added).

Csikszentmihalyi's (1996) study of ten Nobel Prize-winners in science, among another 91 exceptionally creative persons, provided additional evidence for the

existence of a *sense* for an ‘important problem’. He pointed out that Nobel Laureates seem to have an ability to distinguish between ‘good’ and ‘bad’ ideas. For example, Manfred Eigen, Nobel laureate in chemistry, 1967, was one of several scientists in Csikszentmihalyi’s study who asserted that the only difference between them and their less creative colleagues was that they could tell whether a problem was soluble or not, and this saved enormous amounts of time in addition to many false starts. Similarly, at Linus Pauling’s (Nobel laureate in chemistry, 1954) 60th birthday celebration, a student asked him, “Dr Pauling, how does one go about having good ideas?” He replied, “You have a lot of ideas and throw away the bad ones” (Csikszentmihalyi, 1996, p. 67). Likewise, George Stigler, Nobel laureate in economics, 1982, claimed:

I consider that I have *good intuition and good judgment on what problems are worth pursuing and what lines of work are worth doing*. I used to say (and I think this was bragging) that whereas most scholars have ideas which do not pan out more than, say, 4% of the time, mine come through maybe 80% of the time (quoted in Csikszentmihalyi, 1996, p. 61; italics added).

Arthur L. Schwalow, Nobel laureate in physics, 1981, says the following about a similar feeling accompanying his scientific creativity:

... you store in your mind *a feeling for a magnitude of things*, how big things really are, so you’ll get a *feeling whether something will go, or not*, if you try to put two ideas together (quoted in Marton et al., 1994, p. 466; italics added).

Similarly, Niels Bohr’s *feeling for correct and incorrect theories* was a legendary one. For example, after hearing Wolfgang Pauli’s presentation to a professional audience a new theory of elementary particles, Bohr summarized the subsequent discussion by saying that “we are all agreed that your theory is crazy. The question which divides us is whether it is crazy enough to have a chance of being correct. *My own feeling is that it is not crazy enough*” (quoted in Cropper, 1970, p. 57).

In an overview of Robert Burns Woodward’s accomplishments, who was one of the great organic chemists of all time and Nobel laureate in chemistry, 1965, his friend and colleague at Harvard University, Frank Westheimer stated:

Even scientists who mastered his methods could not match his *style*. For there is an *elegance* about Woodward’s work—his chemistry, his lectures, his publications—that was natural to him, and as unique as the product itself (quoted in C. E. Woodward, 1989, p. 229; italics added).

Therefore, the personal accounts of Nobel laureates demonstrate that specific scientific taste is a very

critical facet in scientific creativity of an exceptionally high level. As was documented by various examples, this taste expresses itself in a variety of feelings, senses, and styles.

Feeling of Beauty

Describing his discovery of the positron, Paul Adrienne Maurice Dirac (1977) emphasized that:

It was sort . . . of faith . . . that any equations which describe fundamental laws of Nature must have *great mathematical beauty* in them (e.g.) . . . the *beauty of relativity* . . . (I was working on) the physical interpretation and transformation theory of quantum mechanics . . . (p. 136; italics added).

Also, upon receiving the Nobel Prize for physics, Dirac (1963) remarked:

It seems that if one is working from the point of view of *getting beauty* in one’s equations and if one has really sound insight, one is on a sure line of progress (p. 47; italics added).

Likewise, Dirac (1963), discussing why Ervin Schrödinger failed to publish a relativistic wave equation, asserted that “it is more important to *have beauty in one’s equations* than to have them fit experiment” (p. 47; italics added). Similarly, physicist Allan Cormack, Nobel laureate in medicine, 1979, said in an interview with Rothenberg (1996):

The abstractions (I do in mathematics) are just as *beautiful* (as in art) and I find them more satisfactory . . . I think there’s a great deal of satisfaction in seeing ideas put together or related. And there is a structural thing there just as much as in sculpture or painting or anything of that sort—form and economy of means . . . Very often in biology you say, ‘If such-and-such went that way, will this go that way?’ Very often the reason you ask why is because you found the previous thing to be *attractive* somehow (p. 212; italics added).

Werner Heisenberg (1971) wrote the following about his own feeling of beauty and its role in scientific creativity:

You may object that *by speaking of simplicity and beauty I am introducing aesthetic criteria of truth*, and I frankly admit that *I am strongly attracted by the simplicity and beauty of the mathematical schemes* which nature presents us. You must have felt this too: the almost frightening simplicity and wholeness of the relationship, which nature suddenly spreads out before us . . . (p. 68).

Similarly, describing his investigations in the area of X-ray crystallography, Robert Huber, Nobel laureate in

chemistry, 1988, asserted in an interview with Rothenberg (1996):

It's not just joy. This first stage (in X-ray crystallography) of seeing a crystal is not only a *beauty*, there's also so much promise behind it, so many hopes. And, then, very much later, when analysis has succeeded, ah, to see the molecule for the first time, that's similar (p. 212; italics added).

In the same way, recalling his research on the discovery of the instructed mixture paradigm, Jean-Marie Lehn, Nobel laureate in chemistry, 1987, pointed out in an interview with Rothenberg (1996): "Once you have recognized this *harmony* which exists in self-recognition, then you should say, 'But what is the self/non-self?'" (p. 229, italics added). Ochse (1990) pointed out that "Max Born hailed the advent of relativity as making the universe of science not only grander but also more *beautiful*" (p. 123).

Likewise, R. B. Woodward's daughter wrote about her famous father's "*feeling for art*" in the synthesis of organic compounds (C. E. Woodward, 1989, p. 235, italics added). In the Cope talk of 1973, in which he reviewed the background of his orbital symmetry work in chemistry, Robert Burns Woodward asserted:

For almost 50 years now, I have been involved in an affair with chemistry. It has been throughout a richly rewarding involvement, with numerous episodes of high drama and intense engagement, with the joys of enlightenment and achievement, with the special pleasures which come from the *perception of order and beauty in Nature*—and with much humor (quoted in C. E. Woodward, 1989, p. 230; italics added).

In general, R. B. Woodward perceived an amazing sense of beauty in chemistry. This sense of beauty manifested itself in every facet of his work. For example, he claimed "I love crystals, the *beauty of their forms*—and their formation . . ." (quoted in C. E. Woodward, 1989, p. 237; italics added). His daughter wrote, "the *aspects of art and beauty in Woodward's work* are contained not only in the forms found in or built into the fixed structures of molecules. They have perhaps more to do with the way in which he manipulated the molecules, in his design of the synthetic steps, in a process that was not tortuous but *harmonious*, that *felt right* and was *elegant*" (C. E. Woodward, 1989, p. 234; italics added).

Ethologist, artist, writer, and Nobel laureate in medicine Konrad Lorenz (1952) expressed a general attitude of a man to the beauty of nature when he wrote that:

He who has once seen the intimate *beauty of nature* cannot tear himself away from it again. He must become either a poet or a naturalist and, if his eyes are good and his powers of observation sharp enough, he may well become both (p. 12).

It should be acknowledged that other researchers have also discussed and highlighted the importance of the feeling of beauty so strongly expressed by Nobel laureates. Ochse (1990) considered the feeling of beauty in the context of the analysis of aesthetic sensitivity; Rothenberg (1996) in the context of aesthetic motivation; Kuhn (1970) in the context of aesthetic considerations; and McMorris (1970), Miller (1981, 1992, 1996), and Wechsler (1978) in the context of aesthetics in science as a whole. Furthermore, Kuhn (1970) argued that application of aesthetic sensitivity—that scientists mainly express as a feeling or sense of beauty—was indeed essential to the progress of science:

Something must make at least a few scientists *feel they are on the right track*, and sometimes it is only *personal and inarticulate aesthetic considerations* that can do that. Men have been converted by them at times when most of the articulate technical arguments pointed the other way . . . even today Einstein's general theory attracts men principally on *aesthetic grounds*, an appeal that few people outside of mathematics have been *able to feel* (Kuhn, 1970, p. 158; italics added).

Ochse (1990) suggests that behind every famous scientist's expressions about their sense of beauty is "the suggestion that underlying scientific creativity is an intellectual motivation that is fuelled by a positive evaluation of learning and achievement, and guided by aesthetic sensitivity—which may relate to a need for emotional satisfaction" (p. 124).

Feeling of Direction and Similar Feelings (in one's own scientific activity, in search of mentors and of one's own unique domain in science, and so on)

As it follows from Albert Einstein's (Nobel laureate in physics, 1921) citation at the beginning of this chapter, the feeling of direction played an important role in his work on the development of the Theory of Relativity. Michael S. Brown, Nobel laureate in medicine, 1985, described a similar feeling in a round-table discussion—called 'Science and Man'—with the Nobel laureates in physics, chemistry, and medicine:

And so . . . as we did our work, I think, *we almost felt at times that there was almost a hand guiding us*. Because we would go from one step to the next, and somehow we would *know which was the right way to go*. And I really can't tell how we knew that, how we knew that it was necessary to move ahead (quoted in Marton et al., 1994, pp. 461–462).

It can be said that intellectually creative individuals have very specific manifestations of cognitive direction in the study of scientific problems and of the world as a whole.

Zuckerman (1977, 1983) found that the Nobel laureates, “in their comparative youth, sometimes went to great lengths to *make sure* that they would be working with those they considered the best in their field” (Zuckerman, 1983, pp. 241–242; italics added). This belief (i.e. self-confidence, which is very often explained as good fortune, luck, fate or chance, etc.) led them to the masters of their craft—to the scientists of Nobel caliber. It is thus possible to confirm the existence of a feeling of direction in the scientific elite. For instance, the biochemist Hans Krebs, Nobel laureate in chemistry, (1967) noted:

If I ask myself how it came about that one day I found myself in Stockholm, I have not the slightest doubt that I owe this *good fortune* to the circumstance that I had an outstanding teacher at the critical stage in my scientific career . . . (p. 1444; italics added).

The ‘good fortune’ that Hans Krebs so humbly refers to is nothing else but the deep intellectual *feeling of direction* in the fulfillment of his own scientific career.

Likewise, recalling his work on the creation of monoclonal antibodies, Georges Kohler, Nobel laureate in medicine, 1984, said in an interview with Rothenberg (1996):

I was one of the first Ph.D. students in an institution (Basel Institute) which turned out, later on, to be a very important one. I studied genetic diversity of antibodies and I thought that (the somatic mutation hypothesis) was a very clever idea: to have one gene, and from that somatically you can have many variants. I knew there were variants because I started on that in my Ph.D. And variants were made by Cesar Milstein in the lab, so I said, “*Okay, I’m going to study how these variants are going to be made. I am going to Cesar Milstein . . .*”. I knew that the Cesar Milstein group had done experiments with cell fusion—another field in which I was reading a book and was interested. And I remember that when I was about to go to Cambridge, I was talking to somebody in the library and saying, “*I’m going to Cesar Milstein and make a lot of fusions*” (p. 227; italics added).

These accounts bring to light the exceptional role of one’s ‘feeling of direction’ and similar feelings—which are in fact one’s more latent manifestations of the feeling of direction—to the intellectual activity of Nobel laureates. Their scientific creativity is determined by such feelings, which guide Nobel laureates in their work.

Specific Intellectual Beliefs

Belief in Specific Standards of Performance

Kholodnaya (1991) pointed out that a belief in the existence of some principles and specific standards, by

which the nature of scientific research is determined, and a priori confidence in the truth of a certain vision of things are among important beliefs of outstanding scientists. Thus, C. E. Woodward (1989) highlighted R. B. Woodward’s ‘*feeling for experimentation*’ that was based on his conviction that theory without experimental proof was worthless. “Ideas and theory could have an aesthetic aspect but their beauty and elegance were always tied to a concrete relationship with a physical reality” (C. E. Woodward, 1989, p. 237). Similarly, Zuckerman (1977) found that *elevated standards of performance* (the methods and quality of first rate research) are essential for Nobel laureates.

Specific Intellectual Preferences (e.g. choice of ‘difficult’ scientific problems or problems at the leading edge of science)

Specific intellectual preferences of Nobel laureates manifest themselves in a variety of ways. Some have a preference for ‘difficult’ scientific problems, which were and had remained unsolved for many decades. Richard Feynman is a fine example of this pursuit to solve the unsolved. Feynman, in his early twenties at Los Alamos, was an “*enfant terrible*, bubbling with quick brilliance on the theoretical problems of bomb building that came his way” (Wilson, 1972, p. 10). Feynman’s account is as follows:

It was a succession of successes—but easy successes. After the war, I moved over to the kind of problems (like the self-energy of the electron) that men spend years thinking about. On that level there are no easy successes; and the satisfaction you get when you’re proved right is so great that even if it occurs only twice in a lifetime, everything else is worth it! (quoted in Wilson, 1972, pp. 10–11).

Nobel laureates’ preference for problems at the very frontiers of science is another way their specific intellectual preferences are manifested. This desire to decipher, understand and explore the relatively unknown areas of a particular field is demonstrated as we follow the life trajectory of Nobel Prize winner, Enrico Fermi. In the 1920s, he was:

one of the leaders among the young European physicists who were developing the quantum mechanical wave theories of atomic structure. Then in 1929 Fermi made a sharp decision . . . Fermi felt that . . . the only remaining area of physics to attack where all was still unknown at that time was the heart of the atomic structure—nuclear physics. So in 1929 Fermi moved away from research in atomic theory, where he had made a great reputation, and went into the unknown of neutron physics, where he worked with such ingenuity on the interaction between neutrons and atomic nuclei that within seven years he won a Nobel prize. Fifteen years later, at the end of World War II in 1945, Fermi changed

again. By that time, he probably had learned more about the neutron than anyone else in the world, but now it was nuclear physics that seemed to have been all cleaned up for him. So once again he moved on—this time into the uncharted domain of high-energy particles. To Fermi, it was always necessary to be at work where the big mystery was (Wilson, 1972, p. 16).

Such examples allowed Wilson (1972) to conclude that “when there is no longer enough mystery in a subject to attract” scientists, “they move on to new fields” (p. 16). In other words, they always follow their inner, specific intellectual preferences.

Highly Developed Intuitive Processes

As it was emphasized in the psychological literature, certain individuals have an intuitive feeling, as they begin their intellectual activity, about what their final product will be like (Gardner & Nemirovsky, 1991; Gruber, 1974; Hadamard, 1954; Ochse, 1990; Policastro, 1995; Simonton, 1980). This is especially true in the case of Nobel laureates. It is widely recognized by these great scientists that intuition is an essential component of creative thinking that leads to innovative discoveries. For example, Max Planck asserted that the pioneer scientist working at the frontier of science “must have a vivid *intuitive* imagination, for new ideas are not generated by deduction, but by an artistically creative imagination” (Planck, 1950, p. 109). At the same time, he recognized that intuition alone is not sufficient. For instance, in his autobiographical account on the discovery of the constant and the quantum of action, Max Planck wrote:

So long as it (the radiation formula) had merely the standing of a law disclosed by lucky *intuition*, it could not be expected to possess more than a formal significance. For this reason, on the very day that I formulated this law, I began to devote myself to the task of investing it with true physical meaning (Planck, 1950; p. 41; italics added).

Similarly, Einstein highly appreciated intuition in creative processes. Thus, he wrote about “Bohr’s *unique instinct*, which enabled him to discover the major laws of spectral lines and the electron shells of the atoms”, (Einstein, 1949; cited in John-Steiner, 1985, p. 194). Clearly, ‘Bohr’s *unique instinct*’, as referred to by Einstein, is nothing else but his ‘unique intuition’. Wilson (1972) exemplified the value placed on intuition in this personal observation about the famous Enrico Fermi:

Years ago, as a graduate student, I was present at a three-way argument between Rabi, Szilard, and Fermi. Szilard took a position and mathematically

stated it on the blackboard. Rabi disagreed and rearranged the equations to the form he would accept. All the while Fermi was shaking his head. ‘You’re both wrong’, he said. They demanded proof. Smiling a little he shrugged his shoulders as if proof weren’t needed. ‘*My intuition tells me so*’, he said. I had never heard a scientist refer to his intuition, and I expected Rabi and Szilard to laugh. They didn’t. The man of science, I soon found, works with the procedures of logic so much more than anyone else that he, more than anyone else, is aware of logic’s limitations. *Beyond logic there is intuition ...* (pp. 13–14; italics added).

Another example where the importance of intuition becomes evident came from the work on the discovery of DNA’s structure, for which James Watson and Francis Crick were awarded the Nobel Prize. Thus, following her conversation with Sir Francis Crick, John-Steiner (1985) pointed out that one of Crick’s contributions to the team’s efforts—that led to the discovery of DNA’s structure—was his “*intuition* and his ability to work with a minimum number of assumptions while approaching a problem” (p. 187).

Marton et al. (1994) studied intuition of Nobel Prize winners analyzing interviews conducted between 1970 and 1986 with laureates in physics, chemistry, and medicine by a Swedish Broadcasting Corporation. Practically all the laureates regard scientific intuition as a “phenomenon distinctively different from drawing logical conclusions, step by step” (Marton et al., 1994, p. 468). Eighteen out of 72 subjects in this study emphasized that intuition *feels* different from logical reasoning and cannot be explained in logical terms. Marton et al. (1994) concluded that Nobel laureates consider scientific intuition as “an alternative to normal step-by-step logical reasoning” (p. 468). Nobel laureates in their scientific activity:

do something or something happens to them without their being aware of the reasons or the antecedents. The acts or the events are, however, guided or accompanied by feelings which sometimes spring from a quasi-sensory experience. Intuition is closely associated with a sense of direction, it is more often about finding a path than arriving at an answer or reaching a goal. The ascent of intuition is rooted in extended, varied experience of the object of research: although it may *feel* as if it comes out of the blue, it does *not* come out of the blue (Marton et al., 1994, p. 468).

To date, Marton et al.’s (1994) study is the only one that conducts a systematic investigation of intuition in Nobel laureates.

So far, we emphasized the important positive role of intuitive processes in scientific creativity of an extremely high level by quoting exceptionally

accomplished scientists. However, it is also pertinent to mention the case when the absence of scientific intuition resulted in quite mediocre work. For example,

Robert Oppenheimer was a brilliant interpreter of other men's work, and a judge who could make piercing evaluations of other men's work. But when it came time—figuratively speaking—to write his own poetry in science, his work was sparse, angular, and limited, particularly when judged by the standards he himself set for everyone else. He knew the major problems of his time; he attacked them with style; but *he apparently lacked that intuition*—that faculty beyond logic—*which logic needs in order to make great advances*. If one were speaking not of science but of religion, one could say that Oppenheimer's religiosity was the kind that could make him a bishop but never a saint (Wilson, 1972, p. 13; italics added).

Although the above-mentioned personal accounts of Nobel laureates demonstrate that 'intuition' plays a significant role in highly creative and intellectual processes, we do not know for sure its psychological nature and origin. The common wisdom is to use the term 'intuition' in association with the term 'insight' which does not follow logically from available information, and is interpreted as inexplicable (so-called 'instinctive' insights) (Ochse, 1990). This kind of insight is often considered to be an innate quality explained by superior functioning of the right hemisphere of the brain. Hadamard (1954) described intuition as something 'felt', in contrast to something 'known', emphasizing that it involves emotional empathy.

Ochse (1990) attributed intuitive thinking to the operation of automatic mental routines, "unconsciously triggered by configurations of exogenous and/or endogenous stimuli. More specifically, intuition may be viewed as unconsciously triggered *automatic integration of relevant elements of information*, and an 'intuitive feeling' may be seen as part of the experiential outcome of such processes—somewhat equivalent to a feeling of recognition" (p. 243). His standpoint fits perfectly to Bruner's (1960) idea that "intuitive thinking characteristically does not advance in careful well-planned steps. It tends to involve manoeuvres based on an implicit perception of the total problem. The thinker arrives at an answer which may be right or wrong, with little if any awareness of the process by which he reached it" (pp. 57–58).

Ochse (1990) also suggested that creators develop "well-established bases for intuition because they are constantly involved with their subject of interest, and this practice would lead to the establishment of routines that enable them to integrate relevant actions and items of information. Moreover, creators work

independently rather than following prescribed curricula and instructions, which favors the acquisition of a relatively wide repertoire of *generalizable routines*" (p. 244).

Policastro (1995) distinguishes between phenomenological and technical definitions of creative intuition. According to the first, intuition is defined as "a vague anticipatory perception that orients creative work in a promising direction" (p. 99). This definition is phenomenological in that it points to the subject's experience: How does it feel to have a creative intuition? What is that like? The study by Marton et al. (1994) mentioned above analyzed mainly this kind of intuition in Nobel laureates.

According to the technical definition, intuition is "a tacit form of knowledge that broadly constrains the creative search by setting its preliminary scope" (Policastro, 1995, p. 100). This implies that intuition is based on cognitive foundations in the sense that it arises from knowledge and experience. Similarly, Simonton (1980) stressed that intuition involves a form of information processing that might be more implicit than explicit, but which is not at all irrational. Policastro (1995) emphasized that both definitions (phenomenological and technical) are important because they complement each other in fundamental ways.

Bowers, Regher, Balthazard, & Parker (1990) defined *intuition* as "a preliminary perception of coherence (pattern, meaning, structure) that is at first not consciously represented, but which nevertheless guides thought and inquiry toward a hunch or hypothesis about the nature of the coherence in question" (p. 74). Bowers et al. conducted experimental studies of intuition, two of which revealed that "people could respond discriminatively to coherences that they could not identify" (p. 72). A third experiment showed that this tacit perception of coherence "guided people gradually to an explicit representation of it in the form of a hunch or hypothesis" (p. 72).

In spite of the differences in the psychological interpretation of the nature of intuition in general and scientific intuition in particular, it is clear however that intuitive processes are extremely important for the productive functioning of human mind. The truth is that any successful scientist—and first of all Nobel laureates—relies on his or her intuition. It is important to note that other psychologists also include intuitive processes in their conceptualizations of higher psychological functions. For example, Sternberg et al. (2000) consider intuition as one of the prototypical forms of developed practical intelligence.

Findings from autobiographical and biographical accounts of Nobel laureates as well as related data from the research literature regarding their extracognitive phenomena were presented in this section. The main conclusion is that the above-described specific scientific taste, intellectual feeling of beauty, feeling of

direction, specific beliefs, intellectual preferences, scientific intuition, and their variants are exceptionally important characteristics in extraordinary creative achievements of the world's best scientists, Nobel laureates. The integration of the autobiographical and biographical findings on Nobel laureates with the findings of the psychological studies on these distinguishing scientists demonstrates that their mental functioning is determined—at least in part—by their extracognitive abilities.

Discussion

A range of intellectual phenomena, which describe and comprise the four components of the extracognitive, was presented above. Now I would like to address the issue of the relationship between these components taking as an example the relationship between a feeling of direction and intuitive processes. To start the discussion, it seems appropriate to raise the following question: What is behind the feeling of direction? Marton et al. (1994) suggest that this is one's own intuition. They found that although famous examples of intuition associated with names such as Archimedes, Kekulé and Poincaré emphasize arriving at answers or the solutions to problems, other Nobel laureates in their sample stressed the outcome of intuition as their starting rather than end points. In other words, if intuition is considered by Nobel laureates as outcome or result (i.e. intuition denotes an idea, a thought, an answer, or a feeling), then there are two main alternative ways of experiencing what intuition yields. The first has to do “with direction when moving *from* a certain point *towards* something as yet unknown” (Marton et al., 1994; p. 462; italics added). It concerns “finding, choosing, *following a direction, a path*” (Marton et al., 1994; p. 461; italics added). For instance, 37 out of 72 Nobel laureates see the result of scientific intuition as “finding or following a path” (Marton et al., 1994; p. 462). It seems safe to assert that such an understanding of intuitive processes is behind the ‘feeling of direction’. The other main way of experiencing the outcome of intuition by Nobel Prize winners deals with *coming* to a certain point, *arriving at* an answer, that “which one was moving towards is illuminated and seen clearly” (i.e. end points; Marton et al., 1994; p. 462). Marton et al. (1994) concluded that “the most fundamental aspect of scientific intuition is that the scientists choose directions or find solutions for which they do not have sufficient data in the computational sense” (p. 468). In describing the close relationship between intuition and sense of direction, Marton et al. (1994) came close to the introduction of the concept of the extracognitive in intellectual functioning of gifted individuals, identifying some of its main components.

It seems that there are reciprocal relationships between intuition and various feelings of Nobel laureates described above. I submit that not only do

intuitive processes form a basis for the actualization and subsequent development of these feelings, but also the latter may influence the growth of intuition. As a result of their study of the experience of intuition in Nobel laureates, Marton et al. (1994) described a ‘cumulative structure’ of intuition consisting of its higher and lower levels. On the lower level subjects simply indicated that “the experience of scientific intuition differs from the experience of making explicit, logical conclusions based on available information” (p. 463). On the higher level a crucial component is “a feeling, a feeling of something being right (or, occasionally, something being wrong)” (Marton et al., 1994; p. 464). On the next level again a specific form of this feeling emerges: “the sudden appearance of an idea or of an answer accompanied by a feeling of great certitude” (Marton et al., 1994; p. 464). Consequently, as one can see on the example of the feeling of direction and intuitive processes, the components of the extracognitive are closely related to each other.

The Extracognitive Phenomena and Metacognition

It appears that there is a reciprocal relationship between the extracognitive phenomena and the metacognitive processes of an individual. In other words, if an individual possesses any component of the extracognitive—say, feeling of direction or feeling of beauty (but the findings show that any Nobel laureate has all the above-described components of the extracognitive)—then he or she is also expected to possess highly developed metacognitive abilities.

Metacognition is broadly defined as “any knowledge or cognitive activity that takes as its object, or regulates, any aspect of any cognitive enterprise” (Flavell, 1992, p. 114). The essence of metacognition already implies some psychological phenomena, which exist at the intersection of metacognition and the extracognitive. For example, psychologists studying metacognition use and investigate such concepts as awareness and self-awareness (Ferrari & Sternberg, 1996) and feeling of knowing (Brown, 1978), just to mention a few. The most basic form of self-awareness is the “realization that there is a problem of knowing what you know and what you do not know” (Brown, 1978, p. 82). Very often an individual unconsciously comes to such a realization. Probably, intuition is behind any unconscious understanding of any object of cognition including his or her own cognitive apparatus.

Moreover, the well-known title of Brown's (1978) famous article, *Knowing When, Where, and How to Remember: A Problem of Metacognition*, which can be considered synonymously with the definition of metacognition, indicates that feeling of direction, specific scientific taste, and feeling of beauty also play a role in metacognitive functioning. Thus, the feeling of direction corresponds to ‘where’ (i.e. *guiding function* of the

extracognitive). Specific scientific taste and the feeling of beauty relate to ‘how’ (i.e. *function of evaluation and judgement* of the extracognitive). Altogether—including intuition—they correspond to ‘when’. Therefore, the phenomenon of the extracognitive contributes to the development of a person’s metacognitive abilities. I would even add that the extracognitive lies somewhere in the heart of metacognition and, consequently, allow psychologists to better understand its anatomy and, hence, its nature. In its turn, metacognition leads to the further development of the extracognitive, strengthening and crystallizing its components in an individual’s intellectual functioning. For example, the individual with developed metacognitive abilities will be more open to his or her own feeling of direction, feeling of beauty, and intuitive processes.

Empirical findings support our view about the existence of a direct link between the extracognitive and metacognition. Thus, Marton et al. (1994) concluded that scientific intuition of Nobel laureates can be interpreted in terms of awareness, namely as an “initially global grasp of the solution, a kind of metaphorical ‘seeing’ of the phenomenon being searched for, an *anticipatory perception* of its ‘shape’ or its gross structure” (p. 468). For example, the choice of a direction in scientific work might possibly be understood as “reflecting a marginal (not fully conscious) awareness of the nature of a phenomenon, a metaphorical ‘seeing’ of the phenomenon as a whole without knowing its parts, a seeing ‘through a glass, darkly’” (Marton et al., 1994, pp. 468–469).

The Functions of the Extracognitive in Scientific Creativity

The goal of this section is to discuss the roles that the extracognitive phenomenon plays in intellectual creative activity at exceptionally high levels, as that of Nobel laureates. It appears reasonable to distinguish the following functions of the extracognitive: cognitive function, guiding function, function of evaluation and judgement, criterion function, aesthetic/emotional function, motivational function, quality/ethical function, and advancing function.

Cognitive function implies that intuitive processes, specific intellectual feelings, beliefs, and preferences provide a mode of acquiring new scientific knowledge—in the form of novel ideas, solutions, models, theories, and approaches. As it was mentioned above, intuition can be, for example, interpreted as ‘intuitive understanding’ (Marton et al., 1994) or ‘intuitive thinking’ (Bruner, 1960). The extracognitive is, therefore, a particular cognitive mode of human thinking that appears in advance of any logical, conscious accounts of an individual’s intelligence.

Guiding function of the extracognitive implies that specific feelings, beliefs, preferences, and intuition lead scientists in the process of their creative endeavors

towards right theories, approaches, and models. The extracognitive phenomenon guides scientists’ “sense of ‘this is how it has to be’, their sense of rightness” (Wechsler, 1978, p. 1) or scientific truth. The quotations of Albert Einstein, Michael S. Brown, Hans Krebs, and Georges Kohler highlighted in this chapter clearly demonstrate the guiding function of the extracognitive in their work. Analyzing the Nobel laureates’ views of scientific intuition, Marton et al. (1994) concluded that there appears to be an “experience of the phenomena the scientists are dealing with which is of a quasi-sensory nature and which may encompass all relevant previous experiences of the phenomena. When this experience yields an *intensely felt verdict on the direction to go, the step to take or on the nature of the solution to the problem* the scientist is engaged in what we speak of ‘scientific intuition’” (p. 471; italics added).

The *function of evaluation and judgement* means that the phenomenon of the extracognitive plays a key role in the appreciation and, consequently, acceptance or disapproval and, hence, rejection of any new idea, theory, model or approach. The above considered accounts of Niels Bohr, Stanley Cohen, Paul Berg, George Stigler, Paul Dirac, Werner Heisenberg, and other Nobel laureates underline this function of specific feelings, developed intellectual beliefs, preferences, and intuitive processes. These are just “*feelings* which enable scientists to follow their intuitions in the absence of rational, logical support” (Marton et al., 1994, p. 467).

Probably, the scientists’ very first evaluation of everything new in science is unconscious in its nature. At the same time, as one can see from the Nobel laureates’ accounts, it is not, however, entirely unconscious. The phenomenon of the extracognitive—for example, feelings of direction and of beauty, specific preferences, beliefs, and intuition—provide certain criteria for creative work of scientific minds. This is what the *criterion function* is all about. It should be noted that other functions of the extracognitive also execute to some extent the criterion function (e.g. the aesthetic/emotional function).

The *aesthetic/emotional function* highlights the important role of feeling of beauty and specific scientific taste in scientific creativity. Firstly, passionately pursuing their intellectual quest, scientists feel intense *aesthetic pleasure* (Wilson, 1972) in discovering new laws of nature. Secondly, the phenomenon of the extracognitive helps to generate “*aesthetic criteria of truth*” (Heisenberg, 1971) which aesthetic experience presents to scientists. This is well illustrated by Heisenberg’s (1971) quotation mentioned above which definitely attests to the importance of the feeling of beauty in his work. In this respect the aesthetic/emotional function of the extracognitive is closely related to its function of evaluation and judgement: the feeling of beauty and specific scientific taste delineate

the very initial basis for such evaluation and judgement.

Feeling pride, enjoyment, and delight in discovering new ideas and theories, in finding new problems and fresh perspectives, in penetrating new puzzles of nature, and in solving very old and previously unsolved problems, Nobel laureates experience great pleasure and personal happiness, feelings which motivate them to go further and further in their intellectual search. This is what the *motivational function* of the extracognitive is all about. As Wilson (1972) pointed out, scientists' "*success stimulates* themselves and their colleagues to still more exacting studies of the phenomena of nature" (p. 16; italics added).

Quality/ethical function of the phenomenon of the extracognitive is closely related to scientists' belief in high and far-reaching standards of scientific activity. Having elevated inner standards of performance (Kholodnaya, 1991; Zuckerman, 1977, 1983), outstanding scientists assure an exceptionally high quality of first-rate research choosing or inventing the methods, approaches, and techniques necessary to do so. Because of that, they very often cannot accept a work of poor quality. Due to their own superior standards of work and certain principles, by which the nature of scientific research is determined, Nobel laureates set new, or transcend old, ethical rules in science. This can concern the behavior of scientists, their important role in the public arena, their social and moral responsibility (Gruber, 1986, 1989), and so on. Very often such scientists act as role models for future generations of scientists.

Advancing function refers to the important role of the phenomenon of the extracognitive in advancing science in general and the intellectually creative activity of individual researchers in particular. It is commonly accepted that in order to advance any field of science, scientists must build on it. Not only must they have a great deal of comprehensive and complex knowledge in the particular discipline, but at the same time, they should be able to step outside of it consequently expanding it (Csikszentmihalyi, 1996; Marton et al., 1994). Considering this position of scientists as a paradoxical one, Marton et al. (1994) assert that intuition resolves this paradox providing a sudden shift in the structure of a scientists' awareness. "Scientific intuition is just a special case of intuitive understanding. It is a sudden shift from a simultaneous awareness of all that it takes for that understanding to come about, to a highly singular, focused awareness of that which the understanding is an understanding of" (Marton et al., 1994, p. 469).

Therefore, the phenomenon of the extracognitive plays a critical role in exceptional scientific creativity of Nobel laureates performing the cognitive, guiding, aesthetic/emotional, motivational, and advancing functions, as well as the function of evaluation and judgement, criterion function, and quality/ethical func-

tion. The exceptional creativity results in unique contributions to science, that is, scientific innovations.

Conclusions

The findings presented in this chapter demonstrate that the mental functioning of Nobel laureates is determined in part by subjective, internally developed feelings, beliefs, preferences, standards and orientations, as well as intuitive processes, which constitute the different components of the extracognitive phenomenon. In this light, their negative reaction to any attempts to impose external standards on intellectually creative behavior is not surprising.

The extracognitive phenomenon guides Nobel laureates in their understanding of the nature providing intuitive aesthetic/emotional criteria for the appropriate evaluations and judgements leading to quality work and high ethical standards. This phenomenon also motivates Nobel laureates to go beyond the limits of their intellectual pursuits and advance scientific knowledge about the world.

There are at least a few reasons to assert that the phenomenon of the extracognitive should be considered as the highest level of the manifestation of the intellectual and creative potentials of an individual. First, the fact that so many Nobel laureates—whose extraordinary intelligence and creativity are unquestionable—(a) expressed almost all components of the extracognitive; (b) were very attentive to its manifestations in their own work; and (c) stressed its important role in scientific search testifies to the exceptionally high status of the extracognitive in the structure of Nobel laureates giftedness (Shavinina & Kholodnaya, 1996). Second, taking into account the direct link between metacognition and the extracognitive phenomenon, it becomes apparent that developed metacognition is strongly associated with highly developed intelligence (Sternberg, 1985, 1988). From this, one can suggest that a person displaying feelings of direction and of beauty, specific scientific taste, preferences, and intuition is also distinguished by exceptional intellectual abilities. Third, the phenomenon of the extracognitive carries out such versatile and multidimensional functions in the functioning of the human mind during the process of scientific creativity, which probably no other psychological processes could do. One can, consequently, suggest that if an individual exhibits his or her extracognitive in his or her own activity, then it means that this individual has already reached an integrated, well-balanced, and advanced level in his or her intellectually creative development. Altogether, these reasons allow us to conclude that the phenomenon of the extracognitive is probably the highest level of the manifestation of the intellectual and creative resources of a personality and, therefore, an important criterion of intellectually creative giftedness and a determinant of innovators in science of Nobel caliber.

This conclusion has essential educational implications. For example, this criterion should be taken into consideration in the process of the identification of gifted and talented children and adolescents for special educational options. Also, gifted education programs—both enrichment and acceleration classes—must include elements, which would direct to the development of pupil's extracognitive abilities. At the same time, intelligence and creativity tests should be developed or modified in ways that would allow us to examine an individual's extracognitive abilities.

To conclude, this chapter presented rich findings regarding the phenomenon of the extracognitive that covers a whole field of unexplored or weakly explored scientific phenomena (i.e. specific feelings, beliefs, preferences, and intuition). The above-considered findings indicate that the phenomenon of the extracognitive predicts scientific productivity of the highest level resulting in significant discoveries and, as such, showing an outstanding talent of Nobel caliber.

Research on the extracognitive phenomenon in exceptional individuals is a new enterprise. This chapter does not attempt to account for all possible facets of the extracognitive in Nobel laureates, and it is sometimes both vague and speculative in its formulations. However, it nevertheless provides a useful attempt to understand and conceptualize the valuable psychological phenomena in the successful functioning of Nobel laureates' minds leading to scientific innovations. Future investigations will help to unravel many more unknown components and manifestations of this phenomenon.

Innovation in the Social Sciences: Herbert A. Simon and the Birth of a Research Tradition

Subrata Dasgupta

Institute of Cognitive Science, University of Louisiana at Lafayette, USA

Abstract: Innovation presumes creativity, but creativity does not necessarily entail innovation. The latter involves both the cognitive process of creation and the social-historical process by which the created product is assimilated into a milieu. My concern in this essay is with innovation in the *social sciences*. In particular, I examine how the American polymath Herbert Simon was led to a model of human decision-making that gave birth to a new *research tradition* in the human sciences. For his role in the creation of this research tradition, Simon received the 1978 Nobel Prize in Economics.

Keywords: Innovation; Cognitivism; Research tradition; Simon; Behavioral economics; Nobel Prize; Creativity.

Introduction

Innovation presumes creativity, but creativity does not necessarily entail innovation. Creativity is, fundamentally, a cognitive process, the product of which is a particular concept, idea, scientific discovery, technological invention, new design, or distinctive literary, musical or artistic work. However, we normally reserve the word innovation to mean a change of some sort in a social, economic, cultural or intellectual milieu, brought about by a product of the creative process. Innovation, thus, involves both a cognitive process of (usually individual) creativity, and a social—historical process by which the created product is accepted by, influences, or is assimilated into, a particular milieu. Innovation occurs in every domain of human endeavor. My concern here is with innovation in the *social sciences*. As we all recognize, in the domain of science, a scientist practices his or her craft within a particular framework, which the philosopher of science Larry Laudan (1977) called a *research tradition*. According to Laudan, a research tradition has certain traits including, most fundamentally, the presence of one or more empirical (that is, descriptive) theories, and one or more normative (or prescriptive) ontological and methodological commitments. The emergence of a research tradition in any science signifies, unequivocally, a major innovation in that science. In this essay, I will discuss the cognitive-social-historical process of innovation in the realm of the social sciences. In

particular, I will examine how the American polymath Herbert A. Simon (1916–2001) was led to a particular model of human decision-making which in turn gave birth to a radically new research tradition, first in organization theory and economics, and then in other domains of the human sciences. This new tradition I call the *cognitive tradition* or, more simply, *cognitivism*. For his seminal role in the creation of this research tradition, Simon was awarded the 1978 Nobel Prize for Economic Science.

This essay will also reveal how and why a major innovation in the social sciences faced significant resistance—both before and after the Nobel—to the extent that in economics, cognitivism has neither replaced the dominant (neoclassical) research tradition nor been assimilated into the latter. Rather, cognitivism became (and remains) an alternative research tradition with its own adherents and practitioners. This historical fact gives empirical credence to Laudan's thesis that a given science may be populated by more than one research tradition at any given time—in contradiction to Thomas Kuhn's more celebrated theory, in *The Structure of Scientific Revolutions* (1970), that a science is governed, at any one time, by just one paradigm.

A 'Puzzling' Nobel Prize

When the Royal Academy of Sciences in Sweden awarded the 1978 Nobel Memorial Prize in Economic

Sciences to Herbert Simon, the award occasioned considerable bemusement in the community of professional economists—a reaction that the popular press was quick to sense (Cairncross, 1978; Rowe, 1978; Williams, 1978).

The official Nobel Foundation citation tells us that the prize was awarded for Simon's "pioneering research into the decision-making process in economic organization" (Carlson, 1979). In fact, despite the apparent puzzlement amongst practicing economists in 1978, Simon had come to be regarded, by the early 1960s, as one of the founders of the "behavioral approach to economic analysis" largely because of his emphasis on the process of decision-making in administrative and economic contexts (Cyert & March, 1963; Machlup, 1967; Marris, 1964). A relatively recent history of economics has attributed the origin of the "*behavioural approach* to the theory of the firm" to Simon (Screpanti & Zamagni, 1993, p. 378).

Unfortunately, the words 'behavior' and 'behavioral' in the context of the social sciences are used in somewhat confusing and contradictory ways—and this has obfuscated, to some extent, the precise nature of the 'behavioralism' which led Simon to the accolade of a Nobel Prize. Simon himself made a clear distinction between 'behavioralism' and 'behaviorism'. For him, the former term refers generally to the study of human behavior in social processes and institutions, and includes the processes by which behavior is manifested, while the latter term is restricted to the particular school of psychology associated originally with John B. Watson, and which limits itself to the study of those aspects of human behavior that can only be observed.¹ However, in the economics literature, the two concepts are often conflated. For instance, Machlup (1967, p. 4), in the same breath, spoke of "the program of behaviorism" that relies "only on observations of overt behavior" (i.e. Watsonian behaviorism) and yet is required to observe "by what processes (businessmen) . . . reach decisions", mindless of the fact that recognition of such processes, being mental, are anathema to behaviorist psychologists; Julian Margolis (1958) used 'behaviorism' in the title of a paper to refer to what in the text is clearly *not* behaviorism (in the behaviorist psychologist's sense). Likewise, in discussing the very work for which Simon would later receive the Nobel, Robin Marris (1964) claimed to be writing about 'behaviorist arguments' and, accordingly, presented his 'general view about behaviorism in economics'.

To add to the confusion, when the economist Amartya Sen (1979) speaks of the "behavioral foundations of economic theory" and Simon (1955) of a "behavioral model of rational choice", they are referring to two quite different things. Sen's reference is to

the consumer's *preference* amongst alternative bundles of goods as 'revealed' by the choices they are observed to make; Simon is writing of the *psychological process* by which the economic agent makes a decision.

Clearly, the concept of 'behavioralism' is both too broad and too ambiguous as an accurate descriptor of Simon's contribution to economic thought. And it certainly does not explain *why* Simon's thinking was so much outside the mainstream of economic thought, *circa* 1978, that the Nobel award for that year occasioned so much puzzlement in economic circles.

As we will see, the explanation lies in the novelty and unfamiliarity of the research tradition that Simon brought into being.

Research Traditions

Every scientist practices his or her craft within a particular framework—broadly, an integrated network of theories, facts, methods, assumptions and values. For Thomas Kuhn (1970), this framework constituted a 'paradigm' or 'disciplinary matrix'; Imre Lakatos (1978) called it a 'research programme'; and for Larry Laudan (1977), the framework constituted a 'research tradition'. While there are common features amongst these three proposals, there are also important differences. For our purpose here, the nature of the phenomenon I wish to explore falls most appropriately within the Laudanian concept of the research tradition.

A *research tradition* (RT), according to Laudan (1977, p. 89 et seq.), has the following fundamental traits: (a) It contains one or more *specific theories* some of which are temporary successors of earlier ones while others are 'current' or coexisting at some given time. By 'theory', Laudan meant assertions, propositions, hypotheses or principles that can lead to specific, empirically testable predictions, or can provide detailed explanations of phenomena. Theories are fundamentally descriptive; furthermore, the theories within a RT need not all be mutually consistent; (b) It is characterized by certain *ontological* and *methodological commitments* which collectively distinguish it from other RTs; (c) Because of possible inconsistencies among its constituent theories, a RT may (in order to resolve these inconsistencies) *evolve* through several versions. Generally, then, a RT itself is neither explanatory nor predictive. For one thing, it is too general for specific explanations or predictions to emanate from it; for another, since it is grounded in certain ontological and methodological commitments, a RT has a strong prescriptive role which, by its very nature, makes the RT unsuitable for detailed explanation or prediction; (d) The success of a RT depends on its *problem-solving effectiveness*—that is, its effectiveness, by way of its constituent theories, in adequately solving an increasing range of problems; (e) A RT and its theories interact in a number of ways. First, the RT plays a role in determining the *problems* with which its

¹ H. A. Simon, Personal communication, e-mail, Nov. 14, 1999.

constituent theories must contend. Second, the RT has a ‘heuristic role’: it can provide ‘vital clues’ for theory construction, indeed, it should provide important guidelines as to how its theories can be modified so as to enhance the RT’s ‘problem-solving capacity’. Third, the RT has a ‘justificatory role’: it may help to rationalize or justify theories; (f) An important and distinct aspect of the Laudanian RT is that it explicitly recognizes that problems may be *empirical* or *conceptual*. Broadly speaking, an empirical problem—Laudan (1977, pp. 14–15) also called this a ‘first order’ problem—is posed by the observation or detection of some phenomenon about the basic objects that constitute the domain of a given science. In contrast, a conceptual—or ‘higher-order’—problem arises in the context of a previously established or proposed theory, where the latter is perceived to be unsatisfactory on logical, philosophical or even aesthetic grounds.

More generally, then, a RT is “a set of . . . assumptions about the entities and processes in a domain of study and about the appropriate methods to be used for investigating the problems and constructing the theories in that domain” (Laudan, 1977, p. 813), within the specific constraints described in (a)–(f) above.

Simon’s Model as a Research Tradition

Simon himself never referred to his work in economics (or any of the other domains in which he worked) as a ‘research tradition’. His preferred, and more modest, term was ‘model’ by which he meant a theory that is precise enough to be empirically testable.² For the present, then, I will refer to the work for which he received the Nobel Prize simply as *Simon’s model*.

What exactly was Simon’s model, and how can we demonstrate that it constituted a RT? That is, how can we show that it was not just an invention but the birth of a genuine innovation? My demonstration will appeal to the historical process itself. I will describe how Simon’s model came into existence over a period that began in the late 1930s, but properly took shape between 1952 and 1957. We will see that this model emerged in response to *Simon’s dissatisfaction with the dominant research tradition in microeconomics*. We will further see that the model was not simply a corrective or adjustment to, or a new constitutive theory of, the dominant RT: it neither enriched nor enhanced the problem-solving effectiveness of the dominant RT, nor did the latter provide a ‘heuristic role’ in the construction of Simon’s model. Rather, the model emerged as an *alternative* and, thus, as a *competitor* to the dominant RT in microeconomics. We

will then see that *structurally* Simon’s model possesses all the characteristics of a RT. I will then argue that Simon’s model is fundamentally a *cognitive* model—that is, it is a model that coheres with the way in which cognitive scientists regard ‘cognition’. Finally, we will examine the evidence to argue that Simon’s cognitive model does not just structurally conform to a RT but that it was *historically* the beginning of a new RT, the *cognitive tradition*, not only in economics but more generally in the social sciences.

The Dominant Research Tradition in Economics

The *neoclassical* tradition, the dominant RT in economics, emerged in about the last quarter of the 19th century. As a research tradition, it has evolved considerably in the course of the 20th century, and though it is by no means the only framework guiding economic thought, it is fair to say that in important areas of economic theory and practice, it became, and remains, the dominant tradition.

For the neoclassicist, the social entity of interest is the market and its two principal constituents, the producer and the consumer. The most significant characteristic of this social entity is that producers and consumers are assumed to behave so as to maximize their respective satisfactions—profit in the case of producers, and ‘utility’ in the case of consumers. Neoclassical *Homo economicus* is a ‘maximizer’ of personal satisfaction and, in this precise sense, is a ‘perfectly rational’ being.

Two other characteristics of neoclassicism are worth noting. First, the economic universe is *ahistorical* and *acultural*: the behavior of the market and its constituent actors are taken to be independent of cultural differences and historical time. Second, the economic universe is a *formal world*, amenable to exact mathematical treatment.

Simon’s intellectual acquaintance with the neoclassical tradition reached back to his undergraduate days in the 1930s at the University of Chicago where, he confessed 60 years later, he had had “about as much economics as if . . . I had majored in it”³—though, in fact, his formal baccalaureate and doctoral degrees were in political science. In the 1940s, while teaching at the Illinois Institute of Technology, he had begun to publish papers in such ‘mainstream’ economics journals as the *Quarterly Journal of Economics*, and had started a long and close association with the Cowles Commission for Research in Economics, whereby he was in intellectual exchange with some of the foremost American exponents of the neoclassical tradition.

² H. A. Simon, Personal communication, e-mail, Jan.1, 2001.

³ H. A. Simon, Personal communication, e-mail, Nov. 14, 1999.

Thus, *socially*, Simon was well ensconced in the neoclassical domain.

An Empiricism/Formalism Polarity in Simon's Scientific Style

Yet, steeped though he was in the formalism inherent in the neoclassical tradition, Simon was rooted still more deeply in the empiricism that had guided him in his most substantial work on administrative theory, first as a doctoral student between 1938 and 1942, and then as a young faculty member in the Illinois Institute of Technology and (from 1949) at the Carnegie Institute of Technology. In fact, Simon's long engagement with the social sciences reveals a continuing polarity between empiricism and formalism. On the one hand, there was his 'one long argument' for an empirical science of administration, a science that appealed to the way in which people in organizations actually function and make decisions. Simon's empiricism in administrative theory drew upon case studies reported in the organizational literature, in the observations of psychologists and sociologists, and in his own field studies. Most markedly, perhaps, his empiricism was manifested in his commitment to operational principles, and in the very nature of the specific principles described in his first two books, the second jointly authored with two colleagues (Simon, 1947; Simon, Smithburg & Thompson, 1950).

Coexisting with this empiricism was a strong formal or mathematical strain which, from the very onset of his doctoral work, longed to lend 'precision and clarity' to all the social sciences, including sociology and political science. In the realm of organization theory, Simon's formalism was most evident in his series of papers on group behavior.

Despite the presence of this polarity in what we might call Simon's personal scientific style, there was, yet, a *tension* between these two elements of his style. He was, he explained in 1945, a social scientist not a mathematician, and he was not willing to let "formal theory . . . lead the facts around the nose".⁴ Nor was he prepared to be seduced by the pure mathematician's desire for rigor for the sake of rigor. "Mathematics is a language" which scientists should be able to read, speak and write, he wrote in 1953. But they should not be turned into 'grammarians'.⁵ Furthermore, "mathematical theorizing" must originate in the "field about which the theorizing is to be done" (Simon, 1954).

⁵ H. A. Simon to K. O. May, Nov. 2, 1953, HASP.

The Conflict Between Simon's 'Administrative Actor' and Neoclassical *Homo Economicus*

In his own perception, then, Simon was a social scientist not a mathematician. Theory must originate in the 'field'. Here lay the problem with neoclassical economics: its assumptions did not originate in the 'field'; it was, rather, a case where formal theory *did* 'lead the facts around the nose'. At the very least, the assumptions surrounding the behavior of neoclassical *H. economicus* were inconsistent with the model of the *administrative actor* which, following Chester Barnard (1938), Simon had helped shape. The economic actor, according to the neoclassicist, was a maximizer of satisfaction, a perfectly rational, omniscient being with complete knowledge at his disposal and possessed of the cognitive capability to enforce his maximization objective. Simon's administrative actor was a purposive or goal-oriented being: she desired to take action or make decisions that were conducive to the attainment of that goal. For Simon, purposive behavior is rational if the choice of means leads to the attainment of the goal. However, such purposive behavior faces several oppositions. There are limits to the actor's innate cognitive capability; limits to one's knowledge about the relevant factors that need to be taken into account in order to arrive at a 'rational' choice; limits to the actor's ability to cope with the complexity of the environment in which decisions have to be made, and with the alternative courses of action (choices) and their consequences. Ultimately, all these constraints suggest that *it is exceedingly difficult for an individual to achieve fully rational behavior*. Simon (1947) termed such behavior 'subjective rationality'; exactly a decade later, he reframed this notion and retermed it *bounded rationality* (Simon, 1957).

The contrast between neoclassical *Homo economicus* and Simonian administrative actor was stark. The former exuded a confidence the latter lacked. Both economic theory and Simonian administrative theory concerned themselves with *behavior*. Yet the behavior the actor indulges in according to the neoclassical tradition makes no appeal to the cognitive and other psychological factors that prompted and constrained the behavior of the Simonian administrative actor.

Simon's 'New Problem'

This *inconsistency* between his model of the boundedly rational administrative actor and the perfectly rational neoclassical economic actor became the source of a *problem* for Simon. By the middle of 1950, he was embarking on a new scientific activity, the objective of which was to create a *H. economicus* whose behavior manifested the kind of empirical plausibility—social and cognitive—that had shaped the Simonian administrative decision-maker (Simon, 1950a). His goal, he wrote in 1951, was to construct a bridge between

(T)he economist with his theories of the firm and of factor allocation, and the administrator with his theories of organizations—a bridge wide enough to permit some free trade of ideas between two intellectual domains that have hitherto been quite effectively isolated from each other (Simon, 1951).

However, for Simon, this was to be a one-way bridge, leading *from* administrative theory *to* economic theory. He wished to investigate, he wrote to the mathematical economist Tjalling Koopmans in 1952, “how the processes of rational decision making are influenced by the fact that decisions are made in an administrative context”.⁶

Furthermore, this bridge was to be paved with psychological matter, for

(A)s my work has progressed, it has carried me further into the psychology of decision making processes. I have on several previous occasions expressed my conviction that a real understanding of ‘rational choice’ will require further investigation of these psychological problems.

The *Zeitgeist* Concerning Behavioral Economics, Circa Early 1950s

In effect, Simon wished to espouse an alternative to the neoclassical tradition, one we might tentatively call the ‘behavioral’ tradition. Taken narrowly, this takes into account cognitive, motivational and other psychological factors that enter into economic decision making. More broadly, it extends beyond psychology: as Simon would put it several decades later, the behavioral tradition emphasizes the “factual complexities of our world” (Simon, 1999).

In this broader sense, the behavioral approach reaches back to such thinkers as Thorsten Veblen and John R. Commons. There is no evidence that Simon was influenced by Veblen, but he had read Commons (Simon, 1991) and acknowledged the latter’s influence in *Administrative Behavior* (Simon, 1947, p. 136).

But behavioral economics had more modern practitioners. In particular, there was George Katona. Katona was both an economist and a psychologist (Campbell, 1980), and for him, the psychology of economic behavior went well beyond *behaviorism*. Stimulus and response were not sufficient to comprehend behavior; there were other, internal, ‘intervening variables’ that mediate between stimulus and response. Katona (1951, p. 32) cited as examples, ‘organization, habit, motive, attitude’. Katona was a cognitivist in that he espoused gestalt psychology; he had been influenced by, and had worked with, the gestaltist Max Wertheimer (Campbell, 1980, p. 4). A human being confronted with a set of external situations and factors—a ‘geographical environment’—*perceives* this environment according

to the ‘organization of his perception’. And ‘motives, attitudes and frames of reference’ affect the organization of the person’s perception and how he or she responds to the environment.

In the realm of economic rationality, Katona questioned the assumption of *H. economicus* as a striver of maximum satisfaction (Katona, 1951, pp. 32, 36, 70–71); that the economic actor is entirely egocentric; that the consumer is driven by just one motive. It was obvious to him that psychological research could shed light on these issues.

A particular instance when the psychologist was useful, Katona noted, had to do with the ‘attitude’ toward income and expenditure. Psychologists had studied the *level of aspiration* humans identify in various goal-directed behaviors. A person may wish to hold to some ideal level but such a level has ‘no psychological reality’, since one may not be able to state what the ideal is. Rather, she establishes an aspiration level for which she *can* strive. Aspiration levels *do* have ‘psychological reality’—since one can raise or lower it depending on the success or failure with a prior level (Katona, 1951, pp. 91–92).

Katona was not alone in wishing to draw upon psychology to understand economic behavior. There was already a considerable knowledge base concerning the relevance of psychology to economic decision-making, as Ward Edwards’ (1954) lengthy and critical review article attests to.

Edwards’ article and Katona’s book provide independent evidence of a certain *Zeitgeist*, a certain dissatisfaction with the neoclassical view of economic rationality. However, neither Katona nor Edwards makes any reference to Simon’s theory of bounded (‘subjective’) rationality, originally articulated in *Administrative Behavior* and included in the 1950 text on *Public Administration*.

The Emergence of Simonian *H. economicus*: I. Tentative Steps

Even before Simon confided his intention to Koopmans, he had already made tentative inroads toward the attainment of his goal—tentative in that he *straddled* both the neoclassical RT in economics and the behavioralism or psychologism of his model of administrative man. In a paper published in 1951, Simon addressed a special instance of his ‘problem’. This concerned the question of how an employer/boss and an employee/worker would enter into an employment contract. The neoclassical version of this situation was devoid, Simon claimed, of the reality of how such contracts are made as suggested by administrative theory (Simon, 1951). Simon’s approach was to draw an *analogy* between the boss–worker relation in economic theory and the superior–subordinate relation in administrative theory; he then transferred some crucial concepts from the latter to the former. Thus, he said, a worker (W) enters into an employment contract

⁶ H. A. Simon to T. C. Koopmans, Sept. 29, 1952. HASP.

with a boss (B) when W agrees to accept B's authority to select a particular set of tasks ('behavior') for W to perform. Simon contrasted this with the contractual model assumed in traditional (neoclassical) price theory. There, B promises to pay a sum of money, and W promises in return a specific quantity of labor.

But under what conditions is W willing to give B authority over W's behavior? Appealing to arguments put forth in *Administrative Behavior*, Simon proposes that he will do so if the behavior falls within an 'area of acceptance' or a 'zone of indifference' (Simon, 1947, p. 133). There are other conditions also that will determine how boss and worker, employer and employee, will enter into a contract. For example, if B *does not know* for certain at the time the contract is made what behavior he or she wants for W, then B may be willing to additionally compensate W for the 'privilege of postponing' the choice of behavior until some time after the contract is entered into.

This, Simon suggested, is how people actually behave in a contractual situation; this is what each party is actually prepared to accept of the other's behavior. Here is a glimpse of the effect of imperfectness of information, incompleteness of one's knowledge, on the decision-maker's rationality.

However, *maximization of satisfaction* so precious to the neoclassical tradition remained: Simon assumed that both boss and worker wish to maximize their respective well-being, and that their well-being could be formalized mathematically by a 'satisfaction function'. Here, then, was the maximizing neoclassical *H. economicus* dosed with a sprinkling of the administrative actor's behavioral characteristic.

This same characteristic appeared in another paper published in 1952, in which Simon explicitly compared the microeconomic theory of the firm ('F-theory') with administrative/organization theory ('O-theory') (Simon, 1952a). The decision-maker, according to F-theory (basically the entrepreneur), is an optimizer; the decision-maker according to O-theory (the participant within an organization) is an *adaptive* actor. The firm, according to F-theory, operates to maximize the entrepreneur's satisfaction; the firm, according to O-theory, seeks to ensure its own survival. But Simon also appealed to neoclassically grounded welfare economic theory to introduce a criterion of optimality into O-theory: a viable decision is optimal if no further increase can be made in the net satisfaction of any one participant without decreasing the satisfaction of at least one other participant. Welfare economists refer to this condition as 'Pareto optimality' (Sen, 1979, p. 86). Thus optimality was not eliminated on this O-theoretic view of the firm. Vestiges of neoclassicism were still evident in the behavioralistic O-theory.

The notion of the adaptive decision-maker was not by any means new in Simon's thinking. He had discussed it in *Administrative Behavior*. Just as in the natural world an organism's survival is achieved by its

adapting to new environmental situations, so also in the artificial world of organizations, the latter's survivability is achieved by the adaptive behavior of its members. Such adaptation arises because the organization's objectives change in response to the values, interests and needs of the organization's members as well as to the changing demands of customers. Adaptive behavior is the means by which both organisms and organizations cope with an uncertain future and their inability to predict the future with any degree of accuracy. This very uncertainty, and the paucity of knowledge about the future, places severe limits on the decision-maker's ability to make completely rational decisions. O-theory is predicated on the recognition of this fact; hence the decision-maker adapts from moment to moment to the situation at hand.

Also in 1952, taking up another special problem from the economic domain, Simon further explored the nature of adaptive decision-making. The context was the industrial management of production and inventory (Simon, 1952b). The issue was to control the rate of production of an item so as to minimize the cost of manufacture over a period of time, where 'cost' is a function of the variation in the manufacturing rate and the inventory of finished goods. The latter, in turn, is affected by the number of customer orders per unit time.

Simon once more resorted to *analogy*—this time, between the production/inventory control situation and *feedback mechanisms*. He was thoroughly familiar with the principle of feedback in servomechanisms. As far back as 1935, he had read Alfred Lotka's classic work (Lotka, 1956) in which he had detected "(t)he basic idea of goal orientation and feedback".⁷ He had read the paper 'Behavior, Purpose and Teleology' by Rosenbluth, Wiener & Bigelow (1943) soon after its appearance.⁸ Wiener's *Cybernetics* had also been published recently (Wiener, 1948), and by 1950, he was contemplating the "study of organizations and other social and human servos" (Simon, 1950b).

For our purposes here, two particular aspects of Simon's 1952 study of production control are noteworthy. First, he was able to explore, in some detail, an *economic* decision system that circumvented uncertainty or lack of knowledge about the future by acting adaptively. Like Lotka's adaptive organism, the (human) production controller receives information about the state of the 'environment'. The relevant 'state' consists of the 'optimum'—meaning desired—inventory and customer orders. The controller computes the actual inventory as a function of the production rate and customer orders; the computed value becomes the 'feedback' information which is used to calculate the difference ('error') between

⁷ H. A. Simon, Personal communication, e-mail, Feb. 25, 2000.

⁸ *Ibid.*

optimum and actual inventories. This error value prompts the controller to take action—that is, increase or decrease production. Thus, there is no need to predict the future in order to take action ‘now’. Rather, action is taken ‘now’ based on knowledge of the *immediate past*.

The second and more compelling aspect of this exploration was what it revealed of adaptive behavior compared to optimal behavior. The general criterion of optimality for the production controller was the minimization of production cost. This objective was recast into a goal to adjust the production rate as a function of the error separating actual from desired inventory. Here was a more everyday-sense view of optimality. The criterion of optimality was not to minimize or maximize something; rather, it was to adjust some factor depending on the deviation of actual performance from desired performance. *The neoclassical sense of optimization as a characteristic of rational behavior was noticeably absent from this analysis.*

The Emergence of Simonian *H. economicus*: II. The ‘Model’

As we have seen, in the three papers published in 1951–1952, Simon had taken several steps toward achieving his original goal—to comprehend how rational decision-making in the microeconomic setting is influenced by administrative/organizational contexts. In essence, this meant drawing upon his work on administrative behavior in which he had already worked out a theory of rationality. Thus, he already had a model of rational behavior; but, apparently this model had not infiltrated the world of economic theory.

In a series of publications appearing between 1955 and 1957, Simon completed the task he had tentatively begun (Simon, 1955, 1956, 1957). However, his solution was not a case of simply adapting economic behavior to his model of administrative behavior; rather, it *entailed creating a new model of H. economicus* that: (a) manifested relevant characteristics reflecting the administrative/organizational context in which *H. economicus* resides; and (b) introduced additional features of the decision-maker that were not present in Simon’s administrative actor. In this process, the *language of discourse for describing rational decision-making was revised*—in both the economic and administrative domains.

What were these ‘additional factors’ that Simon introduced? First, he made a distinction between the constraints on which the decision-maker *has no control* and his *actual actions*. In *Administrative Behavior*, the former had been identified in the specific context of administration: they were cognitive as well as social (i.e. organizational) constraints. Now, the constraints collectively constituted the decision maker’s *environment*. One part of this environment lay inside the ‘skin’ of the economic actor and pertained to innate or

(unconsciously) acquired characteristics that the actor possessed: perceptive, cognitive, computational and motor capacities; the other part lay outside the actor’s ‘skin’—external variables beyond the actor’s control (Simon, 1955, p. 101).

Second, Simon adopted the psychological notion of *aspiration level* which Katona (and other psychologists before him) had discussed. The economic actor establishes a level of aspiration as the goal to achieve.

Third, we see the presence in Simon’s model of the idea of *search*. The action or behavior that the decision-maker undertakes entails sequential search for a behavior that meets the aspiration level. In *Administrative Behavior*, Simon had articulated the notions of plans and strategies, drawing on von Neumann and Morgenstern (1946), but the concept of search did not appear there or in *Public Administration*.

Simon’s formulation of search was rather precise and operational, and was intimately linked with strategies employed in chess. In fact, it is difficult to state whether the strategies of the chess player were, collectively, the *source* of his idea of search, or whether the latter came independently, and he noticed a congruence in chess. His interest in chess reached back to boyhood, he recalls; in high school, he had studied the game seriously to the extent that he had mastered the basic decision-making issues in chess and tic-tac-toe.⁹

In the early 1950s, he was aware of some of the first ideas on computer chess published at the time by Claude Shannon (1950) and Alan Turing (1953) and had read, in the original Dutch, the pioneering work by Adrian deGroot (1946) on the psychology of chess.¹⁰

Regardless of the precise temporal and causal link between his knowledge of the psychology of (both human and machine) chess, what we *can* say with confidence is that in 1955, he drew an analogy between the chess player’s rationality in choosing a move and the economic actor’s rationality in making an economic decision (Simon, 1955).

A significant notion that Simon’s analogy brought forth was that the chess player undertakes a *mental search*, indeed a mental *simulation* of the game-in-progress. The concept of mental simulation was not original to Simon. It was discussed, for example, by Kenneth Craik (1943). Simon appeared to be ignorant of Craik’s work. The search stops when an outcome is ‘discovered’ that meets the chess player’s aspiration level, namely, a ‘win’ state. Furthermore, since the ‘space’ of possible strategies the chess player would have to explore before choosing a move would be potentially beyond the cognitive capacity of the player—bounded rationality in action—the player abstracts from this complexity by employing various

⁹ H. A. Simon, Personal communication, e-mail, Nov. 4, 2000.

¹⁰ Ibid.

heuristics to reduce the search process. The economic decision-maker is thus, in Simon's model, a *heuristic* or *selective searcher*.

Fourth, we see the emergence of *computation* as a metaphor for the process of human thinking. This notion was influenced in part by the ideas advanced by Shannon (1950) and von Neumann on the problem of designing a chess computer,¹¹ and in part by his interest in the application of computer technology to decision-making and organization theory—an interest he had expressed in 1950 (Simon, 1950b). Certainly, by 1955 (and probably earlier, in 1953), the computational metaphor had entered Simon's vocabulary. He could freely write about an organism's 'computational capacities' in making rational choice, invoke a model of chess playing inspired by the idea of a chess playing program, and compare the 'I.Q. of a computer with that of a human being'.

The interpenetration of computation with human thinking and rationality was, perhaps, most telling in Simon's fleeting comment that a study of the various 'definitions of rationality' might lead to the design of computers that might achieve "reasonably good scores on some of the factors of intelligence in which present computers are moronic" (Simon, 1955).

Fifth (and finally), the economic actor, administrator, chess player, 'simple-minded' animals and mechanical beings (automata) were all subsumed into a *universal organism*: an organism that compensates for its bounded rationality by adapting its behavior according to its goals and the information received from the environment, and who seeks to *satisfice*; that is, perform, act or behave so as to achieve an aspiration level that may not be optimal (that is, not the very best) but one that is satisfactory or 'good enough'. In Simon's model then, the economic decision-maker, the administrative decision-maker, the exploratory 'simple-minded' animal and the mechanical animal (such as *Machina speculatrix* described by W. Grey Walter (1961) with which Simon was familiar) are all instances of a *universal, boundedly rational, satisficing, adaptive organism*. And with this organism, Simon had finally shed the last vestiges of neoclassical *H. economicus*.

The Coherence of Simon's Model to a Laudanian Research Tradition

So what was the outcome of Simon's endeavor? It was, in fact, a model of the human decision-maker; and shorn of its historical development, we see that it consisted of three major components: (a) a *prescriptive* postulate about the fundamental nature of the model's domain; (b) a set of *descriptive* propositions about

decision-making; and (c) a set of *prescriptive* postulates concerning theories about decision-makers.

The postulate about the nature of the model's domain is that *organizational behavior is a network of decision processes* (Simon, 1947, p. 220).

The descriptive propositions are fourfold: (a) *The Principle of Bounded Rationality (PBR)*: "the capacity of the human mind for formulating and solving complex problems is very small compared with the size of the problems whose solution is required for objective rational behavior in the real world" (Simon, 1957, p. 198); (b) *The Principle of Satisficing (PS)*: the decision-maker establishes 'satisficing' goals as aspirations, and seeks decisions (or choices) that meet such aspirations; (c) *The Principle of Heuristic Search (PHS)*: the decision-maker seeks a satisficing decision by sequentially searching the space of possible choices and selecting the first that meets the satisficing aspiration or goal. The search process employs both the aspiration and the structure and properties of the environment to manage the complexity of search; and (d) *The Principle of Adaptive Behavior (PAB)*: organisms and organizations cope with the uncertainty of the future and their inability to predict the future with any degree of accuracy by means of adaptive behavior—by continually adjusting actions or behavior to the changing environment so as to meet given goals according to information received from the environment.

Finally, there are three prescriptive postulates about decision-making: (a) *Operationalism*: any proposition, hypothesis or theory concerning the behavior of decision-makers must rest on operational concepts, so that one can carry out procedures to confirm, corroborate or falsify the proposition; (b) *Empiricism*: a social science (such as economics or organization theory) must be grounded in the ways in which people actually function, operate and make decisions. That is, the propositions of a social science must appeal to actual human behavior; (c) *Formalism-as-a-Language*: formalism, especially mathematics, is to serve as a language to lend precision and clarity to the propositions of a social science. It should not override operationalism or empiricism.

Stated thus, Simon's model *manifests the structural characteristics of a Laudanian research tradition*.¹² The four descriptive propositions (PBR, PS, PHS, and PAB) comprise the theories of a RT; the three prescriptive postulates (operationalism, empiricism and formalism-as-a-language) constitute methodological commitments; and the prescriptive postulate about the nature of the domain is an ontological commitment.

Simon's Model is a Cognitive Model of Human Decision-Making

As summarized above, Simon's model has no explicit link with economics. It is, rather, a more general model

¹¹ Simon had attended a lecture by von Neumann in 1952 on computer chess and was sufficiently stimulated by it to actually engage, by mid-1953, with the design of chess playing programs. H. A. Simon to J. von Neumann. June 24, 1953. HASP.

¹² See section on 'Research Traditions' above.

of decision-making. There is, yet, another vital characteristic of his model. We noted (in the 'Introduction') that Simon has come to be closely associated with the 'behavioral approach' to economics and administrative theory. We further noted the confusion amongst social scientists about 'behavioralism' and its occasional conflation with the behaviorist school of psychology.

When we examine the structural features of Simon's model, especially its four descriptive principles, both the confusion and the ambiguity surrounding 'behavioralism', as it applies to Simon's model, disappear. This is because Simon's model is something more radical and specific than is suggested by the ambiguous term 'behavioral'. It is not just that decision-making behavior is being modeled; in arguing that such behavior entails cognitive limitations causing bounds on rationality, setting goals, drawing upon information from the environment, mentally searching, and continually adapting action and behavior based on feedback from the environment, the decision-making organism is viewed as a 'cognizer'. In other words, *Simon's model is a cognitive model of human decision-making, and therein lies its originality (and Simon's creativity) in the social sciences.*

How are we justified in claiming that Simon's model of human decision-making is a cognitive model? This depends on what we mean by 'cognition'. We might appeal to one of several elaborate theories of cognition (von Eckardt, 1998), but I think we can capture the essence of the concept in the following terms (Dasgupta, 2000).

On the one hand, we have behavior: observable and overt characteristics of humans and animals, manifested as interactions with the external world. On the other hand, we have the brain: a corpus of physical matter that obeys the laws of physics and chemistry, the various activities of which give rise to behavior.

The problem is, there is a gap between overt behavior and brain matter sufficiently large as to make it difficult to explain behavior directly in terms of neurophysiological events. Furthermore, the latter are subject to natural (i.e. physico-chemical) laws, and such laws are nonpurposive, whereas behavior is purposive. This gives rise to the added problem of explaining how nonpurposive, physico-chemical events and processes can give rise to purposive behavior.

What scientists very often do in order to bridge large conceptual gaps between two types of events that are (believed to be) causally related is to propose or search for one or more *intermediate levels* of abstraction, explanation and description. Effectively, what is created is a *hierarchy* of abstraction levels, the assumption being that scientists are better off attempting to bridge the narrower conceptual gaps thus created between the adjacent levels in such a hierarchy (Pattee, 1973; Whyte, Wilson & Wilson, 1969).

The essence of cognitivism is the proposition that there exists one or more intermediate levels ('cognitive

levels') of organization and explanation between the extremities of overt, purposive behavior and the non-purposive physico-chemical activities of brain matter (Newell, 1990, p. 111 et seq.). The nature of these cognitive levels and how they affect the mapping of behavior onto brain matter is the domain of *cognitive science*. And, while there remains considerable disagreement as to the 'architecture' of cognition, the following assumptions are more or less accepted by most practitioners of cognitive science: cognition: (a) refers to certain *functional entities* that are physically realized by brain matter and that mediate between behavior and brain matter; and (b) explanations of these functional entities entail the generation, organization, manipulation and processing of *representations*.

Returning to our topic, the four propositions PBR, PS, PHS and PAB constituting the empirical theories in Simon's model of decision-making refer precisely to such functional entities. It is because of this that it is not sufficient to call Simon's model a behavioral model; rather, a stronger claim can be made that it is a cognitive model.

Simon's Cognitive Model as the Origin of a Research Tradition

My argument thus far has led to the thesis that Simon has created a distinctly cognitive model of decision-making, and that this model has the characteristic structure of a Laudanian RT. But this does not mean that Simon's model did *in fact* create a research tradition. Paraphrasing Eric Hobsbawm (1983), a tradition, at the very least, must be a significant *practice* that has been in existence for some period of time. How can we demonstrate that Simon's cognitive model of decision-making not only possesses the structural characteristics of a RT but is also a genuine tradition (in Hobsbawm's sense)?

My claim is that this cognitive model achieved the status of a genuine RT because its core theories, viz., PBR, PS, PHS and PAB, *entered into the very languages of discourse of a range of disciplines often called the human sciences.*

Economics, political science, and organization theory were the first of the human sciences in which we see the explicit presence of Simonian cognitivism (Banfield, 1957; Cyert & March, 1963; Leibenstein, 1960; Machlup, 1967; March & Simon, 1958; Margolis, 1958; Marris, 1964; Storing, 1962). But these were not the only ones. Not surprisingly, the language of psychology itself became rapidly infused by both the methodological commitments and the core theories of the Simonian model, after appropriate reformulations in information processing terms. The new cognitive psychology to which the Simonian model contributed became one of the ingredients of the cognitive science that came into being in the mid-1970s (Gardner, 1985; Miller, Galanter & Pribram, 1960; Newell, Shaw & Simon, 1958). And by its influence on cognitive

psychology, the Simonian model entered, from as early as the mid-1960s and expanding over the next three decades, the consciousness of those who practiced and wrote on the design disciplines, in particular, in the realms of architecture, industrial design and computing systems design (Alexander, 1964; Dasgupta, 1991; March, 1976; Steadman, 1979), and what the sociologist Donald Schon (1983) called ‘professional practice’.

Cognitivism as an ‘Alternative’ Research Tradition in Economics

Thus, there is sufficient evidence that by the late 1970s, when Simon was awarded the Nobel Prize, the cognitive model he had created had become the basis and essence of a RT that infused several of the human sciences. This makes it all the more perplexing the issue raised at the start of the paper: Why did the cognitive tradition fail to be assimilated into the theoretical mainstream of economics? As one recent commentator, sympathetic to Simonian cognitivism, has pointed out, college textbooks on microeconomics continue to present the neoclassical version (Earl, 1995, p. 28–29).

The resistance to cognitivism has come from several directions, and the nature of these objections gives us some clues as to the essence of the resistance. But it is worth noting that even before such objections were summoned forth against Simon in particular, other voices had been raised in defense of the neoclassical tradition. In particular, there was Milton Friedman’s influential essay of 1953 in which he argued that whether or not the assumptions underlying a theory are realistic is irrelevant; what is important is that the theory yields accurate or ‘good enough’ predictions about the economic universe, or that the theory yields predictions that are superior to those yielded by alternative theories (Friedman, 1953). From this perspective, it is sufficient, Friedman asserted, to assume that firms and businessmen behave *as if* they are capable of making completely rational decisions; that is, they are capable of making optimal choices. (It is ironic that Friedman himself advanced what was essentially a satisficing argument in support of the neoclassical, omniscient, perfectly rational *H. economicus*!)

At about the same time, the statistician Leonard Savage (1954) admitted that the assumption that a decision-maker assesses all alternatives before making a decision—Savage called this a ‘a look before you leap’ strategy—might appear ‘preposterous’ when taken literally. Nonetheless, he held that ‘look before you leap’ was the ‘proper subject’ of any theory of decision-making.

In an early criticism of Simonian cognitivism—his ‘program of behaviorism’—Fritz Machlup objected that the kind of ‘real world complexity’ that Simon’s economic actor must allegedly deal with does not, in

fact, exist. “The *Homo economicus* I have encountered in the literature was not such a perfectionist; and, indeed, did not need to be so because *H. economicus* does not have to deal with the ‘entire environment’, not even with the ‘relevant aspects of the entire environment’, but only with the relevant changes in environmental conditions”. The axioms of maximizing behavior in the neoclassical tradition are postulated only to predict or analyze such changes. Thus, for instance, “The theory of prices and allocation viewed as a theory of adjustment to change does not call for impossible (i.e. omniscient) performances”. One can, perfectly well, postulate maximizing behavior in such situations (Machlup, 1967, pp. 25, 25n).

Machlup raised a further objection. He considered a particular scenario in which the government placed a certain surcharge on import duties. Neoclassical theory, with its profit maximizing assumption, ‘will without hesitation’ predict that imports will fall. And he asked: “What will satisficing theory predict?” In partial answer, Machlup offered a quote from Simon in which the latter described the *thought process* that would guide decision-making according to his model. Thus, Machlup speculated, satisficing theory does not provide any real “quantitative . . . (or) qualitative predictions” (Machlup, 1967, p. 26n).

The point is, Machlup argued, Simon’s ‘behavioral’ economics applies to a concept of the firm that is relevant to issues in organization theory and management science, but not to the firm or its behavior as relevant to such microeconomic issues as competitive prices and allocation, innovation and growth, and welfare theory. There are no doubt, he admitted, problems to which ‘behavioral theory’ applies. But those problems are not of concern to economists (Machlup, 1967, pp. 30–31).

For the mathematical economist William Cooper (who, with Abraham Charnes, made important contributions to the theory and application of linear programming, one of the major post-World War II optimization techniques that enriched neoclassical economics), and a friend and associate of Simon, the ‘real world’ complexity to which Simon appealed, to argue the case for satisficing, did not merit abandonment of the optimization assumption of neoclassical economics. The very complexity of the real world, Cooper wrote to Simon, may prompt scientists to ‘synthesize artificial problems’ which are easier to deal with and yet have “certain properties in common with the ‘real’ problem”.¹³

Like Machlup, Cooper was suggesting that real world complexity is not necessarily relevant in the realm of effective economic problem-solving.

In 1957, a second edition of *Administrative Behavior* was published. In a review of this edition by Edward Banfield, we detect a resonance with Machlup’s and

¹³ W. W. Cooper to H. A. Simon, April 17, 1961. HASP.

Cooper's reservations, but this time in the realm of organization theory (Banfield, 1957). For Banfield, the principle of omniscient, optimal behavior which Simon's satisficing principle was intended to replace, served a purpose the new principle did not: the former was a prescriptive device for a 'practical science of administration'; Simon's model, in contrast, was 'sociological'—meaning descriptive. There remained a lacuna between the replaced and replacing principles. Simon, Banfield (1957, p. 284) declared,

has destroyed the rationale of the old conceptual schema without offering any new one . . . so far as 'good' administration is concerned, he has no basis for judging what criteria are relevant and what are not.

Like Machlup, Banfield doubted the utility of the satisficing principle as a prescriptive device. Like both Machlup and Cooper, Banfield thought that real world complexity is not always relevant to actual problematic situations.

What exactly was it about the nature of the cognitive research tradition that brought about these various reservations? I suggest that at the very core is the following: the new tradition—its constituent principles in particular—was concerned with cognitive *procedures* (or *processes*); consequently, it demanded a radical *switch in perspective* (what Kuhn might have called a 'paradigm shift') from that underlying the neoclassical tradition.

This change in perspective becomes clearer when we examine one of the seminal texts belonging to the new cognitive RT: Richard Cyert's and James March's *A Behavioral Theory of the Firm* (1963). Cyert and March—both close associates of Simon—began their book by stating a set of propositions which, they claimed, captured the essence of the neoclassical model of the firm. These propositions—part of the constituent theories of the neoclassical RT—are precisely of the predictive form that Machlup had approvingly alluded to.

They then proceeded to present their 'behavioral' theory. Woven into this theory were several ideas distilled from Simon's writings on administrative theory and microeconomics: satisficing, aspiration levels, sequential search, the influence of the order of search on decision-making; the focus of recent organization theory on the 'decision to belong' within an organization, and how positions within the organization impact decision-making, individual goals, and perceptions; the role of plans in organizations; the idea that a firm viewed as an organization is a coalition of participants with conflicting goals that have to be reconciled; the theory of human problem-solving; and the way executives are compensated.

Ultimately, the Cyert–March 'behavioral theory' is presented in terms of a set of economic and organizational concepts. Some of these describe the variables

(factors) that enter into a firm's behavior (e.g. variables having to do with the organization's goals and expectations); others are concerned with the relationship amongst variables (e.g. relationships having to do with the resolution amongst conflicting goals, or with the avoidance of uncertainty).

However, these variables and relational concepts by themselves do not constitute the theory. We get an early glimpse of what their 'behavioral' theory is going to be when they stress that there is, in the theory, "an explicit emphasis on the actual *process* of organizational decision-making as its basic research component" (Cyert & March, 1963, p. 125). It is the explication of *process* which draws upon the variables and relationship between variables as the building blocks that completes the 'behavioral' theory.

How does one describe or understand this process? The 'natural theoretical language' for specifying this process, according to Cyert and March, is "the language of a computer program"; and the "general structure" of the process can be "conveniently represented" in the form of a flowchart (Cyert & March, 1963, p. 125). The computational *metaphor* Simon had employed in 1955 had metamorphosed into the language of *actual* computation in Cyert's and March's theory.

The new theory was, thus, embedded not in the form of the familiar *declarative* form of knowledge in which scientific propositions were habitually stated but in the form of *procedural* knowledge—flow charts, algorithms, and computer programs. *This* was the change in perspective—and a change in the language of discourse—that the cognitive tradition engendered. I suggest that it was because this *procedural worldview* at the heart of the cognitive tradition was (and continues to be) so much at odds with the essentially *declarative* world view underlying the neoclassical tradition that cognitivism failed to be assimilated into the mainstream of neoclassicism, and that as a result, cognitivism became (and remains) an *alternative research tradition* in the realm of microeconomics.

Conclusion

I began this paper with Simon's Nobel Prize, and it seems appropriate to return to this occasion in my conclusion. The main body of the two-page Nobel Prize citation juxtaposes the Simonian model of the firm with the neoclassical model; it compares, in some detail, one with the other. Thus, although it did not speak of 'research traditions' or 'paradigms', or of 'switches in world views' or 'paradigm shifts', the citation leaves the reader in little doubt that the award was, in fact, in recognition of Simon's contribution to the genesis of a radically distinct research tradition in economic science.

In fact—and this is particularly noteworthy—the citation went further: it recognized explicitly that the work for which the Prize was being awarded had

implications for “a number of research fields with similar problems, both in economics and in other disciplines” (Carlson, 1979). Thus, the citation alludes to what I think is the most fundamental feature of the cognitive research tradition which Simon was so instrumental in bringing into being: the fact that it was a *transdisciplinary* research tradition which encompassed not just economics, or organization theory, but a range of the human sciences including (as noted earlier) architecture, computer programming, and other design disciplines, professional practices (such as in medicine), and, since the late 1980s, the history and philosophy of science and technology (see, e.g. Alexander, 1964; Blum, 1996; Cross, 1984; Dasgupta, 1991, 1996; Giere, 1988; Langley et al., 1987; Magnani, Nersessian & Thagard, 1999; March, 1976; Nersessian, 1995; Rowe, 1987; Steadman, 1979; Thagard, 1988; Weber & Perkins, 1994). Ultimately, Simon’s creativity and innovation lay in the trans-disciplinarity and, one might claim, universality of the cognitive tradition.

Acknowledgments

This essay has drawn extensively on unpublished papers and correspondence located in the Herbert A. Simon Papers Collection in the archives of the Carnegie-Mellon University Library. I also owe a debt to the late Professor Herbert Simon for his ready, prompt and patient responses to my queries, in both interviews and through email correspondence. I also thank Professor Amiya K. Bagchi for his comments on an earlier version of this essay. This work was supported by the Computer Science Eminent Scholar Trust Fund of the University of Louisiana at Lafayette Foundation.

Poetic Innovation

George Swede

Department of Psychology, Ryerson University, Canada

Abstract: Every artist wants his or her work to be considered innovative, in both historical and contemporary terms. In this paper, I focus on how and why poets strive towards these goals, but the results generalize readily to other kinds of artistic innovation. My discussion is based on the results of psychological research on poets and their poetry, some literary theory, as well as my long experience as a poet and editor of poetry periodicals and anthologies.

Keywords: Creative; Innovative; Novelty; Personal one creativity; Personal two creativity; Universal creativity; Universal two creativity.

Introduction

I have previously defined creativity in terms of a fourfold typology: universal one and two and personal one and two (Swede, 1993). Creative acts are universal when they stand out as unique and valuable in the history of the human race. Such accomplishments are the ones that get the attention of scholars and sometimes the general public. Most creative behavior, however, exists on another continuum, that of individual life spans. All of us do many things that are new and meaningful for ourselves, but already have been done by others, often for generations, such as falling in love or driving a car for the first time. Personal creativity is the stuff of character and gets noticed by counselors and novelists.

The numbers associated with each type indicate whether one individual or more than one is involved. If only one person is responsible for the creative act, it is called universal one or personal one; if two or more individuals collaborated, it is universal two or personal two. The majority of creative behaviors, whether universal or personal, involve collaborations among two or more individuals, such as the making of a motion picture or winning a local softball championship. Research on innovation tends to focus on universal one creators because individuals are easier to study than groups.

My typology does not distinguish, however, among major and minor achievements within any of the four categories. A throwaway whodunit novel and Dostoevsky's masterpiece *Crime and Punishment* are both considered as universal one. So also are the inventions of the Frisbee and the telephone, although they are

obviously of different social significance (Swede, 1993). Various attempts have been made to develop rating scales for creative acts, but so far little that is definite has emerged (Besemer & Treffinger, 1981). Rating achievements in one field, such as inventions or novels, is hard enough, but the difficulty rises exponentially when comparing across fields, for instance, the telephone vs. *Crime and Punishment*.

The term innovative is almost identical in meaning to creative; therefore, I will use them interchangeably. Thus, universal one and two innovators and creators are the same, as are the personal one and two counterparts. The word creativity, however, has no equivalent among the words related to innovation. It refers to an ability presumed to exist within someone who shows creative or innovative behavior.

For a poem to be considered as universally creative or innovative, it must possess the two criteria mentioned earlier, i.e. be both original and meaningful. These two general characteristics are paramount. No matter how well written, a poem will not be published in a respected journal unless it meets both these criteria. A poem can be original without being meaningful, such as when 20 randomly selected words are strung together. Or, a poem can be meaningful without being original as when a poet imitates a well-known work, such as Edgar Allen Poe's 'The Raven' or Sylvia Plath's 'Daddy'. According to my scheme, such a poem is personally creative (as is the poet responsible). Obviously, it will not pass editorial screening. Poems by eminent poets, however, exist on a different level. They stand out as meaningful and original on the continuum of world history. They reveal universal one

innovation or what Barsalou and Prinz (1997) call exceptional, as opposed to mundane, creativity. The focus of this chapter will be on the poets who write these great poems.

The study of universal innovators in poetry might help us to understand the relationship between language, cognition and imagination. Oral poems were likely the first artistic acts performed by our ancient ancestors. They required no tools except those with which they were born: ears, mouth, tongue, words (even if they were grunts) and some sort of imaginative twist in thinking. What we learn about the production of poetry might help us to understand other realms of human innovation since the mechanics of creative thinking seem to be roughly the same no matter what the activity (see Kaufmann, R. Root-Bernstein & M. Root-Bernstein, Simonton, Sternberg et al., Vandervert, Weisberg, this volume). Of course, any findings will be especially relevant to those endeavors that involve the imaginative use of words, such as the translation of novels and poems as well as scientific and technological discoveries from one language into another, not to mention the generation of new languages to run the super computers of the future.

The Search for Novelty

Most of the work most of us do is routine. Our job definitions certainly do not specify that we be universally creative all the time. Those working in the arts, however, do have this pressure. Artists are expected to do something new or novel *every* time they start a new project. Thus, the pressure on a painter, film-maker, novelist, sculptor, ad writer and poet to be universally creative or innovative is omnipresent. Martindale (1973), who has extensively examined the processes by which poets make their poems, believes that the search for novelty is their main driving force:

The value on novelty is the one value that cannot be violated by the poet since it is the thing that differentiates his role from those concerned with recitation or reproduction (p. 319).

For a poem to be judged as successful, it must stimulate a number of responses in the reader: deep emotions, vivid images, different levels of meaning as well as a sense of truth. But, above all else, the reader must experience the poem as universally new or special. To create such a poem, the beginning poet must develop abilities specific to the poetic craft as well as the capacity to think in an original manner, or what Amabile (1983) calls 'domain relevant skills' and 'creativity-relevant skills' (p. 363). Once the emerging poet is able to make poems editors will want to publish, he or she will begin a lifetime struggle to stay original, i.e. to avoid imitating others as well as oneself.

For some poets I know, the search for novelty becomes such a powerful concern that they limit their reading of poems by contemporaries to avoid uncon-

scious duplication. Harold Bloom (1973), the noted literary scholar, gives the reason for this as being 'the anxiety of influence':

Poets, by the time they have grown strong, do not read the poetry of X, for really strong poets can read only themselves. For them, to be judicious, is to be weak, and to compare, exactly and fairly, is to be not elect (p. 19).

Such an attitude seems to be vital to maintaining the relentless pursuit of the original. Mexican poet Octavio Paz, who won the Nobel Prize in 1990, points out that the endless search for novelty became dominant during the early 19th century, with the rise of Romanticism:

From the Romantic era onward, a work of art had to be unique and inimitable. The history of art and literature has since assumed the form of a series of antagonistic movements: Romanticism, Realism, Naturalism, Symbolism. Tradition is no longer a continuity, but a series of sharp breaks. The modern tradition is the tradition of revolt (p. 17).

This outlook often leads to behavior that others, especially those outside the arts, perceive as egotistical or self-serving (Amabile, 1996; Barron, 1969; Ferris, 1978; Middlebrook, 1991). I suspect the reason is to maintain the belief that poetry is important despite the fact that the 21st-century world considers it almost irrelevant. Billy Collins, former U.S. poet laureate, states that his country needs to have a National Poetry Month to remind the populace that this form of expression still matters:

We don't have National Television Month. We don't have National Go to the Movies Month. So to have a month for something is to admit that there is a neglect taking place, that you should pay attention (Pushing poetry, p. 58).

Czeslaw Milosz, a Polish poet who won the Nobel Prize in 1980, describes this dearth of interest more poetically:

Poets in the twentieth century are by nature isolated, deprived of a public, 'unrecognized', while the great soul of the people is asleep, unaware of itself and learns of itself only in the poetry of the past (p. 30).

A quick perusal of the entertainment segments on TV and radio, in magazines, newspapers and the Internet reveals an utter fascination, bordering on idolization, of movie actors, film-makers, pop, jazz (and even opera) singers, orchestra conductors, various kinds of musicians and pop novelists. Poets and their collections are rarely, if ever, featured.

An advantage accrues to such anonymity, however: poets are freer to be original because they are spared the judgments of, and subsequent control by, the marketplace. Martindale (1973, 1975, 1990) has shown via an ingenious series of studies involving major

English poets (from 1700 to 1840) and French poets (from 1800 to 1940) that the more autonomy poets have been granted by their period in history, the more innovative they become.

Poets have another advantage over other artists, especially novelists. Given the right circumstances, they can complete a poem in minutes. Canadian poet Gwendolyn MacEwen (1980) succinctly describes the experience:

A poem is a much more rewarding thing to write because very often in the space of half an hour or sometimes even five or ten minutes, you can see the whole thing mapped out before you, at least in rough form. And sometimes the first draft can be the final version of the poem, and it's wonderful that relatively little time expires between the original version and the result So I certainly am more immediately satisfied when I'm writing a poem than when I'm writing prose (p. 65).

My own experience, as well as those of other writers with whom I have discussed this particular issue, confirm MacEwen's observations. Thus poets, while almost invisible compared to prose writers, do have more occasions to privately feel a sense of accomplishment. This must be one of the chief reasons to continue composing poems in the absence of more tangible rewards.

Foreground and Background Factors

All universally creative outcomes, whether artistic or scientific, involve the union or fusion of previously unrelated ideas. Koestler (1964) refers to such processes as 'bisociative thought' (p. 121), Rothenberg (1979) calls them 'Janusian thought' (p. 55) and Ward, Smith & Vaid (1997) depict them as 'conceptual combination and expansion' (p. 10). These terms effectively describe the necessary central associations; for instance, Albert Einstein's theory of relativity fuses energy and matter, or, on a simpler level, this one-line poem by Yukio Mishima (1959/1968), "My solitude grows more and more obese like a pig" (p. 1081), unexpectedly connects pig and solitude.

However, such conceptions are misleading because they imply that creative thinking has to connect only two different planes of thought. While two may be central, they are never enough to fully explain what happened. Einstein had to integrate not only energy and matter, but also time, space, motion and light. Mishima had to include the idea of obesity and the considerations of word choice and word order. Without them, the relationship of pig to solitude would never have worked. The union of two thoughts always involves other ideas, considerations or conditions, such as the routines people establish for doing their work (Swede, 1993). The right setting can facilitate creative work, the wrong one inhibit it. Certain routines are well known, such as those of the popular horror-fiction writer

Stephen King. He gets up each day at 9 a.m., swallows a multiple vitamin pill with a glass of water, turns on the radio and types until 5 p.m. with only a few breaks (Kanfer, 1986). The novelist Marcel Proust could only write in a cork-lined room, and the poet Friedrich Schiller had to sniff rotten apple cores before starting on a poem (Gardner, 1982).

Several poets I know do most of their initial drafts and subsequent revisions in busy cafés and restaurants, often sitting at a table for hours sipping cups of coffee accompanied by the occasional doughnut or piece of pie. Perhaps such circumstances enable a poet to reduce the sense of isolation and therefore better focus on writing. However, these settings might actually *increase* feelings of alienation insofar as the poet's sense of being an outsider is heightened by seeing others absorbed in the more ordinary activities of living. There is evidence to suggest that this hypothesis is more correct, i.e. negative mood seems to be a spur for creativity (see Kaufmann, this volume).

As these examples illustrate, creative thinking involves many factors, not just the central ideas in the finished product. Without a coming together of the right thoughts at a suitable time and place, the creative process flounders, and efficiency falls. An individual in a physically threatening environment—extreme heat or cold and with low water and food supplies—is unlikely to muster the cognitive wherewithal to coordinate the variables needed to make a poem, particularly a great one. For this to happen, the poet must feel safe. However, as Martindale's (1975) and Simonton's (1984) historiometric studies have revealed, personal security is not enough. Unless the culture in which one lives stresses achievement and encourages experimentation, creativity will falter, no matter how safe a person feels. Research shows that universal or exceptional creativity requires that certain background conditions, sometimes surprising ones, such as *not* being married (see Simonton, this volume), exist in addition to the core or foreground ideas.

My interest in the importance of background factors began during graduate school when I published a study showing how surrounding colors and shapes became a part of learning tasks without subject awareness (Swede & McNulty, 1967). This finding altered my views on the extent to which a poet should be considered the sole creator of a poem. I could no longer accept the idea that a poet was completely in charge of the creative process and take all the credit for what he or she produces. Not surprisingly, other poets considered my views misguided, if not downright crazy. My position seemed less exotic when Skinner (1972) published an article in *Saturday Review* based on a talk he had given at the New York Poetry Center. Skinner presents a convincing case that a poet can take very little credit for a poem, that it is mainly the outcome of the poet's genetic and environmental histories over which he or she has little control:

The poet often knows that some part of his history is contributing to the poem he is writing. He may, for example, reject a phrase because he sees that he has borrowed it from something he has read. But it is quite impossible for him to be aware of all his history, and it is in this sense that he does not know where his behavior comes from. Having a poem, like having a baby, is in large part a matter of exploration and discovery, and both the poet and mother are often surprised by what they produce (p. 35).

I wish I had been at the Poetry Center when Skinner gave his talk. The question period must have crackled with the sparks generated by disgruntled poets.

In Skinner's view, then, poetic (or any other kind of) originality is either rewarded or not rewarded by the environment. If it is rewarded, then a person is likely to keep writing poems, provided his or her genes predispose to verbal skills. Amabile's (1983, 1996) extensive research into the social factors involved in creativity chiefly confirm what Skinner says, although she cautions that premature and excessive reinforcement, especially in childhood, might undermine the process.

In what follows, I will discuss what is known about how a person becomes and then stays a poet, and by poet I mean, a *published* poet. By published, I mean that the poet's work has gone through a typical editorial process and has been judged as unique and valuable (and therefore universally creative/innovative) by an editor or team of editors working for a recognized periodical or book publisher, traditionally based or on the Internet. Patrick (1935) established a similar set of criteria (without the option of the Internet, of course) in the selection of the 55 poets for her pioneering study of the steps involved in the composition process.

Becoming a Poet

Chukovsky (1925/1971), a Russian writer who studied the word play of thousands of preschoolers, believed that the child from two to five is a 'linguistic genius' (p. 7). Children at this age, in their attempts to master their first language, invent words, and experiment with rhyme, rhythm and metaphor. They see this learning process not as work, but as play. Chukovsky provides numerous examples, for instance this verse by a four-year-old boy:

The raven looked at the moon—oon—oon
And saw in the sky a yellow balloon
With eyes, nose, and mouth in a round face,
Swimming with clouds at a slow pace (p. 76).

Such complete poems are less typical of preschoolers than word inventions or short rhymes. Here are two charming examples of rhymes by Chukovsky's son at four years. The first involved him "mounted on a broomstick, shouting like one possessed":

I'm a big, big rider,
You're smaller than a spider (p. 64).

The second occurred moments later when sitting down to dinner and "scanning with his spoon, he declaimed":

Give me, give me, before I die,
Lots and lots of potato pie! (p. 65).

With Chukovsky as my inspiration, I kept notes on interesting things said by my two sons during their preschool and early school years. Here are two that startle with their originality:

16/7/1972, Andris, age 3 years, 10 months (in anger to his brother Juris): "I'm going to pull your bones out and swim in you". 19/1/1973, Juris, age: 5 years four months: "I had a bad dream last night, a nightmirror" (Swede, 1976).

Juris's 'nightmirror' could be construed as a mistake, i.e. he really meant to say 'nightmare'. But the aptness of the substitution suggests poetic imagination at play. If instead Juris had said 'nightmayor', then the likelihood that he simply made a homophonic error would be greater. However, the statement by Andris is clearly an intentional use of metaphor, worthy of Stephen King.

My examples and the thousands of statements recorded by Chukovsky as well as by Schwartz and Weir (as cited in Winner, 1982), indicate that metaphorical or poetic thinking is an integral part of first language learning during the preschool years. In fact, suggests Chukovsky (1925/1971), this poetic proclivity has much in common with the adult poet. Then, by five or six, when we have mastered the basics of our first language, such as being able to understand and utter complex sentences, our interest in verbal play diminishes as we pursue new challenges offered by school: how to read and write, do arithmetic, understand science and history. For most students, poetry loses its central importance; it becomes just another topic in the curriculum. If this did not happen, Chukovsky (1925/1971) claims that a child by "the age of ten (would) eclipse any of us with his suppleness and brilliance of speech" (p. 7).

More recent research suggests that the school-age child's capacity for linguistic creativity does not decline as much as Chukovsky and others believed:

When children are asked to explain and produce figurative expressions or to create new ones, they exploit the productive nature of language and are able not only to explain the semantic structure, namely whether certain types of idioms mean what they mean . . . but also to produce idioms and create new figurative expressions for concrete events and abstract mental states (Cacciari, Levorato & Cicogna, 1997, p. 173).

Cacciari et al. (1997) also point out the special nature of verbal creativity compared to other kinds of expression, such as drawing from the imagination non-existent creatures:

Whereas language allows individuals to recombine meanings and referents in an almost infinite number of ways (with the important limitation of the balance between novelty and comprehensibility), the ways in which one might imagine (draw) nonexistent creatures are more limited . . . they are more likely to be predictable from what we know about everyday categorization processes (p. 174).

In other words, drawing imagined creatures will be bound to the limited number of existing schemas for human and/or animal shapes. However, developing verbal metaphors for such things can make use of a virtually unlimited number of word combinations taken from both the natural and human-made worlds. Poets have a definite advantage over visual artists.

What, then, determines that only a few students will go on to have careers as poets? Is there a 'poetry gene'? Very likely not, since complex behaviors involve the interaction of both heredity and environment (Simonton, 1999, this volume). Furthermore, as Lykken (1998) points out, the hereditary component is likely to have a polygenic basis which determines not only a specific ability, but also such traits as persistence, concentration, curiosity and certain physical attributes required by the creative activity, such as hand size for virtuoso pianists (Simonton, 1999). Such characteristics will then interact with the background factors of parental upbringing, peer experiences and type of formal education.

Perhaps the answer lies in adult behavior that can then be traced back to similar actions in childhood. The most noticeable characteristic of exceptionally creative people is their remarkable drive to be original (see Weisberg, this volume). They possess in the extreme what Amabile terms 'task motivation' (1983, p. 393). For example, a well-designed study of outstanding social, biological and physical scientists concluded:

The one thing all of these sixty-four scientists have in common is their driving absorption in their work. They have worked long hours for many years, frequently with no vacations to speak of because they would rather be doing their work than anything else (Roe, 1952, p. 51).

Artists are no different. I have already referred to Stephen King's long hours of work, but Walt Disney perhaps was even more driven. When taking his wife out for dinner Disney would often suggest dropping by the studio for a few minutes, only to end up working until the early morning while his wife slept on the couch (Schickel, 1985, p. 167). This workaholic attitude is likely sown during the childhood and adolescent years, as was the case with the Welsh poet Dylan

Thomas who published his first poem at the age of 11 in his grammar school magazine and at 13 sold his first poem to a Cardiff newspaper (Ferris, 1978). Likewise, Gwendolyn MacEwen, at age 15, published her first poem in a national magazine and left school at 18 to pursue writing prose as well as poetry full-time (Pearce, 1980).

Such an intense drive to compose poetry is partly the result of reinforcement for original verbal utterances or writings by parents, teachers or friends as well as others who capture the young person's imagination—family, teachers, friends who are very interested in poetry or are themselves published poets (Amabile, 1996; Skinner, 1972). Some of these influential persons will likewise serve as models for the child to imitate (Bandura, 1997). The general cultural milieu also will have a strong influence. One that values poetry will stimulate more parents to be supportive of children who show an interest in composing poems. Simonton's (1984, 1997, 1999, this volume) extensive historiometric and archival studies have shown that such influences are especially crucial during the developmental periods of childhood, adolescence and early adulthood.

Of course, children are not merely passive recipients of environmental influences and will interpret the feedback they get from their attempts to create poems and act accordingly to formulate realistic goals. Bandura (1997) describes the origins of the feeling of self-efficacy that is required for achievements of any kind:

Self-efficacy beliefs are constructed from four principal sources of information: enactive mastery experiences that serve as indicators of capability; vicarious experiences that alter efficacy beliefs through transmission of competencies and comparison with the attainments others; verbal persuasion and allied types of social influences that one possesses certain capabilities; and physiological and affective states from which people partly judge their capableness, strength, and vulnerability to dysfunction. Any given influence, depending on its form, may operate through one or more of these sources of efficacy information (p. 79).

Thus, accomplishment is more than the result of environmental reward and punishment. It also involves how we interpret such experiences and parlay our understanding into behavior that is effective in getting to our goals, in this case, the writing and publishing of poems.

In his autobiography, the influential American poet William Carlos Williams (1958) provides evidence of all these forces at work. He became seriously interested in poetry at age 16 when forced to give up baseball and running because of a heart murmur, "I was forced back on myself. I had to think about myself, look into myself. And I began to read" (p. 1). Someone else

might have taken up stamp collecting, but Williams from early childhood had been raised in a family that valued language and literature:

My father was an Englishman who never got over being an Englishman. He had a love of the written word. Shakespeare meant everything to him. He read the plays to my mother and my brother and myself. He read well. I was deeply impressed (p. 2).

Williams took the sense of self-efficacy formed by success in baseball and track and redirected it toward other areas for which he was also well prepared—reading and, eventually, writing poems—pursuits which continued even during the rigors of medical school. As mentioned earlier, Dylan Thomas was even more precocious due in large part to a father who was an English teacher and who encouraged Thomas' 'natural passion for words' (Ferris, 1978, p. 29) from the early pre-school years, thus developing even earlier a sense of self-efficacy for poem-making. A look at the biographies and autobiographies of a dozen other poets on my bookshelves revealed similar pre-adult experiences.

However, students shaped by such circumstances to become serious poets face daunting tasks: how to become a voice distinct from contemporaries as well as poets from the past and how to maintain this uniqueness over the course of a career. As mentioned earlier, such a focus on novelty or newness is most acute in the arts, but some other pursuits, such as inventor, research scientist, and explorer, have similar pressures.

Staying Productive and Innovative—Behavioral Traits

An Intense Devotion to Work

In the preceding discussion, I have cited controlled research as well as anecdotal evidence which shows that an intense devotion to work is characteristic of universally creative individuals in all walks of life, not just in the arts. However, much speculation exists about why such driven behavior occurs and how it is maintained. Woodman (1981) examined the explanations of major personality theorists and concludes that none provide the entire answer. Donald MacKinnon (1978) suggests the possible reasons why:

Creative behavior is not different from any other form of behavior in being almost certainly the expression of not only one, but many motives. We need not choose among the different motivational theories of creative behavior. We can find confirming cases for each of them. Our need is to seek for still other and as yet unnoticed motivational factors leading to creative striving, and demonstrate, not how each of them is a given factor in any given bit of creative behavior for a given person, but how they act in concert in the creative striving of persons (p. 197).

MacKinnon's motivational criteria are largely met by Bandura's (1997) theory of self-efficacy which explains the complex interaction of experiences necessary for the high drive needed for great achievement: a sense of mastery from successful achievement (a finished poem); learning from and comparing oneself to significant others (admired, eminent poets); getting the approval from significant others (valued teachers, critics, or eminent poets); and finally, the positive affective and physiological states accompanying these experiences (mental and physical well-being). Self-efficacy theory is thus an effective blend of well-established results from conditioning, social-learning, cognitive science and the physiology of stress and coping.

Quality and Quantity of Output

Of the variables, other than hard work, that seem to be necessary for exceptional creativity, two of the most relevant are high quality and high quantity of output. David Perkins (1981) found that poets judged as superior outperformed less talented colleagues on both measures:

They could get more quantity for the same quality, or more quality for the same quantity (p. 142).

The better poets were simply more efficient in achieving quality, that is, they simply did more good work. Studies of other kinds of universal creators have shown similar results: American scientists who have won the Nobel Prize published an average of 3.24 papers per year compared to 1.48 by a matched comparison sample (Zukerman's study as cited in Simonton, 1984, pp. 84–85); the top 10% of individuals in seven different fields produced 50% of the work (Dennis' study as cited by Simonton, 1984, p. 79).

Perhaps a cause-and-effect relationship exists: quantity begets quality. The more one produces, the more likely something worthwhile will occur, i.e. the more streams a prospector pans for gold, the more nuggets he or she will find. However, this suggests a purely mechanical relationship between effort and success which does not explain individuals concerned chiefly with quantity of output. For instance, during the 1980s, an American artist received media attention for oil-painting thousands of landscapes per year, yet not one of them reached more than a minimally acceptable standard. Around the same time, a Canadian writer gained much publicity for publishing more novels (several hundred) than any other writer in history, but none of his books earned critical acclaim, and likely never will. Obviously, a large capacity for work and a huge output are not enough for greatness.

Then there are those universal innovators whose work reveals a high quality but who have a low output. Gregor Mendel, the father of modern genetics, published only seven papers in his lifetime, and Bernard

Reiman, an influential mathematician, totaled a mere 19 (Simonton, 1984). Compared to others of his stature and longevity, Walt Whitman wrote a small number of poems, all of which ended up in his only collection, *Leaves of Grass*. The first edition of this masterpiece, self-published in 1855, contained only 12 poems, while the ninth and last edition, done in 1892, contained 400 pieces (Whitman, 1969). By comparison, both eminent and average universal poets frequently publish two or three times as many, either during their lifetime, posthumously, or both.

But simply counting the number of poems is a process full of pitfalls. Some poets, like Whitman, write mainly long poems (more than a page with lengthy individual lines, while others, like Emily Dickinson, write chiefly short ones, usually less than a page and with brief individual lines (Allen et al., 1965). To date, Dickinson has had close to 600 of her poems published, mainly posthumously (Dickinson, 2002). This is 50% more than the output of Whitman, but in terms of the number of actual words in print, perhaps Whitman has more. In spite of such technical details, the overall evidence clearly shows that work of high quality is necessary and sufficient for perceived greatness—high output by itself is not.

However, we must beware of the dizzying effects of circular reasoning in relation to quality and greatness. How do we know someone is a genius? Because others say so. And, how do we know the work is of high quality? Because the creator is a genius. This kind of logic is very difficult, if not impossible, to avoid to some degree.

Further complicating matters is the fact that historical assessments of the quality of an artist's work can change dramatically with passing time, i.e. artists' reputations are not constant. Except for literary scholars, who now remembers these poets, celebrated as much as pop music stars in their time: Richard Brautigan, Kahlil Gibran and Rod McKuen? Then there are those poets who were unappreciated while they lived, yet acquired legendary status after their deaths: Emily Dickinson and Walt Whitman.

The Possession of High Standards and the Need to Prove Oneself

What motivates one universal creator to seek high quality and another to hold quantity more dear? Barron (1969) reports on a series of controlled studies at the Institute of Personality Assessment and Research (IPAR) at Berkeley which compared outstanding writers, architects, mathematicians to those with only average success in these fields on a number of personality measures. The former possessed significantly higher ideals for what they produced. The elite group seemed to have higher standards (p. 71), ones that go beyond the norms for professional competence. A typical example of the search for such excellence is Anne Sexton who "would willingly push a poem

through twenty or more drafts" (Maxine Kumin as quoted by Middlebrook, 1991, p. 94).

Another finding reported by Barron has a clinical undertone:

Creative individuals are very much concerned about their personal adequacy, and one of their strongest motivations is to prove themselves (1969, p. 70).

Barron's interpretation suggests that the need to prove oneself is a characteristic different from the possession of high standards. More likely, they are merely different expressions of a strong sense of self-efficacy. Someone who has written outstanding poems in the past will want to maintain his or her high standards in the future. Naturally, some anxiety about possible failure will occur, and this might be what the IPAR research was tapping through their testing and interviewing procedures. Such anxiety is perfectly normal, not pathological, as hinted at by Barron's interpretation.

A problem with the criterion of high standards is that it does not remain constant in the lives of eminent creators. Most of the work they produce is not of the highest quality. Of the two or three thousand poems an outstanding poet typically publishes, only a handful, usually 50 or 60, get reprinted in various anthologies of best poems. The rest are deemed merely very good, but minor works. The same can be said for all other enterprises, scientific as well as artistic (Dennis, 1966; Simonton, this volume; Weisberg, this volume).

A Strong Sense of Reality and Intrinsic Motivation

According to the IPAR studies, a fourth feature of exceptional creators seems to be their strong sense of reality, or what Barron (1969) refers to as 'ego strength' (p. 73). Using the results of interviews and personality tests, such as the Minnesota Multiphasic Personality Inventory and the California Psychological Inventory, Barron reports that the outstanding architects, mathematicians and writers scored consistently higher than representative samples in the same occupation who, in turn, scored higher than the general population. Such findings make considerable sense because writing a poem involves having to make unusual or unexpected connections among disparate objects or events. Only someone with a strong sense of how things actually are would feel secure enough to do this. But again we must be cautious. Mackinnon (1978) points out that no one motive is sufficient. Among the individuals in the general population studied by the IPAR must have been some individuals with a very strong sense of reality but with no desire to become eminent achievers.

Another characteristic, often commented upon, is the independence or intrinsic motivation shown by exceptional creators. The studies reported by Barron (1969) confirm this, and so do many other observations, informal and formal (Amabile, 1996; Kenner, 1971;

Middlebrook, 1991; Simonton, 1984; Winner, 1982). As Amabile (1996) points out, however, not everyone falls into a neat formula. The self-motivation of some creators, especially writers, is vulnerable to external forces. For instance Amabile analyses Sylvia Plath's spiral to self-destruction as the result of over-dependency on the approval of others:

The greatest burden that impeded Plath's writing during her postcollege years is an extrinsic constraint that, perhaps more than any other specific social factor, appears to undermine the creativity of outstanding individuals: the expectation of external evaluation, and the attendant concern with external recognition (p. 11).

While Plath became increasingly reliant on approval from others, her contemporary, Anne Sexton, became more independent with age. She accomplished this despite serious problems with alcohol and drugs and critics who could not abide a woman speaking frankly about "menstruation, abortion, masturbation, incest, adultery and drug addiction at a time (the 1960s) when the proprieties embraced none of these as proper topics for poetry" (Middlebrook, 1991, pp. 143–144).

How do we explain the difference between Plath and Sexton? Amabile (1996) suggests that in childhood Sexton learned how to deal with external pressure and stay true to her beliefs, although not without a price, as indicated above. In Bandura's (1997) terms, she developed the necessary beliefs of self-efficacy, at least in relation to her poetry. Most elite poets with whom I am familiar seem to be more like Sexton than Plath.

Correlation Is Not Causation

So far, I have discussed six traits associated with outstanding universal achievers: hard-working, high output, high standards, a need to prove oneself, fierce independence and a strong sense of reality. But a problem exists: we know of these characteristics only from correlational studies and not from ones designed to discover cause-and-effect relationships. Weisberg (1986) describes the problem succinctly:

If creative artists are more autonomous . . . it is then concluded that the autonomy contributed to their creativity. Such a conclusion is unjustified, however—all that has been demonstrated is a correlation between autonomy and creativity, not that the former was a cause of the latter . . . the exact opposite might be true—being creative might make one autonomous (p. 78).

The eminent universal creators might have become more productive and formed a stronger sense of reality *after* they became successful. This is quite likely if we

consider that positive reinforcement creates a sense of self-efficacy which then leads to more rewards and more feelings of accomplishment and ultimately a strong belief in one's own worthiness (Bandura, 1997).

Creativity and Madness

I have left discussion of the following trait to the last because it has received the most attention and is widely believed to be true: that universally creative artists, writers and scientists are more likely to be crazy than the average person. The following 20th-century writers and their circumstances immediately come to mind: Virginia Woolf, Sylvia Plath, Ernest Hemingway, and Yukio Mishima committed suicide; Dylan Thomas and Jack Kerouac drank themselves to death; Ezra Pound, Theodore Roethke and Robert Lowell spent considerable time in mental institutions. These examples are well known to me because of my involvement with literature. Readers with interests in the visual arts, the sciences or leadership could produce similar lists just as easily.

Recent articles in well-respected journals have reinforced the idea that high achievement and madness are allied. For instance, one of the most widely quoted by the media has been 'Manic-Depressive Illness and Creativity' by Kay Redfield Jamison which appeared in a 1995 issue of *Scientific American*. Jamison marshals evidence to suggest that:

Highly creative individuals experience major mood disorders more often than do other groups in the general population (p. 66)

Her catalogue of elite creative persons with presumed manic-depressive psychosis is impressive. Among the 18th- and 19th-century poets she lists are William Blake, Lord Byron, Edgar Allan Poe, Alfred Lord Tennyson, while the poets from the 20th-century include John Berryman, Randall Jarrell, Robert Lowell, Sylvia Plath, Theodore Roethke, Delmore Schwartz and Anne Sexton. Among other kinds of writers she mentions are Ernest Hemingway, Herman Hesse, Mark Twain, Tennessee Williams and Virginia Woolf. Non-writers include Vincent van Gogh, Gustav Mahler, Charles Mingus, Georgia O'keeffe, Mark Rothko and Robert Schumann. Jamison's main argument is that the manic phase helps spur universal creativity:

The common features of hypomania [mild mania] seem highly conducive to original thinking; the diagnostic criteria for this phase of the disorder include 'sharpened and unusually creative thinking and increased productivity' . . . the cognitive styles associated with hypomania (namely, expansive thought and grandiose moods) can lead to increased fluency and frequency of thoughts (p. 66).

Nevertheless, Jamison cautions against leaving this illness untreated:

Manic-depressive illness often worsens over time—and no one is creative when severely depressed, psychotic or dead (p. 67).

Basically, Jamison points out the dual nature of a particular illness. In its early stages, manic-depressive illness can help *some* persons, not all, to be more creative. But in its later stages, if left untreated, it is more debilitating than beneficial.

In apparent agreement, Barron (1969) reports that exceptional writers have more psychopathology than average writers, and both have more than the individuals at large. Thus, we have a paradox. The highly creative are both more in touch with reality (see above) and also less in touch. However, Barron provides as good an explanation as anyone has to date:

If one is to take these test results seriously, creative individuals appear to be both sicker and healthier psychologically than people in general. Or, to put it another way, they are much more troubled psychologically, but they also have far greater resources with which to deal with their troubles. This jibes rather well with their social behavior . . . They are clearly effective people who handle themselves with pride and distinctiveness, but the face they turn to the world is sometimes one of pain, often one of protest, sometimes of distance and withdrawal; and certainly they are emotional (p. 75).

Of course, this does not mean that a person who has these characteristics will necessarily become exceptionally creative. All we can say for sure is that the traits uncovered at the IPAR co-exist with the capacity for high achievement. We cannot say that they are necessary for creative success, for surely there are persons who are both sicker and healthier who do not accomplish anything, nor have the desire to do so.

Studies which came after those conducted at the IPAR, and which have compared the frequency of psychiatric problems in the general population with those in the sub-group of the exceptionally creative, show that these two populations do *not* differ, i.e. both have the same degree of psychological pathology, around 10% (Simonton, 1984). Yet the belief that madness is married to creativity persists. Perhaps exceptional creators behave in ways that, while not psychotic, are strange or eccentric. And maybe observers call this behavior crazy or mad when they really mean to say the behavior is unusual or beyond the norm. Schubert & Biondi (1977) add some more details to this view:

Some individuals find it difficult to respond creatively while in the mainstream of daily chores. They require . . . unprogrammed activity time for the more

fulfilling release of their creative potential. Withdrawal may provide them with the needed time (p. 192).

The striving for creative goals sometimes requires unusual coping strategies which are misinterpreted by others as abnormal. They are abnormal (read unusual), but they are not crazy in the clinical sense, just eccentric.

Another variable at play here is that people *expect* the exceptionally creative to display strange behavior. And, we know that when others expect us to do something, we tend to oblige. Bandura (1997) succinctly terms this interaction 'reciprocal determinism' (p. 6). The behavior might not really be so strange in itself but be unusual given the circumstances. For instance, a poet in the fever of composition might be late for a wedding at which he is the best man. Continuing with something while inspired is perfectly normal, but not when others are counting on you to perform a duty at a certain time. The groom, however, is likely to excuse his poet-friend precisely because he is a poet, i.e. poets are unreliable. Meanwhile, the poet in question might actually have made a conscious decision to be late because he knows that his friend believes poets tend to be late.

Still one more factor complicates matters: historical variations in cultural expectations for the kinds of thought process which the poet or artist should employ. Quite likely, poets who lived during times when their culture demanded realistic images and a particular form (French Romantic and English Neo-Classical), had different personalities to those who lived during eras which required unusual images and breaks with form (French Symbolist and English Metaphysical). Colin Martindale (1990) found evidence for more psychopathology among the latter group of poets (Baudelaire, Rimbaud and Donne, Marvell) than among the former (Hugo, Chateaubriand and Pope, Dryden). Of course, such finding leads to the classic chicken and egg argument: Do people with psychopathological tendencies become poets when distant associations and a break with convention are the poetic styles or do the demands for unusual imagery and rule-breaking create pathology in poets who started out as normal? Today, no clear cultural expectations exist, and thus poets have more freedom to follow their inclinations. In my experience, persons who show unusual thought processes in their daily interactions also tend to prefer writing poetry that uses primordial thinking and regressive imagery, as found with the Symbolists and Metaphysicals. In other words, the individual appears to select the style best suited to his or her personality.

Staying Productive and Innovative—Background Influences

I have dealt with behaviors common to elite universal creators, focusing on the poets among them. I have also

referred to a number of background influences, such as genetics, family, age and education, historical period and culture. Now I would like to elaborate on four of these—intelligence, higher education, gender and age.

Intelligence, Creativity and Poetic Creativity

Over the years, evidence has mounted that creativity is an ability distinct from intelligence, at least as defined by IQ tests (Sternberg, 1988; see also Sternberg et al., this volume). Nevertheless, creativity and intelligence are positively related. Before persons can be creative in fields such as mathematics or architecture, they need above-average intelligence, that is, an IQ higher than 100. Otherwise, they will be unable to master the body of knowledge required (Simonton, 1984).

But mathematicians, architects, or writers with IQs above those of their colleagues will not necessarily be more creative. In fact, Barron (1969) reports findings at the IPAR which reveal that outstanding and average creators in all fields studied have almost identical IQs. The most eminent writers have IQs no higher than their less illustrious colleagues. Simonton (1984) summarizes the relationship of IQ to creativity in the following way:

There is a positive relationship between intelligence and creativity . . . but it tends to vanish in the upper reaches of intelligence. Beyond an IQ of around 120, further gains in IQ do not increase the likelihood of creative achievement. An IQ of 120 is not a very selective cut-off point: it marks the average intelligence of college students . . . and about 10% of the general population has an IQ of 120 or higher (p. 45).

The implications are important for the education of our children because, for generations, educators have valued intelligence more than creativity. This can be seen in the use of the term ‘gifted’. Educators almost always apply it to students with high IQs. Whether the students also have high creativity or not has little bearing.

In North America, an elementary school student who obtains extraordinarily high marks will be given an IQ test, or some other kind of similar test with definite right or wrong answers, to determine whether the child is truly very intelligent or is an overachiever. If the student scores high on the independent test(s), he or she will be deemed gifted. Creativity tests, in which there are no right or wrong answers, are rarely given in such circumstances.

During visits as a poet to hundreds of schools, I have found that the natural urge for poetic creativity will spring to life in even the most depressed children, ones about whom anxious teachers have warned me beforehand. In a free-spirited, non-threatening workshop environment, such children soon will be not only reading and enjoying all kinds of poetry, but writing

their own as well. In such sessions, the so-called ‘at risk’ children often reveal heretofore hidden above-average capacity for what Root-Bernstein and Root-Bernstein call ‘thinking with feeling’ (see this volume). Dozens of teachers have privately told me how surprised they were that some of their worst students wrote the best poems. A number of other writers who have conducted workshops in schools report similar experiences (Swede, 1990).

What this shows is the importance of inserting creativity sessions (painting, dance, music as well as poetry) into the school curriculum, ones in which there are no grades and, thus, no failures. Given such an opportunity, the poorly performing students, who have practically given up in their regular classes, might discover above-average creative abilities. The subsequent improvement in feelings of self-efficacy would likely result in better school marks.

Higher Education and Poetic Creativity

According to Billy Collins, a recent U.S. poet laureate, over 200 master of fine arts programs offer an education in how to write poetry (‘Pushing Poetry’, 2001). Seemingly, higher education is necessary for creating poems that people will want to read. Ironically, this might be the case for modest, but not for exceptional, universal creators. Simonton (1984) has done historiometric studies on the greatest achievers in science, the arts, humanities and leadership which suggest that the relationship between education and success is not at all straightforward. After examining the educational backgrounds of a large variety and range of universal creators who lived between 1450 and 1850, he found that three to four years of college seemed the optimum for the greatest achievements. Or, put another way, persons with *fewer* than three or four years of college as well as those with *more* than three or four years were universal creators of lesser rank. In fact, the lowest-rated creators were those with doctorates. Simonton also examined the educational levels of 125 20th-century exceptional individuals in the arts and humanities and found an almost identical pattern. But his analysis of 20 modern scientists revealed a slight change from the earlier sample. Most went on to do graduate work, but without getting a degree.

A possible explanation for these findings is that a few years of university stimulate creativity and that further training causes too much dependence on traditional perspectives. Such reasoning is dangerously close to being circular, however, for it goes little beyond what the data reveal in the first place. Simonton offers a better interpretation:

Perhaps the most securely directed and confident geniuses go to school only until they obtain the required knowledge and technical ability, and then quit. Creators of the highest rank tend to split off from conventional perspectives, and they may

discover that higher education does not contribute to goals that lie outside the mainstream. Their less illustrious colleagues, who attain fame not so much by changing the course of history as by advancing it, find that formal education improves their opportunity for achievement. It is important to note that . . . graduate education is (not) detrimental in any direct way to the development of the highest creative potential, but only that it may be irrelevant (p. 73).

This interpretation only has a partial fit for poets. An exceptional physicist will gain the knowledge he or she needs and then quit higher education and go to work as a physicist. But poetry's low popularity makes it necessary for elite universal poets to find other ways to support themselves. None can make a living through sales of books, tapes, and videos, or from fees for public appearances. Therefore, many elite universal poets, like Billy Collins, stay in school in order to qualify for employment in departments of English at universities where they teach literature and usually creative writing as well. Others continue with studies not related to poetry in order to support themselves. William Carlos Williams became a medical doctor to sustain his poetry career. Wallace Stephens became a lawyer. In other cases, a poet will find someone else to support them, as with Anne Sexton who married a prosperous businessman. Sometimes a poet, such as Gwendolyn MacEwen, will do other kinds of writing to supplement her income.

Gender and Poetic Creativity

Most psychological studies of universal innovation continue to be based on men (see this volume: Root-Bernstein & Root-Bernstein, Simonton, Sternberg et al., Vandervert, Weisberg). The chief reason is that exceptional creators have been, and continue to be, almost exclusively male in the domains of science, technology, business, politics and many, but not all, of the arts. Of course, this does not mean that women are uncreative. No evidence exists to show that women are less curious than men, that they have less desire for novelty and change. But there is much data to show how powerful social and political pressures have restricted women's opportunities chiefly to personal one and two kinds of creativity, ones that according to traditional views are unacknowledged as creative: child-rearing, teaching, entertaining, sewing, cooking, gardening and charity work (Swede, 1993)

One has only to look at the history of women's rights to see how recently political circumstances have improved. Less than 100 years ago, in 1907, Norway granted women the right to vote and then was followed by other Western countries over the next decade or so (Swede, 1993). While such legislation changed women's legal rights, social pressures continue to limit the opportunities of women in business, science and technology (Bandura, 1997; Gornick, 1983). Most

women still learn during childhood and adolescence that some occupations are more suitable for men. They internalize such distinctions in spite of wide-ranging efforts by educators, business and governments to encourage girls to consider suitable careers in science and technology (Bandura, 1997; Gornick, 1983). If women do decide to become scientists, their salaries, however, will be below those of men with a similar education and job title (Gornick, 1983).

In the arts, women have fared better, at least according to what we see in the popular media. Female actors, singers and musicians seem to be as successful as their male counterparts, if not more so. This is quite a leap forward considering that Western women were not allowed on stage until the 17th century (Montagu, 1968). But apart from these impressions, no comprehensive data exist on either male or female artists. One reason seems to be that most poets, novelists, painters, and musicians, whether women or men, do not earn enough from their craft and must make money doing other things, with the result that their artistic earnings become difficult to locate in government files on income (Swede, 1993). Another difficulty is the lack of specific criteria for the term 'artist'. How do we classify the sound person on a movie set—as a scientist or artist? What about newscasters: are they actors or not? And are the writers of the memorable jingles for retail products lyricists/composers or business people?

To get a sense of how women are doing in poetry, I tabulated the number of males and females who are in the *League of Canadian Poets-Membership List, 2001/2002*. The full membership criteria, as described in *The League By-Law and Guide For Members*, fit well with my working definition of an average universal poet described earlier insofar as eligibility is ultimately based on 'sufficient poetic achievement' (p. 5). Of the 304 full members, roughly 55% were women. Clearly, in Canada at least, women have taken giant strides in the domain of poetry, their numbers approximating those in the general population (Census, 2002; Statistics Canada, 2001).

The focus of this chapter is, however, on eminent universal poets, ones who go beyond merely being sufficient achievers. Getting data about such persons is a daunting task because one cannot find agreement about whom to include on this list, for no by-laws or membership criteria exist. I finally chose to focus on the Poet Laureates of the United States and England because the selection process is very formal, involving numerous checks and balances. In England, the office was created in 1591 and became official in 1668 and has always been awarded for life. At the time of the Laureate's death, the prime minister nominates a number of possible successors from which the reigning monarch chooses one (Poets Laureate of England, 2002). The U.S. criteria have undergone a number of changes since the office originated in 1937. Today, the rules governing the position are as follows:

The Poet Laureate is appointed annually by the Librarian of Congress and serves from October to May. In making the appointment, the Librarian consults with former appointees, the current Laureate, and distinguished poetry critics (Poet Laureate Consultant in Poetry, 2002, p. 3).

Of the 23 English Laureates, official and unofficial, *none* have been women (Poet Laureates of England, 2002) and of the 41 U.S. Laureates, only eight have been female (Poet Laureate Consultant in Poetry, 2002). These data reveal that gender equality does not extend to the upper levels of achievement. Such a finding is likely due to the different things boys and girls learn are important in life:

The male instrumental role, with its goal and achievement orientation, helps males succeed in work, while the female expressive role, with its emphasis on nurturing and dependency, may not. As a result, women may lack some of the skills, values, and attitudes toward the self that would lead them to the highest levels of occupational achievement (Lemme, 2002, p. 323).

In the literary arts, however, male dominance of the highest rungs of accomplishment is somewhat surprising in light of the long-standing evidence of a slight female superiority in verbal skills (Joseph, 2000). What this demonstrates is the pervasive influence of gender role socialization.

Age and Poetic Creativity

At what age are the exceptionally creative most likely to do their best work? The answer will depend, to some extent, on the kind of activity. Eminent achievement in dance surely reaches an apex before that in more sedentary activities, such as star-gazing or writing poetry. While age and achievement have yet to be studied in many fields—dance and astronomy included—enough data exist to draw some tentative, general conclusions. Creativity, in both quality and quantity, usually peaks around the age of 40, give or take five years (Dennis, 1966; Lehman, 1953; Simonton, 1984). This usually follows a pattern: creativity rapidly rises to this peak and then declines gradually, with the consequence that about one-half of all significant contributions to culture are made by persons 40 years or older (Dennis, 1966; Lehman, 1953; Simonton, 1984).

Another aspect is the relationship of quality to quantity. According to Dennis (1966), the ratio of major to minor achievements remains roughly the same throughout adulthood, and therefore the periods of greatest output also contain the greatest number of significant works. Recent data gathered by Weisberg (this volume) suggest a more complicated relationship, i.e. early major works might be of lesser quality than

those which arise when the universal creator has mastered the required skills more fully.

Dennis (1966) also found differences among the areas of scholarship, science and the arts. Productivity in the arts peaks, as well as declines, earlier than in the sciences and scholarship. Artists tend to be more productive in their twenties than scientists and scholars and less productive in their seventies. In addition, the peak periods in some disciplines within scholarship (history, philosophy) and the sciences (botany, invention, mathematics) occur during the decades of the fifties and sixties.

Dennis provides widely accepted explanations for these differences. He believes that the early peak in the arts is due to less demanding educational requirements. Individuals in the sciences and scholarship must digest vast amounts of formal knowledge before they can conduct original experiments or write a book, whereas those in the arts do not need such extensive background information before putting brush to canvas, foot to stage or pen to paper.

The faster decline in the arts, Dennis feels, can be explained by different working styles. Many artists—painters, novelists, poets, composers—are universal one creators in that they typically work alone. Most scientists and scholars are universal two creators because they get the assistance of graduate students, or they collaborate with colleagues who have the same goals. Working in such teams likely conserves energy and time and thus prolongs creative life.

Explanations, of course, are never that simple. Dennis found that poets peak in the forties and novelists in the fifties. Simonton (1975), in a more precise comparison, found that poets reach their peak at an earlier age than novelists, 39 vs. 43, and provides an explanation for why a difference of four years is significant:

It is large enough to help explain why the reputations of poets may survive even if the poets die at younger ages than do novelists . . . Twice as much of a poet's lifetime output comes from the twenties as is the case for novelists (p. 101).

Both Dennis and Simonton suggest that the reason for this difference is that a novelist requires more life experience to write a novel than a poet does to construct a poem.

A further complication is the fact that many of the arts are as collaborative as the sciences (or even more so). In fact, the most popular of the arts—music and film—always involve universal two creativity in the production phase. A Broadway musical or Hollywood film might start in the mind of an individual composer or writer, but in the end they involve a large number of individuals who are also being creative: the producers and directors, the musicians, the singers, the actors and the various kinds of stage and movie technicians. To

date, no universal two creators have been the subjects of study. Perhaps, because they engage in collaboration, directors, actors and musicians might have longer creative lives than painters, poets and novelists, thus limiting the conclusions of Dennis.

Also, what happens to creativity when a person changes fields? Does a poet who becomes a novelist lengthen his or her creative life? Does a novelist who becomes a poet shorten it? Simonton (see this volume) suggests that both will start with fresh creative potential in their new careers and follow the typical productivity pattern for those endeavors described earlier. Personal observation appears to confirm this view. For instance, Margaret Atwood began as a poet, publishing a pamphlet in 1961, and a book-length collection in 1966, which won Canada's prestigious Governor General's Award. Eventually, she switched most of her energy and time to writing novels and other prose for which she first received worldwide acclaim in the 1980s (Benson & Toye, 1997). But the changeover has not been complete for, in 1995, she published a collection of poetry. Simonton (this volume) believes that such back-and-forth flexibility sustains creativity.

Concluding Remarks

This chapter has looked at what we know about how someone becomes an eminent universal poet. Was information conveyed that would be helpful to students of poetry, to aspiring poets and to literary scholars? My guess is both yes and no. Apart from those who believe that great poetry comes from some sort of divine inspiration, most will not be surprised to learn that to become exceptional, a poet must have experienced early nurturing of verbal skills as well as reinforcement for subsequent poetic displays. Students, poets and scholars will appreciate, however, the attempts to explain the details of how this happens. In particular, they should find Bandura's (1997) efficacy theory helpful in explaining why someone will continue to write poems in a culture that does not value poets as much as it values other kinds of artists, such as novelists, film-makers and musicians.

Examined too were the things a poet must do to remain outstanding. Here again some findings merely confirm the obvious while others do illuminate. That the elite universal poet is driven to work hard and to have an output of high quality and, typically, also of high quantity, will not be stunning revelations to fellow poets and literary critics. Neither will the conclusions that the exceptional poet possesses high standards, a need to prove oneself, a strong sense of reality and fierce independence. However, the suggestion that these characteristics develop as a result of success, rather than being causes of it, should be newsworthy. Not so enlightening will be the finding that personality might determine the kind of poetry someone chooses to write rather than the reverse. But, especially interesting should be the revelation that madness is no more

prevalent among super universal creators than it is among the general population.

This chapter also points out the importance of background influences. The finding that creativity and intelligence are related and yet ultimately distinct definitely will be of interest. That poets do not need to finish a university degree in literature or creative writing in order to produce poems will not come as a surprise, nor will the scarcity of women among eminent poets. The relationship of age to creativity might raise some eyebrows in poetry circles for it is not generally known that poets bloom earlier and fade sooner than scientists and scholars (see Simonton, this volume).

Of course, a few questions remain unanswered. They are mainly about the precise nature of the creative process—how poetically meaningful associations are formed, step by step. As a result of some ingenious studies involving practicing poets, Perkins (1981) concludes that the making of poems is mainly a trial-and-error process and occurs on the conscious rather than unconscious level—findings many poets will not greet kindly. Ultimately, we need to know what happens at the level of brain regions and neuronal circuitry. Data from such research are imminent (see Vandervert, this volume) and will provide a stringent test for Perkins' conclusions.

Directions for Innovation in Music Education: Integrating Conceptions of Musical Giftedness into General Educational Practice and Enhancing Innovation on the Part of Musically Gifted Students

Larry Scripp¹ and Rena F. Subotnik²

¹ *New England Conservatory and Conservatory Lab Charter School, USA*

² *Center For Gifted Education Policy, American Psychological Foundation, USA*

Abstract: Five strategic steps posited here suggest a course of action that can lead to systemic and sustainable innovation in public-school music education: (1) reconcile perspectives regarding the purpose of music education; (2) establish a framework for comprehensive, interdisciplinary programs that are intended to benefit all children; (3) prepare advanced college-conservatory students to contribute to the development and sustainability of innovative programs as 'artist-teacher-scholars'; (4) form networks of college-conservatory, arts organization, and public school partnerships; and (5) explore and promote new conceptions of giftedness that result from the implementation of innovative forms of music education practices in public schools.

Keywords: Innovation; Music education; Innovative programs; Giftedness; College-conservatory networks; Learning through Music; Music in Education; Artist-Teacher-Scholar; Conservatory Lab Charter School.

Introduction

Only an inventor knows how to borrow, and every person is or should be an inventor (Ralph Waldo Emerson).

Research conducted during the last several decades suggests new frameworks for understanding the relationship between conceptions of giftedness in music and innovative music education practices in public schools. Two path-breaking approaches to music education have demonstrated that ordinary young children can develop musical performance ability at a level formerly associated with giftedness in music. The two approaches include: (1) a musical 'language acquisition' system (such as Suzuki's (1981, 1969)

violin study method¹ that builds on the cumulative memorization of progressively more difficult repertoire); and (2) a 'language literacy' system (such as

¹ See Suzuki's *Ability Development from Age Zero* (1981) and *Nurtured by Love* (1969) for descriptions of his 'mother tongue' approach to learning the violin and violin music, an approach which Suzuki claims makes musical skill development analogous to language acquisition. Hence the characterization of his teaching as 'talent development' allows him to claim that prior musical talent has relatively little to do with the success of his violin method. Despite the worldwide acclaim for unprecedented success in training young musicians to memorize violin repertoire at an early age, Suzuki's approach is thought to be too narrowly focused on instrumental skills and does not lend itself well to general musical abilities, including the ability to read, compose, or analyze music.

Kodály's (1974) choral method² based on the ability to use syllables to sight-sing progressively more difficult materials derived from folk songs). Taken together, these practices have greatly expanded educators' and parents' notions of every child's musical potential (Davidson & Scripp, 1989).³

For those unaware of recent innovations in violin instruction, witnessing groups of young children performing violin concertos together remains astonishing. However, parents who support their children in Suzuki violin classes for a few years can take for granted that their children will acquire a level of violin performance repertoire previously demonstrated only by the most advanced children. Similarly, all parents who enroll their children in Kodály classes now can expect their children to develop basic literacy skills that most adults make no pretense of mastering. Although the ability to read books is expected of every child, most adults still believe that only a select number of musically gifted children can sight-sing choral pieces without prior rehearsal or accompaniment (a cappella). In short, measures of basic intelligence expected in other modes of education—the ability to read and recite familiar literature—have widely been considered as exclusively within the purview of education for musically gifted children.

Innovations in pedagogy have made the study of violin playing and music reading accessible to all young children who engage seriously with these pedagogical approaches, yet neighborhood schools remain remiss in providing these opportunities. The lingering impression that musical skill exists as a measure of a special talent keeps music in the box of special education for the gifted. Parents who can afford violin lessons for their children know that all children can benefit enormously from this experience, yet little impetus exists for making high-quality musical education available to all children.

² See *The Selected Writings of Zoltán Kodály* (1974) for descriptions of the training of early literacy skills as the basis for a nationwide choral program in Hungary. The success of his sight-singing methods led to its dissemination in the United States in the 1970s which resulted in modest scale studies of the effect of music reading through sight-singing on academic learning that have been replicated in the 1990s (Gardiner, 2000; Gardiner, Fox, Knowles & Jeffrey, 1996). The Kodaly approach remains a desired professional certification, yet whole school or district implementation in the United States remains elusive, partly because of its focus entirely on choral repertoire for young children and sight-singing skills based on a strict and somewhat inflexible progression of folk tunes.

³ In Davidson & Scripp's 'Education and development from a cognitive perspective' (1989) innovations in music pedagogy are assessed in relation to developmental frameworks for musical development that emerged from their work at Harvard Project Zero.

Failure to incorporate proven innovations in music education also blinds us to the contributions that learning in and through music can make to both the ordinary and the extraordinary public-school student. Environmental 'conditions of support' that can be provided by virtually any family are known now to predict children's musical development (Davidson & Scripp, 1994).⁴ Yet the gap in attitudes toward musical education is widening among parents. One group of parents assumes that young children who do not have access to, or who do not seem to benefit from, formal lessons in violin or music reading early on cannot acquire significant musical ability at a later time. These parents often see no need for their children to pursue any form of music education as part of their public school education. Another group assumes that young children who do profit from early music lessons are by definition musically gifted, confusing normal musical ability with extraordinary talent. A third group of parents understands that music should be an essential element of education, regardless of early indications of musical ability. This group welcomes the innovations of the past century that affirm the view that any child can develop musical abilities and that music education provides important opportunities for cognitive, aesthetic, social-emotional and neurological development far beyond the relatively narrow range of musical performance abilities previously associated with musical talent.

If we mistake early violin performance or music-reading skill as signs of giftedness, we will continue to marginalize music's role in education, and also misidentify those with truly exceptional abilities. Until schools incorporate the music education innovations of the past century into their curriculum and assessment practices, new forms and assessments of learning in the field of education in music will not evolve at the pace of other domains such as language, science, or mathematics.

Breaking the Mold of Music's Role in Public Education

The purpose of this chapter is to demonstrate that the current era of school reform provides a new context for changes in music education. Emerging examples for innovation have resulted from the need to meet three different challenges:

- (1) *To develop a more comprehensive view of music as having value for its own sake. Only by exploiting and assessing a wider variety of learning processes*

⁴ In this article Davidson and Scripp argue that social and environmental conditions that stimulate musical cognitive development in early childhood play a predominant role in the development of giftedness in music.

in traditional music classes⁵ (Gardner, 1989b; Winner, Davidson & Scripp, 1992; Wolf & Pistone, 1991) will music gain status in the public-school curriculum equal to other core subject areas;

- (2) *To incorporate musical content and processes as resources for interdisciplinary learning that is authentic both to music and other subject areas.* Music integrated with other subject areas transcends the traditional boundaries of music as a separate field of study and provides important occasions for 'teaching for transfer' across disciplines (Catterall, 2002; Perkins, 1992; Salomon & Perkins, 1989; Tunks, 1992)⁶ based on fundamental concepts and learning processes shared between music and other subject areas (Bamberger, 2000; Burnaford, Aprill & Weiss, 2001; Gardiner, 2000; Perkins, 1989; Scripp, 2002).⁷ Only when learning in music is integrated with other subject areas will public schools be able to afford comprehensive and authentic music programs for every child;
- (3) *To establish new benchmarks for giftedness in the domain of music.* Determination of musical giftedness will have to keep pace with innovative practices now available to public schools. These practices are based on a deeper and wider view of

learning in music and its application to learning in other subject areas. New expectations for excellence in music in public schools will challenge educators to re-conceptualize conditions and indications of musical giftedness (Davidson & Scripp, 1993) that are both discipline-specific and interdisciplinary in nature.

The impact of innovation also must be evaluated by its degree of application in public schools. For example, if music educators continue to offer the teaching practices envisioned by Suzuki and Kodály only as after-school programs or as an option for interested students once or twice a week, neither the essence nor the scope of music's role as part of the core public-school curriculum will have been realized. Although these innovative practices of the past influenced a whole generation of music educators—both Suzuki's & Kodály's work and writings spawned the growth of professional societies of teachers, professional development strategies, conferences, publications, and instruments—public schools were never able to justify the inclusion of both of these programs into the core public-school curriculum.

However, circumstances emerging from this era of school reform have created new opportunities for change in music education. Recent national and state standards for music education have challenged school communities to consider music both as a basic intellectual capacity to be learned for its own sake (Gardner, 1983)⁸ and as a tool for positive enhancement of academic and social-emotional development (Butzlaff, 2001; Hetland, 2000a,b; Scripp, 2002; Standley, 1996; Vaughn, 2000).⁹ Consequently, innovations in music education most likely will stem from the need to create music programs that feature a broad synthesis of musical skills and processes employed both for the sake of the musical-cognitive development

⁵ The Arts Propel Project, a collaboration among Harvard Project Zero, the Educational Testing Service, and the Pittsburgh Public Schools, stimulated the growth of alternative assessment processes (portfolio assessment, performance assessment) based on evaluating perceptual skills, learning products, and documentation of reflective thinking authentic to the musical, visual, and language arts. These alternative assessment models have become common in progressive public schools' curricula.

⁶ In *Smart Schools*, (1992, pp. 99–130) Perkins argues that learning transfer does not often occur in schools without a conceptual framework and a consistent method for 'teaching for transfer' that draw on earlier seminal essay on transfer with Salomon (1989). Earlier research on music learning and transfer is summarized by Tunks (1992). James Catterall's article *The Arts and the Transfer of Learning* (2002) provides an up-to-date view of the research that supports a growing acceptance of expectations of learning transfer between the arts and other subject areas.

⁷ Scripp (2002), Bamberger (2000), and Gardiner (2002) review research and present curricular design work which suggest that meaningful transfer that occurs between music and other subject areas occurs through the simultaneous employment of fundamental concepts and learning strategies shared among these disciplines. Perkins' (1989) essay is a particular view of standards of coherency necessary for discussing the arts as resources for a deeper understanding of scientific, literary, or historical concepts. Burnaford, Aprill & Weiss (2001) provide design perspectives from a group of arts educators and action researchers who develop curricula from the point of view of teaching for transfer through the arts.

⁸ Gardner's theory of multiple intelligences (1983) is rooted in the premise of separate intelligences that constitute a particular profile of learners and argues for the teaching of disciplines for their own individual contribution to cognitive development; since the emergence of this theory, music has been seen increasingly as 'an early organizer of intelligences' that have particular impact on cognitive and emotional development outside of the domain of music.

⁹ The new publication *Critical Links: Learning in the Arts and Student Academic and Social Development* (2002) contains the latest summary of a very large body of research on the impact of music and other aspects of learning and behavior. Scripp (2002) provides the summarizing essay, Hetland (2000a,b) provides meta-analyses of research on the 'Mozart Effect' and the relationship between musical training and spatial-temporal intelligence, Vaughn (2000) and Butzlaff (2000) summarize research on the impact of music on mathematical and language skills respectively, and Standley (1996) offers a meta-analysis of the impact of music on behavior, cognitive, and social-emotional development.

of every child and for the sake of music's contribution to the whole school curriculum.

Laboratories for Innovation

Innovations in music education are now emerging in laboratory school programs where music teachers, classroom teachers, curriculum specialists, and researchers work together—and in collaboration with consultants from schools of music—to design comprehensive, interdisciplinary music studies for the benefit of all children. These laboratory programs—not to be confused with magnet school programs that accept only musically gifted students—offer music to all students, regardless of ability or degree of initial support from parents. One such example is the Conservatory Lab Charter School, a school created in partnership with the New England Conservatory and its Research Center for Learning Through Music¹⁰ (Street & Scripp, 2002). The mission of this public elementary school is to create a laboratory program that uses the intensive and interdisciplinary study of music to enhance cognitive, physical (neurological), and social-emotional development in all children. The mission of the New England Conservatory—in addition to the training of world-class musicians—is to focus on the effect of the synthesis of authentic and interdisciplinary-based musical studies on school environments.

The Lab School employs methods that draw on the innovations of Suzuki and Kodály, and music is awarded equal status with all core subjects of the school curriculum. That is, throughout the entire six years of elementary school, *all students* are required to:

- take weekly violin lessons and classes and perform in recitals several times a year;
- participate in a comprehensive music curriculum that features lessons based on musical works, music reading, composition, and improvisation;
- participate in special programs or events such as creating opera in schools and both music;

¹⁰ *Learning Through Music* represents a research-based field of inquiry into the wide range of learning that occurs in the context of comprehensive study and experience of music that includes, yet extends beyond the boundaries of musical skill or perception into areas of cognitive or social-emotional development normally associated with other subject areas or contexts; frameworks for comprehensive, interdisciplinary *Learning Through Music* programs were first designed by faculty at New England Conservatory's Research Center and later used as the basis for program implementation and research with public-school partnerships principally including the Conservatory Lab Charter School, a public school founded for the purpose of developing and disseminating a replicable model of Learning Through Music practices to school children selected by lottery and not screened for musical ability.

and academic teachers are required to:

- provide instruction in mathematics, science, social studies, and language arts that include 'Academic Enhancement Lessons',¹¹ both in the music class and in the academic classroom. These lessons result in the study of fundamental concepts and processes shared between music and other disciplines;
- design music listening programs that provide an array of listening experiences for the purpose of developing perceptual skills, priming students cognitively and emotionally for daily activities, finding new ways to make transitions in the school day emotionally satisfying, and serving as a resource for exercises in social or emotional development (Standley, 1996);¹²
- monitor musical development and music-integrated learning across the curriculum and provide evidence, by way of tests and portfolio assessment, of learning both in and through music.

As Lab School parents marvel at their children's ability to play the violin, read music at sight, or simply learn to match pitch, they discover, as Kodály and Suzuki suggested years ago, that all children can develop a significant degree of these abilities in the course of an enriched public-school education. They also witness students learning how to use their understanding of language and musical skills by setting words to music, or investigating the spatial-temporal relationships in musical composition and performance. In addition, these parents see teachers using music to prime and reinforce good behavior and listening skills. Children in violin ensembles begin to exhibit higher levels of self-control and social empathy; by choosing their own music at certain times of the school day, children reflect on the relationship between music they prefer and their own emotional well-being.

Assessment of a comprehensive array of laboratory school practices, not surprisingly, reflects a wider range of learning in and through music than do conventional music education programs. Test results reflect significant, positive correlations among tests of basic musical and academic skills (Gardiner, 1993, 2000; Gardiner & Scripp, 2002), suggesting that music, for very young children, is a tool for developing symbolic processing skills as well as exploring other concepts shared between music, mathematics, and language. As program development continues, the entire school

¹¹ 'Academic Enhancement Lessons' are an essential ingredient of the Learning Through Music Program designed by the New England Conservatory's Research Center and implemented in collaboration with staff at the Conservatory Lab Charter School.

¹² Standley's (1996) meta-analysis of the impact of music on social-emotional development provides a basis for Music Listening Programs designed by New England Conservatory and implemented and evaluated in partnership with the Conservatory Lab Charter School.

Photo 1. This photograph was taken on the first day children received their violin at the Conservatory Lab Charter School. Violin instruction for all children in this public school was part of the Learning Through Music Program developed in partnership with New England Conservatory.

community understands better how the knowledge of music and a command of music symbol systems provide new perspectives of linguistic, musical, mathematical, and behavioral development of young children.

Five Strategies for Innovation in Music Education

The work of laboratory school programs such as the New England Conservatory/Conservatory Lab Charter School Partnership¹³ suggests a strategic framework for innovation.

As inventive as one laboratory program may be, the evolution and large-scale dissemination of new approaches to music education depend on a shared set of principles and responsibilities to which music teachers, classroom teachers, and administrators willingly subscribe. The steps presented below and discussed throughout the rest of this chapter suggest the conditions by which the next phase of music education must evolve beyond musical innovations of the previous century. Already in process in several

communities, innovation in music education can be achieved by partnerships among schools of music, arts organizations, and public-school communities through a series of five strategic steps:

- Strategy 1: Reconcile the false dichotomy between the ‘essentialist’ and ‘instrumentalist’ perspectives regarding the purpose of music in public-school education;
- Strategy 2: Establish a framework for innovative forms of music education based on comprehensive, interdisciplinary programs that are intended to benefit all children in public schools;
- Strategy 3: Create new frameworks for preparing advanced college-conservatory students to contribute to innovative programs as ‘artist-teacher-scholars’;
- Strategy 4: Form a network of college-conservatory, arts organization, and public-school partnerships that are committed to designing and implementing innovative, research-based forms of ‘music in education’ practices, and to influencing policy concerning the essential role of music in the public schools;
- Strategy 5: Explore and promote new conceptions of giftedness that result from the implementation of innovative forms of comprehensive, interdisciplinary music education practices in public schools.

¹³ Similar laboratory programs such as Georgia State University School of Music’s ‘Sound Learning’ Program in Atlanta and Fulton County Public Schools are under way in several communities.

Sample Student Work:

Photo 2. At the Conservatory Lab Charter School, Mona Rashad, a New England Conservatory violin major and Music-in-Education guided intern, documented children's 'multiple representations' of their response to music-listening tasks.

Strategy 1: Reconcile the false dichotomy between the 'essentialist' and 'instrumentalist' perspectives regarding the purpose of music in public-school education.

What we must first seek to answer is whether music is to be placed in education or not, and what power it has . . . whether as education, play or pastime (Aristotle).

A major assumption of this chapter is that innovation in the field of music education will take place only when musicians and educators are able to reconcile two philosophical strands that stand in each other's way. That is, music education must evolve out of the 'false dichotomy' between the 'essentialist' position of music education 'for its own sake' and the 'instrumentalist' position of 'music for education's sake' (Burnaford, Aprill & Weiss, 2001; Hope, 2000).¹⁴

Perhaps one reason policy-makers have been reluctant to support music as a core subject in public schools is that educators, administrators, artists, and parents seem to be divided in their advocacy. On one side, the 'essentialists' argue that music should be taught for its own sake. Essentialists maintain that, while evidence exists for several kinds of ancillary benefits from music instruction, music teachers should focus on music's own set of skills and literature and not be responsible for drawing out 'extra-musical benefits' from this instruction. By contrast, those sympathetic to the 'instrumentalist' point of view believe that music does not exist in a vacuum, that it is connected intrinsically to other subject areas and art forms, and that learning in music inevitably draws on and engages learning processes and fundamental concepts shared across many subject areas—often simultaneously.

As research emerges that establishes stronger relationships between music and learning in other areas of the curriculum,¹⁵ advocates from both camps are caught in a complicated bind. Schools are under tremendous pressure to demonstrate increased academic achievement. Music had been viewed as dispensable even before the arrival of the current climate of school accountability. Clearly, if we ignore aspects of learning transfer between music and other subject areas, music education will remain outside of the mainstream of public education and will survive only as an educational elective for the talented or highly motivated few.

From the school-reform perspective, music educators are expected to cast music as an enhancement to

learning in all subject areas, and as a support for social-emotional goals of the school curriculum. School administrators express *instrumentalist* objectives: music must support the learning goals of other areas of the school curriculum in the same way that mathematics enhances science, and reading is key to the social-studies curriculum.

Kodály and Suzuki teachers have shown how traditional music training can be disseminated effectively through deployment in schools, yet these music educators failed to convince a sufficient number of school communities that 'music for its own sake' is a reasonable and sustainable aspiration for all children. To the extent that the 'instrumentalist's' view prevailed as a rationale for innovative programs of the past, the deployment of these programs for the sole purpose of enhancing math or reading test scores became a symbol of how music's particular value in education could be trivialized. To the extent that these programs were seen from the 'essentialist' perspective only, school communities could ignore music's potential for positive interaction with learning in other domains.

Reconciliation of these opposing views will be a necessary condition for future innovation in education. Although music study takes place in isolation from mathematics and language learning in schools today, research cited above suggests that music functions as a catalyst for cognitive skills and social-emotional development across disciplines. These effects are most evident when conditions for transfer are optimized. Thus, effective music lessons depend on a general education background and they profit by analogous understanding of fundamental concepts of language (theme, character, phrasing, phonemic and phonological skills, decoding skills, etc.), mathematics (quantity, proportion, pattern, sequence, distribution, etc.), and higher-order cognitive skills (systems thinking, analysis, inquiry, invention, discovery, explanation, demonstration, interpretation, hypothesis-testing, reflection, etc.).

Reconciliation of the seemingly opposite purposes of music education will allow the public to recognize a new wave of innovation that transforms the practices and scope of music in public education.

A Taxonomy of Terms Emerging from the Reconciliation of the Essentialist and Instrumentalist Views of Music Education

- The term *music education* is defined for the purposes of this chapter as the extension of pedagogical and training practices based on traditional goals of music education 'for its own sake';
- The term *music-in-education* is offered here as a label for building on innovations in traditional music teaching, and, at the same time, committing music as an appropriate tool that enhances general education;
- The concept of *learning through music* signifies music education's effect on learning outside of the

¹⁴ See Sam Hope's essay, 'Integrity in integrative programs: challenge to learning through music' in the *Journal for Learning Through Music* and Burnaford, Aprill & Weiss's *Renaissance in the Classroom* (2001), for further discussion of the ongoing tension about the role of music and the arts in education.

¹⁵ Such as the *Critical Links* (2002) publication cited previously.

narrow parameters of musical performance, analysis, or aesthetic experience;

- *Comprehensive, interdisciplinary music program* is a phrase intended to capture music educators' intent to reconcile the essentialist and instrumentalist perspectives. Innovation takes the form of programs that are wide ranging in scope and, at the same time, wedded to serving the individual school's core curriculum. The comprehensive study of music is designed to benefit both 'music for its own sake' and music for the sake of learning across the curriculum.

The path of innovation in music education described earlier can be summarized by the matrix below (Fig. 1). This figure plots the evolution of music education from extra-curricular, performance-based programs (top left) to the far more inclusive forms of comprehensive, interdisciplinary programs (bottom right) that may emerge in the future as a result of research-based laboratory school programs. As we shall see later, these innovative programs will depend also on coherent conceptual frameworks for learning, teacher preparation, and cross-institutional collaborations with schools of music.

Strategy 2: Establish a framework for innovative forms of music education based on comprehensive, interdisciplinary programs that are intended to benefit all children in public schools.

My father taught me that the symphony was an edifice of sound. And I learned pretty soon that it was built by the same kind of mind and the same kind of way that a building is built (from *Frank Lloyd Wright*, a film by Ken Burns and Lynn Novick, written by Geoffrey Ward, 1998, the American Lives Film Project, Inc. PBS Home Video).

Frank Lloyd Wright, America's best-known architect of the 20th century, learned to play the piano as a child and developed a view of music as a creative process directly related to his career work. Not only did Wright's son report hearing him play Chopin late at night, but his grandson recalls Wright's insistence on piping music into the fields and workrooms at Taliesin as his staff and apprentices did their work. The concerts, poetry readings, and plays performed every Saturday night at Taliesin, were, Wright believed, "as important as working in the drafting room".

Music educators may aspire to this level of influence, yet no public-school music programs have been designed to expect such a result. First, music educators will recognize that Wright's ability to play piano music by Chopin indicates that his musical education extended far beyond what is commonly expected of an American public-school student today. Second, educators in various academic subjects will recognize that Wright's strong assertion that musical composition and architecture are created by 'the same kind of mind' and

that the professions 'are quite similar', indicates a level of interdisciplinary understanding that is rarely required or assessed in American public schools. Comprehensive, interdisciplinary music programs promise more than innovative approaches to either goal: they offer a progressive view of music as a coherent curriculum that is taught to support learning transfer across the curriculum.

In order for an *interdisciplinary* music curriculum to gain a status equal with other core curriculum subjects, it must be deeply coherent from an intra-disciplinary perspective. In the manner of a rich language arts curriculum that features both the mechanics of reading and writing as well as the study and composition of various literary forms, a *comprehensive* music curriculum should include:

- training in various forms and traditions of performance including improvisation and standard repertoire using the voice and on more than one instrument;
- experience with computer-assisted music composing, drill and practice, and keyboard practice;
- exposure to a wide range of music literature and aesthetic experience through listening skills, concert events, artist-in-residence programs;
- expectations for fluent music reading skill; and
- time to investigate open-ended musical problems.

Although music educators, parents and administrators may endorse a more *comprehensive* music program for those with musical talent, schools have yet to invest in comprehensive programs for all children, let alone comprehensive, fully integrated interdisciplinary approaches to music education that serve the entire school community.

In a comprehensive, interdisciplinary program, music educators can claim that the study of music enhances understanding of basic mathematical concepts in much the same way that the study of mathematics makes for a clearer understanding of music. Singing words increases phonological awareness of language, as the ability to read enhances the study of musical repertoire. In this context, the study of opera provides a natural context for studying language (text setting), history (narrative), social studies (character), and mathematics (geometry of set design or the spatial-temporal aspects of organizing any performance event) (Wolf, 1999).¹⁶

Faced with ever-expanding lists of standards mandated by national and state boards of education, a comprehensive, interdisciplinary music program emerges as a much-needed innovation for both music training itself and for integrated learning in public schools. The argument for investing in innovative, comprehensive, interdisciplinary music programs is

¹⁶ See Wolf's (1999) essay on the value of studying opera in terms of interdisciplinary skill development in the context of an interdisciplinary musical medium.

Changing Contexts for Innovation in Music Education

	Music Education 'for its own sake'	Music in Education 'for the sake of learning in and across the curriculum'
	(as a separate subject or intellectual domain)	(both as a separate subject and as an interdisciplinary study linked with multiple forms of representation, concepts, and skills that are shared across other subject areas or intellectual domains)
<p>Music Learning primarily assessed as a performance skill and offered as an extra-curricular option</p> <p>(The study of music as an isolated discipline or subject that is taught as a non-compulsory subject or provided as intensive performance training for the talented few)</p>	<p style="text-align: center;">Conventional Role Of Music Education In Public School Practices Of The Last Century</p> <p>(Innovations in instrumental, vocal, and music reading instruction in early music education created standards of musical performance for ordinary children formally associated with giftedness in music, yet most public schools ignored these innovations and continued to offer conventional or reduced music programs)</p>	<p style="text-align: center;">Experimental Interdisciplinary Music Programs Over The Last Century</p> <p>(Interdisciplinary music programs, offered in some private schools for all children (e.g., Waldorf Schools) were virtually absent in public school music programs of the previous century)</p>
<p>Music Education taught and assessed from the point of view of a comprehensive curriculum for all children</p> <p>(The comprehensive study of music as part of the compulsory core curriculum and supported by artist in schools programs or interns from schools of music that supports a diverse music education for every child and provides new opportunities for excellence for both ordinary and gifted children)</p>	<p style="text-align: center;">Innovation In Music Education That Supports A More Comprehensive View Of The Music Curriculum Available To All Students</p> <p>(Schools are now finding ways to adopt innovations in music technology and cross-cultural studies and, as a result, design and assess music programs based on more inclusive and comprehensive music curricula that include multiple-instrument instruction, voice and sight-singing classes, opportunities for computer-assisted composition and ear training-music reading drills, and a range of cross-cultural approaches to musical perception, performance, improvisation, composition, and reflective understanding of music)</p>	<p style="text-align: center;">The Evolution of Research-Based Comprehensive, Interdisciplinary Music Programs that Suggests a New Role and Purpose for Music in Public Education</p> <p>(Research that demonstrated the impact of high quality music programs on academic achievement and experimental laboratory school programs that have created innovations in early music education suggest that innovation in music education will take the form of "music in education" programs that require authentic forms of musical performance and reading skill, and, at the same time, provide comprehensive, interdisciplinary programs for learning in and through music for the benefit of every public school student)</p>

Figure 1. A four-way comparison of the focus and scope of the music programs that suggests a path of innovation in music education from performance-based, non-compulsory curricula for the benefit of the talented few toward comprehensive, interdisciplinary programs designed for the benefit of every child in the school community.

made more feasible by charter-school legislation and the willingness of experts in the field of music education to design charter schools as laboratories for innovation.

Yet, in the school-reform world—where many claim they are working creatively on issues of curriculum and pedagogy—school leaders must proceed responsibly. If

a school receives a charter based on the fundamental idea that music can be used as a powerful *medium* and *model* for teaching and learning across the curriculum, the whole school community must work together to dedicate itself as a laboratory for innovation.

The *comprehensive, interdisciplinary* program described below originated through the efforts of the

New England Conservatory faculty and a founding coalition that petitioned for, and received funding for, the Conservatory Lab Charter School, an elementary school dedicated to the development and dissemination of innovative *Learning Through Music* practices (Street & Scripp, 2002). The New England Conservatory created a Research Center to support innovations in music education while the laboratory school provided a platform for implementation in a public-school setting.¹⁷ The basis for innovation in this context is best represented by a set of premises, each of which is necessary, yet not sufficient in itself, for the development of comprehensive, interdisciplinary music programs:

The Premises of the Conservatory Lab Charter School 'Learning Through Music' Program

- (1) Music serves as both a medium and a model for learning in public schools.
 - As a *medium*, musical literature and music-making skills serve as essential components of every child's elementary education;
 - As a *model*, music represents a configuration of teaching and learning processes fundamental not only to music but to other disciplines by way of listening (perception, observation), questioning (investigating, analyzing), creating (inventing, transforming), performing (demonstrating, interpreting), and reflecting (connecting, personalizing, evaluating).
- (2) The comprehensive and intensive study of music should be provided at all grade levels both for its own sake and as a field of study of equal importance with other academic areas.
 - As part of the core public school curriculum, the study of music and the development of musical skill becomes part of the child's compulsory education. The child is evaluated according to standards of musical literacy, skill development, and knowledge of literature at all grade levels authentic to a conservatory preparatory education.
- (3) Music should be used as a model and resource for interdisciplinary learning.

- Comprehensive, interdisciplinary music studies should include art forms intrinsically related to music, such as opera or ballet;
 - Interdisciplinary music studies should address aspects of academic disciplines that share fundamental concepts with music. Some examples include the study of proportion in music and math, the study of themes and character in music and language arts, the study of historical periods from the point of view of music and social studies, and the study of wavelength or resonance from the perspectives of music and physics.
- (4) Music should be employed as a medium and model for social-emotional development.
 - Music listening should be used for exploring concepts of preference, choice, style, and cultural identity among students;
 - The experience of music performance or composing (composing and performing a cappella vocal works, for example) should be used to model social-emotional skills such as empathy, perspective-taking, or cooperative behavior;
 - The systemic home practice of music should serve as a model for self-discipline and the ability to set and evaluate personal goals.
 - (5) Music should be used as a model for curriculum development, teaching, assessment, professional development, and engagement of the whole-school community.
 - Music becomes a model for interdisciplinary learning skills and interdisciplinary content throughout the curriculum;
 - Music becomes a model for teaching that includes a rich array of teaching processes and modalities of learning;
 - Assessing musical development can parallel assessing for such skills as phonemic awareness, diction, calculation, and problem-solving;
 - *Learning Through Music* becomes a new form of teacher professional development as a way to re-evaluate and revitalize teaching in all subject areas;
 - Music-making brings communities together in positive and constructive ways.

¹⁷ Larry Scripp, Chair of Music Education at New England Conservatory, created the founding coalition for the Conservatory Lab Charter School at the same time proposing a new Research Center for Learning Through Music at New England Conservatory. From its inception, the Lab School was proposed as a research-generating public school program where New England Conservatory research faculty (cited extensively in this article) serve as consultants and staff members, and conservatory 'Music-in-Education' students serve as guided interns.

The *Learning Through Music* partnership with New England Conservatory stems from the need to create and disseminate a research-based, replicable approach to innovative curriculum development and assessment practices. At the Conservatory Lab Charter School (CLCS), the premise of *Learning Through Music* informs virtually every aspect of the school's development. One of the most pressing challenges is in the realm of professional development. At CLCS, music and classroom teachers must adapt to strategies and

Learning Through Music Academic Enhancement LESSON PLAN
(independently designed and implemented by either academic or music teacher)

Grade Level 1 **Subject Area(s)** Music Math Language Science

Lesson: The Dinosaur Music Book

List Goals (lesson objectives relevant to Literacy Focus Abstracts):

- Word segmentation
- Vocabulary (for Science Project)

List Chosen Fundamental Concept Shared Between Music and Math and/or Language Literacy

- Text Segmentation matched to word/melodic segmentation (of a well known song)
- Performance of created words/melody and verification of parallel structure of both

List Resources Need (materials, media, worksheets, etc.):

- Paper, pens, rhythm sticks, source materials for theme of the text
- Journal writing materials

List Sequence of Events:

- Read books on dinosaurs and discuss and categorize their various perceptions and reflections of their physical features
- Draw features on paper
- Compose lyrics relevant to the features of the dinosaurs that match the word or syllable segmentation of the words and music of “Mary Had a Little Lamb” onto text-setting sheets
- Have children perform each other’s work and investigate whether the words are matching the melody and the content appropriate to the physical description of the dinosaur.
- Collect all the individual dinosaur pages and assemble them into a book
- Report on Journal writing on the process, goals, and personal meaning of the project

List Chosen Learning Artifact (journal writings, worksheets, work in progress, final products, demonstrations, performances, etc.):

- Journals
- Drawings
- Text Setting Sheets
- Class books

Describe Assessment Process and Expected Results (scoring rubric, student reflections test, teacher observation, etc.):

- Journal writing assessed for detail of perception, richness and specificity of reflective writing
- Text setting is assessed for vocabulary and spelling match between the observations and their incorporation into a song (syllable segmentation, accent, syntactical sense of the music. etc.)
- Pre-post test on dinosaur vocabulary, word segmentation, and melody reading for units, contour and accent

Figure 2. A ‘Learning Through Music’ Academic Enhancement Lesson Planning Sheet used at the Conservatory Lab Charter School. Unlike conventional lesson plans, Academic Enhancement Lessons can be implemented by both the academic teacher and the music teacher. The form requires the teacher to specify concepts shared between music, language and science that will be integrated throughout the lesson sequence. In this case the shared concept is limited to reinforcing academic content through musical song. Later examples illustrate how fundamental concepts such as measurement, proportion, and time can serve as shared “cognates” between math, music, and science.

Photo 3. A page from the 'Learning Through Music' Dinosaur Project as described in the Academic Lesson Plan above. First grade students remember facts about the Brontosaurus by composing new lyrics to the tune, 'Mary Had a Little Lamb' that illustrate the physical features of dinosaurs. See following examples for more sophisticated versions of Learning through Music "Academic Enhancement Lessons".

approaches that have not been a part of their previous teacher preparation and practice.

Strategy 3: Create new frameworks for preparing advanced college-conservatory students to contribute to the development and sustainability of innovative programs as 'artist-teacher-scholars'.

The mission of New England Conservatory is to become an advocate for music's role in our society. This mission is purposefully broad. It includes two primary aspects: first, to provide the best possible training of professional musicians to contribute to the highest standards of music in our culture, and second, to provide ways for musicians to become better communicators, teachers, and, in addition, effective advocates for the contribution music can make to enhance learning in other subject areas in our public schools (Daniel Steiner, President, New England Conservatory of Music).

Innovative music-education practices in schools will not survive without parallel innovation in teacher preparation programs. New England Conservatory, the

longest-running conservatory of music in the United States, is an example of how changes in teacher preparation for the most gifted music majors are needed to foster, evaluate, and sustain innovation in music education.

Until recently, music education has been treated as an area of narrow specialization in higher education. At most music schools, a sharp division has existed between those who will perform and those who will teach. Students who excel in musical performance have been encouraged not to 'dilute' their performance training by taking courses designed for music teachers or scholars; conversely, those with less potential in the performance arena are often relegated to the music education degree program. Because conventional music education offerings (which feature intensive preparation for band, choral, or orchestra directors) are not perceived as applicable to the goals of the aspiring performer, the most advanced performance majors rarely sacrifice precious rehearsal time to take music-education courses.

However, both the young musicians who develop successful careers in music and the performance majors who become interested primarily in teaching

eventually will be expected to bring a high degree of artistic and scholarly sophistication to bear on their roles as educators. Some of the skills commonly required of today's music teachers and professional musicians engaged in education outreach programs, yet not sufficiently developed in conventional music education programs, include: (1) providing a comprehensive array of educational experiences (voice and instrumental instruction, improvisation, computer-assisted composing, cross-cultural approaches to music, etc.) that extend beyond conventional general music and performance ensemble classes; (2) designing and implementing interdisciplinary music programs that connect with school-wide curricula and serve all students at every level of musical skill; (3) campaigning effectively for providing educational experiences in collaboration with community arts organizations (e.g. artist-in-residence programs); and (4) educating policy-makers on the ways in which music enhances other types of learning by identifying relevant research and presenting findings to support the existence of music education. These skills require training more broadly based in *artistry* and *scholarship*—in addition to teaching—than what is typically offered in conventional music-education programs.

The gulf between the training of gifted musicians as performers and the need to prepare conservatory graduates as educators is revealed in a survey of recent graduates of the New England Conservatory. The results of this survey revealed an astonishing statistic: 85% of performance majors teach in some capacity, yet fewer than 5% had received pedagogical training.¹⁸ At least four explanations for these results seem possible: (1) there is little opportunity for musicians to sustain their careers purely as performers, yet there is a terrific demand for music teachers with conservatory training; (2) successful performance careers often demand teaching responsibilities; (3) training as a performance major provides good preparation for teaching; and (4) teaching is a desirable and productive way to sustain development as a performer.

At the New England Conservatory, all four explanations appear relevant and, as a result, faculty—with support from the senior administration—decided to pursue a new framework for curricular reform in music education. They resolved to:

- (1) regard the development of the Artist/Teacher/Scholar (ATS) as part of the core mission of the school;
- (2) create a Music-in-Education Concentration as an institution-wide service to all performance majors who wish to prepare themselves sooner, rather than

later, for the integration of teaching and scholarship relevant to their career as musical artists.

The figure below suggests how the Artist/Teacher/Scholar framework integrates seemingly isolated strands of any musician's education or professional career. Young musicians invariably begin their musical studies strictly as performers. At first, students only view their private instructors as gifted artists who can also demonstrate how young performers can play their instrument better. The most gifted students know that schools of music determine the admission of students almost entirely on the basis of their performance audition. Although subsequent professional training includes required studies in music theory, history, and liberal arts, students at first experience these subjects as ancillary, if not irrelevant, to their career as a performing artist. By the third year of undergraduate training, however, it becomes increasingly clear to music students that the integration of these subject areas can contribute significantly to their aspirations for a career in music. With the added option of pedagogical or music-education internships, young musicians then begin to adopt a new mode of development. That is, they begin to understand that teaching experiences force them to reflect on and communicate what one knows which, in turn, enhances their development as complete musicians. Typically, New England Conservatory students who graduate with an undergraduate degree in performance with a music-in-education concentration reflect on their development as performing musicians in terms of a developing synthesis of learning and teaching. As one voice major states in an exit interview:

The great joy and intellectual enrichment comes from being deeply challenged and excited by my work in the music-in-education program. Teaching has become a source of inspiration, fueling my own journey of music learning. My desire to become a better musician is now inseparable from my desire to become a better teacher.¹⁹

The most gifted music students invariably teach. Whether in outreach programs in symphony or opera programs, or as faculty members of college or community school programs, conservatory graduates typically thread their career in music with teaching. Although conservatory faculty may specialize in teaching performance, composition, theory, or music history as separate subjects, virtually all faculty members report that they later integrate the three facets of the framework as inseparable from their continuing involvement as musical artists, educators, and think-

¹⁸ Similar statistics are obtained in other major schools of music, such as the Juilliard School or the Manhattan School of Music.

¹⁹ Interview data and other reports concerning the development of the Music-in-Education Program at New England Conservatory are available in an internal FIPSE report from the NEC's Research Center.

	Musician As Artist	Musician As Teacher	Musician As Scholar
Artistry	The Practice, Habits of Mind, and Products of the Musical Artist	(The musician who develops the artistry of teaching music)	(The musician who produces scholarship focused on music, music history, creative process, etc.)
Teaching	(The musician who teaches or guides the development of the musical artist)	The Practice, Habits of Mind, and Products of the Music Educator	(The musician who teaches or guides scholarship in music and musical processes)
Scholarship	(The musician who focuses on the scholarship of music and musical processes)	(The musician who focuses on the scholarship of teaching and learning music)	The Practice, Habits of Mind, and Products of the Music Scholar

The Artist/Teacher/Scholar (ATS) Framework is based on the belief that a successful musical education must foster the development and integration of all three aspects of musicianship: artistry, teaching, and scholarship. The Framework demands high standards of every musician in the areas of:

- **Artistry**¹ (the ability and desire to engage and command artistic processes resulting in high-quality musical performance, composition, listening and reflective thinking skills, as well as knowledge of musical works, creative processes, and learning skills that can be applied to a wide range of disciplines);
- **Teaching**² (the ability and desire to provide effective instruction, coaching, and personal mentoring in a range of musical settings as well as abilities as a public presenter or liaison at presentations of diverse musical works);
- **Scholarship**³ (the ability and desire to generate inquiry, research, and reflection on one's personal artistic and educational work while taking into account other perspectives, including a wide range of historical, psychological, social, and artistic sources).

¹See *Music and the Mind* by Anthony Storr or *Artistry: The Work of Artists* by Vernon Howard for philosophical frameworks for defining musical artistry.

²See *Artistry In Teaching* by Louis J. Rubin, Margaret Gullette's *The Art and Craft of Teaching*, or Allan Pearson's *The Teacher as* references on teaching in conjunction with artistry.

³See *We Scholars*, for David Damrosch's criticism over specialization and the lack of socialized or collaborative scholarship and Ernest Boyer's *Scholarship Reconsidered* for a discussion of the four new aspects of scholarship now being reassessed in universities—the scholarship of research, applied scholarship, integrative-interdisciplinary scholarship, and the scholarship of teaching.

Figure 3. The Artist/Teacher/Scholar (ATS) Framework.

ers.²⁰ Thus, for a successful faculty member, the 'teaching of musical artistry' is as important as their concerns for 'artistry of their teaching' (or the ability

to communicate or impart knowledge as artists). Likewise, the 'teaching of scholarship' (e.g. conducting historical research) is as important as the 'scholarship of teaching' (e.g. educational research or personal reflections on teaching). The developmental track of the Artist/Teacher/Scholar most often begins with private lessons, then studio teaching, and listening to recordings of the works they are studying. The path of Artist/Teacher/Scholar is a course where each area is increasingly synthesized into the whole.

²⁰ Interview data are analyzed as part of an internal report on the development of the Artist/Teacher/Scholar Committee and Music-in-Education Program at New England Conservatory sponsored by the United States Department of Education's FIPSE (Funds for the Improvement of Post Secondary Education) Program.

On the surface, the mission statement cited above may not suggest a framework for innovation in music education. However, the conception of the Artist/Teacher/Scholar reflects the need for schools of music to integrate three *complementary* responsibilities: to provide every student with the means of becoming a ‘complete’ musician, to enable students to handle the diverse challenges of a life in music, and to ensure that music will play a vital role in the overall education and development of school children. Innovation in music education for gifted performers at major schools of music can support the highest caliber of professional training for musicians and concurrently nurture innovation in public schools through the comprehensive, interdisciplinary programs described above.

Educating gifted artist-teacher-scholars requires intensive curriculum development. The United States Department of Education’s Funds for the Improvement of Post Secondary Education grant (FIPSE) supported New England Conservatory in its efforts to create a Music-in-Education Concentration program, a curriculum open to all graduate and undergraduate performance and composition majors.

Music-in-Education guided internships provide five entry points for conservatory students to engage with public schools: private lessons, music classes, performance ensemble classes, music-based interdisciplinary classes or projects (e.g. the Creating Original Opera program designed by the Metropolitan Opera Guild), and artist in residence programs. Taken together, these internships—when guided by conservatory faculty—promote the success and sustainability of authentic, comprehensive, and interdisciplinary school learning programs.

With new courses and internship opportunities available to students in all majors, music education has moved from the periphery to the center of NEC’s curriculum structure. Prior to the establishment of the Music-in-Education Concentration in 1998, 3% of all NEC students enrolled in music education courses. Three years later, that figure has increased to 18%. By the end of the 2000–2001 academic year, 64 students were engaged in internships with partnering schools and arts organizations where they gained valuable, hands-on experience in dealing with the challenges that all musicians—including performers, administrators, teachers, and scholars—face in society today.

Music students are not the only beneficiaries of Music-in-Education activities. An unanticipated boon created by the internship program is the extent to which supervision of internships, and associated involvement in public schools, has constituted valuable professional development for conservatory faculty. For the first time, conservatory faculty members invest their time developing classroom materials, collaborating with public school teachers on project design and implementation, observing projects in action, providing

feedback on student and teacher work, and engaging in assessment.

In the context of these new curricular structures, gifted performers become not only artists but also emissaries for music’s role in education—to the benefit of both. Participating conservatory students who were interviewed provide evidence that a Music-in-Education program can transform their view of the role and impact of the performing musician in public schools. A brass performance major who led an honors ensemble at New England Conservatory and continues to work in educational outreach programs reports:

Since leaving NEC to become a faculty member at the University of Maryland, I have discovered that NEC is taking a leadership role in the field of music education programs both by training musicians for outreach and preparing performers to present *Learning Through Music* principles in concert master-classes and interdisciplinary activities.

Similarly, participation in the Music-in-Education program expands the level of engagement of faculty members who choose to serve as mentors for students involved in a wide variety of educational settings. Conservatory faculty members report that gifted young performers, in the midst of intensive professional training, benefit greatly from contact with the outside world of public education while it stimulates faculty to discover new contexts for mentoring and developing aspiring Artist-Teacher-Scholars. Faculty and students both report that guided internships benefit, often in tandem, a musician’s performance skills, audience or classroom communication skills, the ability to reflect on their own education as artists, and their desire to contribute positively to the needs of the local community.

Exit interviews reveal that conservatory students who participate in education internships at laboratory school settings, for example, become better prepared for teaching opportunities in school districts that hold music programs responsible for contributing to the overall goals of the school district. Mona Rashad, a conservatory-trained violin major, states that the work she did as a teaching intern confirmed the value of teaching as a musical performer who can advocate for music’s essential role in the public-school curriculum:

The chance to work at the Lab school has really given me the confidence and experience I need. My interview for a teaching position in a string program ended with an immediate offer. I had previously thought that the Music-in-Education program was way ahead of its time. After talking with school administrators and teachers, I realize now that the Conservatory’s program is exactly where educators and administrators are going.

Ms. Rashad contrasted her experience with a traditional music education experience by saying that it

Figure 4. Graph demonstrating the effect of the Music-in-Education Programs on student performance majors and continuing education teacher professional development enrollment.

“would never have prepared me to be so ready to meet the expectations of music education as it is now being practiced”. She continues:

... after the interview was over, the superintendent told me that the team had come to talk to the state Department of Education about the same issues we discussed in my interview. He said that our discussion about interdisciplinary aspects of teaching music was far better than the one they had with the state people! That really opened my eyes.

The shift from music education degree programs to the creation of Music-in-Education concentrations for performance majors led to a new consensus on the value of education in the training of gifted musicians

committed to a conservatory education. This innovation—the first systemic curricular change at New England Conservatory in 40 years—has had a significant impact on the quality and diversity of the institution’s music education experience. Student responses such as the one below continue to inspire many faculty and staff as they work on this project with the hopes that a flexible, more inclusive, and more socially committed Music-in-Education program will benefit gifted music students as much as the institutions and communities who employ their talents in the future:

Teaching has become a source of inspiration, fueling my own journey of music learning. My desire to

become a better musician is now inseparable from my desire to become a better teacher (voice major).

Strategy 4: Form a network of college-conservatory, arts organizations, and public-school partnerships that are committed to designing and implementing innovative, research-based forms of 'Music-in-Education' practices, and to influencing policy concerning the essential role of music in public schools.

The secret of success is constancy of purpose (Benjamin Disraeli).

Another strategy for successful innovation in music education concerns the dissemination of new practices at music schools who partner with public schools. In September 2000, a conference at New England Conservatory entitled 'Making Music Work in Public Education: Innovative Practices and Research from a National Perspective'²¹ brought together researchers and administrators from arts organizations and college/

conservatories to discuss the integration of two approaches to music education. After an initial presentation a principal question emerged: How can arts organizations, institutions of higher education, and public schools network together to establish high standards for Music-in-Education practices informed by 'best practices' in the fields of both music-integrated interdisciplinary instruction and authentic music curricula in the context of school reform?

The discussions and presentations at this conference led to the formation of a National Consortium for Music-in-Education, now funded by a U.S. Department of Education grant and the National Endowment for the Arts. The principal consortium members are nationally known arts and education organizations that have expanded their initiatives to include a wider array of perspectives. The mission of the consortium is to develop, evaluate, and disseminate nationally:

- (1) a shared practice-based theory of music in education that will reveal the effectiveness of music programs in enriching and sustaining academic and artistic excellence;

²¹ Sponsored by the Spencer Foundation.

Photo 4. The Borromeo Quartet, the quartet in residence at the New England Conservatory, provides a Learning Through Music presentation for children at the Conservatory Lab Charter School.

- (2) cross-institutional professional development of teachers and artists who promote national standards of comprehensive, interdisciplinary music education goals in the context of arts in education programs;
- (3) shared standards for learning, teaching, and community support for music in the curriculum of public school education;
- (4) training for young, talented musicians as role models for music in education in public school settings.

The principal organizations of the consortium complement each other by design. New England Conservatory, along with Northwestern University, Georgia State University and the Mannes College of Music have created several different models for Music-in-Education programs in laboratory-school partnership settings. The Metropolitan Opera Guild, Boston Symphony Orchestra, and the Ravinia Festival Orchestra Program in Chicago are models of cultural organizations dedicated to transforming school curricula through opera, orchestral music, and the participation of local performing arts groups in educational programs. The Kenan Institute for the Arts and the Chicago Arts Partnerships in Education offer extensive cultural and arts education initiatives through local partnerships supported by city and state educational policy. *From The Top*, a nationally syndicated radio show, collaborates with New England Conservatory to promote the role of young artists as peer role models and cultural leaders in schools.

The consortium's work will be guided by key conceptual and organizational frameworks for innovation in music education, including the Artist/Teacher/Scholar Framework. From each consortium member's perspective, this framework will be used to expand the focus of music from the more traditional model of 'music education' as a separate, often ancillary curriculum in schools, toward several Music-in-Education program models which support performing artists as guided interns in a variety of educational settings. Finally, the consortium will serve as a model for the 'triangulation' of community cultural and educational partnerships focused on improving the quality of learning in and through music for children and youths.

The structure of the consortium represents an opportunity for influencing changes in the way music education is defined and applied in public schools, and its work is intended to support the emerging field of Music-in-Education. Some examples include:

- (1) *A Music-in-Education Professional Development Exchange Program* for training musical artists as teachers and as 'action researchers' (a form of scholarship of teaching), based on the exchange of data and practice models between the researchers and artist educators within each organization. Evaluation of this program will focus on the

effectiveness of professional development programs that increase the capacity of musicians and music students to serve as 'Artist/Teacher/Scholars' trained to work with children and youths. The evaluation should provide evidence for the effectiveness of the consortium's professional development practices, and it will be referenced to standards set by the National Board for Professional Teaching Standards.

- (2) *The Publication of Music-Integrated Learning Curricular Units* with explicit learning objectives based on authentic, comprehensive, and interdisciplinary Music-in-Education practices, will represent new forms of collaboration between higher education faculty, teaching artists and classroom teachers in the curriculum design and implementation process. This collaboration works also to evaluate and prepare curricula for publication in a consortium-approved Music-in-Education 'handbook of proven and promising practices'. Program evaluation will focus on the impact of the consortium's curricular units toward increased knowledge, skills, and understanding of music, musical processes, diverse musical literature, and learning related to other subject areas through music by public-school children and youths. The evaluation of the data (student interview responses, academic and musical performance with respect to curricular units, expert evaluation of student portfolio work, and the evaluation of academic achievement results with respect to learning in and through music) will provide evidence of the effectiveness of the consortium's curricular units and will be referenced to national and state standards within and across disciplines relevant to the consortium institutions.
- (3) *Models for Sustainable Practices* based on collaborations among educators, artists, and K-12 teachers who stress the musical arts as a model for community involvement with schools (parent classes, parent-teacher performing groups, parent roles which affect school cultures, parent-child engagement, and other opportunities for the entire school community to support Music-in-Education practices in their schools). The evaluation of the Consortium's work in each city will focus on the capacity of each participating organization to influence local policy and sustainable community practices that support Music-in-Education programs. The evaluation of the data (interviews with stakeholders of each organization, expert analyses of the quality of research conducted throughout the consortium, and expert analyses on the consortium as a model for increasing local community collaboration and resources that support arts learning) will provide evidence of the effectiveness of the consortium's programs and assess the group's future as an organization capable of setting stan-

dards for, and providing leadership on behalf of, the field of music in education.

In order for the form of innovation in music education described here to take root in standard educational practice, the soil must be prepared for acceptance by a

larger constituency of stakeholders than was typical in the traditional music education organizations of the last century. Research cited above suggests that comprehensive, interdisciplinary music programs will succeed in transforming schools not just because of the uniqueness of musical studies, but because music

involves a wide range of experiences which, like other art forms, will contribute to the entire school community by:

- connecting learning experiences to the world of real work;
- enabling young people to have direct involvement with the arts and artists;
- requiring new forms of professional development for teachers;
- providing learning opportunities for the adults in the lives of young people;
- engaging community leaders and resources.

Comprehensive, interdisciplinary music programs constitute a medium for learning that provides unique musical entry points into other subject areas by virtue of fundamental learning processes, concepts, and representations shared between music and other disciplines. As the research cited above suggests, positive conditions for the appropriate interaction of music among several disciplines rely on high-quality instruction in each discipline. Only in schools where mathematics, music, and language are all taught effectively and with an equal degree of emphasis can we assume that music will promote learning transfer across disciplines.

The work of such a consortium will more likely raise public consciousness of the essential role of music in education than would each of the consortium's participating organizations in isolation. As research reported in popular media continues to expand its coverage to include evidence that connects music to many aspects of human potential, the National Music-in-Education consortium can provide practical guidelines for innovative program development and education policy based on a responsible interpretation of this research.

Strategy 5: Explore and promote new conceptions of giftedness that result from the implementation of innovative forms of comprehensive, interdisciplinary music education practices in public schools.

Man's mind stretched to a new idea never goes back to its original dimension (Oliver Wendell Holmes).

Once comprehensive, interdisciplinary music programs become available to every child in a school, larger numbers of students will more likely be able to attain higher levels of musical development. As a result, the bar for what parents or music educators would deem evidence of giftedness in music will be raised.

Consider this example of what is commonly expected at the Conservatory Lab Charter School: the ability to play the violin and sing at the same time. That is, every student learned to sing the names of notes and the German text of Beethoven's 'Ode to Joy', at the same time they performed the melody or various harmonic underpinnings of the tune on the violin (see Fig. 6 below). This skill was demonstrated when these

elementary-school children performed this work with the New England Conservatory's Symphony Orchestra.

The coordination of simultaneous and multiple representations of this tune indicates to most musicians a deep and broad understanding of a musical skill. That is, the Lab School children's ability to sing while playing the violin demonstrated a highly coordinated and integrated knowledge of the theme from 'Ode to Joy'. Orchestra members performing with the Lab School students were astonished to see that a skill required of all conservatory students in their advanced musicianship classes constituted a baseline requirement for these elementary-school children who had studied the violin in a public school for little more than a year.

The classroom and music teachers in the Lab School's comprehensive, interdisciplinary program have observed other aspects of academic and musical development that might have been associated with giftedness in the past. The ability to read and pronounce phonetic German spelling, the ability to start with any word in the text and sing the song from that point (at actual pitch), and the ability to sing the song with scale degree numbers (sometimes backwards and forwards) all indicate a deep operational and relational knowledge of the song.

Another example of musical ability that might have been considered an indication of giftedness is young Maya's ability to represent her knowledge of her violin music. The figure below illustrates how this second-grader used a matrix to represent the first phase of a folk song she played on the violin. She later created a mirror image of the melody on a second sheet of paper. When asked to sing the forward and backward versions of the tune, she exclaimed, "I like this both ways!" as she proceeded to explore symmetrical relationships in other musical tunes and original compositions throughout the project work.

In comprehensive, interdisciplinary music programs, broad and deep investigations of musical tunes become a standard component for all children in their violin, general music, language, and mathematics classes. Given these expectations for all children, indications of giftedness will more likely be characterized by creative and analytical engagement in multiple modes of performance knowledge, a symbolic grasp of music, composition, and a reflective understanding of musical design and meaning through interdisciplinary-based investigation.

As comprehensive, interdisciplinary music programs become a standard for public schools, music educators will undoubtedly discover new forms of musical giftedness based on:

- *Music as a medium for the integration of skills.* Rather than looking first toward accelerated performance skills based on imitation of conventional

practices, we will view musical talent as the ability to create or improvise diverse forms music, analyze systematically diverse styles and genres of music, and translate music into mathematical representations and vice versa;

- *Music as an indication of the ability to work with multiple representations.* Rather than thinking of the ability to read music as a mechanical, stimulus-response mechanism that a gifted student may learn more quickly, we would view the ability to switch performance representations flexibly (from playing to singing, from silent imagination to external performance). In addition, symbolic representations (numbers, notes, words, gestures, etc.) would provide a more useful framework for evaluating and nurturing musical talent;
- *Understanding musical concepts and skills through investigation of other subject areas.* Seen through the lens of interdisciplinary music programs, giftedness will more likely be evaluated by a student's ability to translate information from one field to another, or explain concepts intrinsic to music by borrowing

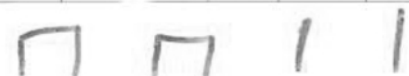

fundamental concepts shared with other disciplines (such as probability in mathematics, or sonic analysis related to physics);

- *Music as a model for artistic process.* Giftedness in music will more easily be judged by how individuals relate music to other art forms (such as theater, opera, dance, or film) in terms of subject matter, social context, emotional effect, and structural content;
- *Music as a medium and model for understanding interpersonal relationships.* Music is predominately a social art form and relies ultimately on working with fellow performers, teachers, and audiences. Interpersonal giftedness in music can be discerned in individuals who teach or coach others, who present music effectively to audiences, and who learn from others in different performing and studio ensemble contexts;
- *Music as a medium and model for intra-personal giftedness.* Musical development is predicated also on the ability of an individual to sustain personal practices consistently and profitably over long peri-

ods of time. Giftedness in music can be seen in terms of the ability to set goals and priorities, and in the ability to derive satisfaction from personal practice and constructive self-assessment;

- *Music as a form of self-education for social good.* Giftedness in music should be measured by more than the ability to follow instructions or to adhere to a set of prescribed procedures. Giftedness in this area is characterized by awareness of the worth of music both to one’s personal development and to the community to which musicians belong.

From the perspective of higher education, redefining giftedness in music can stimulate changes in the entire process of a college education or professional training. Gifted music students can be admitted on the basis of diverse forms of musical ability (as indicated above) and their willingness to embrace a broader view of the place of music in society. In this context, the Artist/Teacher/Scholar framework serves to further a musical

giftedness by way of artistic development integrated with teaching experiences and rigorous scholarship. The result may lead to rethinking what form musical concerts can take, what roles musicians can play in music education, or what contribution the education of gifted musicians can make toward creating better citizens in our society.

It is up to today’s educators to decide whether the testimony of last century’s most influential musicians and scientists should inform models for giftedness in contemporary public education. If education policy-makers can see that the musical process is an essential ingredient and inspiration for public education, then we all will make better sense of learners who link artistic production conjoined with the higher-order cognitive skills as indications of giftedness in both the arts and academics. Perhaps only then will educators in the arts and academics use the words of master artists such as Pablo Picasso as a means for others to understand that creative processes are virtually indistinguishable from

critical thinking skills associated with scientific method or academic excellence:

paintings are but research and experiment. I never do a painting as a work of art. All of them are researches. I search constantly and there is a logical sequence in all this search (Pablo Picasso, cited in Gardner, *The Arts and Human Development: A Psychological Study of the Artistic Process*, 1973).

Comprehensive, interdisciplinary programs in music education that raise expectations for literacy and performance skills for all children not only will suggest new criteria for the determination of gifted musicians but also will enlarge the range of responsibilities and roles that these musicians will be expected to play in furthering our society's understanding of the relationship between music and education.

Implications for Innovation in Music Education

Creative thinking may simply mean the realization that there is no particular virtue in doing things the way they have always been done (Rudolph Flesch, educator).

Music has reached an uncertain plateau in American public school education. Bolstered by innovations of the past, new standards exist for instruction in music-reading and instrumental skill development, yet these resources are not made available in public schools. Without adopting a new set of strategies for building toward a more progressive view of music programs that serve all children in public schools, educators and parents will continue to see musical ability as a special talent assessed primarily from the relatively parochial view of early emergence of musical performance skill.

At this point, however, there appears no particular virtue in maintaining current music-education practices. A summary of research conducted over the past two decades suggests four important themes that inform the basis for invention of new programs in music education (Scripp, 2002):

- (1) Theme 1: Meta-analyses on large bodies of research over the last few decades reveal consistently strong, positive relationships between music and learning in other subject areas. This unambiguous finding should be studied carefully so as to maximize its application to public-school Music-in-Education practices.
- (2) Theme 2: Generative neurological and cognitive frameworks for learning transfer have emerged from research on music and learning; studies that suggest learning transfer through music, especially in—but not limited to—the field of spatial-temporal skills, should continue to be tested in school settings for their application to, and impact on,

learning in comprehensive, interdisciplinary school programs.

- (3) Theme 3: Although the strong relationship between music and learning in other subject areas now is recognized, there is an underlying tension between the 'one-way cause and effect' and 'two-way interaction' models of research on music and learning. There is a need to interpret and design new research studies to help school communities understand the complexities of learning both in music and in the academics, and to better teach the principles shared between these subject areas.
- (4) Theme 4: The use of music as a tool for social-emotional development and behavior modification in schools has been well established in recent meta-analyses; the systemic employment of music-listening and music-making needs to be employed for goals outside of the traditional performance arena or aesthetic education and made available to classroom and music teachers as a tool for measurable outcomes in the areas of inter-personal and intra-personal skills.

Based on these findings and the preliminary work of innovative schools such as the Conservatory Lab Charter School and their partnerships with schools of music and other arts organizations, it is time to implement new conceptions of music education built on the innovations in music instruction of the past. Yet now we also must include a wider range of entry points, assessments, and interdisciplinary connections.

Researchers studying the effect of arts-integrated instruction on academic achievement warn, however, that to oversimplify expectations for learning transfer between music and the academics may limit our ability to assess the impact of innovative music programs on the whole school community (Adkins & McKenney, 2001; Catterall, 1998; Corbett, McKenney, Noblit & Wilson, 2001; Nelson, 2001)²². Furthermore, researchers at the Center for Arts Education Research at Columbia University report, for example, that significant instances of learning transfer across domains occur primarily because of the inherent interdependency of the subject areas, and not because one subject area 'causes' learning in another.

Arts learning . . . calls upon a constellation of capacities and dispositions that are layered and unified in the construction of forms we call paintings, poems, musical compositions, and dances. . . . What is critical is not that the capacities and

²² Reports from the A+ Schools Project in North Carolina (Corbett, McKenney, Noblit & Wilson, 2001; Nelson, 2001 in particular) show that the evaluation of the impact of arts programs in schools should not be limited to test score results as evidence that suggests 'causal links' between A+ arts programs and academic achievement.

Photo 7. All students at the Conservatory Lab Charter School performed with the New England Conservatory Symphony Orchestra their rendition of 'Ode to Joy'.

dispositions transfer from the arts to other subject areas, as has often been argued, but that they are exercised broadly across different knowledge domains. Given this interpretation, no subject has prior rights over any other subject, for to diminish one is to diminish the possibility and promise of them all. If the arts help define our path to the future, they need to become curriculum partners with other subject disciplines in ways that will allow them to contribute their own distinctive richness and complexity to the learning process as a whole (from Burton, Horowitz & Abeles, 1999).

In order for systemic change to occur in public schools, innovation also must be supported by a wider and more cohesive array of resources and institutional partnerships. In order for Music-in-Education programs to be successful they will need to rely on institutional partnerships with colleges of music, local arts organizations, and publications that serve the professional needs of teachers. The National Consortium for Music in Education has been formed for the specific purpose of sharing resources and research needed to support changes in educational policy with regard to the role of music in public-school education. The Artist/Teacher/Scholar conception of the conservatory-trained musician, the evolving role of gifted musicians as resources for public schools, and the scope of Music-in-Education programs now serve as guiding principles for sharing innovative practices and research for a new national consortium of schools of music, arts organizations, and their partnering public-school communities.

Furthermore, the dissemination and sustainability of innovation in music education face many challenges and obstacles that only new forms of teacher preparation, ongoing professional development, curriculum development, and evaluation methods may solve. Comprehensive, interdisciplinary music curricula will require music teachers who demonstrate a deep and diverse understanding of music and academics as is necessary to understand and facilitate connections across disciplines for all students. One cannot teach effectively the relationship between the concept of proportion in relation to musical rhythm without significant background musical skill; similarly, one cannot incorporate the concept of rhythm to the teaching of proportion without a deep understanding of mathematical problem-solving skills. It will be the shared understanding of the interactions between musical and academic learning processes that will enable entire school communities to accept music as an invaluable subject for its own sake and as a resource for enhancing learning throughout the school curriculum.

Should the five strategies for innovation in music education discussed in this chapter become established in the next decade, innovations resulting from these strategies will challenge the lingering perception that

learning in music is primarily a rare talent that is first and foremost measured by performance ability and has no direct bearing on the benefits of a musical education for all children across the school curriculum. Giftedness redefined as a synthesis of learning in and through music and the education of professionally trained musicians as artist-teacher-scholars both promise to serve our musical culture and education system equally well.

Determinants of Technological Innovation: Current Research Trends and Future Prospects

Vangelis Souitaris

The Entrepreneurship Centre, Imperial College, London, U.K.

Abstract: This chapter is a review of several methodologies, which have been used to identify the distinctive characteristics of innovative firms (determinants of technological innovation). Some of the problems affecting this research field are the diverse nature and non-standardised definition and measurement of innovation itself, non-standardised measurements of the determinants, interrelated variables, different characteristics of firms targeted and finally different economic regions where the surveys take place. The chapter presents a portfolio model, which synthesises previous research results and may be used for country or industry specific studies.

Keywords: Innovation; Technological innovation; Determinants of technological innovation; Portfolio model.

Introduction

The evidence from the literature strongly supports the view that technological innovation is a major influence on industrial competitiveness and national development (Tidd, 2001; Zaltman et al., 1973). Some firms are more technologically innovative than others, and the factors affecting their ability to innovate are important to management scholars, practising managers, consultants, and technology policy-makers.

The author adopted the OECD definitions of technology and technological innovation. Technology can be interpreted broadly as the whole complex of knowledge, skills, routines, competence, equipment and engineering practice which are necessary to produce a product or service. A new product requires a change in this underlying technology. Technological innovation occurs when a new or changed product is introduced to the market, or when a new or changed process is used in commercial production. The innovation process is the combination of activities—such as design, research, market investigation, tooling up and management—which are necessary to develop an innovative product or production process (OECD, 1992).

The factors that affect a firm's innovation¹ rate are called 'determinants of innovation'. They derive from a wide range of aspects of the company such as internal and external communications, managerial beliefs, the financial situation, size, structure, quality of personnel, R&D effort, technical capabilities and market conditions (Souitaris, 1999).

This chapter examines the methodologies and tools researchers have used in order to identify the determinants of technological innovation, within organisations. The results of a large number of studies are summarised and a framework is extracted. Afterwards, some current research trends are presented. Finally a view of what should be done in the future is proposed, in order to expand upon our current knowledge.

On the Methodology of Studies on Determinants of Innovation

From as early as the late 1950s, much literature has been published on the determinants of technological innovation. To illustrate the amount of academic research in this area, Rogers (1983) refers to 3,085

¹ Wherever the word 'innovation' is used in the text, it always refers to technological innovation.

publications about the diffusion of innovation, of which 2,297 are empirical research reports. He also adds that the number of publications was almost eight times more in 1983 than in 1962 (Rogers, 1983, p. xv).

In order to present better the objectives and the methodology of these studies, we can use the following categorisations:

(1) Categorisation according to the approach.

- (a) Studies researching at the project level, looking for the determinants of success or failure of innovative projects.

The main characteristic of these studies is that the sample comprises new technological projects. The objective is to correlate the success rate of the projects to a number of predefined possible determinants. This kind of research is known as the 'innovation or decision design' (Downs & Mohr, 1976) or the 'object approach' (Archibugi et al., 1994). Examples of the object approach are the following research works: Rubenstein et al. (1976), Rothwell (1977, 1992), Maidique & Zinger (1984) and Cooper (1979, 1999, 2002).

- (b) Studies researching at the firm level, looking for the determinants of the firms' ability to innovate.

The unit of analysis in these studies is the firm, and this kind of research is known as the 'multiple innovation research' (Downs & Mohr, 1976) or the 'subject approach' (Archibugi et al., 1994). There are two possibilities in this approach: the variables can determine either the firm's rate of innovation, or its ability to succeed and to benefit from its innovative technology. The interest in the rate of innovation as a dependent variable stems from the implicit hypothesis that firms introducing innovation regularly are more likely to sustain a large number of successful innovative products and processes (even if some of the projects fail). Examples of the subjective approach are the following research works: Mohr (1969), Miller (1983), Ettlé et al. (1984), Khan & Manopichetwattana (1989a) and Hajihoseini & de la Mare (1995).

(2) Categorisation according to the number of tested determinants of innovation.

- (a) Studies testing a large set of factors. These studies try to identify important determinants of innovation, testing integrated models with a wide range of variables. They usually have the intention, using regression equations with the determinants as independent variables, of pre-

dicting the highest possible proportion of the variation of the dependent variable (innovation rate). Examples of research works of this kind are: Duchesneau et al. (1979), Miller & Friesen (1984), and Swan & Newell (1994).

- (b) Studies that test one or a few specific factors like, for example, participation in professional associations, or formalisation of structure. Usually those studies use more sophisticated and detailed measures of the variable(s), intended to identify a possible correlation between the tested variable(s) and the dependent variable (innovation). However, they are only able to explain a portion of the variance in the rate of innovation. Examples of research works of this kind are: Mansfield (1963) on size and structure, Sapolsky (1967), and Hage & Dewar (1973) also on structure, Kets de Vries (1977) on personality of the entrepreneur, Tushman & Scandell (1981) on technology gatekeepers, Miller et al. (1982) on top executive locus of control, Chon & Turin (1984) on structure and decision-making procedures, Newell & Swan (1995) and Swan & Newell (1995) on membership in professional associations (for detailed lists of studies see Chiesa et al. (1996) and Brown & Eisenhardt (1995)).

The Problem of the Inconsistency of the Results

To date, the research carried out has been unable to conclude on the relevant variables or their exact impact on innovation. Although similar variables have been tested by different researchers, the results have shown differing degrees of impact on innovation. Most often, from the tested set of determinants, different ones were found to be significantly correlated to the innovation rate in each empirical survey. In some cases there was even disagreement as to whether a factor actually correlated positively or negatively to the rate of innovation (Downs & Mohr, 1976; Wolfe, 1994). For example, firm size is a highly disputed variable (Khan, 1990). The instability of the determinants from case to case frustrates integrated theory-building efforts. (Downs & Mohr, 1976; Tidd, 2001; Wolfe, 1994).

Duchesneau et al. (1979) demonstrated this inconsistency of results, duplicating a large number of previous studies. They deliberately used the same measures of determinants, but the sample was from one specific industrial sector (footwear industry). Their results were different from the original studies, mainly concerning the relative extent to which different variables correlate to innovation.²

² We should mention here Damanpour's (1991) objection to the various assertions about instability of results. His view is based on a meta-analysis of previous results and is worth reading.

Having reviewed a large number of studies, the author has identified a number of possible reasons for the inconsistency of these results (Souitaris, 1999). Determinants of innovation, and in particular their degree of correlation to the rate of technological innovation, are dependent upon the following factors:

- (1) Nature, definition and measurement of innovation itself.

The important determinants can be differentiated by the nature of innovation, for example high-cost vs. low-cost innovation, simple vs. complex innovation and incremental vs. radical innovation (e.g. Dewar & Dutton, 1986; Tornatzky & Klein, 1982). Determinants of high-cost innovation appear very different to those of low-cost innovation. Downs & Mohr (1976) found that a wealth of resources would predict the former very differently to the latter. Ettl et al. (1984) found that, while 'incremental' innovation may be enhanced by a decentralised structure, 'radical' innovation requires a more centralised structure with particular emphasis on decision-making and a higher level of support and involvement from top management.

More recent innovation typologies are produced by Clark & Wheelwright (1992) (research or advanced development; breakthrough development; platform or generational; derivative or incremental) and Christensen (1997) ('sustaining' innovation vs. 'disruptive' innovation).

An additional problem is the lack of a standard definition of technological innovation (Garcia & Calantone, 2002). What is included in, or excluded from, the definition of technological innovation is an important issue which needs to be addressed. Should aesthetic improvements in the matters of style, design or re-packaging be included as technological innovation? What degree of change is required for a product or process to be considered as technological innovation? There is a difficulty in interpreting the terms used in definitions such as 'significant' or 'considerable' (Smith, 1988 outlines the variations in the definition of innovation). In addition, should the definition distinguish between product and process innovations or between the development of completely new products and the incremental modification of existing products in a systematic way? The different definitions and interpretations of technological innovation have led to variations in the identified determinants—hence the ongoing research interest into this subject (for good and current discussions of this problem see Garcia & Calantone, 2002; Souitaris, 1999; Tidd, 2001).

Also, there is no standard measurement of technological innovation. There are two levels of innovation measurement referred to in literature

(Duchesneau et al., 1979). Firstly, at the micro-level—where the adoption of a number of industry specific innovations is measured—innovations are selected as being representative, by a group of industrial experts or by the researchers reading industry specific magazines. Second, there is the aggregated level where the rate of innovation of a firm is measured in various ways such as the number of new products and processes, the percentage of sales due to new products or the number of patents filed. Whatever decision is taken on the measurement of innovation to be used in a particular study can influence the results on the innovation determinants.

- (2) Measurement of the determinants of innovation.

In the literature, there are two types of determinants of innovation. The first type includes variables measuring facts such as the size of the firm, number of graduates, size of innovation budget, etc. The above are straightforward and easy-to-measure variables, with highly reliable measurements. They are also easily transferable over different studies. For instance, the number (or the logarithm) of personnel is a generally standardised measure of a firm's size (see, for example, Kimberly & Evanisko, 1981).

The second type of variables includes perceptions and attitudes of the respondents (such as perceptions of the intensity of competition or attitudes towards risk-taking), as well as general and usually subjective concepts (like centralisation of power,³ complexity of knowledge⁴ and awareness of strategy). Many of those variables are then broken down into a number of items and are measured using scales (see section 'The Portfolio Model of Starting Variables' for references on individual constructs and measures).

This second type of variables is no less important a predictor of innovation performance than the hard measures of the first type. However, the definitions of the soft variables are subjective and depend upon the author's perception. There are no consistent definitions and measures of concepts as general as the 'scanning of the environment' or 'environmental heterogeneity' (Miller & Friesen, 1984), or 'formalisation'⁵ and 'centralisation' (Hage & Aiken, 1970). The concepts may be similar but the way in which they are actually broken down into variables and measured using scales differs. The different definitions and

³ Degree to which power and control in a system are concentrated in the hands of relatively few individuals.

⁴ Degree to which an organisation's members possess a relatively high level of knowledge and expertise.

⁵ Degree to which an organisation emphasises following rules and procedures in the role performance of its members.

measurement of determinants referring to similar concepts makes the comparison of results more difficult.

For example, it is difficult to compare a general variable called “scanning of the environment” (Miller, 1983)—which is measured using a large number of scale items including many forms of communication with the external environment—with specialised variables like “the number of contacts made each year with representatives of machinery suppliers” and “the number of trade journals read or scanned by innovation decision makers” (Webster, 1970). In both cases the variables refer to the same concept of collecting information but they are not directly comparable, due to the different scope of the definitions.

Another problem for someone trying to compare previous results is that not all studies define the measurements of each variable clearly. Many of them (especially journal papers) give just lists of determinants, underestimating the importance of their actual measurement (for example, in the seminal work of Miller (1983), the measurement of the variables is not clear).

In addition to this, it is worth mentioning that most of the variables are interrelated, and this creates problems in the interpretation of the results. For instance, size is probably a surrogate measure of several dimensions that lead to innovation such as total resources, slack resources and organisational structure (Rogers, 1983). These relationships between variables and their effect on the final results are not easy to understand clearly due to the complexity of the issue.

- (3) Effect of different stages of innovation process on innovation rate.

Inconsistent results and low correlations of organisational structure variables with innovation can also be caused by some of the variables being related to innovation in one direction during initiation of innovation, and in the opposite direction during implementation of innovation. It has been argued that low centralisation, high complexity and low formalisation can facilitate initiation in the innovation process and that the same structural characteristics can also hinder the implementation of an innovation within an organisation (Sapolsky, 1967; Zaltman et al., 1973).

- (4) Different kind of firms used as sample.

Miller (1983), Khan & Manopichetwattana (1989b) and Damanpour (1991), among others, found that different types of firms show different determinants of technological innovation. For example, Rothwell, (1974, 1977) showed that the factors associated with innovation were significantly different, or at least showed a different order

of importance, in different industrial sectors. For example, within the chemical industry, technical factors were most important, while in the scientific instruments industry, market factors dominated (Rothwell, 1974). Mohr (1969) has also referred to a moderating effect of the size of the firm on the relative importance of its determinants of innovation. For example, top management characteristics and attitudes were found to be more important innovation determinants for small firms, due to the more active involvement of top managers in the innovation process (also see Carrier, 1994; Lefebvre et al., 1997).

These and similar findings indicated that studies which only look at the industry as a whole cannot be generalised. They cannot be directly compared to studies, which deal only with one industrial sector, or one particular type of organisation (e.g. multinational). The fact that different results are achieved, according to the type of firm, illustrates the problem involved in trying to achieve a unified theory of determinants of innovation, which can be applied to all situations.

- (5) Different geographical regions in which the empirical surveys take place.

Much of the available literature in this area is biased towards investigating determinants of innovation in the U.S. or other industrialised Western countries. Often the importance of the region in the interpretation of the results is overlooked (Boyacigiller & Adler, 1991; Drazin & Schoonhoven, 1996).

White (1988) and Souitaris (1999), among others, indicated that the characteristics of innovative firms are strongly influenced by economic development and the management culture in the region.

In conclusion, the fact that there seemed to be no unified theory concerning the determinants of innovation has reduced the amount of published studies and the effort devoted to the subject after the late 1970s. Rogers (1983) argued that after several hundred studies of organisational innovativeness were completed in the 1950s, 1960s and 1970s, this approach to innovation in organisations became passé. However, the problem was not resolved, and the crucial question of what the determinants of innovation are still remains open.

The Portfolio Model of Starting Variables

Forrest (1991) and Tidd et al. (1997), among others, argued that there is no one best way of managing the innovation process as it depends on firm specific circumstances. Nelson & Winter (1977) introduced the concept of ‘routines’, which are particular ways of behaviour which emerge as a result of repeated experiments and experience around what appears to be

good practice. Different firms use different routines with various degrees of success. There are general recipes from which general suggestions for effective routines can be derived, but they must be customised to particular organisations and related to particular technologies and products (Tidd et al., 1997).

It is difficult to produce a universally applicable model of the determinants of technological innovation. Differences in the industrial sectors and geographical regions all have an effect, which is very hard to quantify or exclude. Taking this into account, the author has developed a working ‘portfolio model’ of potential determining variables (Souitaris, 1999, 2002). The full list of determinants in the model is not always applicable—there are different sets of important determinants, depending upon certain environmental dimensions that underlie the analysis (such as economic development and managerial culture). The study’s model is intended to be a starting point for empirical research, in order to explore the contingencies.

The routines associated with innovation are extensive, and their strength of association is specific to particular conditions for reasons explored in the previous section. However, collectively the determinants of innovation tend to cluster around key themes (Tidd et al., 1997) presented in Table 1. The table demonstrates a comparative presentation of models in the literature that attempt to integrate the determinants of innovation. Common classes of factors appear throughout the different models focusing on ‘context’ (external environment and firm’s profile), ‘strategy’,

‘scanning external information’ and ‘organisational structure’.

Innovation textbooks (such as Ettlie, 2000; Tidd et al., 2001; Trott, 1998) and papers with practical orientation (Bessant, 2003; Cooper, 1999, 2002) advise students and practitioners drawing from this generally acceptable body of knowledge. However, despite the apparent similarity of integrative models of determinants of innovation at the aggregated level, there is more variety when it comes to operationalisation and empirical testing. The literature includes a large number of individual indicators falling into the above general variable categories;⁶ The variables in our portfolio model were categorised in four classes, in line with the integrative models of determinants of innovation reviewed previously (see Table 1 and Fig. 1).

The presentation of the portfolio model which follows covers two types of sources: (1) conceptual works that introduced the general themes and proposed their relationship with firm innovation; and (2) studies (mainly empirical) that associated innovation rate with specific indicators, within the general themes.

(1) Contextual Variables.

Organisations are viewed by several theoretical perspectives as adaptive systems, and this suggests that contextual variables may have a causal influence on strategy and structure. Examples of such theoretical perspectives are the contingency

⁶ Chiesa et al. (1996) and Souitaris (1999) offered detailed literature-based frameworks of operational indicators.

Table 1. A comparison of ‘integrated’ models of determinants of innovation.

Source: Souitaris (2002a).

theory (Burns & Stalker, 1961; Donaldson, 1996), institutional theory (Parsons, 1966), resource dependence (Aldrich, 1979; Barney, 2001), population ecology (Hannan & Freeman, 1977), and industrial economics (Freeman, 1982). The literature also includes interesting discussions on the impact of environmental variables (Miller & Blais, 1992). There are those who consider the impact of the environment on the firm's strategy and behaviour to be highly important (Weber, 1947), and others who claim that it is the organisations which select and even structure their environment (Miller, 1989). For an excellent review and critique of all the above main theories in the 'environmental school' of the management literature see Mintzberg et al. (1998).

The current study has used two types of contextual variables in the portfolio model:

- (a) Firm's profile: Literature in this area connects innovation with factors such as the age of the firm (Nejad, 1997), growth rate (Smith, 1974), profitability (Mansfield, 1971) and earnings from exports (Calvert et al., 1996);
- (b) Competitive Environment: Evidence in the literature points to the fact that the high rate of change of customer needs and intense competition are closely associated with a high innovation rate (Khan & Manopichetwattana, 1989a; Miller & Friesen, 1984).

(2) Strategy-Related Variables.

A firm's strategy can be viewed as a network of decisions, which need to be made in order to position the firm within its environment and to create the organisational structure and processes. Since the 1960s, when the idea of corporate strategy was first noted, there has been much debate between the two main schools of thought: the 'rationalist' school (Ansoff, 1965) and the 'incrementalist' school (Mintzberg, 1987). Porter (1980) explicitly linked technology to 'five forces' which drive competition within the industry (bargaining power of suppliers, threat of new entrants, bargaining power of buyers, threat of substitutes and intensity of rivalry). Porter's 'rationalist' approach suggests that managers need to analyse the external environment and, based on this analysis, they must define a course of action. However, the 'incrementalists' Teece & Pisano (1994) suggested a different approach to corporate strategy, that of 'dynamic capabilities' underlining the importance of dynamic change and corporate learning.

Cooper (1984) was one of the first of the empirical scholars to identify an association between corporate strategy and innovation performance of firms (see also Cooper's chapter in

this volume). Our model incorporates four subsets of strategy-related indicators:

- (a) *Innovation budget*. Literature showed that where there is a budget for innovation and in particular when this budget is consistent over time, the rate of innovation will be increased (Khan, 1990; Twiss, 1992);
- (b) *Business strategy*. In firms with a well-defined business strategy, including plans for new technology, the rate of innovation was found to be higher (Rothwell, 1992; Swan & Newell, 1995). Moreover, those firms, which had a strategy with a long-term horizon and could communicate it to their employees, showed a higher rate of innovation (Khan & Manopichetwattana, 1989a);
- (c) *Management attitude*. Literature also indicates that top managers of the more innovative companies have an internal 'locus of control'. They consider that the performance of their firm depends on manageable practices rather than the influence of external environmental factors which they cannot control. (Miller et al., 1982). In addition, the top managers of the most innovative firms appear to have less fear of risk-taking (Khan & Manopichetwattana, 1989b) and recognise that in a shorter-than-expected time scale, the new technology costs can be recovered (Eurostat, 1996). Finally, these managers consider that there is a 'performance gap' between how the firm currently performs and how it could perform in an ideal situation (Duchesneau et al., 1979);
- (d) *CEO's profile*. This particularly relates to the age and status of the CEO—i.e. whether he/she is also the owner or an appointed executive. The literature implies that a younger CEO who is also the owner will be more receptive to innovation (Khan & Manopichetwattana, 1989b).

(3) External Communications.

Another positive influence on the rate of innovation identified in the literature is the acquisition and scanning of information (Tidd et al., 1997). Therefore, three subsets of innovation-related communications variables have been incorporated in the model.

The first subset comprises the factors related to *communication with the firms' stakeholders*. These are:

- (a) Customers: personal meetings (Chiesa et al., 1996; Maidique & Zinger, 1984; Rochford & Rudelius, 1992), panel discussions (Chiesa et al., 1996), postal or telephone feedback (Chiesa et al., 1996), or quantitative market

research for a broader customer profile (Khan & Manopichetwattana, 1989b);

- (b) Suppliers of machinery and equipment: (Duchesneau et al., 1979; Rothwell, 1992).

The second subset incorporates the factors related to the *collection and scanning of information* which can be from sources such as public agencies (Carrara & Duhamel, 1995) or other firms (Alter & Hage, 1993; Bidault & Fiscer 1994; Trott, 2003). The membership of professional associations, (Swan & Newell, 1995), subscription to scientific and trade journals (Khan & Manopichetwattana, 1989b), attendance at trade fairs (Duchesneau et al., 1979), access to and use of the Internet, and use of electronic patent and research databases to search for new technology are other ways of collecting information on innovation, albeit less direct. A 'technology gatekeeper'—i.e. someone whose role is specifically to search for information on new technology—is another determining variable according to some literature (Allen, 1986; Rothwell, 1992). Finally, simply by monitoring one's competitor's activities, a great deal of useful and critical information can be discovered (Chiesa et al., 1996).

The third subset refers to the *co-operation of the firm with third parties* such as universities and research institutions (Bonaccorsi & Piccaluga, 1994; Lopez-Martinez et al., 1994); public and private consultants (Bessant & Rush, 1995; Pilorget, 1993); other firms in the form of joint ventures (Alter & Hage, 1993; Rothwell, 1992; Swan & Newell, 1995) or licensing (Lowe & Crawford, 1984); and financial institutions as a source of venture capital (EUROSTAT, 1996). The absorption of public technology funds, where they are available, can be another determinant of innovation. (Smith & Vidvei, 1992).

- (4) Variables Related to the 'Organisational Context'.

Bureaucracy theory (Weber, 1947), classical management (Gulick & Ulrick, 1938) and organisational sociology (Blay & Schoenherr, 1971) all emphasise the dominant influence of the structural attributes of an organisation on its behaviour. However, this appears to work both ways—while predefined structural factors may either hinder or encourage innovation, yet others insist that structure can be modified as a function of strategy to enhance the innovative potential of firms (Miller & Blais, 1992).

The organisational competencies incorporated in the portfolio model are classified into six subsets and are all based on the empirical literature:

- (a) *Technical competencies*. Both the intensity of R&D (Duchesneau et al., 1979; Ettl et al., 1984) and the intensity of quality control

(Rothwell, 1992; Zairi, 1996) are associated with innovation;

- (b) *Market competencies*. Cooper (1984) and Maidique & Zinger (1984) and Veryzer (2003) associated an effective marketing programme and a broad distribution system with innovation.
- (c) *Education of personnel*. In firms which had a higher number of educated and technically qualified staff, there appeared to be a more responsive attitude to innovation (Carter & Williams, 1957; Nejad, 1997). Miller & Friesen (1984) suggested that 'technocrats' came up with more than average innovative ideas.
- (d) *Breadth of experience of personnel*. The broader the base of employees within a firm who had managerial responsibilities, the higher the rate of adoption of innovations (Becker & Stafford, 1967). Organisations in which the staff have more varied backgrounds, for example working experience in other companies and/or abroad will generally have a more positive attitude towards innovation (Carroll, 1967). Such employees can often suggest and implement ideas for innovation.
- (e) *Training*. Hage & Aiken (1970) and Dewar & Dutton (1986) associated innovation with 'knowledge depth', measured by the level of professional training. On-the-job training has also been linked to the rate of innovation by more recent authors (Nejad, 1997; Swan & Newell, 1995)—this training refers to both professional training for engineers and managers and technical training offered to the production employees.
- (f) *Internal 'process' variables*. Innovative companies are less formalised than non-innovative ones (Cohn & Turin, 1984). The business innovative performance can be also enhanced by introducing thinking (or 'slack') time for engineers and management (EUROSTAT, 1994) and by using cross-functional interdisciplinary teams (Clark & Fujimoto, 1991; Cooper, 1990; Hise et al., 1990).

Another critical factor influencing innovation is the existence of a 'project champion' (Cooper, 1979; Hauschildt, 2003; Rothwell, 1992). The 'project champion' is an individual who dedicates herself to an innovation project and will give a personal commitment to fulfilling that project (Scon, 1973). Burns & Stalker (1961), Rogers & Shoemaker (1971) and Rothwell (1992), have identified an association between internal communication and technological innovation. Finally, authors such as Felberg & DeMarco (1992), Twiss (1992) and Chiesa et al. (1996) made a case that a firm's innovation potential can be enhanced by allowing

employees to generate their own new ideas, by encouraging the circulation and communication of such ideas, and by offering incentives of some form to the employees.

It is worth stressing again that the model of this study was not intended to be exhaustive. The factors that can be related to innovation are numerous and possibly change over time as management practice is a dynamic process.

More Recent Issues and Considerations

Measuring Innovation—Using Portfolios of Indicators

One of the major problems facing innovation research is the absence of common ground or definition. The most commonly used indicators at the ‘aggregated level’ are technology-based ones, including capital expenditure, expenditure on research and development and patent activity (OECD, 1982; Tidd et al., 1996) and these have been used for the longest time. The strengths and weaknesses of technological indicators have long been recognised (see Pavitt & Patel, 1988; Smith, 1992). Although the definitions of these indicators are relatively consistent and data are collected on a routine basis, it can be argued that they measure innovation input (effort towards innovation) rather than innovation output (actual results from the innovation effort).

More recently, there has been a tendency for those undertaking innovation surveys to use innovation output or ‘market’ indicators, such as the number of new products and new processes adopted during a specific time period (for good reviews of innovation surveys see Archibugi et al., 1994 and Smith, 1992). These ‘innovation-count’ indicators have the drawback that products and processes are not directly comparable across different industries. Neither can they account for the economic significance of the innovations (Smith, 1992).

As a response to these disadvantages, some researchers have used ‘impact’ indicators, which attempt to collect data on the proportion of sales directly related to new products over a particular time period (see for example Meyer-Krahmer, 1984). These indicators show the rate at which a firm changes its product lines and vary across different industries and probably over time. However, impact indicators are good measures of both technological newness and economic significance (Smith, 1992).

Empirical literature seems to have suffered from inconsistent results over the years because of the difficulty in capturing the complexity of innovation with a simple, accurate measure (Duchesneau et al., 1979). Saviotti & Metcalfe (1984) and Tidd (2001) suggested that multi-indicators of innovation performance can offer a more complete picture of innovation performance, since the issue could be investigated from several different points of view and the problem of incomplete-

ness of each one of the individual measures could be minimised. Hence, I propose a portfolio of seven widely used innovation indicators:

- (1) Number of incrementally innovative products introduced in the past 3 years;
- (2) Number of radically innovative products introduced in the past 3 years;
- (3) Number of innovative manufacturing processes introduced in the past 3 years;
- (4) Percentage of current sales due to incrementally innovative products introduced in the past 3 years;
- (5) Percentage of current sales due to radically innovative products introduced in the past 3 years;
- (6) Expenditure for innovation in the past 3 years over current sales. This includes R&D expenditure as well as a wide set of other expenditures related to innovation, such as the acquisition of technology and know-how, tooling up, industrial engineering, industrial design, production start-up, training linked to innovation activities and marketing of new products;
- (7) Number of patents acquired in the past 3 years.

Three types of indicators are used in the above portfolio:

- (1) ‘Input’ measures (variables 6 and 7) indicating the effort made towards innovation;
- (2) ‘output’ measures (variables 1, 2 and 3) capturing the rate of implementation of innovation; and
- (3) ‘impact’ measures (variables 4 and 5) indicating the impact of the company’s innovative products.

Each type of measure is in itself incomplete (see Hansen, 1992; Smith, 1992; Souitaris, 1999), but collectively they can be used to measure innovation activity. They have now been accepted by the OECD as standardised tools for future innovation surveys (OECD, 1992). One of the limitations of this indicator-portfolio model is its inability to capture innovation failure and therefore to reveal the project success vs. failure ratio (Smith, 1989). This is a limitation which has to be acknowledged, because the level of analysis is the firm as a whole and not the individual project.

Two more ‘composite’ indicators that future readers might want to consult before selecting their innovation measures are presented by Hollenstein (1996) and Coombs et al. (1996).

Narrowing the Scope—Taxonomies of Firms with Similar Determinants of Innovation

As a response to the inconsistency of the innovation determinants, the contingency school of thought emerged (see Burns & Stalker, 1961; Downs & Mohr, 1976; Tidd et al., 1997, 2001), suggesting that there is no universal ‘best’ way to manage innovation as the phenomenon is context-specific. In order to make the results more meaningful and comparable, Wolfe (1994) urged future researchers to define clearly the contextual

settings of their surveys (i.e. the stage of the innovation process, the innovation attributes and the organisational context).

Many researchers have realised that innovation determinants can vary in different contexts and have narrowed down the scope of their work. Some have decided to concentrate on a narrow range of firms—by selecting similar firm size (for example small and medium-sized enterprises) or firms of the same industry. For instance, Khan & Manopichetwattana (1989a) and Rothwell (1978) focused only on small firms and Duchesneau et al. (1979) on the footwear industry.

Some authors proposed taxonomies of firms with different determinants of technological innovation. The first taxonomy was proposed by Burns & Stalker (1961). They distinguished between ‘mechanistic’ and ‘organic’ organisations. Mechanistic organisations have a lower complexity, higher formalisation and centralisation, and lower internal and external communication than organic organisations. In the 1980s, Miller & Friesen (1984) identified two types of firm configurations⁷ with different innovation determinants. These were ‘conservative’ firms with positive and significant correlation of innovation with information-processing, decision-making and structural variables, and ‘entrepreneurial’ firms with negative correlation of innovation with information-processing, decision-making and structural integration variables. The structure of the firm took a back seat while the goals and strategies of the company were viewed as the more important driver for innovation. Khan & Manopichetwattana (1989b) developed five clusters of small firms with different strategy, structure and managerial attitudes. Each of these was shown to have its own specific factors determining innovation.

These taxonomies (for good discussions on innovation taxonomies see Souitaris (2002a) and Tidd (2001) had an unquestionable and novel value in the innovation management literature, accepting that the characteristics of highly innovative firms are specific to particular conditions and trying to identify clusters of firms with common important determinants of innovation. However, the proposed classifications were weighted towards perceptual criteria (such as the risk-taking, proactiveness, entrepreneurial strength and belief in luck) rather than the factual measures such as size, industrial sector and common innovation type, hence the ongoing requirement for development of more precise and factual taxonomies. These could help to clarify conflicting research results on determinants of innovation (see section ‘The Problem of the Inconsistency of the Results’).

⁷ Readers that would like to know more about the configuration school in strategic management (supporting the idea of taxonomies), should refer to Miller (1986 and 1996) and Dess et al. (1993).

The author of this chapter tested the applicability of Pavitt’s (1984) taxonomy (which derived from the economic school of thought) as an effective factual classification that could benefit the management literature searching for the determinants of innovation. Pavitt suggested that industrial sectors differ greatly in the sources of technology they adopt, the users of the technology they develop, and the methods used by successful innovators to appropriate the benefits of their activities. He produced a simple and practical classification with four categories of firms:

- (1) ‘*Supplier-dominated firms*’. These firms are usually small, they do not place much emphasis on R&D, and they have lower engineering capabilities. They take the majority of their innovative ideas from firms, which supply them with equipment or materials;
- (2) ‘*Large-scale producers*’. These firms tend to be much bigger and instigate their own process technologies. They concentrate their resources in this area, and usually diversify vertically into technological equipment, which is related to their own technology. As a result they contribute to a large extent to innovation in all sectors of their activity;
- (3) ‘*Specialised suppliers*’. These firms tend to be smaller, perhaps mechanical or instrumental engineering firms. They also produce a high proportion of their own process technologies but focus more of their innovative activities on new products for use in other sectors. There is little diversification of technology and a relatively small contribution to innovations produced in their principal sector of activity. Their end users and other firms outside the sector make a more significant contribution;
- (4) ‘*Science-based firms*’. These companies are usually firms in the chemical, pharmaceutical and electrical and electronic engineering sectors, whose main source of technology is internal R&D. They produce a relatively high proportion of their own process technology and of product innovations used in other sectors of the industry. Usually large, most of their technological diversification is within the corporation, and they produce a relatively high proportion of all the innovations made in their principal sector of activity.

Pavitt’s taxonomy was selected for the test because it produced firm classes with a similar size, industrial sector and innovation type (three important moderators causing result instability in the management literature). The author expected that a simultaneous ‘control’ of all the three moderators would reduce the variation of the innovation determinants within classes and increase the variation across classes.

An empirical test in a sample of 105 Greek companies showed that firms in different trajectories (categories of firms) of Pavitt’s taxonomy showed

differences in the rate of technological innovation (for the detailed results of the study, see Souitaris (2002a)). Innovation for 'supplier-dominated' firms was related to the competitive environment, acquisition of information, technology strategy, risk attitude and internal co-ordination. For 'scale-intensive' firms the important determinants were related to the ability to raise funding as well as the education and experience of personnel. For 'specialised suppliers' innovation was associated with high growth rate and exporting, as well as training and incentives offered to the employees to contribute towards innovation. 'Science-based' firms depended upon technology-related variables, education and experience of personnel, growth in profitability and panel discussions with lead customers.

Using Pavitt's taxonomy management scholars can simplify the problem of multi-dimensional moderation. Size, industrial sector and type of innovation are combined into a single dimension: the 'technological trajectory'.

On the basis of my own research described above, I propose a 'two-step' methodology to identifying the distinguishing characteristics of innovative firms:

- (1) A classification of firms according to 'industrial-level' moderators. Pavitt's taxonomy has a high practical value at this level. It conveniently aggregates 'industrial-level' factors, producing four sectoral firm classes, rather than a long list of sectors;
- (2) Identification of a set of management-related determinants of innovation specific to each sectoral class. In practice, this method offers the opportunity to customise innovation questionnaires and measure the right 'type' of variables according to the firm's class.

The International Dimension

Most of the empirical research on the determinants of innovation has been carried out in industrialised developed countries. Recently, there has also been some interest in the particular conditions in Asian Newly Industrialised Countries (NICs) (see Hobday, 1995; Kim et al., 1993), in developing countries such as Iran (Nejad, 1997) and in transition economies in Eastern Europe (Inzelt, 2003). Several authors suggested that using the findings of innovation studies in technologically advanced countries to explain the innovative behaviour in countries with a less developed technological base is likely to be inappropriate (Drazin & Schoonhover, 1996; Mishra et al., 1996; Nejad, 1997; Souitaris, 1999).

A number of research paradigms have attempted to explain the international differences in technological development and innovation at a conceptual level. Neo-classical economic theorists have placed emphasis on the importance of a local supply of skills, specific local demands, openness of communication, pressure from

competition and market structure (Nabseth & Ray, 1974; Porter, 1990). The 'national innovation systems' paradigm underlined the important role of deliberate intangible investment in technological learning activities (involving institutions such as other firms, universities and governments and the links among them). Innovation systems theorists also stressed the national incentive structures of temporary monopoly profit from innovation and the firm-specific competencies (Lundvall, 1998; Patel & Pavitt, 1994). The neo-contingency school of thought put forward the case for the way in which the diffusion and utilisation of innovation in different countries could be affected by systematic differences in business strategies, organisational forms and specific social processes, all of which are mutually dependent (Slappendel, 1996; Sorge, 1991). The neo-institutional theorists placed more importance on the prevailing national institutional frameworks and networks (e.g. professional associations). These could create standards of best practice which would encourage some technologies to be diffused more widely than others (Di Maggio & Powell, 1983; Swan et al., 1999).

In spite of all the research into the national differences in the patterns of technological innovation, there is a need for more empirical research in order to fully understand the complexity of the issue (Moenaert et al., 1994; Patel & Pavitt, 1994; Swan et al., 1999). Moenaert et al. (1994) proposed an operational framework for future empirical research, which combines the elements of most of the conceptual paradigms. According to Moenaert et al. the innovation process in different countries depends upon four 'socio-economic' dimensions: technological heritage, administrative heritage, market structure and regional entrepreneurship with additional influence of the national 'cultural context'.

I have attempted to use this framework in order to empirically identify the determinants of innovation in Greece (an example of a European newly industrialised nation with a less developed technological base).⁸ The 'Greek studies' (Souitaris, 2001a, 2001b, 2002b) are based on a sample of 105 manufacturing companies in Greece, and the results are briefly summarised below.

Major importance 'organisational competencies' determining innovation were found to be the intensity of R&D, strength in marketing, proportion of university graduates and engineers in the staff, proportion of staff with managerial responsibility, proportion of professional staff with previous experience in another company and incentives offered to the employees to contribute to innovation (Souitaris, 2002b). Regarding

⁸ The average GDP per person is \$11,739 per annum, which indicates a medium-level development compared for instance to \$23,478 per annum for a large Western European country like the U.K. and \$1,352 per annum for a developing country like Iran (Economist, 1998).

'strategic variables' important determinants of innovation included incorporation of technology plans in the business strategy, managerial attitude towards risk, perceived intensity of competition and rate of change of customer needs and finally status of the CEO (owner-CEOs were associated with a higher innovation rate than appointed CEOs). In general, top-management characteristics proved to be more important 'strategic' determinants of innovation for the Greek firms than corporate practices (Souitaris, 2001b). Regarding 'external communications' the empirical results supported two hypotheses for industrialising countries (proposed by Souitaris, 2001a): (1) searching for product-specific information is more important for innovation than scanning more general market and technological information; (2) the co-operation with partnering organisations (such as investing firms and joint venture partners) is more important for innovation than the co-operation with assisting organisations (such as universities, consultants or government agencies) (Souitaris, 2001a).

A common observation which emerged from the 'Greek studies' is that the 'major importance' determinants were generally scarce in the country's context. For example, the Greek national culture is generally risk-averse (Hofstede, 1991), but the attitude towards risk was a highly important variable (Souitaris, 2001b). In Greece there is a low indigenous production and supply of technology (Giannitsis & Mavri, 1993), but the R&D intensity and the incorporation of technology planning into the business strategy were important predictors of a high innovation rate (Souitaris, 2001b, 2002b). The Greek market has a traditionally low level of competition because of protectionism measures, but the perception of intense competition and demanding customers was strongly associated with a high innovation rate (Souitaris, 2001b). Despite the fact that Greece suffers from an outdated educational system which does not consider the needs of the industry (Tsipouri, 1991), education-related variables proved important determinants of innovation (Souitaris, 2002).

The findings of the Greek studies put forward the hypothesis that the most important determinants of innovation in newly industrialised countries are those which are generally absent in the country-specific institutional market and social context. In other words, the most innovative companies are those which can overcome the traditional rigidities of the context of their countries and incorporate rare attitudes and practices for the local business environment. This hypothesis requires further testing in innovation research.

Where are We Going from Now?

As time passes by and management styles evolve, new determining variables appear, and the relative importance of the old ones changes. Hence, it is recom-

mended that holistic empirical surveys be carried out periodically, to act as yardsticks of our current knowledge. Qualitative methodologies such as observation and case studies would be useful from time to time in order to explore the perceptions of practising managers, to capture emerging determinants and to identify new lines of thinking for further quantitative research.

The fact that the results show different patterns depending on the region and/or the sectoral class, should be accepted and lived with. Hence, instead of devoting time and resources to the search for a unified theory of innovation, we can use portfolio models such as that presented in this chapter as a starting point and then identify the determining variables with the highest predictive power for the particular context. Using the set of important determinants as a base, auditing systems can then be developed putting the research results into practice.

In my view, the most fruitful direction for further research would be to untangle the 'black box' of the contingency theory. Contingency theory has been accused of having rather abstract and vague dimensions of the environment (Mintzberg et al., 1998). We need to map what determinants work under what exact environmental circumstances. Despite the fact that this is a highly complex problem due to the number of intervening variables, I propose work in two directions.

- (1) Empirical research on the important determinants of innovation in countries and regions with different managerial cultures and stages of economic development. International surveys carried out under exactly the same conditions (same industries and same measurements for innovation and its determinants) would be particularly useful;
- (2) Empirical research in order to confirm and establish the use of taxonomies, such as Pavitt's 'technological trajectories'. The creation of taxonomies of firms is encouraged in theory development, as it allows large amounts of complex information to be collapsed into more convenient categories, which are easier to comprehend (Carper & Snizek, 1980).

We always have to keep in mind that research on the determinants of innovation can have immediate usable and practical outcomes. The results of these studies will be valuable for: (1) company managers and consultants who want to identify the keys to high rate of innovation and (2) public policy-makers, who can see the impact of general 'infrastructure' variables like education, training, venture capital and information on the company's innovation potential.

Acknowledgments

The author would like to thank Dr. R. F. de la Mare for his contribution to these ideas and particularly Deborah

Salmon for her valuable language-related editing of the text.

Innovation in Financial Services Infrastructure

Paul Nightingale

Complex Product System Innovation Centre, Science Policy Research Unit (SPRU), University of Sussex, U.K.

Abstract: Financial infrastructure is essential to the world economy yet is largely neglected within the academic innovation literature. This chapter provides an overview of innovation in financial infrastructure. It shows how external infrastructure technologies between institutions improve market liquidity by increasing the reach of markets. Internal infrastructure technologies within institutions are used to co-ordinate the profitable allocation of resources. The heavy regulation of the industry, the software intensity of modern infrastructure technologies, the way in which they have multiple users and their increasing complexity create extra uncertainties in their design and development. As a consequence, they have very different patterns of innovation from traditional consumer goods.

Keywords: Innovation; Capital goods; Infrastructure; Technology; Financial services.

There have been, since the world began three great inventions. . . . The first is the invention of writing, which alone gives human nature the power of transmitting, . . . its laws, . . . contracts, . . . annals, and . . . discoveries. The second is the invention of money, which binds together . . . civilised societies. The third is the Oeconomical Table . . . which completes (the other two) . . . by perfecting their object: (This is) the great discovery of our age, but of which our posterity will reap the benefit.

Adam Smith, *The Wealth of Nations*, IV (ix), 38

Aims

This chapter aims to give an overview of how innovation takes place in financial infrastructure, and uses a contingency theory approach to show how it can be conceptualised using established models of innovation in capital goods.

Introduction

Within the academic innovation literature, services have traditionally been considered non-innovative.¹

This perception is reflected in the disproportionate bias towards research into mass-production manufacturing technologies. This may partly be attributed to a relative lack of visibility compared to consumer goods, and partly to the fact that service innovation is often intangible or dependent on innovation in bespoke infrastructures, and is therefore poorly reflected by traditional innovation indicators, such as patents. However, it is also because the nature of innovation in services is different from innovation in the mass production consumer goods traditionally studied in the literature.

This academic neglect is unfortunate given the importance of service innovation to GDP growth, employment, the economy, social change and the geography of global cities such as London or New York (Barras, 1986, 1990; Freeman & Perez, 1988; Soete & Miozzo, 1989). In the OECD, services account for approximately two-thirds of employment and economic value added (Bryson & Daniels, 1988; Gallouj & Weinstein, 1997; cf. Eurostat, 1998). The fact that the extent of employment of scientists and engineers in services overtook manufacturing in the USA in 1990 suggests that services are not as low-tech as their profile in the literature might suggest.

If one looks at financial services in OECD countries, they typically represent some 5–10% of GDP and a

¹ Important exceptions can be found in Bell (1973) and Fuchs (1968).

similar proportion of employment. For example, 5.4 million people are employed in the U.S. banking sector, which is more than twice the combined number of employees in automobiles, computers, pharmaceuticals, steel and clothing (Frei et al., 1998, p. 1). Banking is also extremely high-tech: global banks often spend over \$1 billion a year on IT (the cost of technology is second only to wages for most financial services companies) and, as Barras (1986, 1990) has argued, it is a vanguard sector that has been one of the first to adopt and diffuse new information technology.

This chapter will use a contingency theory approach to achieve three aims: firstly, to identify and explore the key features of innovation in financial services; secondly, to relate these specific features to various empirical studies on innovation; and thirdly, to try and explain how the contingent features of innovation in financial services infrastructure—in particular, complexity, software intensity, its multi-user nature and heavy regulation—can explain the various aspects of their patterns of innovation. It aims to provide an overview of how innovation takes place within financial infrastructure projects in order to draw out the important features.

The chapter explores the history of innovation in financial services and provides definitions of some of the terms used in this chapter; compares innovation in infrastructure and complex capital goods with innovation in mass production consumer goods; and explores the specific problems associated with innovation in embedded software. The final section draws conclusions.

Financial Services—Definitions and History

Early research on services tended to stress their intangible nature, heterogeneity, and the importance of time constraints on service delivery (Lovelock, 1983). Time is important because the output of services is often a 'performance rather than an object' (Lovelock, 1983; Lovelock & Yip, 1996; McDermott et al., 2001, p. 333). Storage is impossible when production and consumption are simultaneous, making the reliable and timely co-ordination and control of resources highly important. More recent academic literature has tended to move away from clear-cut distinctions between intangible services and tangible manufacturing and now understands them as a continuum (Brady & Davies, 2000; Miles, 1996; Uchupalanan, 2000). The intangible aspect is dominant in certain areas such as teaching, and the tangible aspect in areas such as detergent production. There is also a large middle ground where they overlap, such as fast food. In this chapter, the difference between services and manufacturing along this continuum is understood in terms of the tangibility of functions, so that service firms are paid to *perform a function*, while manufacturing companies produce objects that are bought to *provide a function* (Nightingale & Poll, 2000b).

The financial system performs the overall function of moving money between savers and borrowers. This allows people to *transfer their ability to use money to transform the world through time and space*. This links the present to the future, allowing borrowers and savers to switch between current income and future spending.² Prior to the development of money, a barter system was used for trade but was limited to the 'here and now'. Gradually, precious metals began to be used as *commodity* money to *measure* and *store value* through time and space as a medium of exchange. Coins, for example, were in use by the eighth century BC. Later on, the risk and cost of carrying around large amounts of precious commodities saw the development of *contract* money that could be exchanged for deposited gold and silver. Contract money gradually developed into *fiat* or *fiduciary* money that maintains its value even though it is not backed by gold. This development allowed a more extensive allocation of resources through time and space, but its geographical locus was limited by its basis in personal rather than institutional trust. Financial institutions perform various functions within the financial system, including using technological infrastructure to profitably and reliably deliver services, and so extend the institutional trust upon which the financial system depends.

Financial institutions are typically used to mediate the relationship between savers and borrowers because they have specialised technical capabilities (see Merton, 1975a, 1995; Merton & Brodie, 1995; Nightingale & Poll, 2000a). Firstly, they have extensive specialised knowledge of the risks involved. Secondly, there are generally large differences in the amounts of money that borrowers and lenders have or need. Thirdly, the liquidity requirements of lenders and borrowers are different. Liquidity refers to the ability to turn assets into cash quickly and cheaply. Lenders generally want quick access to their cash, while borrowers want longer-term, more stable funding. Fourthly, financial institutions allow the pooling of savings and risk which increases the liquidity of long-term debt. Lastly, financial institutions can take advantage of economies of scale by spreading the fixed costs of investments in infrastructure over a large number of contracts.

The development of specialised financial institutions and a sophisticated division of labour came about through an expansion of the market for financial services following the emergence of the fiscal-military state in the 16th and 17th centuries. As early-Modern wars were fought by attrition, the ability to allocate funds through time and space effectively determined military power and enabled smaller countries like

² Money and financial contracts in general are only means to other ends—they allow one to inter-convert goods and labour through time and space: for example, allowing the young to borrow to buy a house and the old to save productively.

Holland and England to take on France and Spain.³ This ‘financial revolution’ started when the provincial States of Holland accepted collective responsibility for war loans by securing them on future tax returns (Dickson, 1967, p. 63). The Bank of Amsterdam was set up in 1609, with the English waiting until the cost of a war with France in 1689 forced them to form the Bank of England in 1694.⁴

Improved commercial finance quickly followed to fund the activities of the newly emerging joint stock companies. The first joint-stock company, the Muscovy Company, was set up in London in 1553. As trade expanded, merchant banks emerged and acted as *accepting houses* that charged interest and commission on the bills of exchange that were used to finance trade. A virtuous cycle emerged in which expanded trade provided capital for financial institutions, who in turn provided capital for expanded trade and new firms. As joint stock companies became more important, the buying and selling of shares became more formalised, and exchanges were set up. The New York Stock Exchange was started under a buttonwood tree in 1792. The institution that would develop into the London Stock Exchange was started in 1760, renamed in 1773 and officially regulated in 1809.

Distinct institutions emerged within this heavily regulated financial system. While there is huge diversity within the sector, the three main forms of financial institutions are *banks*, *exchanges* and *investment institutions*. The institutional differences are determined by functional differences in how firms move money between savers and borrowers. Each method used, in turn, defines the technological trajectories (Dosi, 1982) that the firms follow, and influences the kind of technologies and infrastructure they use (Buzzacchi et al., 1995; Penning & Harianton, 1992).

Banks are traditionally divided into two kinds, depending on how they move surplus funds from investors to borrowers (Berger et al., 1995). Commercial or retail banks rely on deposits drawn from individual savers that they re-lend at a profit; the savers are typically paid a nominal amount of interest. Investment banks, however, make their money through fees charged from arranging complex financial deals (Eccles & Crance, 1988). Unlike commercial banks that load the assets they hold, investment banks help allocate surplus savings by underwriting securities that are sold to other investors. Securities have the advantage of being liquid, and consequently allowing investors to make rapid changes to their portfolios.

Exchanges are institutionalised markets for the trading of financial contracts. The two main types of

contracts sold on exchanges are company shares (which are sold in equity markets), and government and company debt (which are sold in bond markets).⁵ Markets have an advantage over institutional investment mechanisms in that they publicise information about the price of resources, allowing financial actors to improve their resource allocation. Exchanges are normally closed institutions with their own rules and regulations, which allow well-established financial processes to be developed and used in a more ‘trustworthy’ environment, improving the liquidity of trading. Since the value of assets generally increases with their liquidity (though there are exceptions), the ability to easily trade a contract has important economic implications.

Investment institutions such as pension funds, mutual funds (called unit trusts in the U.K.) and life-insurance companies are a fairly recent development. Up until the late 19th century, private individuals were the main investors, but after that date, investment trusts became increasingly important, followed by unit trusts in the 1930s (Golding, 2000). In the 1960s, pension funds took off, and the life-insurance industry became a major force in financial investment. Investment institutions now hold about two-fifths of U.S. household financial assets, and the largest five fund managers place assets larger than the combined GDPs of France and the U.K. They bundle together the savings and insurance contributions of individuals to invest in a range of assets on a long-term basis. Strictly speaking, investment institutions rely on fund managers for their investment management, but in practice most investment institutions are directly involved in investing in quoted companies. During the 1980s and 1990s, investment institutions grew rapidly, until they now control approximately US\$26 trillion of funds, US\$13 trillion of which are in the U.S.—approximately three times the GDP. Each type of investment institution has different investment preferences. Pension funds have predictable long-term liabilities, while insurance funds require more liquid assets in case they should have to pay out for a disaster.

Because financial services are so important to the wider global economy, they have traditionally been heavily regulated (Berger et al., 1995). Understanding regulation and regulatory loopholes is essential for understanding the development of the financial services industry (Calomiris & White, 1994; Hall, 1990; Merton, 1995b). In the USA regulations limited the ability of financial institutions to compete in a range of product and geographic markets. In Europe and Japan the operations of financial institutions are similarly regulated, which in turn influences what they do, and the structural possibilities of the technologies they use

³ Philip II had been defeated in 1575 not because of military superiority but because the cost of his army had bankrupted him, and he could no longer pay his troops.

⁴ London did not emerge as a financial centre until the Napoleonic wars eliminated Amsterdam.

⁵ Equities, unlike bonds, are ‘real assets’ that can protect the owner from inflation.

(Channon, 1998). Because financial infrastructure technologies influence firm behaviour, their development will almost inevitably involve national and possibly international regulators. These regulators may require changes to legal frameworks, which complicates and lengthens the design and development processes. While this is true of other sectors, it does not normal occur to the same extent.

The shift towards more market-based regulation in the late 20th century is commonly referred to as 'de-regulation', but is perhaps better thought of as a process of re-regulation. Specific restrictions have been removed, but government and international regulators still play a vital role in the functioning of financial markets.⁶ The ongoing changes in national and regional regulations have led to an increased internationalisation of markets and capital flows. This has, in turn, produced a corresponding increase in the geographical scope of infrastructure and allowed firms to exploit new economies of scale, generating market growth and increased concentration.

The Importance of Liquidity

The increasing concentration of the financial services industry over the 1980s and 1990s has seen the emergence of investment institutions with extremely large capital funds. The size of these funds has intensified concern about liquidity and the corresponding ability to cheaply adjust portfolios when markets move. For example, a fund of US\$500 million will not be able to make significant changes to its performance without trading units of about US\$10 million (Golding, 2000, p. 67). Buying or selling such an amount of shares in an 'illiquid' firm that trades only US\$250,000 of shares a day is going to be both time-consuming and expensive, and is likely to alert other players in the market, pushing the price up or down.

As a consequence, institutional investors have a preference for firms with large market capitalisation and very liquid shares. The size of modern financial institutions means that they have a major influence on market behaviour (and that the economist's notion of large numbers of small independent investors is becoming unrealistic).⁷ Since the 1980s, there has also been a trend towards the securitisation of a range of assets. This means that financial assets such as mortgages and credit card liabilities have been pooled and resold as contracts in markets where they can be traded. These bonds, backed by securitised assets, tend

to be substantially more liquid:⁸ not only are there fewer bonds than shares to choose from, but they are also more frequently traded. The New York Stock Exchange, for example, trades about US\$350 billion of bonds a day, compared to only US\$28 billion a day in equities.

Given that the liquidity of assets is determined in part by the number of potential buyers, infrastructure technologies that can bring a larger, more diverse set of buyers into contact with sellers will increase liquidity and the value of assets. Financial institutions rely on infrastructure technologies to do this. These technologies need not, however, be owned by the same people who operate the markets, and the divergent technological trajectories of stock exchanges and telecommunications networks has produced a shift towards the outsourcing of telecommunications.

Financial Institutions as Socio-Technical Systems

Financial institutions provide, monitor, and maintain the processes whereby funds are pooled, matched to borrower's requirements, and then allocated. Financial institutions take financial contracts (funds, bonds, etc.) as their inputs, and then process them, before reengineering them into new forms of contract that are then sold to customers. In doing so, they use sophisticated processes comprising people, knowledge and technology, to match the financial requirements of borrowers to those of savers. As such, they can be conceptualised as socio-technical systems (Hughes, 1983, 1987), where technology is used to improve the processes involved in matching financial contracts to customers by replacing person-based (and often market-based) mechanisms with an organised technology-based mechanism. This allows financial institutions to provide better services, develop new products, and exploit improved economies of scale, scope and speed (Barras, 1986, 1990; Ingham & Thompson, 1993; McMahan, 1996; Nightingale & Poll, 2000b).

The relationship between innovation in infrastructure technologies and performance improvement is fairly well understood in large manufacturing firms following the work of Alfred Chandler (1990). He showed the way in which firms invest in high fixed-cost infrastructures that improve the capacity and speed of production processes. The effective use of technology could then generate the fast, high-volume flows that would turn low-cost inputs into high-value outputs. In this way, the high costs of the infrastructure are then spread over a large volume of output to keep unit costs low.

If the volume of production is too low, then high fixed costs cannot be adequately spread and unit costs

⁶ The links between internationalisation and regional regulation have led Howells (1996) to question the usefulness of the concept of globalisation.

⁷ It is now not uncommon for large British companies to have 80–90% institutional ownership (Golding, 2000, p. 31).

⁸ Bonds backed by regular mortgage payments can be sold instantaneously and very cheaply, while repossessing and selling several thousand homes is extremely costly and difficult.

will rise (Chandler, 1990, p. 24). As a result, manufacturing firms organise and co-ordinate the resources required to fully utilise the capacity of production processes and increase the average speed of 'flows'.⁹ This is done in two ways. Firstly, firms developed sophisticated managerial techniques for controlling processes and, secondly, they exploited external and internal infrastructure technologies such as the telegraph and railway systems to ensure that production was uninterrupted.

Within the financial services sector things are slightly different. Profitability is linked to the efficient contextualisation and processing of information rather than the utilisation of capital machinery (Nightingale & Poll, 2000a). This means that profits are far less constrained by infrastructure technology than they are in manufacturing. For example, the profitability contribution of a worker on a production line or in a steel mill is largely determined by the technology itself, and a worker would be hard pressed to increase profits substantially. By contrast, a trader in a bank who was smarter, faster or had superior analysis than others in the market could very easily make significantly more profits with very few restrictions from technology. The amount of profit made on a trade of US\$100 million will be more than on a trade of US\$1 million, even though the same telecommunications system might be used. This is called *leverage*.

The flip side of high leverage is that while profits are almost unlimited, the same is true of losses, creating an incentive to understand and manage the extent and likelihood of these losses occurring, namely *risk*. As infrastructure technology has allowed larger and more complex contracts to be produced and traded, understanding risk has increased in importance- and risk-management technologies are key aspects of modern financial service infrastructure.

These differences underpin Barras' (1986, 1990) concept of the reverse product life cycle, whereby innovation in financial services is process- rather than product-driven (1986, 1990). Following Vernon (1966), Utterback & Abernathy (1975) argued that innovation in manufacturing follows a cycle that initially concentrates on product innovation until an established design is formulated, after which time competition is based on process innovation. Barras (1986, 1990), by contrast, argues that financial services follow a pattern whereby innovations in processes (and infrastructure technologies) allow new products to be introduced (1986). Both Utterback & Abernathy (1975) and Barras' (1986, 1990) ideas have been heavily criticised (Pavitt & Rothwell, 1987; Uchupalanan, 2000). In financial services, where the process is often the product, the sharp analytical distinction between product and proc-

ess innovation is questionable (cf. Easingwood & Storey, 1996).

Another way to look at innovation in financial services is to look at how, on the one hand, technology is used to increase the scale and liquidity of financial transactions by increasing 'reach' and bringing more buyers and sellers into contact with one another and, on the other hand, at how technology can be used to better match savers and lenders. In this way the manufacturing categories of process and product innovation are subsumed into the overlapping categories of service provision and control. This has the advantage of allowing us to see how innovation in financial service infrastructure co-evolves with innovation in infrastructure technologies outside the financial system. For example, the infrastructure of the railway network co-evolved with the telegraph system and the development of new financial products and services, which allowed the transportation of goods to be profitably co-ordinated.

It also allows one to conceptualise the direction of innovative activity. Infrastructure technologies that allow increases in the scale and liquidity of financial services tend to do so by expanding the range of savers and borrowers with whom firms interact because the scale and liquidity of financial transactions are closely related (Peffer & Tuunainen, 2001). For example, prior to the introduction of the telegraph, the New York Stock Exchange only managed to sell 31 shares over a single day in March 1830 (DuBoff, 1983, p. 261). However, infrastructure technologies that improve the internal allocation and control of service provision tend to focus on improving the accuracy, scope, speed and reliability of control processes (Nightingale & Poll, 2000b).

Technologies of communication and transportation are therefore particularly important for financial services, as delays in communication lead to deviations in market prices and opportunities for arbitrage. Consequently, the evolution of the financial services sector has been influenced by developments in information and transportation infrastructure technologies. For example, when communication between London and Amsterdam was dependent on sailing boats, it took three days for information to travel between the markets. This inefficiency in the communication of market information created opportunities for arbitrage. Similarly, when communication within Britain was undeveloped and irregular local exchanges flourished, but with the advent of regular mail coaches, leaving from Lombard Street in the City of London (starting in 1784), there was a pull towards the larger market in London (Michie, 1997, p. 306).

The development of the telegraph was a significant advance in infrastructure technology. Starting in the United States in 1844, by 1860 there were 5 million messages being transmitted annually along 56,000 miles of wire and 32,000 miles of telegraph poles

⁹ One way to maintain capacity utilisation (and therefore lower unit costs) is to exploit unused production capacity in new product lines, thereby generating economies of scope.

(DuBoff, 1983, p. 255). In 1851 a link was introduced between London and Paris which transcended the previous 12-hour communication times and allowed real-time price communication. In 1866 the first link between London and New York was set up, by 1872 the telegraph had linked London and Melbourne, and by 1898 there were 15 undersea cables (only nine were working) under the Atlantic (Michie, 1997, p. 310). By 1890, information could travel the 400 miles from Glasgow to London in 2.5 minutes (ibid.).

The telegraph had important implications for commodity exchanges as, together with improved infrastructure of railroads and storage, it allowed contracts to be linked to the point of production. As a consequence 'to arrive' contracts started to replace advanced payment based on 'certified' samples (DuBoff, 1983). This produced greater price stability, as large amounts of commodities were not being dumped in the illiquid markets of commercial centres. With the advent of the telegraph a far wider range of buyers and suppliers could be searched enabling exchanges and market makers to better match supply and demand. Infrastructure technologies such as the telegraph therefore increased liquidity and allowed the centralisation of exchanges (DuBoff, 1983).

The telegraph technology was very limited until the 1860s, with transmission rates of about 15 words per minute. With the invention of the stock telegraph in 1867, this went up to 500 words per minute, which again improved market performance (DuBoff, 1983, p. 263). Middlemen could be cut out of transactions, buyers and sellers did not need to travel, time lags were reduced, and there was a substantial reduction in the risks involved. As DuBoff notes:

The expected savings from a given market search will be higher the greater the dispersion of prices, the greater the number of production stages, and the greater the expenditure on the resources or service. For example, the only way to know all the prices which various buyers and sellers are quoting at a given moment would be to bring about a complete centralisation of the market, only then will costs of canvassing, or search, be at a minimum. Conversely, with infinite decentralisation these costs will reach a maximum. To lower them it pays to centralise—to reduce spatial dispersion and the number of independent decision makers (1983, p. 266).

The temporal and geographic reach of buyers and sellers was further improved by the introduction of the telephone. The geographic scope was increased again when the first transatlantic telephone cable was laid in 1956. The previous radio-based telephone infrastructure could only deal with 20 people, but by 1994 submarine cables could handle some 600,000 calls at a time (Michie, 1997, p. 318).

While much of the early innovation in infrastructure involved financial services firms 'piggybacking' on

established technologies like the telegraph, by the late 1980s firms were investing heavily in their own communications networks that could link local branches together. In doing so they relied heavily on external suppliers such as telecommunications companies and specialised financial information suppliers like Reuters, Dow Jones/Telerate, Knight Ridder and Bloomberg. By linking more institutions and people together with technical infrastructure, financial institutions have been able to save time in allocating financial contracts and increase the scope and number of buyers and sellers. This has made markets more liquid and allowed customers to reduce their inventories and the financial resources needed to maintain them. In doing so, the process of buying and selling has become disintermediated, with middlemen who traditionally matched buyers and sellers being replaced. This process of centralisation allows larger institutions to exercise improved control and secrecy, which in turn allows them to exploit new economies of scale (cf. Berger et al., 1995; DuBoff, 1983).

Internal Infrastructure

Once telecommunications systems had increased the reach of markets, and railroads had made improved national transportation of goods possible, market liquidity and the scale of transactions improved, creating new innovation challenges. Firms making large numbers of transactions needed to work out how best to allocate resources between different customers. Until recently, this had been done using unsophisticated technologies, largely subjective assessments of risk, and a 'my word is my bond' trust-based attitude towards risk control.

Since the 1980s the development of sophisticated theoretical tools in financial engineering has allowed products to be better priced and controlled (Marshall & Bansal, 1992). The initial developments came in 1952 when Harry Markovitz developed the fundamentals of portfolio theory (1952). William Sharpe helped develop the Capital Asset Pricing Model (CAPM) in the 1960s, and in the 1970s, Merton, Scholes & Black developed their option-pricing model (Black & Scholes, 1973). These theoretical developments have co-evolved with developments in internal IT infrastructure technologies that can integrate data and perform complex pricing and risk calculations (Bansal et al., 1993; Nightingale & Poll, 2000a).

The ability to value options has transformed finance because it has allowed risk to be approximated mathematically (Berstein, 1996). As a result, internal risk-management processes that previously relied on individual bankers' subjective assumptions, can now be modelled. This allows risk management to be more accurately related to the real risk exposures that financial institutions face. The development of these new tools and new internal software-intensive, IT infrastructure technologies increased the ease and

Table 1. Qualitative changes in risk management infrastructure.

Feature	Craft	Mass Standardisation	Complex
Number of servers	1–100	100–1000	1000+
Maintenance	Craft-based	Standardised	Very complex
Architecture	Decentralised	Centralised	Centralised
Key factor	Automation	Change function	Risk & reliability
Problems	Few	Predictable	One in a million
Importance	Limited	Business cost	Business critical
Risk analysis	Limited	End of day	Quicker and wider

Adapted from Nightingale & Poll (2000a).

accuracy of analysis and product pricing, and has allowed a range of new products and services to be developed (Nightingale & Poll, 2000a).

The shift towards a more theoretical basis for financial engineering was dependent on a transformation in the relationship between front and back office functions. Previously, the back office function in financial institutions had been automated to reduce costs. Risk exposures were typically computed on large mainframe technologies that would provide analysis of positions at the end of the day. With the development of sophisticated computer workstations and analytical software packages on traders' desks, many back-office functions were brought to the front office where they could be carried out closer to the customer. Risk analysis is typically now performed at various organisational levels within financial institutions, and traders, for example, will have a degree of sophisticated analysis available at their desks. This analysis can be performed in close to real time, allowing improved control over positions and exposures, but also imposing a large cost on organisations (Brady & Target, 1996).

This shift in the architecture of control has been dependent on the development of increasingly powerful software-intensive technologies and systems that are able to perform complex calculations quickly on large data sets. This has required a number of the larger financial institutions to develop technological capabilities in information technology, and these capabilities are beginning to be detected within the patent statistics (Pavitt, 1996). Financial service firms are developing their own capabilities in IT and in the mathematical algorithms needed to derive solutions to their risk and pricing calculations.

Nightingale & Poll (2000a) described how an investment bank developed the internal infrastructure technology needed to produce an increasingly sophisticated range of financial products. They showed that the ability to control the pricing and risk of financial contracts is dependent on the scope of the data that are accessed, the accuracy of the models, the speed of calculation and the reliability of the system.

The scope of control is important because calculated risk exposures will come closer to real risk exposures if the infrastructure allows the scope of risk analysis to extend and include more trades that the bank is party to. For example, if the bank's offices in London, New York and Tokyo are all exposed to the same position, each office may be within its local risk limits but the bank as a whole may be over-exposed. This exposure can be reduced if a wider scope of trades is included in the analysis.

Similarly, the ability to calculate exposures and prices is dependent on the accuracy of the models used and the power of the computer systems. If the models are inaccurate, or it takes a long time to calculate a position, the quality of the approximation will be reduced as inaccuracies build up or markets move. These two factors, and the drive towards more scope, lead to increases in the size and power of these IT systems. As Table 1 shows, increases in size and complexity lead to qualitative changes in the technology. Problems that might occur very rarely on individual workstations, for example, may occur every day in IT systems comprising several thousand globally linked servers, making maintenance a very complex and increasingly centralised process. Consequently, modern financial institutions are among the most innovative and demanding customers for the telecommunications and IT sectors (Barras, 1986, 1990).

Financial Infrastructure

Financial institutions depend on innovation in infrastructure technologies in two main ways. Firstly, they depend on *external* infrastructure technologies to underpin their trading and bring buyers and sellers together. Typically these infrastructure technologies, like the old railroads and telegraphs or modern IT and telecommunications networks, link wide geographic areas and allow financial firms to co-ordinate an increasingly diverse selection of customers. This increases the liquidity of markets, reduces middlemen and allows centralised firms to exploit new economies

of scale and scope. Often these technologies are produced and maintained by external suppliers, but many firms possess sophisticated technological capabilities and may operate their own Virtual Private Networks with telecommunications suppliers.

Secondly, once financial institutions have reached a certain scale they can exploit *internal* infrastructure technologies to calculate and control how their internal resources should be allocated. This use of internal infrastructure technology is dependent on firms building their internal technological capabilities to develop and use IT. Even when firms outsource their IT and telecommunications, they must still have sufficient technical capabilities to be intelligent customers and operate and use the infrastructure reliably.

This first half of this chapter has explored why infrastructure is important to the financial services industry, showing the importance of regulations and regulatory compliance to their development, and how the technologies comprise a range of complex, software-intensive capital goods that form part of, and are linked to, wider Large Technical Systems, such as global telecommunications networks. Despite their economic importance, there is little academic literature on the specific problems of financial infrastructure innovation, compared to other industries such as pharmaceuticals, for example. Consequently, the next section looks at the wider innovation literature, and examines what it can illuminate about the features of infrastructure outlined here. It will explore how infrastructure is similar to, and differs from, the mass production consumer goods traditionally studied in the innovation literature, and how the particularities of financial services influence the relevance of this wider research.

Innovation in Infrastructure

The Nature of Innovation

Innovation is generally characterised by high levels of uncertainty and sector specificity (Dosi, 1988; Freeman, 1982; Pavitt, 1984, 1989). Technological novelty and complexity contribute towards uncertainty, and mean that attempts to develop and use innovations often run into difficulties. These uncertainties can, however, be managed (Tidd et al., 1997) and a series of empirical studies have attempted to establish the factors that contribute to success. Project 'SAPPHO' was one of the first attempts to systematically identify what differentiates pairs of successful and unsuccessful innovations (Rothwell et al., 1974; SPRU, 1972). Although the original study was based on process innovations in the chemical industry and product innovations in the scientific instruments sector, three major findings came through clearly and have been supported by subsequent studies (Bacon et al., 1994; Clark et al., 1989; Cooper, 1983; Cooper & de Brentiani, 1991; Cooper & Kleinschmidt, 1990, 1993;

Prencipe, 2002; Shenhar et al., 2002; Tidd et al., 1997). These are: the importance of understanding user needs, the importance of good internal knowledge co-ordination, and the importance of having strong internal technical capabilities in order to access and incorporate external sources of knowledge.

While these findings remain important for understanding innovation in financial infrastructure, care must be taken to recognise the sector specificity of technical change (Freeman & Soete, 1998). Pavitt (1984) has produced a taxonomy of sectoral patterns of innovation that divides innovations into three types with different characteristics. These are: supplier-dominated, production-intensive and science-based. More recently the taxonomy was updated to include information-intensive software and services (Pavitt, 1990, cf. 1996). While the original paper is highly cited, many people miss that it added an additional "fourth category . . . to cover purchases by governments and utilities of expensive capital goods, related to defence, energy, communications and transport" (1984, p. 276).

The notion that innovation in complex capital goods is different from innovation in consumer goods was developed in the military-technology literature (Walker et al., 1988). Walker et al. (1988) formulated a hierarchy of military technologies that extends from very-low-cost materials and components (such as nuts and bolts), to high-cost components (such as jet fighter engines), and on to entire military systems costing billions of dollars (such as missile defence systems). They noted that:

as the hierarchical chain is climbed products become more complex, few in number, large in scale, and systemic in character. In parallel, design and production techniques tend to move from those associated with mass-production through series- and batch-production to unit production. Towards the top of the hierarchy, production involves the integration of disparate technologies, usually entailing large-scale project management and extensive national and international co-operation between enterprises. Thus, the pyramid is also one of increasing organisational and managerial complexity (Walker et al., 1998, pp. 19–20).

During the 1980s and 1990s a growing body of research analysed these highly engineered, bespoke capital goods. The research found that they tend to be produced by temporary networks of systems integration firms and their suppliers and regulators (Burton, 1992; Hobday, 1998; Hughes, 1987, 1983; Miller et al., 1995; Prencipe et al., 2002; Shenhar, 1998; Walker et al., 1988). Research on the management of their development has stressed the importance of good project management, good risk management, and effective control over the various suppliers involved in

Table 2. Contrast between innovation in complex capital goods & commodity products.

Feature	Complex Capital Goods	Commodity Products
Product Characteristics	Very high cost Multi-functional upstream capital goods Complex components and interfaces Many bespoke components Hierarchical and systemic High degree of embedded software	Low cost Single function downstream consumer goods Simple components and interfaces Small number of standardised components Simple architectures Little software
Production Characteristics	One-off projects or small batch production Highly uncertain Systems Integration Scale-intensive mass production not relevant	High volume Well understood Efficient production Incremental process cost improvements
Innovation Process	User-producer-driven Highly flexible craft-based Innovation and diffusion collapsed Innovation path agreed <i>ex ante</i> among suppliers, customers and regulators	Supplier-driven Formalised Innovation and diffusion separate Innovation path mediated by market selection
Industrial Co-ordination	Elaborate temporary network Project-based, multi-firm alliances	Structured around large firms and their supply chains Mass production by single firm
Market Characteristics	Duopolistic structure or internal provision Few large transactions Business to business Administered markets Heavily regulated and often politicised	Many competing buyers and sellers Large number of transactions Business to consumer Regular market mechanism Limited regulation

project development (Dvir et al., 1998; Hobday, 1998; Lindkvist et al., 1998; Might & Fischer, 1985; Miller et al., 1995; Morris, 1990, 1994; Pinto et al., 1993, 1998; Shenhar, 1998; Shenhar et al., 2002; Shenhar & Dvir, 1996; Tatikonda & Rosenthal, 2000; Williams, 1995; Williams et al., 1995 for a review of recent research). Insightful work has also revealed the particular problems associated with large-scale software development (Boehm, 1991; Brady 1997; Brooks, 1995; Gibbs, 1994; Parnas, 1985; Walz et al., 1993). In an important study of 110 Israeli defence projects Dvir et al. (1998) found that the balance of success factors was far from universal, with software projects being very different from hardware projects, and risk management and budget control less important for small-scale projects but vital for large ones.

In two seminal papers Hobday explored innovation in complex products and systems (CoPS) and noted that they are characterised by their business-to-business, capital good nature, their batch production processes, high-cost, inherent uncertainty, and the degree of embedded software. They tend to have production process that are based on temporary, negotiated and bureaucratically driven project-based firms (PBFs) and organisations (involving webs of users, producers and regulators) (cf. Gann & Salter, 1998; Lemley, 1992; Marquis & Straight, 1965; Might

& Fischer, 1985). This is particularly true of financial infrastructure, like the CREST or TAURUS systems, which are used and developed by many firms. Further research has highlighted the importance of early user involvement and the heavily regulated, bureaucratically administered nature of the market and development processes (Burton, 1993; Morgan et al., 1995; Morris, 1990; Sapolski, 1972; Walker et al., 1988). These features can be contrasted with mass-production goods that are low-cost, well understood, contain little embedded software and are sold in largely unregulated markets. This contrast can be seen in Table 2 (derived from Hobday, 1998, p. 699).

The Process of Infrastructure Development

The combination of high technological complexity and uncertainty, complicated user needs, long development times, high costs and high risk makes infrastructure development extremely difficult. There tends to be substantially more stress on risk management, project co-ordination, and uncertainty management than in traditional innovation processes. Despite these attempts at dealing with uncertainty, infrastructure projects suffer from a range of innovation problems and frequent project failures (Flowers, 1996; Hobday, 1998; Morris, 1990; Nightingale, 2000; Sauer & Waller, 1993; Tatikonda & Rosenthal, 2000).

One way of dealing with the uncertainty and high risk is to reverse the traditional method of *ex post* selection of consumer products in markets. Consumer goods innovation typically starts with R&D and moves into development, then production, then marketing and finally product launch and the selection of products by market mechanisms (see, for example, Utterback & Abernathy, 1975, cf. Barras, 1990).

By contrast, in complex infrastructure technologies the high risks and costs involved mean that customers, suppliers, regulators and government bodies negotiate contracts, product designs and production methods before development is begun (Hobday, 1998; Peck & Scherer, 1962; Walker et al., 1988; Woodward, 1958). This is intended to reduce risk and ensure that the end product matches the various stakeholders' requirements. As a consequence, infrastructure innovation processes will typically start with marketing and sales, and only after an outline design and production process is specified will the contracts be signed and development started.

The importance of understanding user needs throughout the development process is well recognised within the innovation literature. The SAPPHO project found it to be the major determinant of success (Rothwell et al., 1974; SPRU, 1972). This has been supported by subsequent research (Cooper, 1986; Grieve & Ball, 1992; Keil & Carmel, 1995; Lundvall, 1988; Mansfield, 1977; Rothwell, 1976; Teubal et al., 1977). In particular, von Hippel (1976) has shown the importance of users as sources of innovation, and the case studies of the SAPPHO project illustrated the importance of users making adjustments to technologies after they had been acquired (Rothwell, 1977). Bacon et al. (1994) found that using development engineers rather than marketing staff to liaise with customers, and using prototypes to aid customer feedback, produced superior results.

This initial stage of infrastructure development involves understanding user requirements, dealing with technical uncertainties, finding solutions that are acceptable to the various customers and users and then obtaining commitment from a whole network of stakeholders to an uncertain and potentially very risky venture. Simply getting the various users and customers, as well as national and international regulators, to define the infrastructure's function in any detail can be extremely difficult. Infrastructure technologies' initial cost estimates and overarching function are generally vague enough to interest a range of parties, but once one moves to the more specific architectural layout of the technology, the engineering trade-offs become increasingly politicised.

Choices about technologies become politicised because the implementation of new infrastructures often causes disruptions to established practices within institutions. The changes potentially impact a range of actors who may be resistant to the proposed project if

they feel that their interests will suffer. The 'Big Bang' in the City of London, which moved the City towards electronic trading, for example, required a large push from the U.K. government and met resistance from established groups within the City. The introduction of any major technology will have positive and negative effects for different groups, and those who are negatively affected may have very rational reasons to be against the project. The very late shift towards electronic trading in the New York Stock Exchange, for example, is indicative of the power of entrenched interests. Even with a largely positive group of users, it is not necessarily the case that they will have the same requirements or demands, and substantial negotiation is needed to define acceptable solutions (cf. Moynihan, 2002). These negotiations will necessarily involve trade-offs and the final proposals may not necessarily match anyone's specific requirements, a feature that applies as much within organisations as it does between them (Barki & Hartwick, 2001).

The problems involved in specifying the functions of a major infrastructure technology are complicated because many firms and institutions lack the technology capabilities to be 'intelligent customers'. Infrastructure technologies, after all, are not produced by banks everyday. As a consequence, financial institutions are susceptible to being misled by consultants and contractors into producing overly complex technologies that do not match their needs (Collins, 1997). Despite the substantial in-house capabilities that financial institutions have for developing and using information technology, many still lack the expertise needed to fully comprehend the complexities and potential difficulties they face in developing and implementing new infrastructure. Software firms are generally reluctant to be open about these potential problems, as they have an incentive to downplay them in order to secure contracts (Flowers, 1996). Even using external consultants to assess the bids may not overcome this problem, as their independence from the software industry is often questionable (Collins, 1997; Flowers, 1996).

The costs, complexities and risks involved in developing infrastructure mean that development projects require commitment from a range of actors. This typically comes in the form of written legally enforceable contracts, organisational commitment, and political endorsement. Unfortunately, these can easily lock counter-parties into a particular direction of technical change that may involve using inferior technologies and architectures (Collingridge, 1983; Walker, 2000). Similar problems emerge within organisations and make changes to heavily committed decisions difficult to undertake (Flowers, 1996). The process of securing commitment to a technology can make 'pulling the plug' on failing projects very difficult. This is a common problem in IT-intensive infrastructure. Keil et al. (2000a) found that between

30% and 40% of all the information systems in their sample exhibited some degree of “escalation of commitment to failing courses of action”, where the projects in question spiralled out of control (cf. Keil, 1995; Keil et al., 2000b; Keil & Montealegre, 2000; Smith et al., 2001). As with infrastructure projects in developing countries, larger projects require greater commitment, which makes changes in the light of potential failure more difficult.

Project Uncertainty and Process Flexibility

Once the initial specifications are defined and the customers are committed, the process moves to the next stage where engineers and technologists propose, test and modify solutions. As Vincenti (1990, p. 9) notes, the design process:

for devices that constitute complex systems is multi level and hierarchical . . . The levels run more or less as follows from the top on down:

- (1) Project Definition—translation of some usually ill defined military or commercial requirement into a concrete technical problem for level 2;
- (2) Overall Design—layout of arrangements and properties . . . to meet the project definition;
- (3) Major Component Design—division of project . . . ;
- (4) Subdivision of areas of component design from level 3 according to engineering discipline required . . . ;
- (5) Further Division of categories in level 4 into highly specific problems.

Thus, for complex infrastructure technologies the design process will involve specifying components and architecture in increasing detail. This process is complicated for infrastructure technologies because many sub-components are systemically related. As Nelson points out:

A particular problem in R&D on multi-component systems arises if the appropriate design of one component is sensitive to the other components. Such interdependencies mitigate against trying to redesign a number of components at once, unless there is strong knowledge that enables viable design for each of these to be well predicted *ex ante* or that there exists reliable tests of cheap models of the new system (1982, p. 463).

This systemic complexity means that the effects of incorrect design are magnified as design modifications spread to other systemically related subsystems.

The inherent uncertainties involved mean that initial solutions will rarely work correctly (Petroski, 1986). Instead, an iterative process of trial and error design is used to bring proposed solutions closer to the desired function. Each design iteration will cause the innova-

tion process to *feed back* to earlier stages *adding to its cost and schedule* (Nightingale, 2000; Williams et al., 1995). With simple technologies this process is rarely problematic, but with complex infrastructure technologies there are a larger number of possible feedback loops and potential failures within and between components.

If the process of updating design specifications takes time, the design changes are extensive, or the components are related to a large number of ‘sensitive’ components, the amount of redesign work can be very large. There is consequently a danger of ‘redesign chain reactions’ that spread through the different systems with disastrous effects (Nightingale, 2000). As the next section will show, this is a particular problem with software-intensive systems which tend not to scale in a linear way, so that small, local design modifications have the potential to grow into fundamental design changes at the project level.

The complexity of infrastructure projects means that even without these redesign loops, unforeseeable emergent problems can develop during the production process. As a consequence, production and development overlap to a far greater extent than in traditional innovation processes, where development problems are typically ironed out before production begins. The overlap between development and production is also required because the long timescales involved in developing infrastructure technologies (often years) mean that some component technologies can undergo radical technical changes during the lifetime of the project. This is especially true of rapidly changing technologies such as IT. Consequently, the project’s designs and processes need to be flexible and able to incorporate new developments as the project proceeds (Hobday, 2000).

The fluidity of design specifications and the high risk and cost of infrastructure make good internal, cross-functional knowledge co-ordination important for project success. Research on other sectors has highlighted the performance differences between firms that integrate functional disciplines and those that have a sequential innovation process (Bowen et al., 1995; Clark & Fujimoto, 1991; Leonard-Barton, 1995; Iansiti, 1995; Rothwell, 1992, 1993; Womack et al., 1991). The importance of organisational structure for knowledge integration has been highlighted by Galbraith (1973), Wheelwright & Clark (1993) and Clark & Fujimoto (1991), building on the original insights of Burns & Stalker (1961). The importance of different organisational forms in the development of large, complex technologies has been well recorded in the literature (Burns & Stalker, 1961; Larson & Gobeli, 1987, 1989; Miles & Snow, 1986). Larson and Gobeli, for example, show how the success of projects is dependent on appropriate organisational structures and relate that to the complexity, technological novelty, managerial capabilities and functional definition of

projects (1989). Rothwell (1993, 1992) has shown how information technology can be used to improve the integration of knowledge (cf. Bacon et al., 1994).

The Importance of Embedded Software

The problems associated with financial infrastructure innovation are exacerbated by the increasing importance of embedded software. This software is used to control how financial information is routed and processed and can radically improve infrastructure performance (Nightingale & Poll, 2000a). However, the incorporation of software adds to the complexity and uncertainty of development (Nightingale, 2000, p. 5) and turns what were previously straightforward engineering tasks into high-risk development projects (Brooks, 1986; Hobday, 1998).

Software development is problematic because of its vulnerability to errors and fragility (Brooks, 1995; cf. Boehm, 1981, 1991; Mills, 1971; Parnas, 1985; Ropponen & Lyytinen, 2000; Royce, 1970; Willcocks & Grithiths, 1994). Software is more vulnerable to design errors than other technologies because the abstract construction of interlocking concepts, data sets, relationships, algorithms and function invocations that make up a piece of software must all work perfectly if the software is to function properly. Unfortunately, the potential problems inherent in a string of code are not easy to find, making debugging and testing embedded software extremely difficult and time-consuming, and as a result, systems are often launched without being properly tested (Flowers, 1996).

The fragility of embedded software refers to the difficulties involved in modifying software as compared to many other technologies. As software is vulnerable to 'bugs', must work almost perfectly, and typically scales in non-linear ways, minor changes in code can necessitate extensive redesigns. These, in turn, can produce feedback loops within the software development process that can snowball into resource-intensive redesign processes and lead to increasingly fragile and low-quality products.

Software also adds to the development problems associated with the more tangible parts of the infrastructure because it may increase the degree of systemic interactions between physical sub-systems. While this can improve system performance, it can also reduce the ability to break complex innovation problems into sub-problems and modularise development.

The problems associated with producing large software systems are well recognised in the literature (Collins, 1997; Flowers, 1996; Fortune & Peters, 1995). This literature is mainly drawn from large projects that developed software from scratch, but financial service infrastructure often involves building on older legacy systems. Such systems may have inappropriate architectures and data structures that were designed for an older generation of infrastructure.

Similarly, the code may be written in a language that is no longer in common use, and the system experts may no longer be with the organisation, or, if they are still within the organisation, they may be committed to the older system and highly resistant to change.

The intangible nature of software further complicates the testing process. With a physical piece of infrastructure such as a road, it is possible to reliably evaluate how much further work is needed, but with software this is often extremely difficult. Software engineers have a saying that software is '90% finished 90% of the time'. This difficulty in evaluating the extent of further work creates extra uncertainties that can delay the cancellation of a failing project well beyond the point at which it would have been stopped had the full extent of the required work been known (Block, 1983; Flowers, 1996; Staw & Ross, 1987).

The problems involved in developing software-intensive infrastructure can be gauged by Gibbs' (1994, p. 72) point that "for every six new systems that are put into operation, two others are cancelled. The average software development project overshoots its schedule by half; larger projects generally do worse and some three quarters of all large scale systems are 'operating failures' that either do not function as intended or are not used at all". Similarly, the General Accounting Office has reviewed large U.S. government IT projects and noted:

During the last 6 years, agencies have obligated over \$145 billion building up and maintaining their information technology infrastructure. The benefits of this vast expenditure, however, have frequently been disappointing. GAO reports and congressional hearings have chronicled numerous system development efforts that suffered from multi-million dollar cost overruns, schedule slippages measured in years, and dismal mission-related results (GAO, 1997, p. 6).

Since financial services are significant users of IT infrastructure, they are particularly vulnerable to these large-scale IT failures. There have been a number of failed projects within the sector, ranging from the high-profile TAURUS system in the London Stock Exchange to a whole host of lower-profile failures within other institutions. These smaller failures are often covered up as financial institutions attempt to maintain their reputations for reliability, but interviews suggest that they are extremely common. Even more difficult to analyse are the numerous operational failures that produce significant losses for the institutions involved. Typically a software glitch or design error may cause a financial institution to miss-sell a series of trades. Whether these operational failures are due to the technology, training and operations, or auditing and management, may be impossible to tell. Whatever their cause, there are numerous cases of

financial institutions losing hundreds of millions of dollars.

Implementation and Failure

In addition to the difficulties described above, the implementation of financial infrastructure projects can also cause a successful design project to ultimately be an operational failure. To a large extent, successful implementation is dependent on effective project management (Pinto & Slevin, 1997, cf. Currie, 1994; Pinto & Covin, 1989; Slevin & Pinto, 1987). This includes, first and foremost, realistic planning in terms of both resources and time (*ibid.*) and recognising the importance of 'soft' human resource issues (Corbato, 1992; Levasseur, 1993). Within the U.K. financial-services sector, contractors work on a rule of thumb that implementation will be twice as expensive and take twice as long as the best initial estimates.

As infrastructure technologies are often business-critical, and financial services are time-dependent, the introduction of new systems can be very risky (Nightingale & Poll, 2000a). The business-critical nature of these technologies means that back-up systems must be in place and maintained to a very high standard. It is not uncommon for system failures to result in significant financial loss and damage to reputation. One interviewee likened the implementation process to "changing the foundations of a house with the house still standing" and added that "you also, at any given time, must be able to return the foundations back to their original state without anyone noticing you are there". The business-critical nature of these technologies often means that multiple back-up systems are put in place (many of which are used for simulation-based training).

One particular area of risk involves data conversion and migration from old to new systems. In some instances this may be so difficult that it is judged quicker and easier to re-key all the data. This problem is gradually receding as more and more products are built on similar database platforms and are released with Other Data-Base Connectivity (ODBC) drivers. This highlights the point that effective design involves considering implementation issues at an early stage, in particular customers' end-to-end business systems and requirements. Unfortunately, the changes that new infrastructure make to these processes are extremely difficult to foresee before implementation begins.

The risks and uncertainties involved in system implementation mean that it is common to run parallel systems, often for months, in order to iron out last-minute design problems. These systems are also used for staff training before implementation. Typically, within the City of London at least, and where it is technically feasible, the new systems will be run in a minimum of three environments; a live system, a QA (or quality assurance) system, and a test system. The test system often contains scrambled data (allowing

wider access than confidential customer information would permit) and is used for training and experimental late-stage design. The QA system is used for more sophisticated and rigorous testing of design changes, before components are implemented into the live system. There are limitations to the use of parallel runs, particularly in larger, more complicated, real-time, environments and where systems are being installed that are fundamentally different from the earlier technology.

The problems associated with the design and implementation of financial service infrastructure, highlighted in this chapter, mean that project failures are extremely common. No reliable figures are available, but anecdotal evidence suggests that at least a third of these projects are terminated or are operationally compromised. A classic, and well documented, example of financial infrastructure failure was the City of London's TAURUS system (cf. Currie, 1997; Flowers, 1996).

The TAURUS System

The TAURUS (Transfer and Automated Registration of Uncertified Stock) system was an infrastructure project within the City of London that was intended to create a paperless share-trading environment. Legal requirements in the U.K. meant that registers of all share trades had to be held by all publicly listed companies. Consequently, even small trades involved a very inefficient process whereby at least three pieces of paper were physically moved around the City. Unsurprisingly, an international report had criticised the settlements system, and it was clear that the system would be unable to cope with the mass share ownership that would follow the privatisation of U.K. public utilities. By August 1987, for example, a backlog of nearly 650,000 unsettled deals had built up (Flowers, 1996, p. 101).

Moving to a computerised system would, it was hoped, reduce time and cut costs by removing the need to physically transfer paper during trading, and the middlemen who controlled the process. The London Stock Exchange (LSE) had previously installed a less ambitious Talisman system in 1979 as part of a computerised share settling system, and its success led to the proposal in 1981 to automate the entire market and end paper trading. Consequently, work started on the system that was to become TAURUS in 1983, and the LSE as an institution committed itself very publicly to develop a world-class system that would ensure its dominance over other European exchanges.

The original architecture of the project involved replacing the registrars (who recorded information on trading) with a single large database administered by the LSE. Unfortunately, the project had many stakeholders who had vested interests in maintaining their positions. Instead of re-engineering from scratch, and then automating, the project recreated the highly

inefficient organisation of the exchange. The initial design was pushed forward before the various parties had reached agreement about what it should do, before legislation and regulations had been changed and before the processes had been simplified. The registrars quickly saw that the technology would deprive them of their lucrative (but inefficient) livelihoods and became an entrenched group of actors hostile to the new technology (Drummond, 1996a, 1996b).

The LSE carried on with the project from 1983 until 1988, but the share registrars' opposition produced an independent technical review. This showed that the proposed project would be extremely costly (£60 million) and very technically complex, requiring two IBM 3090 mainframes and 560 disk drives to cover the transactions in the trillion or so shares in issue by the LSE (Flowers, 1996, p.102). Taurus 1 was consequently cancelled, and the Bank of England (the U.K. financial regulator at the time) became involved and set up the Security Industry Steering Committee on Taurus (SISCOT Committee).

In the spring of 1989, the SISCOT Committee suggested the far cheaper and less risky option of extending the Talisman system from the original 32 Market Makers to around 1,000 other financial institutions (*ibid.*) Shares would be held in accounts on behalf of clients by TACs (Taurus Account Controllers) who would maintain the records. However, TACs could pass the maintenance of records on to registrars, which had the unfortunate effect of replicating the previous paper-based system in parallel with the electronic TACs. This design, however, made it extremely difficult for companies to know who owned their shares, and consequently, if they were being prepared for a hostile takeover. Together with stockbrokers, who were concerned about costs, the large firms forced through a series of design changes.

In March 1990 a detailed outline of the project was published, and in October 1990 the technical specifications were published. These showed that rather than build a system from scratch, the project would involve buying and modifying a U.S.-based system. The development work was however based on split locations, with 25, out of a team of 40, based at Vista Concepts New York office (Drummond, 1996a, 1996b; Flowers, 1996). By December 1991, as costs escalated and schedules slipped, the new legal framework for the operation of TAURUS was produced. By this time the press were becoming hostile as rumours emerged about software-development problems. By February 1993, a technology review predicted that it would take another three years to build the system and that its costs would double. By March the project was cancelled at a cost of about £75 million. The total costs to the City were probably in the order of £400 million.

The Taurus project illustrates the range of problems involved in producing financial infrastructure. In particular, it shows the major innovation problems in

financial infrastructure concerning the 'soft' issues involved in co-ordinating a wide range of users who have divergent needs and concerns about the technology. The main cause of the failure was the inability of the various agents involved to restructure the inefficient internal processes before the development of the technology was begun. This meant that the project re-created vested interests who were hostile to changes. The slow-moving regulation process, the decision to undertake substantial redesign of a packaged system, and confusion about ultimate control over the project further complicated matters.

The complexities inherent in the design of such a substantial system were made worse by constant design changes. The software-intensive nature of the project meant that it was very difficult to know the extent of further redesign work. The lack of organisational co-ordination within the development process, and in particular the use of two main development sites on different sides of the Atlantic further complicated the process. The story does, however, have a happy ending. After the Taurus fiasco, the Bank of England project managed the development of the CREST system which appeared on schedule and to budget in the mid-1990s.

Conclusion

This chapter has given a brief overview of an extremely complex field. It has shown both the diversity of different forms of financial service infrastructure, and the heterogeneity of the various firms and organisations that use it. Financial services are extremely high-tech in many areas, and the traditional view of services as un-innovative clearly needs to be revised. While there are encouraging signs that this is taking place, our understanding of innovation in services, and financial services in particular, is a long way behind our understanding of manufacturing innovation.

Financial services differ from manufacturing because they involve firms performing functions for customers rather than providing goods that perform functions. These functions are typically consumed as they are produced, making their provision time-dependent in a way that manufactured products which can be stored are not. Firms rely on a range of infrastructure technologies for this temporal control of their internal processes. The internal processes themselves are also typically dependent on infrastructure.

Financial services are also different in that they depend heavily on the liquidity of markets. This liquidity can be improved by using external infrastructure technologies to bring together larger numbers of diverse buyers and sellers. As they are based on the contextualisation and processing of information, rather than physical materials, financial services have the potential to leverage technology to produce more profits than is possible in manufacturing. Unfortunately, the ability to generate large profits goes hand in hand with the ability to suffer substantial losses. This,

in turn, creates a much larger incentive for managing risk than is common in manufacturing.

In this chapter, we have divided infrastructure technologies into internal and external. Infrastructure that is external to financial institutions is often provided by third parties and is used to increase the reach of markets in time and space. This makes markets more liquid and improves the financial value of assets, and makes trading more efficient. Typically, these technologies will involve telecommunications systems that have historically ranged from the earliest telegraph systems to today's high-powered settlement systems and global networks.

Internal infrastructure technologies, however, are used within firms to allocate resources to customers. They involve technologies such as customer-focused information systems, ATM machines and their networks, and internal risk-management systems. In both cases, there is a tendency for the infrastructures to increase in size and complexity. External infrastructure increases in size and complexity because this allows the liquidity of markets to improve. Internal infrastructure is driven towards increasing coverage, computing power, speed and reliability, because this improves the ability to profitably control transactions.

The tendency towards increases in the size and complexity of these infrastructure technologies has consequences for innovation. As projects increase in size and complexity they become more uncertain and more risky. This increased uncertainty comes from unpredictable emergent phenomena caused by components interacting in new ways, from technical changes to sub-systems as the time taken for the projects increases, changes in regulations, and changes in business practice. All of these factors make defining the systems' requirements and freezing them extremely difficult. The complexity has become even more problematic in the last two decades with the introduction of embedded software, and the need to work with legacy systems.

The complexity and uncertainty of innovation mean that when problems emerge, the design process has to feedback to earlier stages in the innovation process. This adds to the cost and schedule of the project. Within software the problem is exacerbated as repeated redesign can lead to an increasingly unreliable and fragile product.

However, the really important issue in innovation in financial infrastructure is not technical at all. The big problems concern 'soft' issues about dealing with multiple users, dealing with regulators and coping with the politics of the organisational and institutional changes that the introduction of new infrastructure brings (Murray, 1989). These factors probably go further towards explaining why the financial services industry is riddled with failed infrastructure projects that have not delivered what they were intended to provide.

Despite the constant stream of failed projects and, in particular, IT-based failures, the financial services industry does manage to produce infrastructure that is reliable and performs its task well. Failure may be common, but successes abound. Given the complexities of the innovative tasks involved, this success in both development and operation is a major achievement. Given the importance of these successes to the modern financial system, and by extension their impact on the global economy, understanding the nature of their innovation is important and worthy of further research.

Innovation in Integrated Electronics and Related Technologies: Experiences with Industrial-Sponsored Large-Scale Multidisciplinary Programs and Single Investigator Programs in a Research University

Ronald J. Gutmann

Center for Integrated Electronics, Rensselaer Polytechnic Institute, USA

Abstract: University research innovations in integrated electronics are presented with a focus on the impact of industry support. University knowledge-based innovations are divided into discontinuous (or radical) and continuous (or incremental), with the relative contributions affected by program funding guidelines, program review methodology, industrial mentoring, and in-house industrial research and development in such a rapidly evolving industry. The impact of the Semiconductor Research Corporation (SRC) initiated in 1981, SEMATECH initiated in 1988 and the Microelectronics Advanced Research Corporation (MARCO) initiated in 1998 is highlighted.

Keywords: Integrated electronics; Discontinuous/radical innovations; Continuous/incremental innovations.

Introduction

The semiconductor/integrated circuit (IC) industry has made significant continuous and discontinuous innovations in the past four decades, thereby fueling the information-technology revolution that has transformed our society. During the past two decades this industry has financially supported and guided research universities in the required disciplines, both to obtain a source of research and development personnel and to obtain leading-edge research; the latter can be divided into continuous (or incremental) innovations, often involving contributions to the scientific knowledge base, and discontinuous (or radical) innovations, namely high-risk, high-payoff ideas which are not embedded in critical paths of the industry roadmap. This paper presents a single investigator perspective of the research university role in both types of innovation,

derived from three decades of experience of involvement.

The main tenets of the chapter include the following: the semiconductor/IC industry has been very astute in dealing with research universities; the research universities have benefited tremendously from the financial support and guidance; continuous or incremental innovations are more easily accomplished and more easily measured, often involving insight into the underlying knowledge base of industry practice; discontinuous innovation in this field is dominantly achieved by industrial research laboratories, with research universities as fast-followers; large-scale multi-investigator programs are very effective for continuous innovations and for providing multidisciplinary educational and research experiences, but have not established a strong record of discontinuous innovation; programs work best with a strong personal

commitment for research success in a professional and enjoyable environment.

Innovation by the semiconductor/IC industry has fueled the information-technology (IT) revolution that has transformed our society. The technology base was established mostly by industrial organizations, both vertically integrated high-tech companies like AT&T (now Lucent) Bell Laboratories and IBM as well as Silicon Valley companies that grew with the semiconductor/IC industry explosive growth like Intel. The cost reductions and performance enhancements of this industry as succinctly summarized by Moore's Law are well known; less well known is the role of the semiconductor/IC industry in supporting, and working with, research universities—in many ways as unique a characteristic of this industry as IC performance advances.

This chapter is a personal reflection of an individual participant in the university research and education enterprise. The author has served as Program Director at the U.S. National Science Foundation (NSF), where he was on the first Technical Activities Board (TAB) of the Semiconductor Research Corporation (SRC)¹ in a government liaison role. He has also served two terms on the University Advisory Committee of the SRC and on the SEMATECH¹ University Advisory Board. He has served as co-Director of a SEMATECH Center of Excellence (SCOE) on Multilevel Interconnects at Rensselaer and participated in other SRC, NSF Engineering Research Center (ERC), Defense Advanced Research Program Agency (DARPA), and industry-sponsored multi-disciplinary programs—and many smaller research programs sponsored by U.S. government agencies and national/international companies. For five years, the author served as Director of the Rensselaer Center for Integrated Electronics.

The chapter emphasizes the research university role in innovation for the semiconductor/IC industry and highlights the role of the SRC (and related industry organizations); the role of U.S. government support from NSF, DARPA and other mission agencies is only briefly mentioned in highlighting innovative issues, as this role is similar in all disciplines. Innovation is divided into two categories: continuous (or incremental) innovation and discontinuous (or radical) innovation. One main tenet of the paper is that the SRC-based funding has been extremely successful in continuous innovation (as well as in providing funding for graduate student education and training) but has been less successful in achieving discontinuous innovations.

The semiconductor/IC industry has recently moved to more discontinuous innovation-focused funding through the Microelectronics Advanced Research Corporation (MARCO). MARCO is a wholly owned

subsidiary of SRC, enabling utilization of SRC management functions (such as contracting agreements) as appropriate. MARCO was established because of both the decline in long-range research funding in major industrial laboratories and the increasing impediments to scaling as projected by Moore's Law and delineated in industry-generated roadmaps (the National Technology Roadmap for Semiconductors (NTRS) and the more recent International TRS and ITRS).

Normally radical and incremental innovation refers to business practices or products in a business environment. In the context of this chapter referring to university research, discontinuous (or radical) and continuous (or incremental) innovation refers to the effect of the research results. University knowledge-based research often provides the scientific underpinnings of current technological practice, thereby enabling better engineering design. However, university research often establishes new technological approaches that lead to significantly improved performance, lower-cost and/or higher-reliability technology. When successful, these higher-risk endeavors are referred to as discontinuous (or radical) innovations.

The remainder of this chapter is organized as follows. First, a brief history of the industry funding of universities is presented, focusing on the major role of the SRC, but also including SEMATECH and MARCO. Second, the major tenets of the paper are developed, using the technology area of most involvement by the author (IC on-chip interconnects). Third, these tenets are discussed using the recently initiated MARCO Focus Centers as a benchmark on these tenets. Finally, the author's perspectives are summarized.

Semiconductor/IC Industry Funding of Research Universities

The semiconductor/IC industry initiated a collaborative method of funding research universities in 1982, when the Semiconductor Industry Association (SIA) established the Semiconductor Research Corporation (SRC). Originally three center-type programs were established (single-university multiple-investigator programs) with many smaller single-investigator programs. The emphasis was entirely on silicon-based research, as the U.S. government-sponsored university research programs were dominantly in compound semiconductors. The SIA clearly established the program both to establish a source of pre-competitive silicon-based research and to increase the source of graduates with education and training in silicon IC technology and design.

In the first decade the SRC funding clearly impacted the U.S. research programs in semiconductors/IC technology by funding both center and single-investigator research programs at major research universities, and by establishing educational programs

¹ The SRC and SEMATECH are described more fully in the next section of this chapter.

(both funding selected curriculum developments and graduate fellowships for U.S. citizens and permanent residents). The SRC is a research management organization, with various industry boards to provide input into funding decisions and program evaluations. The SRC-sponsored core programs have always been focused to industry concerns and more micro reviewed than government funded university research, with the anticipated pluses and minuses of such a research management process. However, the SRC funding and program mentoring clearly was positive for the university research community and for the graduate students involved, although the micro-review process has often been a source of friction. Originally considered by many university researchers as a minor supplement to government-funded research, the SRC evolved into an important complementary component of university research within a decade. The industrial leveraging of government-funded research established a broad-based three-way partnership (industry, government and research university).

In the late 1980s the SIA established SEMATECH as a research and development cooperative to help revitalize the U.S. semiconductor industry. As part of the post-site selection process in which Austin, Texas was selected as the venue for SEMATECH, various SEMATECH Center of Excellence (SCOE) research programs were established in 1989. The SCOE's focused on different research areas of semiconductor manufacturing, received approximately \$1,000,000 (\$1M) per year for five years, and were managed by the SRC with its already established infrastructure for managing and reviewing university research programs. Generally the SCOE's were focused on shorter-range research than the SRC programs, although the time line is difficult to establish firmly in such a rapidly evolving area of research. Some conflict arose between the more focused view of SEMATECH with a well-defined research and development agenda and the SRC with a longer research mission and a longer time line for research results (although shorter range than many government-sponsored research programs). After the initial five years, the research funding for the SCOE's was incorporated into the SRC program to a large extent, although SEMATECH continues to fund smaller, nearer-term more-focused university research programs directly.

The second decade of the SRC was marked by full incorporation into the fabric of U.S. research universities, relative stability of a mode of operation, absorption of SCOE program emphasis and research funds (as described above), establishing a close working relationship with U.S. government funding agencies (particularly NSF and DARPA) including joint support of center programs, establishing a new SIA-funded SRC-managed multi-university research center funding organization (MARCO) and the internationalization of both the SRC and SEMATECH. The

SRC is fully established as a major university funding source for semiconductor/IC materials, processing, devices, design and manufacturing research, with an agenda varying from short-term to long-term focus (although still not as long range as government-sponsored research except for the newer MARCO programs). Moreover, the past five to eight years has seen significant collaboration with U.S. government funding agencies in areas of mutual interest, including formal agreements and collaborative funding.

The two more recent modifications have resulted from the internationalization of the SRC and the establishment of the MARCO Focus Centers. While the impact of the former is small at this time, the impact could be significant in the next five years as international companies (particularly European and Pacific Rim) participate in collaborative university research and the SRC funds more research at international universities. The company overhead required to fully take advantage of the SRC program (including participation in program reviews, funding authorization/allocation meetings, and long-range policy meetings) may inhibit a rapid evolution to internationalization of the SRC; full internationalization will be difficult to achieve.

The second recent modification has clearly been significant, namely the establishment of MARCO Focus Centers for multi-university collaboration in long-range research necessary to maintain the rate of advancements of price and performance predicted by Moore's Law in the presence of upcoming limitations to CMOS IC scaling as delineated in the NTRS and ITRS reports. The SIA, stimulated by Dr. Craig Barrett of Intel, established MARCO to lead a new university research thrust with a long-range focus in such technology needs. The first two multi-university centers were established in 1998 (Interconnect as well as Design and Test), with two additional centers established in 2000 (Materials, Structures and Devices as well as Circuits, Systems and Software) and two more anticipated in 2002–2003. Steady-state funding of each center is projected to be \$10 million/year.

These MARCO centers are impacting the research university landscape in a manner similar to the NSF Engineering Research Center (ERC) program begun in the mid-80s and the earlier DARPA (now NSF) Material Research Laboratory (MRL) program begun in the 60s. The long range impact of MARCO centers compared to the long-standing MRL and ERC programs is difficult to project, but the impact could become as significant if the industry continues a commitment to such large-scale, long-term university research throughout its cyclic business environment. Since the MARCO program is jointly supported by SIA Board of Director companies (50%), equipment/materials/software suppliers (25%) and DARPA (25%), funding stability and broad support have been established in a relatively short time frame.

Development of Major Tenets

In this section the author combines his experience and background outlined in the Introduction with the Semiconductor/IC Industry research funding/impact outlined in the previous section to develop the major tenets of this paper. The section is split into three parts: first, a technology summary of IC on-chip interconnects so that the experience and perspective described can be focused more specifically; second, personal experiences from major interconnects research programs such as the SCOE on Multilevel Interconnects, the SRC Center on Advanced Interconnect Science and Technology (CAIST) and the MARCO Interconnect Focus Center (IFC) for Giga-scale Integration, complemented by related single investigator programs; third, an innovation perspective abstracted from these experiences.

IC On-Chip Interconnects: A Technology Summary

In the late 1980s CMOS technology scaling indicated that conventional IC on-chip interconnects would limit microprocessor speed within the next decade. On-chip interconnects had gradually evolved in the number of metal interconnect levels, but the technology had not changed significantly—aluminum lines (or trenches), oxide interlevel dielectric (ILD), patterning of metal lines followed by ILD deposition with gap fill and planarization constraints, and a change from aluminum to tungsten vias for vertical interconnection between aluminum lines. As the minimum feature size continually decreased, CMOS devices become faster, but the interconnect delay does not scale similarly. As a result the interconnect delay continually increases relative to the device delay, projecting that microprocessors would become interconnect-limited.

In the search for reduced interconnect delay, metals with a higher electrical conductivity and dielectrics with a lower dielectric constant (low-k ILD materials) were explored in the 1990s. The Research Division of IBM led the development, both in copper and alternative high conductivity conductors and in polymers and other low-k dielectrics. While IBM had done appreciable research in the mid-1980s and beyond, other companies and the research universities did not become appreciably involved until the 1990s when the interconnect bottleneck became more widely realized and the limitations of aluminum and oxide as the key on-chip interconnect materials became clear.

Since the choice of conductors is relatively limited (copper, silver and gold) and the choice of low-k ILDs is relatively large, the industry settled initially on copper as the interconnect conductor of choice. However, since copper cannot be patterned by reactive ion etching (RIE) at room temperature (easily done with aluminum), an alternative patterning strategy was established for copper. In the so-called Damascene technique, the ILD is patterned for trenches (or lines)

and vias, followed by copper and appropriate liner deposition and then chemical-mechanical planarization (CMP) to eliminate copper and liner between the trenches and vias. The CMP process was originally introduced to planarize the ILD and/or vias in interconnect structures to allow an increasing number of on-chip interconnect levels, but the use in a Damascene patterning strategy was a key development for on-chip copper interconnects.

The research and development in this field was highlighted by the IBM announcement in the Fall of 1997 when copper was announced as going into manufacturing, with products introduced within a year. Three years later IBM announced the first low-k ILD to go into manufacturing, a spin-on polymer from Dow Chemical called SiLK (for silicon low-k technology). Numerous IC manufacturers, both large vertically integrated companies and manufacturing foundries, have introduced copper interconnects in manufacturing, with some low-k ILDs (mostly organosilicate glass rather than SiLK).

In summary, the 1990s was the interconnect technology decade, with four major advances being introduced into IC manufacturing:

- (1) CMP enabling six-to-eight metal levels of on-chip metallization with high yield during IC manufacturing;
- (2) copper metallization for lines and vias to replace aluminum lines and tungsten vias for improved electrical conductivity and electromigration capability;
- (3) dual Damascene patterning to replace metal reactive ion etching (RIE) and dielectric gap fill to improve line definition and to lower manufacturing costs;
- (4) low-k ILDs to replace oxide for lower line and coupling capacitance and, when combined with copper trenches, lower interconnect delay.

SCOE, CAIST, MARCO and Related Research

The recognition of the growing importance of on-chip interconnect technology in the late 1980s coincided with the establishment of SEMATECH and the funding of the SCOEs. The New York SCOE was established at Rensselaer in 1988–1989 in Multilevel Interconnects, with research activities to extend the knowledge base in more conventional technology as well as in new areas of copper metallization and CMP. The award of this program initiated a multi-disciplinary research program in IC interconnects at Rensselaer and has led to ensuing center-based programs such as the SRC CAIST launched in 1996 (centered at Rensselaer) and strong participation in the MARCO Interconnect Focus Center (IFC) led by Georgia Tech and launched in 1999. Faculty at Rensselaer who have had key leadership roles in this decade-plus thrust in IC

interconnects include Tim Cale, Dave Duquette, Bill Gill, Ron Gutmann (author), Toh-Ming Lu, Jim Meindl, Shyam Murarka and Arjun Saxena, full professors from four different academic departments.

In parallel with this semiconductor/IC industry consortium support, this support was highly leveraged with other research support, both cost-sharing funds from Rensselaer and New York State and additional research support. The latter includes both U.S. government support and single company support for specific research. While most of these programs were relatively small, a large-scale program that was funded by IBM in parallel with the SCOE emphasized polymer materials for low-k ILDs, an area not funded in the SCOE at the time. This interactive program with IBM allowed Rensselaer to establish a useful base in low-k materials, processing and characterization, and completed an advanced interconnect technology portfolio.

The Rensselaer programs in copper CMP and copper metallization technology (liners, alloys and Damascene patterning strategies) became particularly well known, with Rensselaer established as a major research university in IC interconnects as a result of the SCOE and CAIST programs (and related leveraged research support). However, the role of IBM Research in initiating and leading the development of copper interconnect research is clear, with Rensselaer and other research universities providing an underlying science base in many areas and in providing a database for other company investments and directions. The differences between the industrial contributions and the research university contributions are best compared by tracking not only refereed journal articles and conference papers, but also the patent literature.

The author believes that the SRC program review, a relatively micro-look at deliverables and annual results, is effective in educating graduate students for industrial opportunities and in providing a desirable scientific knowledge base for industrial practice (i.e. continuous innovation). However, the process does not encourage long-term research focused on discontinuous innovations, as the programs are reevaluated and redirected with modified budgets on an annual basis. Most importantly, the industry participants are asked to evaluate individual tasks based upon the impact of the research to their company rather than to the industry at large. While this approach is desirable to keep individual companies pleased with their SRC investment, the impact on long-term research of a high-risk high-payoff nature with discontinuous innovation results can be (and has been in the author's opinion) negative.

The SIA has recognized the need for different mode of research management to better encourage 'out-of-the-box' thinking and discontinuous innovation in establishing MARCO as a new subsidiary of the SRC. National and international roadmaps by the industry (NTRS and ITRS) indicate many future needs where

no known solutions exist, resulting in a consensus that increased funding of consortium-managed university research was essential. The resulting major differences between MARCO and SRC core research programs have been the individual program size, the emphasis on long-range research and the increased emphasis on discontinuous innovation research results, as well as the mode of research management. The SIA requires more high-risk high-opportunity research in all the MARCO programs, and anticipates many discontinuous innovations to emerge.

As an example, the Rensselaer IFC program (part of the New York State program led by the University at Albany) emphasizes wafer-scale three-dimensional (3D) ICs, optical interconnects for chip-to-chip and on-chip broadband interconnect, terahertz technology for interconnects and characterization, carbon nanotubes for interconnects, nano-metrology techniques and multiscale materials and process modeling. The 3D program uses the on-chip interconnect technology, fundamental understanding and research experience from the 1990s to establish a new approach to monolithic wafer-scale 3D ICs, using dielectric adhesives to bond two fully processed IC wafers and copper Damascene patterning to form inter-wafer interconnects. Such a program would not be possible without the research expertise established by the SCOE, CAIST and related interconnect programs, companion research expertise in IC design and packaging technology and the new funding paradigm established by the MARCO Focus Centers.

Innovation Perspective

Based upon this experience and perspective, the author believes that the SRC-funded core research programs are effective at continuous innovation, with the university research community providing the scientific underpinnings for recently developed industry innovations. In addition, the research universities can be effective fast followers when stimulated and mentored by leading industrial research laboratories, thereby contributing to truly discontinuous innovations affecting the semiconductor/IC industry. The more recent MARCO program has been initiated to provide incentives and freedom to pursue truly discontinuous innovations by the research university community. The results of this initiative will take five years or more to evaluate fully.

Another perspective is the generally inhibiting role of large university centers on truly discontinuous innovation. While in some disciplines centralized shared facilities may require larger multi-investigator programs, the relatively small single (or an interactive few) investigator(s) may be best for truly discontinuous innovations, where new approaches may be investigated over some extended duration in relative privacy without specific deliverables and milestones. Large multi-disciplinary programs have many advantages and

many attractive results, but the author does not believe that discontinuous innovations are best achieved in such an environment, particularly with traditional means of SRC program management and review. Effective management of technological innovation is difficult enough within an industrial organization, as described by both J. Bessant and R. Katz in this handbook.

In fact, a main purpose of this chapter is to put forth a personal perspective (rather than fully annotated with references) to stimulate further discussion, not only in the semiconductor/IC research community, which has been extremely innovative in dealing with universities and where these issues have been examined, but also in other industrial sectors. The SRC core and traditional center programs have clearly been successful; complementary programs like the SCOE's have had an important role. The MARCO program may be another complementary program with a relatively short lifetime, but the MARCO program is a great opportunity for the university research community to extend its role in the discontinuous innovation arena. Hopefully, MARCO will become a long-term important ingredient of the SRC research portfolio, with many discontinuous innovation accomplishments. Challenges in innovation management as described by J. Bessant in this handbook are magnified with such industrial consortia. However success can be achieved with commitment and vision.

This unique industry support of integrated electronics has been in parallel with government support. Research and innovation contributions of such programs have not been included here, but the integrated electronics field has a similar history as presented by Y. Miyata elsewhere in this handbook. However, the impact of the U.S. Semiconductor industry support of universities described here is more positive than the more general evaluation by Miyata (2003). Perhaps this research field is unique in ways the author has been unable to abstract.

Discussion of Specific Tenets

Main tenets of the chapter include the following: the semiconductor/IC industry has been very astute in dealing with research universities; the research universities have benefited tremendously from the financial support and guidance; continuous or incremental innovations are more easily accomplished and more easily measured, often involving insight into the underlying knowledge base of industry practice; discontinuous innovation in this field is dominantly achieved by industrial research laboratories, with research universities as fast-followers; large-scale multi-investigator programs are very effective for continuous innovations and for providing multidisciplinary educational and research experiences but have not established a strong record of discontinuous innovation; programs work best with a strong personal

commitment throughout. In this section these major tenets are presented with a brief discussion of each.

Semiconductor/IC Industry Astute in Dealing with Research Universities

The SIA in launching the SRC in 1982, the SCOE program with SEMATECH in 1988–1989 and the MARCO Focus Research Centers in 1998 has demonstrated an ability to understand the operation of research universities and to establish a mode of operation which accommodates professorial independence and creativity for the industry advantage. Like any effective enterprise, the SRC has established a basic operating mode in becoming a permanent fixture in research university support.

The research university community has benefited significantly from SRC programmatic interactions, in the funding support that is provided (direct costs and 'full' government-equivalent indirect costs) and in the mentoring of research program directions and graduate students. While the SRC mode of operation is different than government funding agencies or single company support/interaction, the complementary nature of the time frame of the research focus and the review process offers a complementary breadth to more classical sponsor interactions.

Continuous Innovations More Easily Accomplished and Mentored

The SRC core programs, both center-based and individual investigator-focused, are more amenable to continuous innovations with major contributions to the scientific underpinnings of present or near-future industry practice or relatively small advancements to the field. The proposal and program review practices are the major factors, as the research activities are reviewed in detail annually from the perspective of the individual company sponsors. This process mandates continuous contributions, which leads to short-time horizon research.

Discontinuous Innovations Led by Industrial Research Laboratories

Key discontinuous innovations in the semiconductor/IC industry have resulted from major industrial research laboratories. While this statement may be debatable in isolated areas, the author believes that the tenet is widely true and has presented the IC on-chip interconnect paradigm shift in the 1990s as an example. Universities can be fast-followers and make major contributions and may occasionally introduce discontinuous innovations from SRC and government funded programs (e.g. Rensselaer in interconnects in the 1990s), but the overall record is not outstanding. The new MARCO Focus Centers are an excellent opportunity for research universities to become a stronger contributor in discontinuous innovation, at a time when major industrial research laboratories are

often shrinking their time horizon and when discontinuous innovation is needed to maintain progress according to Moore's Law as CMOS shrinking becomes more difficult and more expensive. The MARCO research objectives, funding level and research management approach provide such an opportunity.

Large Center Program Perspective on Innovation

Large center programs have a few tremendous advantages, both those within a research university and those with multiple research university participation. They encourage/require meaningful multi-disciplinary interactions, sharing of expertise and facilities, and effective interactions among faculty, research staff, graduate students and industrial researchers and managers. The experience for all stakeholders is worthwhile, particularly for graduate students. However, as described, the author feels strongly that such programs tend to focus on continuous innovations rather than discontinuous innovation where a greater risk of failure is involved. The MARCO program removes most of the impediments; five years will be needed before the impact can be evaluated.

Strong Personal Commitment Necessary for Success

All such programs work best where there is a true commitment to the objectives of the program, principally the participating faculty and the industrial mentors. Clear and honest communication, including respecting the intellectual property (IP) of the participants, is a necessary ingredient for achieving the most effective research results in a professional and enjoyable environment.

Summary

The author's perspectives and major tenets of this chapter are presented in the previous section. While the perspectives presented are a personal viewpoint, the author believes that many in the SRC research community hold similar views, both the university researchers and industrial mentors. Whatever the view toward continuous and discontinuous innovation, the SIA has clearly changed the scope and focus of research universities in the field of semiconductors/ICs, both in the past two decades and for the foreseeable future. The initiative with the MARCO Focus Centers indicates that the SIA continues to evolve different funding mechanisms in the future, but probably not until the MARCO Focus Centers become fully established (5-year funding ramp anticipated) and can be fully evaluated (2008 time frame). Other industry sectors could well benefit from a careful review of the two-decade experience of the semiconductor/IC industry in forging new relationships between industry, government and research universities. The research university role in the contributing to the semiconduc-

tor/IC industry has clearly been enhanced by these SIA investments as managed by the SRC.

Acknowledgments

The author gratefully acknowledges his faculty colleagues for their technical contributions to the Rensselaer program and for shaping the author's perspectives presented here, namely T. S. Cale, T. P. Chow, D. J. Duquette, P. S. Dutta, W. N. Gill, T. M. Lu, J. F. McDonald, J. D. Meindl, S. P. Murarka, K. Rose, E. J. Rymaszewski and A. N. Saxena. He has also benefited over this period from supervising many talented doctoral students, including S. Banerjee, C. Borst, K. Chatty, T. Chuang, M. Heimlich, C. Hitchcock, Y. Hu, N. Jain, J. Jere, S. Khan, V. Khemka, B. C. Lee, T. Letavic, P. Lossee, K. Matocha, D. McGrath, J. Neiryneck, D. Price, R. Saxena, P. Singh, S. Saroop, B. Wang, C. Wong, Y. Xiao, and A. Zeng. The author's perspective on discontinuous innovation has been influenced by interactions with faculty in the Rensselaer Lally School of Management, namely R. Leifer, C. McDermott, J. Morone, G. O'Connor, L. Peters, M. Rice and R. Verzyer.

Discussions over these issues with many industrial research leaders have helped shape the author's perspectives, particularly J. Carruthers (Intel), G. DiPiazza (AMP), D. Fraser (Intel), D. Havemann (TI), W. Holton (TI/SRC), R. Isaac (IBM), J. Ryan (IBM), R. Schinella (LSI Logic), W. Siegle (AMD), L. Sumney (SRC) and B. Weitzman (Motorola). Discussions with colleagues from other research universities have also been very beneficial, particularly J. Gibbons (Stanford), G. Haddad (University of Michigan), D. Hodges (University of California, Berkeley), A. Kaloyeros (University at Albany), N. Masnari (North Carolina State University), T. McGill (Cal Tech), R. Reif (MIT), A. Tasch (University of Texas, Austin), and E. Wolf (Cornell).

The funding of the SIA through the SRC, SEMATECH and MARCO, many semiconductor/IC companies and government agencies over this period is gratefully acknowledged and is much appreciated.

The Barriers Approach to Innovation

Athanasios Hadjimanolis

Department of Business Administration, Intercollege, Cyprus

Abstract: The nature of barriers is first clarified and their effect on innovation is broadly outlined. The various taxonomies of barriers are presented and critically evaluated. Their impact and mechanisms of action are then developed. The pattern of barriers in different contexts is considered and various aspects of a theoretical explanation of barriers are discussed. Since barriers are especially important in small firm innovation and in difficult environments, e.g. in small countries, these special cases are studied in some depth. Finally, the empirical studies on barriers are reviewed. The chapter ends with suggestions to overcome barriers and a conclusions section.

Keywords: Innovation; Barriers.

Introduction

The importance of innovation for the competitiveness of firms and as an engine of growth at a regional or country level is widely recognized (Hitt et al., 1993; Tidd et al., 1997). At the same time it is believed that there is an 'innovation problem', in the sense that the majority of organizations are not doing enough to introduce or adopt innovations (Storey, 2000). One of the approaches to examining the reasons for inadequate innovation is the study of constraints or factors inhibiting innovation—that is the 'barriers to innovation' approach (Piatier, 1984). There exists a large amount of literature on innovation barriers (Bitzer, 1990; Piatier, 1984; Witte, 1973). Despite the extensive empirical research on barriers it seems that there is, however, no conceptual framework that would integrate the factors acting as barriers and would permit an explanation of their combined effect.

What follows is a relatively selective review that attempts to present a reasonably comprehensive account of the theory and the existent research. The study of barriers provides an insight into the dynamics of innovation, while it is also a first step in the process of overcoming them. Bannon & Grundin (1990) argue that the existence of barriers in innovation is the rule rather than the exception and that:

"In most cases organizational and business procedures work against both successful development and use of innovative products" (Bannon & Grundin, 1990, p. 1).

The *aim* of this chapter is therefore to relate the review of innovation barriers to a practical understanding of the innovation process and to action for its facilitation with the elimination of barriers.

Innovation as a complex phenomenon needs a multilevel model of analysis (Drazin & Schoonhoven, 1996). Barriers can then be studied at various levels starting from the individual and moving up to the firm, the sector or community, and the country level. While all levels are considered in the following sections, the main emphasis is on barriers to innovation at the level of the firm. The other levels are also considered mainly in relation to the firm. For example, innovative action at the individual level is considered from the point of view of managers or employees, rather than consumers or members of social groups. Innovation is initially viewed in a very broad sense; later the focus is on technological innovation in the context of the private firm. The following broad definition is used:

"Innovation is the search for and the discovery, development, improvement, adoption and commercialization of new processes, new products and new organizational structures and procedures" (Jorde & Teece, 1990, p. 76).

Technological innovation mainly focuses on new processes and new products.

In the following sections the nature of barriers is first clarified, and various ways of classifying barriers are considered in detail. The broad classification into internal and external barriers is used for a descriptive

exposition of the main barriers. The next section discusses the role of barriers within the innovation process, their points of impact, as well as their effects on innovation. Since barriers may act at various points of the innovation process, this process is briefly discussed and the various models for innovation are mentioned. The static view of considering barriers as antecedents of innovation and predictors of outcome is expanded in this section into a dynamic analysis of their evolution, and interaction, during the various phases of the innovation process.

Next, the theoretical explanations for the existence of barriers are considered. Barriers—especially internal ones—may emerge as symptoms, and their deeper causes and underlying factors have to be accounted for. Since barriers are especially critical in the case of innovative small firms, as well as in difficult environments, as is the case with small and developing countries or countries in transition, these special cases are studied in some depth. The section also includes a short overview of some of the existing empirical data on barriers in both industrial products and services innovation in small firms. Then the methodological limitations of such empirical studies are discussed. Some measures and ways to overcome barriers by the firm itself and by regional/national authorities are proposed. The chapter ends with conclusions and suggestions for further research.

Nature and Classification of Barriers

Nature of Barriers

A barrier to innovation is any factor that influences negatively the innovation process (Piatier, 1984). The factors with a positive influence are called facilitators. Barriers to, and facilitators of, innovation are, however, related. On the one hand, facilitators may turn to barriers, or vice versa, as the firm evolves throughout its life cycle stages or as external conditions change (Koberg et al., 1996). However, many barriers are actually due to lack of facilitators. It is only then, for analytical convenience, that barriers are studied separately from facilitators of innovation and for a complete picture the study of both is necessary. Barriers are also known as obstacles, constraints, and inhibitors. Although there may be subtle differences in the meaning of these terms, they are used as synonyms here.

It is important at this point to consider some assumptions in the barriers approach.

- An implied assumption is that innovation is inherently a good thing and any resistance to it by employees or managers, which could be interpreted as a barrier, is unwelcome (Frost & Egri, 1991). This is not always true, and resistance or skepticism may

be actually well founded and a positive action for the good of the firm (King, 1990).

- It is also frequently assumed that removal of barriers will somehow restore the natural flow of innovation. This is far from true, because innovation is a relatively unnatural phenomenon in the sense that it needs motivation, extraordinary effort, tolerance to risk and coordination of the activities of many actors (Hadjimanolis, 1999; Tidd et al., 1997). It seems that the removal of barriers is a necessary—but not a sufficient condition—for innovation to take place.
- A third assumption is that existence of barriers is by itself a bad thing, and all efforts should be made to remove them. While this is generally the case, barriers may occasionally turn into positive factors stimulating innovation or providing valuable for the future learning experience for the firm (Tang & Yeo, 2003). For example learning to live with barriers or their gradual elimination at a local level may be a necessary first step in the internationalization process of innovative firms. Internationalization is sometimes vital for the long-term survival and success of firms having small national markets (Fontes, 1997).
- A dubious assumption is that focusing on innovation barriers is more important than focusing on reinforcing positive factors for innovation. Perhaps both are equally necessary and complementary.

Classification of Barriers

Due to the multitude of barriers, a classification scheme would be useful in their study. Barriers can be classified in a number of ways, and there are several typologies. They are usually based on the origin or source of barriers. A useful classification is in distinguishing between internal to the firm and external to the firm barriers (or endogenous and exogenous respectively (Piatier, 1984)). Similarly other types of barriers, e.g. export barriers, are classified into internal and external (Leonidou, 1995). External barriers have their origin in the external environment of the firm and cannot be influenced by it, while the firm can influence internal barriers. Barriers can further be classified into direct/indirect according to their impact on the innovation process and into general /relative. General barriers are barriers affecting all firms, while relative barriers selectively affect some of them (e.g. in specific sectors). Barriers could also be classified as tangible or objective and cognitive or perceptual. The latter are not 'real' barriers, but are subjective and perceived by the firm. This distinction is further considered in the next sections, although it should be noted that the existence and significance of all barriers is related to the perceptions of the firm's managers and employees.

As mentioned above, obstacles can also be considered at various levels starting from the micro-level and ending up at the macro-level. These are the individual, group, firm level, inter-organizational level, and regional/national level (King, 1990). The first three

Table 1. External and internal barriers to innovation.

External	Internal
1. Market related	1. People related
2. Government related	2. Structure related
3. Other	3. Strategy related

can be considered as internal barriers, and the last three as external. Barriers can refer to the presence or absence of some factors. The most common classification of external and internal barriers is used here for a discussion of barriers. Table 1 illustrates the classification with some sub-categories of each major type. *External* barriers can be subdivided into market related, government related and other.

External Barriers

(i) *The market-related barriers* refer to various types of market failure and other market induced innovation-hampering factors. One type of market failure refers to insufficient appropriability (i.e. ability of the innovating firm to capture rents or profits created through innovation (Teece, 1986)). Other types include market risk, inadequate size of R&D that is undertaken by private firms, and externalities (Cohen & Noll, 1991; Sanz-Menendez, 1995). The public good character of innovation may lead to know-how leakage and other spillovers, which impair innovation incentives and may act as barriers (Jorde & Teece, 1990). Supply and demand deficiencies may also present barriers. For example lack of skilled employees in the market or lack of innovative users. The nature and intensity of competition within the market affect the profitability and strategy of firms and are indirect causes of barriers.

Another market-related barrier is what has been called the 'short-termism' problem (Storey, 2000). It is an effect of pressure, e.g. from the stock exchange market on public quoted firms, to show profits in the short term. Investments with a long-term payback period, as many innovation projects tend to be, are then neglected in firms with a short-term horizon. Such projects are however necessary for the success and eventual survival of the firm, although they may have an adverse short-term impact on profits.

Under the market-related barriers the most frequently mentioned type is that of financial barriers (Piatier, 1984). These barriers may result from the reluctance of lenders, e.g. commercial banks, to share—the perceived as high-risk of innovation projects. Information asymmetry between lenders and borrowers is especially high in the case of innovation, and outside capital providers have difficulty in the financial assessment of innovative projects (Pol et al., 1999). This fact aggravates the risk and uncertainty factor. Innovators are also frequently unable to provide the collateral for loans as a security for the bank.

Financial barriers are especially important for small firms and for start-ups (Storey, 1994). The lack of venture capital for innovative high technology start-ups is a frequent complaint as further discussed in a later section.

(ii) *Government* and its policies and regulations are a frequent source of barriers to innovation (Piatier, 1984; Pol et al., 1999). Many policies directly or indirectly related to innovation are designed to correct market failure. Problems may arise, however, due to unintended consequences of such policies and side effects of regulations. Standards imposed by government or by supra-national organizations, such as the European Union, may also act as obstacles to innovation. Bureaucratic procedures in getting licenses or grants and in other contacts with governmental organizations are also a frequent cause of barriers. Problems in policy communication may induce discrimination against some firms, e.g. micro-firms and small firms, preventing them from getting the support they are entitled to.

Laws and regulations may give rise to barriers due to either their side effects or inadequacies in implementation. Firms have to comply with regulations at the local, regional, national, and even supra-national level (for example European Union directives). Regulations may discourage innovative activities and hinder firms from entering new markets, by increasing uncertainty and risk. They may also prevent some firms from undertaking promising projects, because they increase their time frame, cost and risk (Preissl, 1998). In other instances, they may impose unnecessary limitations on the operations of the firm. It is important to note that the same regulations may be beneficial for innovation in some industrial sectors and detrimental in others.

Examples of legal constraints include labor and consumer protection legislation, environmental regulation, and anti-trust legislation (Jorde & Teece, 1990). The legal frame for the protection of intellectual property has an even more direct impact. A weak intellectual property regime, for example, allows the easy copying of innovations and acts as a disincentive and inhibitor for firms to undertake costly innovation that could easily, and at a fraction of cost, be exploited by their competitors (Chesbrough, 1999). The tax system is a potential source of indirect barriers by reducing incentives to innovate. Trade barriers, for example, the so-called non-tariff barriers, may prevent foreign market entry and reduce the commercial success of an innovative new product.

Regulations, standards, and rules mentioned above are examples of institutions. Institutions related to innovation include the science and technology infrastructure and the physical infrastructure. Many institutions are therefore under the direct or indirect control of central or regional government. The term 'institutions' is however used here in a very broad sense to include all political, social and cultural

institutions—formal and informal—and also all related rules and procedures. These institutions characterize a society and cannot easily change without the cooperation of wider social forces, e.g. firms and their associations, labor and government (Sanz-Menendez, 1995).

Lack of suitable institutions, inadequate performance of existing ones, and what has been called institutional inertia or rigidity, i.e. resistance of old institutions to change, may lead to innovation barriers (Freeman, 1994). Institutional structures may have adverse effects on transaction costs, making innovation more costly or hardly affordable. Institutional factors also affect the extent of cooperation, trust and mutual consideration of firms and the formation of alliances and other forms of cooperation.

(iii) *The 'other' category* includes *technical, societal and inter-organizational barriers*. Technical barriers may originate from predominant standards, e.g. in telecommunications, or arise due to changes in technology (Freeman, 1994). Risk of technology obsolescence, destruction of a firm's competences with change of technology, and dangers from picking the wrong technology, are major considerations in some fields of high technology (Starbuck, 1996). Other technical obstacles are due to the scale of capital requirements for entering a particular new technology field and scale of experience effects (technological entry barriers).

Societal factors may form important innovation barriers (Shane, 1995). Norms and values of a society and attitudes towards science, socio-economic change and entrepreneurship determine the innovation climate (Piatier, 1984). The latter, if it is negative, has an adverse effect on innovation efforts and on the willingness of Government to assist innovation.

External barriers may also arise at the *inter-organizational* level when firms have to cooperate at a regional, national or international level (Tidd et al., 1997). For example, barriers to innovation occur during cooperation along the supply chain, when customers discourage product changes or access to distribution channels is problematic for a new firm. Although the latter example refers to vertical cooperation, there are similar problems in horizontal cooperation between firms of the same sector when there is no tradition of such cooperation or there is lack of trust.

Inter-firm networks are frequently seen as facilitators of innovation by being sources of ideas, information and resources (Swan et al., 2003). They can, however, act as obstacles to innovative change due to technical, knowledge, social and administrative dependencies. There are barriers to exit from a network arising from investments made by the company itself and by other network members (Hakansson, 1990). While inter-organizational barriers are treated here as external, there is also an internal dimension in the

sense that firms should have special competences in order to develop, maintain and take advantage from inter-organizational relationships.

Internal Barriers

Internal barriers relate to the characteristics of organizational members, the characteristics of the organization, and the management of innovation as a change process. They can be conveniently classified into people related, and structure- and strategy-related.

(i) *People related*. They can be studied at the individual and the group level and, if necessary, separately for managers and employees. They are due to perceptions, including biases and lack of motivation, deficits in skills, but also to vested interests and personal goals differing from organizational ones. For example, innovation may affect the status and privileges of experts by making their expertise obsolete. Such experts then resist innovation and change. To overcome this natural resistance, so-called 'innovation champions' are needed, and their absence may prove a major barrier to innovation (Gemuenden, 1988; Hauschildt, 2003). An innovation champion is an individual recognizing the potential in a new technology or a market opportunity, adopting the relevant project as his/her own, committing to it, generating support from others and advocating vigorously on behalf of the project (Markham & Aiman-Smith, 2001). The role of champions is further discussed in a later section.

Management may be preoccupied with the current operations and have a conservative attitude, which may lead to perceiving innovation as being risky and difficult. Lack of commitment of top management to innovation, as indicated by not rewarding risk taking and lack of toleration of failure, is mentioned as a major innovation barrier (Hendry, 1989). The decision-making process of managers, constrained by their bounded rationality, and its organization regarding search procedures, information sources, and evaluation rules, is also a source of barriers (Schoemaker & Marais, 1996).

Witte (1973) classifies people-related barriers into two categories, i.e. those due to lack of will, and those due to lack of competence. Barriers of the first category refer to the attraction of the status quo and fear of the unknown, but also fear of failure and being blamed for it (Bitzer, 1990). Factors causing will-related barriers include the effects of specific personality traits and feelings of managers and employees—acting as individuals or as members of teams. For example, perceived favoritism, jealousies and resentments have detrimental effects on innovation (Webb, 1992). Causes of people-related barriers are considered in more detail later.

Competence barriers are due to lack of creativity and specific new knowledge required by the innovation (Tang & Yeo, 2003).

Inhibiting factors or blocks to individual creativity, such as lack of training, autonomy, and extrinsic motivation are closely related to innovation barriers and have been extensively studied, but their detailed examination is beyond the scope of this chapter (Amabile, 1997). The lack of skills, as a competence barrier, has several dimensions. For example, Yap & Souder (1994) refer to the lack of both breadth and depth of personnel (i.e. number and variety of specialists) as an innovation barrier. Similarly, Staudt (1994) refers to the lack of suitably qualified managerial personnel as a barrier to innovation, but also to incumbent managers having competences in fields becoming obsolete, rather than competences in emerging fields.

(ii) *Structural*. Structure affects the behavior of organizational members during the innovation process and determines the problem-solving capacity of the firm. Structural obstacles include inadequate communication flows, inappropriate incentive systems, and obstruction problems by some departments (Hauschildt, 2001). The latter is also referred to as lack of inter-functional integration (Hitt et al., 1993). Collaboration between marketing and R&D for example is vital, especially for product innovation. Problems in this collaboration, due to different values, motivations, and goals, have an adverse effect on innovation (Hendry, 1989).

Centralization of power in an organization affects negatively innovation in older firms (while being positively correlated with innovation in new ventures (Koberg et al., 1996)). Mechanistic structure (i.e. a rigid hierarchical structure without many participation possibilities for employees) in a turbulent environment has been mentioned as a barrier to innovation in early studies on innovation (Burns & Stalker, 1961). Schoemaker & Marais (1996) refer to firm inertia and formalized procedures as obstacles to process innovations. Webb (1992) mentions the contradiction between formal organization and actual management practices as a problem leading to defensiveness and distrust on the part of employees, with detrimental effects on innovation. Lack of time is a frequently mentioned internal barrier (Hadjimanolis, 1999). While time can be seen as a resource, it is also clearly related to structural issues like organization of the work, delegation of tasks, and specialization.

Structural inertia may be accompanied by cultural inertia and internal politics games (Maute & Locander, 1994; Starbuck, 1996). Culture refers to the shared norms, values, and beliefs of the firm (Armenakis & Bedeian, 1999). Cultural barriers are then due to the existing beliefs and values of the firm that are not supportive of change. A culture of blame and fear of responsibility, for example, obstructs experimentation, change, and innovation. Cultural barriers are related to motivation and reward and punishment systems, and are intertwined with the people-related barriers men-

tioned above. The work environment has a direct impact on the intrinsic motivation for creativity and innovation, and an adverse environment may stifle innovation efforts (Amabile, 1997).

Problems related to *systems* may also be included here. Inadequate search and information acquisition systems from external sources (Madanmohan, 2000) and problematic internal dissemination mechanisms may hamper innovation (Sheen, 1992). Other examples are out-of-date accountancy systems (Rush & Bessant, 1992) and lack of planning systems.

(iii) *Strategy related*. Many internal barriers are related to strategy. Lee (2000), for example, mentions the failure of strategy in British firms to connect the introduction of flexible manufacturing systems with the long-term aims of the firm, e.g. its competitive position. Technical people may also be unaware of strategy and objectives, and cannot therefore persuade senior managers of the benefits and necessity of new technology, while senior managers—being technologically ignorant—cannot see these benefits themselves. Other barriers may be goal-related in the sense that senior managers may fail to appreciate the necessity for innovation or are too risk-averse to attempt to innovate. Markides (1998) mentions complacency, satisfaction with the status quo, and reluctance to abandon a certain present (adequately profitable) for an uncertain future, as potential innovation barriers. Fear of cannibalizing sales of existing products may be a more specific excuse for avoiding innovation.

Strategy is today related to the development of core capabilities and resources that are difficult for competitors to imitate (Peteraf, 1993). Some key capabilities related to innovation are technological ones, such as the capacity to produce ideas and develop them to products. Other capabilities are, marketing and service skills and legal skills to protect the firm's intellectual property. Also ability to network, form alliances and span inter-firm boundaries (Rosenkopf et al., 2001). The lack of the above capabilities, or their inadequate level, may form major internal barriers to innovation. Core capabilities may however turn to 'core rigidities' with environmental, e.g. technological change and develop into traps and barriers when they stop offering a competitive advantage (Leonard-Barton, 1995). Rigidities are also related to the 'sunk cost' fallacy and commitment to existing technologies (Schoemaker & Marais, 1996).

Resource-related barriers include lack of internal funds (e.g. from cash flow), and lack of machinery, testing or other technical equipment (Bitzer, 1990). Important barriers may arise from the lack of an own R&D department, a low percentage of organizational resources dedicated to development work, and technical problems due to inadequate experience or knowledge. Resource-related are also what Teece

(1986) has called appropriability constraints, i.e. lack of complementary assets or capabilities to take full advantage of an innovation that a firm has developed or adopted. Slack resources are considered important for innovation, but there is disagreement over whether their lack, forms a barrier to it. Nohria & Gulati (1996) claim that there is a U-shaped relation between the degree of slack and innovation. Initially innovation increases, with an increasing degree of slack, up to an inflection point; then negative effects set in and innovation decreases.

Impact of Barriers on the Innovation Process

Innovation Process Models

We have briefly considered above the nature of barriers. This section describes their effect or impact on the innovation process and also the frequency of their occurrence and their intensity. The relevant actor, whose action is inhibited by a barrier, could be an individual, a group, a firm, etc. The emphasis here is on private firms as actors. Barriers may act on one or more stages of innovation, and their impact may be different at their various points of action. Of particular interest is the role of barriers during the initial stages of the innovation process, since inability of the firm to overcome them leads to a passive attitude and avoidance of innovation. In order to facilitate the discussion of the impact of barriers, we have first to describe briefly the innovation process.

The traditional linear model of innovation conceived innovation as a linear sequence of events from research to development, production and commercialization. It has since been recognized that the innovation process is a much more complex phenomenon with many players and feedback and feed-forward loops between the various stages. The simultaneous model (Kline & Rosenberg, 1986) corrected some of the deficiencies of the linear model by recognizing the existence of tight linkages and feedback mechanisms between the stages of the innovation process.

The current interaction models of innovation (for example the system integration and networking model (SIN) of Rothwell (1992)) emphasize the internal interaction among the various departments of the firm and the external interaction with suppliers, customers, technology providers, and governmental institutions—even competitors.

The interaction model is an outcome of a systemic approach to innovation, which recognizes that firms do not innovate in isolation, but as a part of a much broader system. The innovation system can be conceived at a local or regional level, at a national level or even at an international level. The regional dimension of innovation will be considered in the next section, while the national innovation system (NIS) concept is discussed in more detail in the section entitled 'Barriers in Special Cases'.

The interaction model gives an indication of the complexity of the innovation process, the many actors involved, and the multiplicity of interaction. It implies, therefore, the fluidity of the process. Another dimension of this fluidity is the fact that goals are not fixed at the beginning of the innovation process. They change along the decision process as new alternatives appear and interact with the problem-solving activities (Gemunden, 1988). Barriers have, therefore, a dynamic nature due to the characteristics of the innovation process itself. They should not then be considered as pre-existing and given (i.e. as antecedents of innovation), but rather as fluid and evolving. This fact adds further difficulties to their study and evaluation.

While the identification of barriers, the estimation of the frequency of their appearance, and the ranking of their importance, is not without problems, the evaluation of their impact is much more difficult due to a number of reasons presented below. By 'impact' we mean the exact final effect on innovation, i.e. its partial or complete inhibition. In other words the barrier may stop innovation completely, delay innovation or increase its cost. Apart from these negative effects, positive effects may also arise, for example an increased sensitivity and awareness of barriers and a valuable learning experience for future innovation efforts. Evaluation of the impact of barriers includes the determination of the point or stage of the innovation process at which they act and the mechanism of action.

The main difficulties of this evaluation are as follows:

- barriers may have a dynamic nature, i.e. a systematic variation according to the stage of innovation. Their evolutionary character increases the difficulty of assessing their exact impact;
- barriers may not act in isolation, but may interact mutually, reinforcing their action and leading to a vicious circle. Mohnen & Rosa (2000) refer to the complementarity of barriers and suggest a systemic approach for their elimination or reduction;
- barriers may not act directly on the firm, but may have their effect during one or more stages of the innovation process through intermediates, such as banks, customers or competitors (Piatier, 1984). This implies that barriers tend to act on the interfaces of the firm with other actors within the innovation system.

Patterns of Barriers in Different Contexts

We have so far discussed barriers to innovation in general. Most studies, however, challenge the universality of barriers and tend to suggest that their nature, frequency and impact probably vary in accordance with the context of innovation (Pol et al., 1999). There are therefore different patterns of constraints for

different contexts. Some of these contexts include the type of innovation, the type of innovator, the size of the firm, the sector, the location, and probably even the business cycle. They are briefly considered below.

(i) *Type of innovation.* Incremental or radical innovation types probably involve different types of barriers. In other words, the degree of novelty of the innovation is related to the level of difficulty to innovate. What matters, as an innovation barrier, is the *perceived* degree of novelty by the innovation actor (Tidd et al., 1997). The type (product, process, or social innovation) and characteristics of innovation and its complexity determine to some extent the difficulties that the firm finds producing or adapting innovation to its needs. With increasing complexity of innovation, for example, problems of communication and process management become more severe (Hauschildt, 2001).

(ii) *Type of innovator.* We can distinguish here between non-innovators, new venture innovators (start-up firms), first time innovators (but already established firms) and frequent innovators, i.e. firms that are experienced innovators and innovate on a continuous basis. The type of innovator is therefore both related to the firm's life cycle, from start-up phase through maturity to decline, and the firm's experience in innovation. Barriers tend to be higher during the transition stages from one phase to another. Mohnen & Roeller (2001) suggest that innovation intensity in established innovators and the probability of becoming an innovator are two different innovation processes that are subject to different sets of constraints. There are also differences between producers of innovation (that is those developing their own innovations internally) and adopters of innovation developed elsewhere. In the case of adoption, barriers to diffusion and technology transfer have to be considered (Godkin, 1988), as well as, the problem of internal resistance to a foreign innovation, also known as NIH (Not Invented Here) syndrome (Katz & Allen, 1982).

(iii) *Size of the firm.* Barriers may vary by the size of the firm, i.e. for small and large firms (Mohnen & Rosa, 2000; Piatier, 1984). The size of the firm probably determines not only the nature, but also the importance of barriers, with small firms perceiving their impact as more severe. It is widely believed that the main innovation barriers in large firms are largely the internal ones, while such firms have the resources and the know-how to overcome any existing external barriers (Vossen, 1998). Internal barriers arise from their complexity and are due to lack of motivation, problems of communication and coordination and possibly lack of incentives. According to Quinn (1985) the main bureaucratic barriers to innovation in large firms include top management isolation from produc-

tion and markets, intolerance of entrepreneurial fanatics, short time horizons, the accounting practices, excessive rationalism and bureaucracy, and inappropriate incentives. In the case of small firms external barriers are very important, while resource-related, internal ones may also be critical. Barriers in small firms, due to their importance, are further considered in the section entitled 'Barriers in Special Cases'.

(iv) *Sector.* Barriers probably vary by sector (Preissl, 1998). Some barriers may be industry-specific in the sense that they are typical for the firms of one sector, but not for firms of other sectors. Similarly, the perceived importance of export barriers is reported to vary across industries due to industry-specific factors (Leonidou, 1995). The inter-sectoral differences in barriers arise from business demographic differences, i.e. firm size distributions by sector, but also from the context for innovation and the level of innovation in each sector. Innovation is expected to be much higher and continuous in high technology sectors with a high percentage of R&D such as information technology and biotechnology, against low technology sectors as glass or woodworking. Barriers may also be related to the industry life cycle, since opportunities for innovation and resources may differ between these stages. While traditionally there are many studies on barriers in various sectors of the manufacturing industry, studies on innovation barriers in services have only recently received attention (Mohnen & Rosa, 2000; Preissl, 1998).

(v) *Business cycle.* Barriers may also vary during the different phases of the business cycle of the economy, i.e. recession and growth, due to the differentiated availability of resources and the investment climate. Their variation may also be attributed to the different extent of government interference in the economy in each of these phases.

(vi) *Location.* We refer here to the effects of the specific location of the firm, any regional resource deficits and problems of the national innovation system of the country. Country specific institutions, regulations, and other conditions create country specific barriers. National cultural factors may also affect differentially the perception of barriers (Shane, 1995). The size of the country and its level of industrial development are major factors in innovation and the existence of barriers. Country effects are further elaborated later. The regional dimension of innovation has received considerable attention in recent years (Love & Roper, 2001). A number of tangible factors, such as the local industrial structure, local institutions and regional policies and regulations may affect innovation. There are also several intangible factors, such as culture, social capital, and the extent of local networking that may be relevant.

Theoretical Explanations of Barriers

Barriers have been studied by various disciplines such as economics, sociology, psychology and management. We discuss briefly each of these approaches.

Economists tend to concentrate on external barriers, i.e. those resulting from market failures, governmental policy implementation, institutional inadequacies or rigidities and supply/demand deficiencies. They concentrate on externalities, imperfect and asymmetric information available to the various actors involved in innovation and imitation, as well as their effect as incentives and disincentives for innovation. Economists also study the effect of various factors on costs, including opportunity costs, and how they impact on the perceptions of risk and uncertainty. The transaction costs perspective (Williamson, 1985) is a useful approach in such studies. When they study internal barriers, economists focus on incentives and resources. The aim of the economic approach is frequently to connect the problems with national policy aspects and suggest policy changes.

The resource-based view (Conner & Prahalad, 1996; Peteraf, 1993) is an interesting perspective in the economics and strategic management literatures, which could illuminate some aspects of the appearance of barriers. This view concentrates on the unique resources and capabilities owned by the firm and contributing to the development of its competitive advantage. The acquisition of resources and capabilities is a long-term, evolutionary, and cumulative process. Innovation depends on the availability of technological resources and knowledge and demands a number of capabilities. The lack of these resources and capabilities can be manifested as internal barriers to innovation. Obtaining these resources from the environment is costly and difficult. Cohen & Levinthal (1990) have suggested that the firm must have an 'absorptive capacity' in order to be able to obtain, to adapt, and use externally available technological information and knowledge.

Even economists recognize the importance of perceptions. Competitive intensity, for example, is not just a matter of market concentration, but also an issue of perception by the firm itself. There is now a branch of evolutionary economics studying aspects of perceptions, mental models, and learning processes, their impact on innovation, and other economic issues (Howells, 1995). The study of perceptions is however mainly the realm of social psychologists. The latter give emphasis to the internal barriers and study the role of attitudes of managers and employees at an individual and a group level. Psychologists also examine perceptions of mainly internal, but also of external barriers. We shall briefly consider various aspects of the social psychology approach to the understanding of barriers.

Innovation implies change; it usually represents a major change for the organization involved. The study of the more general phenomenon of organizational change can then provide a useful framework for the study of barriers and their effects (Armenakis & Bedeian, 1999). Barriers to innovation can then be considered as a subset of barriers to change and have analogies and similarities to barriers identified in other organizational changes. As examples of such changes we can cite barriers to growth of small firms (Chell, 2001; Storey, 1994), barriers to export and internationalization (Leonidou, 1995), barriers to learning (Kessler et al., 2000; Steiner, 1998), as well as barriers to structural reorganization (Armenakis & Bedeian, 1999).

In order to understand barriers to change, we have to study the perceptions, assumptions, interpretations and cognitions of managers and employees. Particular emphasis is given to managers (especially in the case of small firms), since managers determine organizational priorities and make resource allocation decisions (Storey, 2000). Their perceptions are therefore vital for change and innovation. Organizational members interpret environmental signals and the external reality in a sense-making process (Weick, 1995). In this process they form mental representations and models and develop their cognitions. Carl Weick (1979) has introduced the concept of the enacted environment, which is shaped by managerial interpretation and strategic choice in contrast to the 'objective' reality of an external environment. Mental models affect the readiness for change (Swan, 1995). For example, deeply held assumptions about the market may affect the process of identifying or creating opportunities and may therefore act as barriers to adoption of new ways of thinking in technological innovation. Perceptions filter information and therefore affect the assessment of benefits and costs of innovation to be developed internally or adopted from external sources (Tidd et al., 1997). Different perceptions of risk within the organization may prevent managers from reaching an internal consensus on the need to innovate.

A more specific model that could serve as a basis for the understanding of barriers, is the cognitive infrastructure model of the intent to innovate (Krueger, 1997), which uses the Ajzen-Fishbein framework based on their theory of planned behavior. The model maintains that attitudes, beliefs, and social norms affect intentions, which subsequently influence the readiness for change and innovation. The intentions themselves are also affected by perceived competencies and other factors. The model is useful because it incorporates the main influences on the intention to innovate. It could be criticized as giving a partial picture of the phenomenon of barriers since many barriers operate at its second stage. These barriers appear between the formed intentions and the realization of innovation, where the model does not give much information on factors—

other than good intentions—that affect the particular innovation.

Innovation, both as development of new products or processes within the firm and as technology adoption, can be seen as a learning process (Dodgson, 1993). At the same time perceptions and mental models of managers and employees are formulated and reformulated during the processes of change (and innovation is such a process of change) by learning and interaction between members of an organization. Organizational learning links, then, cognitions and innovation action. Thus a powerful perspective, which can be used in the comprehension of innovation barriers, is that of learning. While learning at an individual level has long been recognized as an essential process for the adaptation of human beings to the changing environmental conditions, more recently the organizational learning process has received attention by social psychologists, organizational and management scientists (Steiner, 1998).

Adaptive learning processes in organizations frequently have a collaborative and interpersonal nature, which leads naturally to the consideration of these interpersonal relations in a network perspective (Tidd et al., 1997). We consider, then, the role of such learning networks in innovation. Learning can be classified as internal, when the firm creates new knowledge leading to innovation internally, or as external learning when knowledge is obtained from external sources. Internal and external networks are involved, respectively, in the learning process. Different sets of barriers operate in these two cases (Kessler et al., 2000). For organizational learning to take place, information and knowledge have to be transferred throughout the organization and shared across many different groups. Then information should be stored, retrieved, processed and finally utilized. Impediments to internal learning may originate from the culture of the organization if values such as risk-taking, communication openness and appreciation of teamwork are absent. Even if formally espoused, but not properly rewarded, they may act as barriers.

Barriers to external learning, i.e. obstacles to the transfer of knowledge from external sources such as universities, research centers, or other firms, may come from a lack of boundary-spanning individuals or from political resistance to externally generated ideas. This resistance is known as the NIH (Not Invented Here) syndrome (Katz & Allen, 1982). It happens especially if the ideas appear revolutionary and threatening to the current status of managers or other employees, and there is no innovation champion or promotor (Hauschildt, 2001). The innovation champion may be the same person as the boundary-spanner or another individual. External learning faces more barriers than internal learning. Learning has, however, sometimes to be preceded by ‘unlearning’ of ineffective technologies and practices (Starbuck, 1996).

Sociologists and organizational scientists concentrate on political processes, power structures and status within firms, as well as their role in change processes as, for example, innovation (Frost & Egri, 1991). Innovation may alter the status quo and balance of power within the firm, leading to intense political activity of the affected individuals or groups (Gemunden, 1988). Political games and use of power to access resources and to protect vested interests or improve career prospects may present powerful barriers to innovation (Burns & Stalker, 1961). Collaboration between rival interest groups is frequently problematic (Hendry, 1989). The concept of organizational inertia is useful in visualizing the role of barriers. Organizations tend to resist new ideas, adhering to old routines and maintaining hierarchies and power structures, and innovate only when a particular force pushes them to overcome this inertia (Aldrich & Auster, 1986). Such forces, acting as catalysts, include innovation champions and environmental threats.

Management theorists try to integrate the concepts of the various disciplines mentioned above. Their models for the explanation of barriers include many personal (e.g. attitudes and leadership), structural, and systems variables. They recognize the interaction of these variables and their dynamic nature (Tidd et al., 1997). Management scientists suggest that barriers are frequently due to the failure of the firm strategists to evaluate the competitive and long-term implications of investing (or not investing) in new technology and developing new products in time. The risk of not innovating is not immediately visible. Management writers also emphasize the bounded rationality limitation in strategic decisions (i.e. that they are not necessarily rational or top-down, but a result of political and cognitively-biased processes (Schoemaker & Marais, 1996)).

Pol et al. (1999) view barriers as a component of the innovation climate of a country in line with a systemic approach to innovation. Other components or parts of the innovation climate include the national innovation system, incentives to innovation, and international linkages. This is an interesting conceptual framework for external barriers, but it could be criticized in that the innovation climate itself, incentives and barriers to innovation, can also be seen as components of the national innovation system. An extension of this model would consider the internal innovation climate within the firm and the interaction of internal and external ‘climates’. The concept of internal innovation climate emphasizes the interplay of structural, cultural and political factors.

Barriers in Special Cases

Disadvantages Facing Small Firms in Innovation

While there may be barriers to innovation in large firms, due to the complexity of their organization as

already mentioned, it is widely recognized that small firms, because of their size and limited resources, face particular challenges and barriers to innovation (Vossen, 1998). We follow the definition of the European Union for small firms, i.e. those with up to 50 employees. Medium-size firms, i.e. those with up to 250 employees, frequently face similar problems, perhaps to a lesser degree, and are often included in this discussion.

The liability of smallness is a well-established concept in the literature (Aldrich & Auster, 1986). Small firms face resource gaps in terms of time, staff, and money (Garsombke & Garsombke, 1989) and tend to depend on the external infrastructure for technological and other services. They have, however, a weak ability to interface with the infrastructure (for example universities and other technological centers), even if this is available for their support (Major & Cordey-Hayes, 2003). This weakness is due to lack of time, and inadequate managerial resources, knowledge and experience. Small firms lack economies of scale and scope in production, and R&D, and have a low ability to influence evolving technical standards (Yap & Souder, 1994).

Small firms are not usually able to match the wage rates, career opportunities and job security of larger firms and cannot easily recruit skilled labor and managerial talent. These recruitment barriers may prove major innovation barriers, although they are not insurmountable. Sometimes there are advantages in working in small firms, such as recognition and a better work environment. Small firms may also face a bureaucratic burden, i.e. a disproportionate cost of dealing with government agencies (Levy, 1993). Barriers may also arise in intellectual property protection, i.e. in searching for existing patents, filing for patents or defending them in case of infringement, due to the high cost and lack of suitable personnel.

Small firms depend on the capacity of their owner to receive/interpret signals from the market environment and identify opportunities for innovation. In contrast, large firms have a formal mechanism for such activities, including teams of scientists and managers. The innovation strategies of small firms focus on flexibility and exploitation of market niches (Keogh & Evans, 1999; Vossen, 1998). Small firms have some advantages in that they have simple structures, direct face-to-face communication, and a friendly internal climate, which tend to eliminate many internal barriers (Rothwell, 1984).

We briefly present here the results of empirical research on innovation barriers in small firms. According to Piatier (1984) the three major barriers to innovation in small firms are: 'education and training', 'finance', and 'product standards'. The top five external barriers in another empirical study (Hadjimanolis, 1999) include 'innovation too easy to copy', 'government bureaucracy', 'lack of governmental assistance',

'shortage of skilled labor', and 'bank policies on credit'. In the same study, the importance of barriers as perceived by the owners/managers of firms was not found statistically correlated to innovativeness. One possible explanation offered was that innovative small firms find ways to overcome barriers, while less innovative firms are not adequately aware of them. The top ranking barriers according to a survey of Garsombke & Garsombke (1989) include lack of capital, staff, time, and knowledge of available technology. A recent ADAPT project study (Schemman, 2000) found finance and lack of skilled workers to be major barriers in small European firms. Similarly Keogh & Evans (1999) have found 'lack of cash and finance' as the top barrier. A thorough review of the empirical studies is beyond the scope of this chapter. There are, however, remarkable similarities in the nature of barriers in the empirical studies, although importance ranks may vary.

Small firms form an extremely heterogeneous group, and some categorization regarding their innovation features would be useful. According to Tidd et al. (1997) they can be distinguished into supplier-dominated, specialized supplier firms, and new technology-based firms (NTBFs). Supplier-dominated firms only need competencies to adopt and assimilate technology developed by others, usually their suppliers. Specialized supplier firms have little R&D, but significant design and production skills. New technology-based firms are start-up firms in electronics, software or biotechnology. The latter deserve some further discussion in terms of innovation barriers.

Start-up firms attempting to innovate, face more—and to some extent different—barriers than established firms. Due to complexity and riskiness, they have problems in obtaining finance in the first stages of their development, especially in countries where venture capital finance is underdeveloped (Storey, 1994). New innovative firms entering an industry may face significant entry barriers, which can be overcome if their technology is clearly superior to that of the incumbent firms (Love & Roper, 2001).

The Case of Small and Less Developed Countries

The size of a country has a direct impact on the local supply and demand of technology and affects in other ways the national innovation system (NIS). A national innovation system is defined as:

“The network of agents and a set of policies and institutions that affect the introduction of technology that is new to the economy” (Dahlman & Frischtak, 1993, p. 414).

Small national innovation systems are usually also 'weak' systems. The smallness of the local market and in the case of small peripheral countries, isolation and distance from major foreign markets limit the

opportunities for technological innovation (Hadjimanolis & Dickson, 2001).

Nations differ in their institutional environments (Chesbrough, 1999). This is especially true when small countries are compared with large ones. The national institutional setting in small countries is frequently a source of problems. Vital institutions may be totally lacking, for example institutions providing technological services and research results, or their number is limited, such as business incubators and technology parks. Institutions include not only formal organizations, but also informal rules and procedures. Institutional rigidities and resistance to change is another problem (Souitaris, 2003). In addition, national institutions constrain the state capacity to define and implement an innovation policy and shape its outcome (Sanz-Menendez, 1995).

A usual problem faced by small national innovation systems is difficulties in flows within the system—for example human flows of researchers between universities and private firms—or financial flows towards innovating firms. Linkages between institutions and firms, necessary for such flows, may be limited or non-existent (Argenti et al., 1990). All the above factors raise external barriers to innovation and require extra efforts from the firms to innovate. The majority of these firms are small or very small and have, in addition, the liability of smallness as mentioned above. Opportunities for innovation in small firms are much more influenced by the national innovation system than those for large firms, since they depend more on others for innovation, e.g. their suppliers (Tidd et al., 1997). In the case of small countries, barriers to international technology transfer are also quite significant, since small countries depend on such transfer for a large part of their technological needs.

Less developed countries face similar problems to the smaller industrialized countries regarding their national innovation systems, but these problems are usually much more acute in their case. Countries in transition such as those in Eastern Europe are undergoing wide-ranging institutional and societal change, and face unique innovation barriers. The discussion of such barriers (Staudt, 1994) is beyond the scope of this chapter.

Methodological Difficulties of Empirical Studies on Innovation Barriers

Some indicative empirical studies on innovation barriers have already been summarized in the previous section. The present section focuses on the methodological difficulties in researching barriers.

Researching barriers is a difficult undertaking. Most empirical studies are based on surveys using lists of barriers derived from the literature. They investigate the opinions and beliefs of managers (very rarely those of employees) and their perceptions of barriers. The fact that the studies are not based on a sound theoretical

Table 2. Main difficulties in studies on barriers.

- | | |
|----|--|
| 1. | Failed and disappeared innovators not counted |
| 2. | Overemphasis on external barriers by managers |

| 4. | Inadequate methodology and analytical techniques |
| 5. | Dynamic nature of barriers |

framework leads to difficulties of interpretation of the results and to heterogeneity. It also creates problems of comparison with previous research and of generalization beyond the current research context.

Research based on case studies permits a deeper understanding of the particular context, although the above-mentioned problems are not avoided. There are additional difficulties in studies on barriers, whether surveys or case studies, which are summarized in Table 2 and then briefly analyzed.

Enterprises that failed to innovate and subsequently disappeared are not counted in the research, although barriers are most operative in such cases (Piatier, 1984). In addition, managers tend to attribute major importance to external barriers. This shifts attention away from internal barriers and shifts responsibility away from managers to some external and uncontrollable sources. This *ex post* rationalization by managers pointing to external constraints, when in fact internal constraints were the problem, is frequently mentioned in research (Barkham et al., 1996). Another major difficulty is that the sensitivity of the innovator, i.e. the level of awareness of barriers, and the problems and obstacles that are *actually* encountered are inextricably linked.

In the analysis of results, researchers frequently use factor and cluster analysis in order to bundle barriers together, in order to investigate underlying factors or classify firms into groups according to the barriers they face (Hadjimanolis, 1999). These techniques illuminate interrelations of barriers, but do not go far enough toward an explanation of why barriers occur and which factors affect their appearance. The dynamic nature of barriers is also a major problem. Barriers may change when environmental forces change; even the perception of barriers by firms is affected by environmental change.

Overcoming Barriers

While concentration on opportunity thinking, in contrast to obstacle thinking, is a preferable thought pattern (Neck et al., 1999), the realistic awareness of barriers is justifiably necessary. Identification of barriers is then essential in order to deal with them and attempt to eliminate them, thus increasing the innovation performance of the firm. The usual types of firms' response to barriers are either the avoidance of dealing with them or the *ad hoc* approach. A systematic approach to overcoming barriers is more rarely observed. Piatier (1984) proposes a *perception cycle*

for barriers. Initially the problem is not appreciated; its existence is even denied or underestimated. At a second step the problem is exaggerated (seen as bigger than it actually is). Then it is properly assessed, and in a final step it is effectively surmounted.

Research into barriers was referred to earlier as an external academic or consultancy approach, having as an aim to increase knowledge in this field and help firms and public policy makers in the identification and prioritization of barriers, as well as, the evaluation of their adverse effects on innovation. We can also visualize an internal process of continuously identifying and overcoming barriers to innovation. Staudt (1994) refers to the useful analogy of developing a radar system to navigate through a sea with icebergs.

This internal process should start with a realization of the importance of identifying barriers and a systematic look into their sources, both externally and within the firm. The organization has usually control over the internal barriers, but their elimination cannot be successful without a detailed plan of action. While raising awareness and attention is a first step, their classification by importance and devising ways to overcome barriers are equally important steps in the process of eliminating barriers. It is particularly important to eliminate or minimize barriers at the early stages of innovation. Methods to reduce barriers probably have to be specific to each stage of the innovation process (Bitzer, 1990). Mohnen & Roeller (2001)—in a study, which used European data on obstacles to innovation—have found that:

The lack of internal human capital (skilled personnel) is complementary with all the other obstacles in almost all industries (Mohnen & Roeller, 2001, p. 15).

Measures against barriers at both the firm and the innovation policy level should then concentrate on improving human capital as a first priority. Measures for such improvement include training, but also a suitable motivation system with rewards (monetary, promotion, etc) and sanctions.

The role of champions or promoters in overcoming resistance to innovation as emphasized in the literature (Hauschildt, 2003) has been mentioned above. They are frequently necessary in addition to any other structural and system-related arrangements (King, 1990). To summarize, we would say that barriers need a specific strategy and resources, within the frame of a systematic course of action, to be overcome successfully. The overall aim should be to create a favourable innovation climate within the firm, which encourages idea generation, circulation, experimentation and risk-taking. To this effect, suitable organizational mechanisms and systems are needed, e.g. for developing new ideas and rewarding creative work (Amabile, 1997). The internal organizational process of overcoming barriers can be helped by benchmarking, i.e.

observing innovation management best practice in successful innovating firms. What such firms do to avoid and overcome the inevitable barriers, provides a useful yardstick for action.

Although most discussion in the existing literature is on ways to overcome barriers, a proactive approach to *prevent* barriers before they occur is apparently a more rational strategy. This implies proactive management of the innovation change process and periodic measurement of the innovation potential of the organization, in order to determine gaps and take the necessary action.

While firms should do their part, regional authorities and national governments must also act against external barriers by trying to control and remove them. This is usually done in the context of a national innovation policy that addresses barriers according to their importance. It is essential to emphasize that the nature and importance of barriers should be established for the particular context through research. Measures should then be based on the results of such research, rather than subjective perceptions of policy makers of what could possibly constitute barriers. Different sets of measures are probably needed to increase the innovation intensity in established innovators on the one hand, and to stimulate entry to innovation among non-innovators on the other (Mohnen & Roeller, 2001). An important consideration is that barriers frequently arise as side effects of support policies with good intentions. The ‘*ex ante*’ and ‘*ex post*’ evaluation (i.e. before and after implementation) of innovation support policies should, then, consider the occurrence of side effects and a possible modification of the original policy to remove them.

Conclusions

The barriers approach to innovation focuses on the main problems that may occur during the complex and delicate process of innovation. The innovation process is fraught with difficulties, as it demands the close cooperation—over an extended period of time—of many people. The actions of all these people have to be coordinated, and their talent combined with internal and external resources for a successful outcome. The difficulties of motivation, coordination, development of capabilities, and acquisition of resources emerge as barriers to innovation. The available theories provide only a partial comprehension of the underlying mechanisms that generate these barriers. Based on that knowledge, a process of identifying and eventually overcoming these barriers can be set up within the firm. At the same time regional authorities and national governments have a significant role to play in the elimination of external barriers.

Much research is still needed to illuminate the joint action of barriers as a system, and their dynamic nature. The usual top-down approach in research that is focused on top managers and their views on barriers should be complemented with more ‘bottom-up’

research, i.e. with investigation of the views of employees. There is also need for longitudinal research to follow the development and interaction of barriers during the innovation process and to find causal links between innovation barriers and innovation performance.

More comparative research (inter-country and inter-sectoral) is required to illustrate the patterns of barriers in different contexts, their similarities and differences and lessons that can be drawn from them. Similarly Drazin & Schoonhoven (1996) call for more comparative studies of alternative forms of organizing for innovation on a global scale. There is a particular need to focus on studying barriers in the case of non-innovators, i.e. use the latter not as a reference group during studies of barriers for innovators, but as the main group for study. Such an approach was already followed for non-exporters in the case of export barriers (Leonidou, 1995).

Knowledge Management Processes and Work Group Innovation

James L. Farr¹, Hock-Peng Sin¹ and Paul E. Tesluk²

¹ *Department of Psychology, Pennsylvania State University, USA*

² *Department of Management & Organization, University of Maryland, USA*

Abstract: Following a selective review of theoretical models and empirical research on work group effectiveness and innovation, we present a dynamic model of work group innovation. Our model integrates recent advances in taxonomies of work group processes and stages of the innovation process with a focus on the temporal nature of innovation. We also provide a discussion of the specific inputs, group processes, emergent states, and outcomes that appear to be most relevant for each of the various stages of work group innovation.

Keywords: Work group innovation; Group processes; I-P-O models.

Introduction

Our focus is to bring together three streams of theory and research that have separately addressed factors that are thought to influence organizational effectiveness: group-based work, knowledge management, and innovation. Although each of these domains has received considerable attention from organizational scholars in the past decade, little empirical research or conceptual development has occurred that might integrate them. We argue here that knowledge management processes related to how work groups seek, share, store, and retrieve information relevant to their performance (both taskwork and teamwork) are important factors associated with group effectiveness, including group innovation. We present an original theoretical framework based on several existing Input-Process-Outcome (I-P-O) models of group effectiveness that provides our initial understanding of how work groups' knowledge management processes influence their capacity for generating and implementing innovative solutions to problems. Our focus is primarily on the group level of analysis, but include relevant factors at the individual (e.g. knowledge and skill) that influence group-level knowledge management processes and innovation in important ways.

We present brief reviews of the extant literature on work group effectiveness, work group innovation, and knowledge management, focusing on recent theoretical frameworks in each domain. These reviews are followed by our model.

Work Group Effectiveness

Work group effectiveness is most often studied through a lens that uses an (I-P-O) perspective (Guzzo & Shea, 1992; McGrath, 1991). Because it is the dominant perspective for studying work groups, the I-P-O framework can be used to examine different approaches to innovation in work groups from a common vantage point. One of the advantages of the I-P-O paradigm is that it is inherently temporal (Marks, Mathieu & Zaccaro, 2001) and, because innovation involves consideration of criteria that can be viewed from both short-term (e.g. idea generation) and long-term (e.g. implementation, learning) perspectives, the I-P-O framework is useful for incorporating this time-based perspective.

Following the I-P-O lens, *inputs* refer to factors such as group composition, design, leadership, and organizational context conditions (rewards, training, information systems) that influence the processes by which group members engage with each other and their environment as they work toward their objectives. *Outcomes* are often considered to be in three forms:

- (1) the productive output of the team as defined by those who evaluate it;
- (2) the satisfaction of team members; and
- (3) the capabilities of the members of the team and their willingness to continue working together over time (Hackman, 1987).

Processes have been defined in a number of different ways but typically are considered to be interactions among members of a team and/or with other groups or individuals outside the team that serve to transform inputs (e.g. members' skills) and resources (e.g. materials, information) into meaningful outcomes (Cohen & Bailey, 1997; Gladstein, 1984; Marks et al., 2001). They are, therefore, typically considered as mediating the relationship between input factors and group outcomes (McGrath, 1991), and in most models of team effectiveness, processes are depicted as serving a central role (e.g. Gist, Locke & Taylor, 1987; Gladstein, 1984; Guzzo & Shea, 1992; Hackman, 1987). Indeed, an accumulating amount of research in different team settings has shown that processes such as coordination and communication facilitate team performance in terms of outcomes such as productivity and manager ratings of group effectiveness (e.g. Campion, Medsker & Higgs, 1993; Hackman & Morris, 1975; Hyatt & Ruddy, 1996). Yet, while there is clear evidence of their importance to team effectiveness, group process remains very much a 'black box' when it comes to looking past short-term or immediate outcomes to understanding innovation in the team context. One of our objectives is to suggest new directions for research to better understand how team processes impact innovation in team settings.

Group processes from a temporal perspective. A clear reality and challenge for many teams is how to manage multiple tasks and objectives simultaneously and adjust to shifting priorities. To understand the role of how processes enable teams to do this requires incorporating a temporal perspective. While demonstrating the importance of team processes, existing research tells us little about how teams balance the interests of competing outcomes from internal/external and short-term/long-term perspectives. Because this requires understanding how teams manage multiple goals and sets of activities over time (McGrath, 1991), recent theoretical work taking a temporal perspective to team processes is particular promising for understanding the functioning of healthy teams.

One perspective is offered by Kozlowski, Gully, Nason & Smith (2001), who identify the critical phases in team development, how they build upon and transition from one to another, and the primary processes that take place at individual, dyadic, and team levels as teams progress in their development. According to their framework, after their initial formation, teams focus on establishing an interpersonal foundation and shared understanding of the team's purpose and goals through socialization and orientation processes. Then, attention shifts to members' development of task competencies and self-regulation through individual skill acquisition experiences. This, in turn, enables team members to immediately develop an understanding of their own and their teammates' roles and responsibilities. Finally, once team members have

a good understanding of each other, their own individual task requirements, and their teammates' roles and responsibilities, the team then focuses on how they can best manage interdependencies both in routine and novel situations by attending to the network of relationships that connect team members to each other.

What the Kozlowski et al. (2001) perspective makes clear is that adaptable teams are those that are able to successfully manage the different challenges presented in each phase of their development. Their model also suggests that, because the phases are progressive and yield enable team capabilities that build on each other and are necessary for meeting the requirements for the next set of developmental challenges, teams that fail to effectively engage in critical sets of processes at earlier stages of development and achieve requisite cognitive, affective, and behavioral outcomes will be at a distinct disadvantage at later developmental stages. For instance, even mature teams with a substantial shared history will be limited in their adaptability and learning capabilities if team members do not develop a high level of familiarity with their team members and a strong team orientation through team socialization experiences.

Marks and colleagues (2001), who also use a temporal approach to describe team processes, offer another complementary theoretical perspective. Although they do not take a developmental view of how teams build progressively complex capabilities *per se*, they do focus on team performance as a recurring set of I-P-O action and transition episodes where outcomes from initial episodes serve as inputs for the next cycle. Thus, consistent with Kozlowski et al. (2001), team outcomes at earlier stages influence team functioning in subsequent phases. Furthermore, Marks et al. (2001) present a taxonomy that organizes different forms of team processes depending on the phase of task accomplishment. Sometimes groups are actively engaged in working toward goal accomplishment and so *action processes* are dominant (e.g. coordination, communication, team and systems monitoring). At other times, groups are either planning for upcoming activities or reflecting on past performances and so members are involved with *transition processes* (e.g. planning, performance analysis, goal specification). Finally, other interactions that involve *interpersonal processes*, such as managing conflict, affect, and teammates' motivation, occur during both transition and action phases of teamwork. Together, these different types of processes capture unique forms of member interaction, but merge together as a sequenced series of team member activities and interactions as a team goes about performing its work.

This distinction between different types of processes based on when they occur during a team's set of performance episodes is helpful both in terms of theory and practice. For instance, interactions supporting a

climate that encourages openly discussing problems, mistakes, and errors—a necessary condition for innovation through learning to occur in teams (Edmondson, 1996)—depends on interpersonal processes such as affect and conflict management in order to help raise alternative perspectives and dissenting viewpoints and keep disagreements focused on the task rather than becoming personally directed at team members (Jehn, 1995). These types of interpersonal processes are necessary both when a team is actively working toward task accomplishment as well as during transition periods such as, during routine pre-/post-shift meetings. Effective interpersonal processes are important not only for contributing to a team's ability to recognize and interpret errors and utilize its experiences to derive learnings that enhance capabilities to meet future demands, but also for maintaining the long-term viability of the team by supporting cohesion and members' commitment to the team by constructively managing disagreements, conflict and contributing to individual team members' skill development and team longevity.

In contrast, if we are interested in studying how teams prioritize being innovative, attention should be focused on transition processes such as whether, and how, teams specifically identify, discuss, and emphasize innovation as an explicit goal during transitional phases in a team's life cycle. From an intervention standpoint, this might mean training teams on how to more effectively utilize opportunities such as pre-shift meetings or 'down-time' periods to work on prioritizing process improvement goals and reviewing their performance and conditions influencing the development of new ideas. To help teams more effectively weight potentially competing goals such as achieving high levels of productivity and generating novel ideas, interventions could also be designed to help teams explicitly identify, prioritize, and try to balance different, and perhaps competing, team objectives.

Work Group Innovation: I-P-O-Based Models

While most researchers have adopted the I-P-O model of work group effectiveness, it has been noted that the conceptual development of the outcome domain has been the least developed (Brodbeck, 1996). Most studies have relied on the group's productive output (i.e. task performance) as the default criterion measure for its effectiveness. Another common criterion measure for group effectiveness has been team viability, or the extent to which members want to continue their team or group involvement. In one sense these two output variables correspond with Hackman's (1987) suggestion that a comprehensive assessment of success in ongoing groups must capture current effectiveness (i.e. task performance) and future effectiveness (i.e. team viability). However, Brodbeck (1996) pointed out that two other important effectiveness dimensions for

work group research are individual well-being and group innovation.

An emphasis on work group innovation is consistent with contemporary writings that note, organizations must continually innovate in order to increase or even maintain competitiveness (see e.g. Banbury & Mitchell, 1995; Hamel & Prahalad, 1994; Wolfe, 1994). Innovation can occur at the organizational level, the work group level, and the individual level, but the group level has been less researched than either of the other two levels (Anderson & King, 1993), despite the increasing use of work groups as the basis for accomplishing work tasks in many organizations. Recently, however, West et al. (1998) have proposed a group-level model of innovation.

West, Borrill & Unsworth (1998) Model of Work Group Effectiveness

Drawing on Brodbeck's (1996) work, West et al. (1998) included team innovation as one of the outcome variables in their review and synthesis of the research related to IPO models of work group effectiveness. They suggested three possible input variables that might influence team innovation. First, heterogeneity in group composition is considered important as it has been found to be related to group innovation (e.g. McGrath, 1984; Jackson, 1996). For instance, although not directly examining this issue, Ancona & Caldwell (1992) found that when a new member from a certain functional area joined an existing team, communication increased dramatically in that functional area. This, in turn, might favor innovation through the introduction of additional and different ideas and models (Agrell & Gustafson, 1996). More direct evidence has come from Wiersema & Bantel (1992), who studied a sample of top management teams in the Fortune 500 companies and found that the top managers' cognitive perspectives, as reflected in the team's demographic characteristics, were linked to the team's strategic management initiatives. Specifically, teams with higher educational specialization heterogeneity were more likely to undergo changes in corporate strategy. Bantel & Jackson (1989) reported that more innovative banks were managed by more educated teams who were heterogeneous in terms of their functional areas of expertise. Similarly, a more recent study (Drach-Zahavy & Somech, 2001) has found that team heterogeneity, as defined by differences in organizational roles, was positively related to team innovation. Therefore, heterogeneity might affect team innovation because team members possess different skills and expertise and, hence, have broader informational resources and knowledge.

Second, West et al. (1998) noted that team tenure might have a negative effect on team innovation. For example, Katz (1982) suggested that as team tenure increases, team members are less likely to communicate internally within the group or externally with

key information sources. In addition, there is some evidence that team tenure might be related to team homogeneity, which, in turn, may have negative effects on team innovation (e.g. Jackson, 1996). On the other hand, Bantel & Jackson (1989) did not find a direct effect of average team tenure on team innovation. West & Anderson (1996) also reported no correlation between average team tenure and overall level of innovation among a sample of top management teams, but did find a positive relationship between average team tenure and impact of innovation on staff well-being.

Third, West et al. (1998) suggested that group composition with respect to personality or dispositional characteristics of the group members might be related to group innovation. For example, West & Anderson (1996) reported that the proportion of innovative members within the group predicted the introduction of radical innovation. This is consistent with the assumption that idea generation is a cognitive process residing in individual group members, although the translation from ideas to actions still requires a variety of situational attributes (Mumford & Gustafson, 1988). In addition, McDonough & Barczak (1992) found that when the technology was familiar, an innovative style on the part of the team as a whole led to faster product development, but that the leader's style was not a significant predictor.

Drawing on previous reviews (e.g. Agrell & Gustafson, 1996; Guzzo & Shea, 1992), West et al. (1998) also identified four possible group process characteristics that might influence group innovation. First, the existence and clarity of group goals or objectives was found to be positively related to group effectiveness in general (e.g. Guzzo & Shea, 1992; Pritchard, Jones, Roth, Stuebing & Ekeberg, 1988). Pinto & Prescott (1988) studied the life cycle of over 400 project teams and found that a clearly stated mission was the only factor that predicted success at all the four stages of the innovation process. They suggested that clarity of goals aided the innovation process because it enabled focused development of new ideas.

Given that innovation is not solely stimulated through a burst of creativity by a talented individual, but is influenced by an interactive process among the team members (Agrell & Gustafson, 1996; Mumford & Gustafson, 1988; West, 1990), West et al. (1998) argued that high levels of participation of group members in decision making should result in more innovation. According to Agrell & Gustafson (1996), although the innovation process begins with the production of ideas from individuals, often the potential innovation may be abandoned or defeated if these ideas are not properly discussed in a dialogue that involves the whole team.

Task-related team conflict, which implies divergent thinking and perspectives, appears to serve as an important process that contributes to successful innova-

tion or generation of ideas (Mumford & Gustafson, 1988). Tjosvold and colleagues have provided some interesting empirical evidence that constructive controversy leads to improved quality of decision-making and, therefore, innovation. For example, Tjosvold (1982) reported that supervisors who used a cooperative-controversy style explored, understood, accepted, and combined workers' arguments with their own to make a decision. It was concluded that task-related controversy within a cooperative context can result in curiosity, understanding, incorporation, and an integrated decision. In another study, Tjosvold, Wedley & Field (1986) asked 58 managers to describe successful and unsuccessful decision-making experiences by indicating the extent to which those involved in making the decision experienced constructive controversy. Results indicated that constructive controversy was significantly related to successful decision-making. De Dreu & West (2001) found that minority dissent (the public opposition by a minority of a group to the beliefs, ideas, or procedures of the group majority) stimulated divergent thinking and creativity, and that such dissent, when combined with high levels of participation in decision making among group members, led to more frequent group innovations.

Fourth, innovation is more likely to occur when the organizational and/or group contexts are supportive of innovation (Amabile, 1983). Burningham & West (1995) examined the contribution of individual innovativeness and team climate factors to the rated innovativeness of work groups in a study of 59 members of 13 teams in an oil company. Support for innovation was found to be the most consistent predictor for predicting externally rated group innovativeness. In addition, West & Anderson (1996) found that support for innovation was positively correlated with their measures of overall amount of team innovation, the number of innovations introduced, and the rated novelty of the innovations.

West's (2002) Model of Work Group Innovation and Creativity

Drawing on the earlier model of work group effectiveness (West et al., 1998) that we have just described, West (2002a) has recently proposed a model focused on the work group innovation process. This model suggests that four sets of factors are the primary determinants of work group innovation. They include characteristics of the group task, group knowledge diversity and skills, external demands on the group, and integrating group processes. The effects of group task characteristics and group knowledge diversity and skills on innovation are both hypothesized to be fully mediated by integrating group processes, whereas external demands are hypothesized to have both a direct effect on innovation and an indirect effect, also mediated by group processes. In addition, West argues that the innovation process includes two stages,

creativity and innovation implementation. Creativity is concerned with idea generation and development, whereas innovation implementation is the application of those ideas to produce innovative products, services, and procedures (West, 2002). West further proposes that external demands on groups can have very different effects on creativity and innovation implementation, although he argues that the effects of task characteristics, knowledge diversity and skills, and integrating group processes on creativity and implementation are similar.

An examination of the West (2002) model's specific content of the four determinants of creativity and innovation implementation and of the forms of the effects they are hypothesized to have both clarifies how West believes that the innovation process unfolds and raises some questions about the model. First we present more details of his model and then we note some concerns.

Group Task Characteristics include factors taken from sociotechnical systems (e.g. Cooper & Foster, 1971) and Job Characteristics Theory (Hackman & Oldham, 1980), such as autonomy, task significance, task identity or completeness, varied demands, opportunities for social interaction, opportunities for learning, and opportunities for development. The model predicts that higher levels of these factors will be correlated with higher levels of both creativity and innovation implementation.

West contends that *requisite diversity* of knowledge and skills among group members is needed for creativity and implementation innovation, that is, an 'optimal' level of knowledge diversity exists for a given task that will encourage creativity and innovation through enhanced task performance capabilities, varieties of perspectives and approaches to problems, and constructive conflict. Too little diversity leads to conformity and common approaches to problems. However, too much diversity (or insufficient overlap in knowledge and skills) among group members may result in disparate mental models and poor levels of coordination and communication that, in turn, negatively affect the innovation process. Thus, diversity is likely to have a curvilinear relationship with group processes that mediate its link with creativity and innovation implementation.

Certain work group processes, termed *integrating group processes* by West (2002a), are affected by group task characteristics and knowledge and skill diversity and mediate the impact of the task and knowledge factors on the innovation process. Integrating group processes allow group members to work collaboratively to capitalize on their diverse knowledge and skills (West, 2002a). Integrating group processes include clarifying and ensuring commitment to group objectives, participation in decision making, managing conflict effectively, minority influence, supporting

innovation, developing intra-group safety, reflexivity, and developing group members' integration skills.

West (2002a) argues that the external context of the work group affects directly the group's innovation process and also the group's integrating processes. The external context, whether internal or external to the organization of which the group is a part, makes demands that can have differential and complex effects. Demands can motivate, but they can sometimes be perceived as threats to the group. In general, West predicts that external demands inhibit the creativity stage of the innovation process, but facilitate the implementation of innovation, although excessive demand levels may make effective implementation be seen as impossible and lessen group members' motivation to implement the proposed innovation. External demands may also force the development of more effective group integrating processes by serving as a driver of change in the ways that group members work together.

In summary, the model of the innovation process proposed by West (2002a) makes important contributions by clearly delineating two major stages of the process, a creativity stage and an innovation implementation stage; by specifying the roles of group tasks characteristics, the diversity of group members' knowledge and skills, and integrating role processes in the innovation process; and by noting the differential effects that external demands and threats have on the creativity and implementation stages. However, we believe that West's model does not fully address very recent advances in thinking about I-P-O models of group effectiveness (e.g. Marks et al., 2001). In addition, we believe that how work groups manage their individual and team knowledge requires more extended elaboration than it has received in existing models of group innovation. Consistent with this belief, we now consider recent research and theory concerning knowledge management. Following that, we present our conceptual framework for work group innovation.

Knowledge Management

Increasingly, organizations that have effective means of creating, storing, and transferring knowledge have been seen by organizational scholars as having competitive advantage over those competitors who do not (Nahapiet & Ghoshal, 1998; Thomas, Sussman & Henderson, 2001). We will use *knowledge management* (see e.g. Hedlund, 1994) to refer to the way in which an organization and its units acquire, store, retrieve, share, and transfer information both across organizational units and among members of a single unit.

Because we are primarily interested in work group-level phenomena, most of our attention and theoretical development related to knowledge management is devoted to this level. Hedlund (1994) has noted that the work group is the level at which much knowledge

transfer and learning takes place in organizations, especially with regard to innovation and product development. Hinsz, Tindale & Vollrath (1997) in a review of research and theory on groups as information processors note that a distinction can be made in terms of the contributions (including knowledge) that individual members bring to the group interaction and the processes involved in the way these individual contributions are combined (aggregated, pooled, or transformed) during group interaction to produce group outcomes. Thus, the knowledge of individual group members is an individual-level input and the combination of the members' knowledge is a group process in an I-P-O approach to group effectiveness.

Following Mohammed & Dumville (2001), we organize our discussion of knowledge management within the context of team mental models. Team mental models are shared understandings and knowledge structures that team members have regarding the key elements of the group's environment, including the group task, equipment, working relationships, and situations (Mohammed & Dumville, 2001). We suggest that knowledge management within a work group that is attempting to create and implement an innovation is ultimately concerned with the development of: (a) a shared mental model of the desired end-product (the innovative product, service, or system) and the means by which it can be achieved; and (b) an accurate inventory of the task-related and teamwork-related knowledge and skills possessed by group members. The shared mental model defines the requisite knowledge and skills perceived to be needed for an effective innovation. A comparison of the requisite needs and the inventory of existing knowledge and skills defines the necessary knowledge and skill acquisition that the group must attain by learning or other means.

Several specific aspects of group-level knowledge management have interesting implications for work group innovation, including transactive memory, cognitive consensus, knowledge distribution and information sharing, imputation of own and others' knowledge, and group learning behavior. We briefly discuss these below.

The concept of *transactive memory systems* was introduced by Wegner (1987) and has been applied to groups (e.g. Moreland & Myaskovsky, 2000). It refers to systems of memory aids that groups may use to help ensure that important information is recalled. Such memory is a social phenomenon and individuals within groups may use each other as a form of external memory aid to augment personal memory. For transactive memory to be effective, group members must have a shared awareness of what knowledge is known by what members of the group. Furthermore, new knowledge that comes to the group should be stored with the member who is the group's expert for that knowledge domain, resulting in increasing specialization among individual members' memories

(Mohammed & Dumville, 2001). We suggest that the type of information may moderate whether such specialization is desired: specialization of task-related information memory may reduce cognitive load and be useful, whereas teamwork-relevant knowledge may require that it be stored in the memory of all group members. Most existing research in transactive memory has emphasized task-related knowledge (Mohammed & Dumville, 2001), so there may be limits to generalizing to team mental models that include other forms of information.

The members of work groups that are formed to represent a wide range of perspectives and constituencies (e.g. cross-functional teams and task forces) and charged with developing an innovative solution to a complex organizational problem frequently have very different perspectives and interpretations of the issues involved (Mohammed & Dumville, 2001). Such groups need to reach *cognitive consensus* on the interpretation of the issues before they can develop effective and mutually acceptable decisions about courses of action to take (Mohammed & Ringseis, 2001). While cognitive diversity has been suggested as predictive of idea generation and creativity, cognitive consensus may be required in order to develop an acceptable group mission or set of goals.

Research on knowledge distribution and information sharing in groups (e.g. Stasser, Taylor & Hanna, 1989) suggests that group members tend to discuss what they believe to be shared information known to all group members. This finding implies, that groups in which knowledge is distributed may not effectively use their diverse knowledge unless group processes explicitly elicit unique knowledge from all group members (Mohammed & Dumville, 2001). Stasser (1991) has suggested that group members be told that they each may hold unique information and that others may also have unique information.

While one might assume that most individuals in work groups would understand that information is so distributed among members, Nickerson (1999) in a review of the research on *imputing what other people know* concluded that individuals often impute their own knowledge to others, i.e. assume that others know what they know, especially when they have little direct experience with the other people. While the tendency to overimpute one's knowledge to others decreases as one learns more about others, there is a danger in newly formed work groups for errors to occur that may hinder the development of shared mental models. To the extent that groups do not develop transactive memory systems and fail to discuss their unique knowledge, however, such learning about others may not occur effectively and erroneous knowledge imputation may continue.

Edmondson (1999) suggested that work groups would be more effective to the extent that they engage in *team learning behaviors*, such as seeking feedback,

sharing information, asking for help, talking about errors, and experimenting. However, some of these learning behaviors are potentially costly because an individual exhibiting such behaviors may appear to be incompetent and, thus, threaten his or her image (Brown, 1990). Despite the potential benefit of learning behaviors for the team or organization, research has shown that people are generally reluctant to disclose their errors and are often unwilling to ask for help (Lee, 1997). Therefore, when faced with situations that are potentially embarrassing, people tend to behave in ways that inhibit learning (Argyris, 1982). Such behaviors would be detrimental for successful group innovation.

That said, Edmondson (1996) found that people are more likely, and willing, to ask for help, admit errors, seek feedback, and discuss problems when they perceive the interpersonal threats in the situations as sufficiently low. Drawing on these insights, Edmondson (1999) proposed that teams differ in their levels of team psychological safety, which is defined as the “shared belief that the team is safe for interpersonal risk taking” (p. 354). Psychological safety is a team climate characterized by interpersonal trust and mutual respect such that people are comfortable and willing to engage in learning behaviors that make them vulnerable to threats and ridicules (Robinson, 1996). For example, Edmondson (1999) found that: (a) team psychological safety was positively related to team learning behavior; (b) team learning behavior was positively related with team performance; and (c) team learning behavior mediated that relationship between team psychological safety and team performance. Therefore, teams with higher levels of team psychological safety engaged in more learning behavior, which in turn led to higher levels of team performance. Equally important, Edmondson also found that team psychological safety mediated the effects of team leader coaching and contextual support on team learning behavior. In other words, coaching and context support promotes team psychological safety, and team psychological safety promotes team learning.

Integration of Current Research and Theory on Group Effectiveness and Innovation

As we have noted earlier, West and colleagues (West et al., 1998; West, 2002) have provided valuable insights concerning work group effectiveness and innovation. We seek to elaborate West’s (2002) model of work group innovation in three ways. First, although West emphasized the important difference between a creative or an idea generation stage and an innovation implementation stage in the overall innovative process, we draw from Marks et al. (2001) and suggest that the creativity stage and the implementation stage each contain both a transition phase and an action phase.

Second, again following Marks et al. (2001), we emphasize the distinction between team processes and team emergent states. Specifically, team processes are interdependent acts members take to yield collective outcomes. However, emergent states refer to “constructs that characterize properties of the team that are typically dynamic in nature and vary as a function of team context, inputs, processes, and outcome” (Marks et al., 2001, p. 357). We contend that some of the processes (e.g. intragroup safety) presented in West’s (2002) model should be regarded as team emergent states. The distinction between group processes and emergent states is an important one. Team processes depict the nature of team member interactions (e.g. participation, conflict management), whereas emergent states depicts the cognitive (e.g. team efficacy; shared mental model), affective (e.g. team cohesion and team psychological safety), and motivational (e.g. team’s intrinsic motivation) states of the teams. In addition, emergent states can be considered as both inputs to the team’s current phase of the innovative process and as proximal outcomes that then become inputs for the next innovative phase.

Third, West (2002) proposed in his model that most influences on the innovative process (i.e. task characteristics, diversity in knowledge and skills, and integrating group processes, but not external demands) have identical relationships with both the creativity and innovation implementation stages. Instead, we propose that our elaborated temporal perspective of work group innovation suggests that different input and process variables are relevant and important in predicting the respective outcomes in each phase of the innovation process. Concomitantly, we attempt to include a more comprehensive and inclusive set of variables that are relevant for the investigation of work group innovation. In particular, we elaborate on the knowledge management processes and systems that groups use during innovation.

We now present our model in more detail.

Dynamic Model of Work Group Innovation

Figure 1 depicts the temporal sequence of various phases in the process of work group innovation, drawing on both West (2002) and Marks et al. (2001). (Although it is clear that the innovation process is not linear (West, 2002), we have portrayed it in Fig. 1 as if it were for sake of parsimony in our graphic depiction of the process.) First, there are two distinct stages in the innovation process: creativity and innovation implementation. Within both the creativity and implementation stages are transition and action phases. Nested within each phase are various input and process variables that influence the interim outcomes for that phase. Table 1 presents our initial thoughts about specific inputs, processes, and outcomes that are most relevant for each of the four phases of the innovation

Figure 1. Dynamic model of work group innovation.

process. Below we briefly discuss the major components of our model.

Outcomes

We believe it is helpful to first discuss the outcomes because they help to demarcate the change from one

phase of the innovation process to another. Referring to Table 1, there are clearly identifiable outcomes that punctuate the phases. In the transition phase of the creativity stage, the team interprets the relevant issue(s) and identifies the problem the team or organization is facing. Once issues are interpreted and the problems

Table 1. Inputs, processes, task-related outcomes, and emergent states in work group innovation.

	Creativity Stage		Innovation Implementation Stage	
	Transition Phase	Action Phase	Transition Phase	Action Phase
Inputs:				
• Task characteristics	Autonomy, Completeness, Significance <i>(Intrinsic motivation)</i>			Autonomy, Completeness, Significance <i>(Intrinsic motivation)</i>
• Individual	Expertise	Goal orientations Openness to experience	Expertise Agreeableness	Goal orientation Conscientiousness
• Group	Leader behavior <i>(Psychological safety)</i>	Requisite diversity in knowledge and skills Demographic diversity	Requisite diversity in knowledge and skills	Diversity in personality and attitudes Social network
• External demands	Competition Uncertainty	Goal orientation <i>(Group efficacy)</i> Time constraints Threats	Problem importance	Goal orientation <i>(Group efficacy)</i> Time constraint
Processes:				
• Transition	Mission analysis <i>(Shared mental model)</i>		Goal specification Strategy formulation <i>(Shared mental model)</i>	
• Action		Monitoring progress toward goals		Monitoring progress toward goals Team monitoring Coordination System monitoring
• Interpersonal	Conflict management Affect management <i>(Group cohesion)</i>	Conflict management Affect management <i>(Group cohesion)</i>	Conflict management Affect management <i>(Group cohesion)</i>	Motivation and confidence building <i>(Group efficacy)</i>
Task-related outcomes	Interpretation of issues Problem identification and recognition	Generation of creative ideas/solutions	Evaluation and selection of ideas/solutions	Application of ideas/solutions to problem
Group outcomes: Emergent states	Psychological safety; Group efficacy; Shared mental models; Group cohesion; Group affect			

identified, the team moves into an action phase where the goal is to generate creative ideas and solutions pertaining to the problem. The transition phase of the innovation implementation stage starts when the team begins to evaluate and assess the ideas and solutions generated earlier. Finally, the action phase of the implementation stage is the team's concerted effort to apply the idea or solution to the problem. Note that there is also a 'feedback loop' from the end of implementation stage to the beginning of the creativity stage (see Fig. 1). This happens when the team identifies related problems or fails to implement the initial innovation successfully.

Input Variables

Task Characteristics

Based on socio-technical systems theory (e.g. Cooper & Foster, 1971) and job characteristic theory (Hackman & Oldham, 1975), West (2002) proposed that certain task characteristics help to evoke 'task orientation' or intrinsic motivation in the team which will in turn facilitate innovation. In other words, when teams experience autonomy, perceive the team as responsible for completing a whole task, and consider the task to be important, a state of high intrinsic motivation is more likely to emerge. According to Amabile and colleagues, a high level of intrinsic motivation is fundamental to creativity and innovation (Amabile, 1983; Amabile & Conti, 1999). We reason that high levels of intrinsic motivation are most crucial when teams face uncertainties or difficulties requiring novel approaches. Hence, ensuring high levels of intrinsic motivation is beneficial during the transition phase of the creativity stage, where the team is still trying to assess and make sense of the problem at hand. Similarly, intrinsic motivation is crucial during the action phase of the implementation stage because the team is likely to encounter significant roadblocks and obstacles.

Individual Variables

Some individual level variables that are relevant for understanding innovation are level of expertise, personality, and goal orientation. First, level of expertise is considered important because knowledge is the basic requirement before one can create something new within a particular domain (Amabile & Conti, 1999). However, Sternberg (1999) has noted that extremely high levels of expertise can also be a hindrance to creativity and innovation. (Diversity in the types of expertise within a team can help to reduce this problem as we discuss later.) We believe that expertise is most relevant during the transition phase of the creativity and implementation stages because problem identification and evaluation of ideas link directly to domain knowledge.

Second, research at the individual level has found some relationships between personality and innovation.

For example, Barrick & Mount (1991) reported in their meta-analytic finding that openness to experience is related to various learning and training criteria, which suggests that individuals who are high on openness to experience are more likely to adopt new ways of thinking and to embrace changes. We reason that openness to experience is most relevant in the action phase of the creativity stage because that is when new or even seemingly 'wild' ideas must be entertained and encouraged. Next, agreeableness has been found to be negatively related to creative achievement but not with creative thinking (King, Walker & Broyles, 1996). In other words, individuals who are agreeable may suggest more ideas but also often find it difficult to evaluate or find fault with others' ideas. Hence, we propose that agreeableness is relevant during the transition phase of the implementation stage when lower levels of agreeableness may result in better evaluation and selection of ideas. Patterson (2002) reasoned that conscientiousness might be negatively associated with innovation because individuals high on conscientiousness tend to comply with rules and organizational norms (e.g. Hogan & Ones, 1997). We would agree for the creativity action phase. However, we propose that conscientiousness might be positively related to innovation implementation (i.e. action phase of the implementation stage) because a high level of persistence is needed when there are resistance and obstacles to change (e.g. Amabile, 1983).

Third, we propose that goal orientation is relevant during both action phases of the innovation process. Dweck (1986) has demonstrated that the way in which individuals approach a task can influence their behavior in a number of respects. When approaching a task from a learning goal orientation, the individual's main objective is to increase his or her level of competence on a given task. Alternatively, when approaching a task from a performance goal orientation, individuals are primarily concerned with demonstrating their competency to others via task performance. Farr, Hofmann & Ringenbach (1993) reviewed the goal orientation research and noted ways that it could be applied to work behavior, including learning. A number of these suggested research directions have been recently pursued. For example, Colquitt & Simmering (1998) found learning orientation to be positively related to motivation to learn both initially and after performance feedback had been given, whereas performance goal orientation was negatively related to motivation to learn. VandeWalle & Cummings (1997) found in two studies that learning goal orientation and performance goal orientation were positively and negatively related to feedback seeking, respectively. Hence, during the action phase of the creativity stage, we suggest that individuals with strong learning goal orientations will be more willing to participate in idea generation without fear of appearing incompetent. In addition, individuals with strong learning goal orientations may

be more persistent when encountering problems and obstacles during the action phase of the implementation stage.

Group Variables

Some group level variables that are relevant for understanding innovation are diversity, social networks, and leadership role behavior. After reviewing the extant literature, Milliken & Martins (1996) suggested that various types of work group diversity (observable traits, such as demographic characteristics; unobservable traits, such as personality and values; and functional characteristics, such as knowledge, skills and organizational experience) may be differentially related to group processes and outcomes. We propose that all three types of diversity (i.e. demography, personality and attitudes, and knowledge and skills) are important predictors of work group innovation but are differentially important in different phases of the innovation process. To summarize our predictions, we believe that demographic diversity is most relevant for idea generation, diversity in knowledge and skills is relevant for both idea generation and evaluation, and that diversity in personality and attitudes is more relevant for application and implementation of the ideas. Since very high levels of diversity can result in dysfunctional conflict within a team (Milliken & Martins, 1996), we use West's (2002) concept of requisite diversity to suggest that there are optimal levels of diversity that lead to effective creativity and innovation implementation.

Second, research has shown that the team's social network within the organization is related to the action phase of the implementation stage (e.g. Tsai, 2001; Tsai & Ghosal, 1998). Tsai & Ghoshal (1998) found that social interaction and trust among organizational teams were related to the extent of resource exchange among teams and product innovation within the company. Drawing on a network perspective on organizational learning, Tsai (2001) found that organizational groups can produce more innovations and enjoy better performance if they occupy central network positions that provide access to new knowledge developed by other units but only if units have the ability to successfully replicate the new knowledge. Thus, empirical evidence from network research suggests that teams that are connected and embedded within the social network of the organization can more readily garner support and resources that result in successful implementation of their innovative ideas.

Third, as noted earlier, Edmondson (1999) found that team leaders' coaching on learning behaviors promotes psychological safety in teams, an emergent state which we believe is crucial for efficient communication and interactions among team members, especially in the idea generation and idea evaluation phases of the innovative process.

External Demands

According to West (2002), competition and uncertainty in the external environment will facilitate innovation. Hence, they are relevant in the transition phase of the creativity stage in that they set off the whole innovation process. West (2002) also noted that having time constraints pushes the teams to actively implement the innovation, but that external demands that are perceived as threats or constraints on the team are likely to result in fewer ideas of lower novelty being generated by a work group.

Next, while goal orientation is often conceptualized as a dispositional characteristic, its theoretical foundation also recognizes that it can be activated by a variety of situational factors (Dweck, 1986; Farr et al., 1993). For example, Martocchio (1994) found that trainees in a situation that elicited a learning goal orientation experienced a significant decrease in computer anxiety between pre- and post-training assessments, but not those trainees in a situation that led to a performance goal orientation. Also, trainees in the learning goal orientation condition experienced a significant increase in computer efficacy beliefs, while trainees in the performance goal orientation condition experienced a significant decrease in computer efficacy between the pre- and post-training assessments. Relatively few studies have looked at goal orientation in group or team research aside from considering fit between individual and team goal orientations (Kristof-Brown & Stevens, 2001). However, given that goal orientation is closely related to learning behaviors (Colquitt & Simmering, 1998; VandeWalle & Cummings, 1997), it is potentially a useful variable to be considered in team research, especially in the area of group innovation. For example, the proportion of members with learning or performance goal orientation within the group might predict the level of learning behaviors engaged by the team, which lead to amount and/or quality of group innovation. It might also be possible to enhance the emergent state of group efficacy by manipulating and inducing a learning goal orientation in the work environment (Martocchio, 1994; Winters & Latham, 1996).

Process Variables

As described earlier, Marks et al. (2001) provide an excellent taxonomy of team processes that are relevant for different phases of task accomplishment. In the following section, we briefly describe each process and how they might be relevant for various phases of the innovation process.

Transition Processes

Three activities included as transition processes are, mission analysis, goal specification, and strategy formulation. For mission analysis, the team's major objective is to identify the main tasks at hand, which is most crucial for the innovation process during the

transition phase of the creative stage, where the team has to identify the target problem and interpret the relevant issues. Goal specification refers to “the identification and prioritization of goals and subgoals for mission accomplishment” and strategy formulation refers to “the development of alternative courses of action for mission accomplishment” (Marks et al., 2001, p. 365). We propose that both goal specification and strategy formulation are particularly relevant during the transition phase of the implementation stage, where the team has to develop concrete plans of actions to implement the ideas. Note that all the three transition processes help to cultivate the emergent state of shared cognitions or team mental model in the team. It is likely that cognitive consensus (Mohammed & Ringseis, 2001) is important for both of the transition

Action Processes

Action processes include activities such as system monitoring, goal monitoring, team monitoring, and coordination. Groups monitor progress toward their goals by assessing the discrepancy or gaps between the goals and the current situation, which is needed both when the team is generating ideas as well as when implementing the solutions. Team monitoring involves feedback, coaching, or assistance to other group members in relation to task accomplishment. Coordination refers to actions targeted at managing the interdependent actions of team members toward task accomplishment. System monitoring refers to activities that track the team’s resources as well as the environmental conditions. Note that all four action processes are important when the team is engaging in the innovation implementation, whereas we propose that goal monitoring is the primary action process needed in the creativity stage.

Interpersonal Processes

Conflict management, affect management, and motivation/confidence building are processes that work groups engage in to manage their interpersonal relationships. Conflict management can include both preventive and reactive approaches to managing interpersonal disagreements or disputes. Note that effective conflict management is not a focus on conflict avoidance, because task-or idea-focused conflict can be constructive to the innovation process (West, 2002). Affect management involves monitoring and regulating the team members’ level of emotional arousal. Both conflict and affect management are especially important during idea generation and evaluation given the higher probability of disagreement and conflict. Note that effective conflict and affect management will enhance the team’s emergent state of group cohesion. Motivation and confidence building involves activities that preserve or enhance the team’s sense of efficacy beliefs. Hence it will lead to the emergent state of group efficacy, which is crucial during the implementa-

tion stage since the team is likely to encounter high level of resistance and obstacles toward change.

Summary

We have provided an I-P-O model of the work group innovation process that identifies transition and action phases with each of two major stages of innovation: a creativity stage and an innovation implementation stage. The transition phases both involve primarily planning and evaluation tasks that guide later goal accomplishment. The action phases are both involved primarily in acts that directly contribute to goal accomplishment. Within the creativity stage, the transition phase consists of interpretation of issues and problem identification and the action phase consists of idea generation. Within the innovation implementation stage, the transition phase consists of the evaluation of the generated ideas as possible solutions and selection of the one(s) to implement and the action phase consists of the application of the idea(s) to the problem. We also provide our initial thoughts on the specific inputs, group processes, and emergent states that are important for each phase of our model. We trust that our model will generate innovative research examining and extending it in novel ways.

Creativity and Innovation = Competitiveness? When, How, and Why

Elias G. Carayannis and Edgar Gonzalez

School of Business and Public Management, The George Washington University, USA

Abstract: In this chapter, we propose to look at both for-profit and not-for-profit entities to examine:

- (a) when, how, and why creativity and innovation occur;
- (b) how and why creativity triggers innovation and vice versa; and
- (c) what are the connections and implications for competitiveness of the presence or absence of creativity and innovation using empirical findings from both the public and private sectors.

We combine literature sources (including those of the authors) as well as field interviews on the practice and implications of creativity and innovation from the perspective of competitiveness.

Keywords: Innovation; Creativity; Competitiveness; Institutional learning; Entrepreneurial learning; Public-private sector partnerships.

Introduction

Zum sehen geboren; Zum schauen bestellt:

{Born to see; Meant to look}

(Faust, Goethe)

In Greek, the word for creator also denoting God, is the word *poet*. This underlines the dynamic underlying creativity, in that it encompasses both a structured, disciplined, scientific as well as an artistic element: one could say that creativity emerges from the interplay and interfacing of science and art—in a way, it could be conceived of as being *the art of science and the science of art* (Carayannis, 1998b).

The relationship between creativity, innovation and competitiveness at a very basic level appears readily apparent: creativity is a necessary (but not sufficient) factor enabling innovation, and innovation of different types can improve national economic competitiveness. This relationship is extremely significant, however, in that it links three levels of analysis: creativity (mostly at the *individual level or micro level*), innovation (mostly at the *organizational or meso level*), and competitiveness (mostly at the *national or macro level*) (see Figs 1, 3 and 8). Understanding the specific links and dynamics contained within this relationship may provide significant insight into the ability of nations to build and sustain conditions of competitiveness.

In this chapter, we explore what creativity and innovation are and what their significance and role is for people and organizations (and by extension potentially nations) as ingredients, catalysts, and possibly inhibitors of competitiveness. We look at both *for-profit and not-for-profit* entities to examine:

- (a) when, how, and why creativity and innovation occur;
- (b) how and why creativity triggers innovation and vice versa; and
- (c) what are the connections and implications for competitiveness are of the presence or absence of creativity and innovation.

Creativity

Management is, all things considered, the most creative of all arts.

It is the art of arts, because it is the organizer of talent.

(Jean-Jacques Servan-Schreiber)

Starting at the individual level, **creativity** may be defined as the capacity to ‘*think out of the box*’, to think laterally, to perceive, conceive, and construct ideas, models, and constructs that exceed or supersede established items and ways of thinking and perceiving.

Creativity is related to the capacity to imagine, since it requires the creator to perceive future potentials that are not obvious based on current conditions. From a cognitive perspective, creativity is the ability to perceive new connections among objects and concepts—in effect, reordering reality by using a novel framework for organizing perceptions.

Creative types such as artists, scientists, and entrepreneurs often exhibit attributes of *obsessed maniacs* and *clairvoyant oracles* (Carayannis, 1998–2002, George Washington University Lectures on Entrepreneurship) as well as the capacity and even propensity for creative destruction that is how Joseph Schumpeter qualified innovation. Albert Szentgeorgi, a Nobel Prize laureate, defined creativity as ‘*seeing what everyone sees and thinking what no one has thought before*’.

Innovation

Discovery consists of looking at the same thing as everyone else and thinking something different.

Albert Szent-Gyorgyi—Nobel Prize Winner

Innovation is a word derived from the Latin, meaning to introduce something new to the existing realm and order of things or to change the yield of resources as stated by J. B. Say quoted in Drucker (Drucker, 1985).

In addition, innovation is often linked with creating a sustainable market around the introduction of new and superior product or process. Specifically, in the literature on the management of technology, technological innovation is characterized as the introduction of a new technology-based product into the market:

Technological innovation is defined here as a situationally new development through which people extend their control over the environment. Essentially, technology is a tool of some kind that allows an individual to do something new. A technological innovation is basically information organized in a new way. So technology transfer amounts to the communication of information, usually from one organization to another (Tornazky & Fleischer, 1990).

The broader interpretation of the term ‘innovation’ refers to an innovation as an “idea, practice or material artifact” (Rogers & Shoemaker, 1971, p. 19) adopted by a person or organization, where that artifact is “perceived to be new by the relevant unit of adoption” (Zaltman et al., 1973). Therefore, innovation tends to change perceptions and relationships at the organizational level, but its impact is not limited there. Innovation in its broader socio-technical, economic, and political context, can also substantially impact, shape, and evolve ways and means people live their lives, businesses form, compete, succeed and fail, and nations prosper or decline (see Fig. 1).

Specifically, Fig. 1 attempts to illustrate the nature and dynamics of an emerging globalization framework in which creativity and innovation—as enabler of technological effort in manufacturing and as an engine of industrial development—can lead to improved competitiveness and sustained development. On the other hand, lack of creativity and innovation constitutes a factor for failure in manufacturing performance and, as a result, is a factor for failure in economic performance, too. For those countries in which creativity and innovation is applied effectively, globalization can be an engine of beneficial and sustainable economic integration. However, globalization can be a powerful force for deprivation, inequality, marginalization and economical disruption in those non-competitive countries.

Government or market success or failure is determined by how they take advantage of the four major elements that shape the setting for creativity, innovation and competitiveness in the globalized world:

- (1) the coordination and synergy in the relationship between governments, enterprises, research laboratories and other specialized bodies, universities and support agencies for small and medium enterprises (SMEs);
- (2) the power of information and communication technology;
- (3) the efficiency that managerial and organizational systems can bring to production and commerce; and
- (4) the international agreements, rules and regulations.

All the four elements of this framework will impact on creativity and innovation at the micro level (firm level) as well as on innovation and competitiveness at the macro level (industry, national, global).

Competitiveness

Competitiveness is the capacity of people, organizations, and nations to achieve superior outputs and especially outcomes, and in particular, *to add value*, while using the same or lower amounts of inputs (see Fig. 2).

Moreover, entrepreneurial value-adding and entrepreneurial learning by doing, learning by analogy, and learning by failing, does not belong to the realm of for-profit entities only, but also in the domain of not-for-profit entities. This is shown in Fig. 2 with the overlapping circles connecting creativity and innovation activities across for-profits and not-for-profits.

The standard for judging whether these results are ‘superior’ can encompass both prior capabilities of a particular organization or nation and a comparison with other organizations or nations. The critical assumption of competitiveness, then, is that it is accomplished through a process of organizational improvement, where the institutions in an economy leverage people,

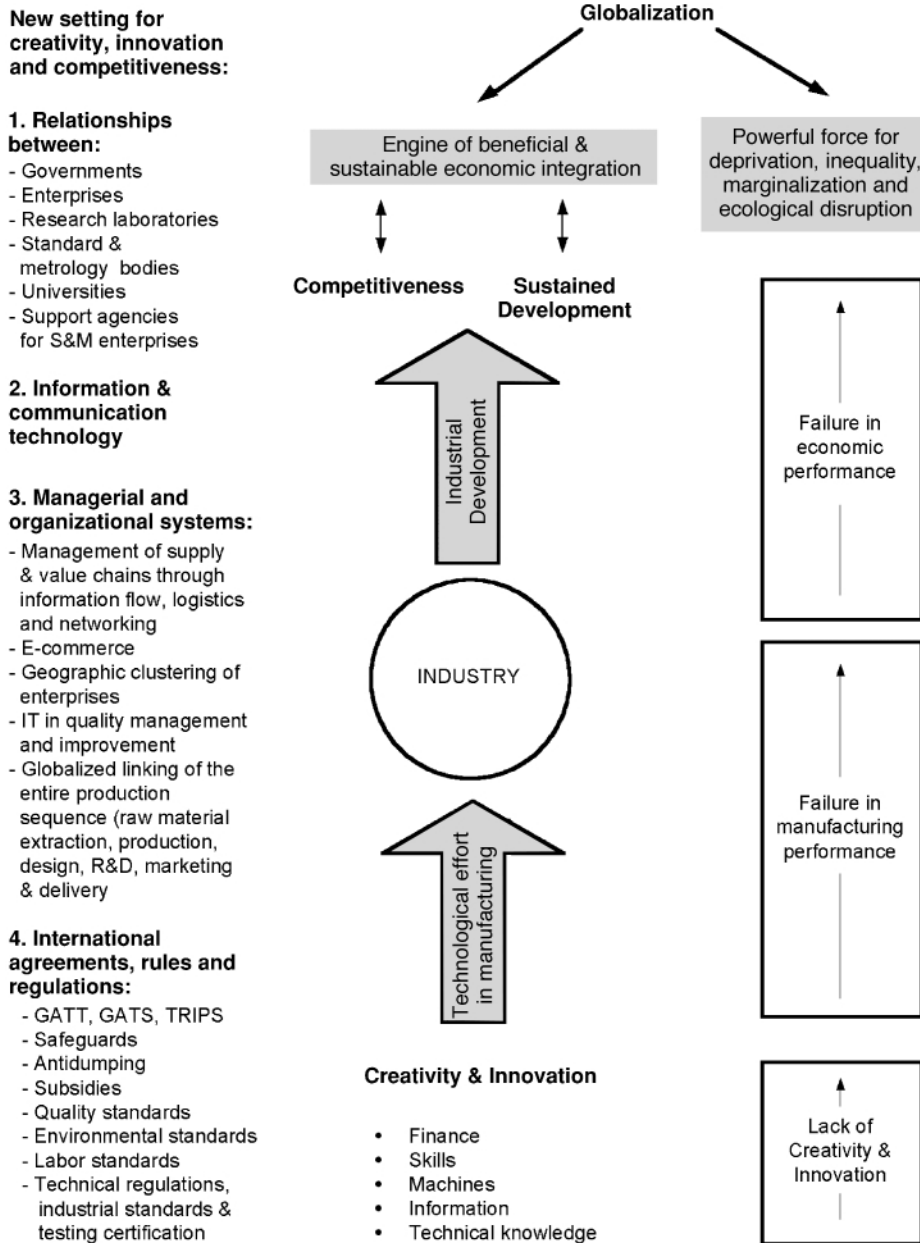

Figure 1. The CIC value chain: Global and local perspectives.

knowledge and technologies to rearrange relationships and enable higher states of production.

creative imagination and marks real advance in science.

(Albert Einstein)

When, Why and How Creativity Arises

Imagination is more important than knowledge. To raise new questions, new possibilities, to regard old problems from a new angle, requires

The problem with ‘creativity’ is that it is an intangible. While we generally know when something is creative, we often don’t know why. It seems difficult to articulate a precise definition of the topic.

Figure 2. CIC: Value-adding and learning topology.

Aristotle, for example, suggested that inspiration involved a form of madness whereby great insights began as a result of a person's own thoughts progressing through a series of associations (Dacey & Lennon, 1998, p. 17). This view of the creative individual as mad, or potentially so, continued through the nineteenth century.

Freud believed creative ability was a personality trait that tends to become fixed by experiences in the first five years of life (Dacey & Lennon, 1998, p. 36). He maintained that creative expression was a means of expressing inner conflicts that otherwise would result in neuroses. Creativity was a sort of emotional purgative that kept men sane (Kneller, 1965, p. 21). During the first half of the twentieth century, B. F. Skinner and other behaviorists considered creative production to be strictly the result of 'random mutation' and a product of appropriate reinforcers provided by society (Dacey & Lennon, 1998, p. 138).

Cognitive View of Creativity (Personal Creativity)

Kneller (1965, p. 3) suggested that definitions of creativity seem to fall into four categories. Creativity is considered from the standpoint of the person who creates, in terms of mental processes, in terms of its products, or focuses on environmental and cultural influences. He states that "an act or an idea is creative not only because it is novel, but also because it achieves something that is appropriate to a given situation" (1965, p. 6). We create when we discover and express something that is new to us. The operative phrase is 'new to us'; even if another person has discovered something, it is still creativity if we have rediscovered it for ourselves.

Amabile (1996, p. 33) appears to provide the most complete definition available to date. She suggests a two-part definition of creativity:

(1) that a product or response is creative to the extent that appropriate observers independently agree it is

creative. Appropriate observers are those familiar with the domain in which the product or the response articulated (p. 33); and

(2) that a product or response will be judged as creative to the extent that it is both a novel and appropriate task at hand, and the task is heuristic rather than algorithmic. She defines algorithmic tasks as those for which the path to the solution is clear and straightforward; heuristic tasks are those for which algorithms must be developed. She calls these tasks 'problem discovery' (p. 35).

Amabile (1996, p. 90) also lists personality traits that appear repeatedly in summaries of empirical work on the characteristics of creative persons:

- High degree of self-discipline in matters concerning work.
- Ability to delay gratification.
- Perseverance in the face of frustration.
- Independence of judgment.
- A tolerance for ambiguity.
- A high degree of autonomy.
- An absence of sex role stereotyping.
- An internal locus of control.
- A willingness to take risks.
- A high level of self-initiated, task-oriented striving for excellence.

Of their nine principal traits, it may be helpful to further define three: stimulus freedom, functional freedom, and flexibility. Stimulus freedom (Getzels, Taylor, Torrance, cited by Dacey & Lennon, 1998, p. 100) occurs when people are likely to bend the rules to meet their needs, if the stated rules of a situation interfere with their creative ideas. Functional freedom is the ability to use items for other creative, or unique uses. Dacey and Lennon contend that the more education a person has, the more rigid his or her perception of function is likely to become. Also,

because education tends to encourage complexity of thought, this may produce a convoluted thinking style which works against producing simple ideas—the ones that comprise many of the world's greatest solutions. Flexibility is the capacity to see the whole of a situation, rather than just a group of uncoordinated details.

Gestalt psychologists believed that creative problem-solving is similar in important ways to perception. They argued that it is primarily a reconstruction of gestalts, or patterns, that are structurally deficient. Creative thinking begins with a problematic situation that is incomplete in some way. The thinker grasps this problem as a whole. The dynamics of the problem itself and the forces and tensions within it, set up similar lines of stress within his or her mind. By following these lines of stress, the thinker arrives at a solution that restores harmony of the whole (Kneller, 1965, p. 27). Restructuring and productive thinking often do not occur because problem-solvers tend to become fixated on attempting to apply past experience to the problem, and thus do not deal with the problem on its own terms (Weisberg, 1992, p. 51).

Creativity in an Organizational Context

Culture is the invisible force behind the tangles and observables in any organization, a social energy that moves people to act. Culture is to the organization what personality is to the individual—a hidden, yet unifying theme that provides meaning, direction, and mobilization.

(Killman, R., *Gaining Control of the Corporate Culture*, 1985)

In the business context, creativity now is championed by certain authors as the critical element enabling change in organizations. Kao (1996, xvii) defines creativity as:

the entire process by which ideas are generated, developed and transformed into value. It encompasses what people commonly mean by innovation and entrepreneurship. In our lexicon, it connotes both the art of giving birth to new ideas and the discipline of shaping and developing those ideas to the stage of realized value.

Kao views creativity as the “result of interplay among the person, the task, and the organizational context” (cited in Gundry et al., 1994). Drazin et al. (1999) agree with this assertion. They conclude that creativity is both an individual and group level process. Complex, creative projects found within large organizations require the engagement of many individuals, rather than just a few. It is often difficult to assign credit to any one individual in a creative effort (Sutton & Hargadon, cited in Drazin et al., 1999). Creativity, they believe, is an iterative process whereby individuals develop ideas, interact with the group, work out issues

in solitude, and then return to the group to further modify and enhance their ideas. Their sense making perspective of creativity illustrates the notion that individuals are influenced in their creative efforts by such factors as conflict, political influence, and negotiated order at the group level.

Environmental Effects on Creativity

When I am, as it were, completely myself, entirely alone, and of good cheer . . . it is on such occasions that my ideas flow best and most abundantly. *Whence and how* they come, I know not; nor can I force them. Those ideas that please me I retain in memory.

(W. A. Mozart, quoted in Brewster Ghiselin, 1952, p. 34)

Woodman & Schoenfeldt (1990, p. 18) stress the importance of social environment. They state: “it is clear that individual differences in creativity are a function of the extent to which the social and contextual factors nurture the creative process. Research on creativity has led to a recognition of the fact that the kind of environment most likely to produce a well-adjusted person is not the same as the kind of environment most likely to produce a creative person”. Because of the dearth of research in this area, we will briefly examine the factors through an ever-widening circle of social influences—from family to culture.

Amabile (1996, p. 179) reports that there appear to be three social factors that are important for creative behavior:

- Social facilitation (or social inhibition), brought about by the presence of others: She reports that the presence of others can impair performance on poorly learned or complex tasks, but enhance performance on well-learned or simple tasks (p. 181). In addition, there is much evidence that subjects perform more poorly on idea-production tests when they work together than when they work alone.
- *Modeling, or the imitation of observed behavior*: Research suggests that a large number of creative models in one generation will stimulate general creative production in the next generation (Simonton, cited on p. 189). At the individual level, the pattern of influence seems to be complex. At the highest levels of creative eminence, modeling may be relatively unimportant. In addition, although exposure to creative models may stimulate early high-level productivity, it may be important at some point to go beyond the examples set by one's mentors.
- *Motivational orientation, or an individual's intrinsic or extrinsic approach to work*: Studies suggest that intrinsic orientation leads to a preference for challenging and enjoyable tasks, whereas an extrinsic orientation leads to a preference for simple, predictable tasks (p. 192).

There is some evidence that cultures may promote or inhibit creativity. Arieti (1976, p. 303) explored cultural influences on creativity and suggests that the potentiality for creativity is deemed much more frequent than its occurrence. Some cultures promote creativity more than others and he labeled these cultures as 'creativogenic'. He held that people become creative (or to use his term, 'genius') because of the juxtaposition of three factors:

- (1) The culture is right. He uses the example that the airplane would not have been invented if gasoline had not been invented.
- (2) The genes are right. The person's intelligence, which is known to be genetic, must be high. Creativity, which may or may not be genetic, must also be high.
- (3) The interactions are right. He offers the example of Freud, Jung, and Adler. If Jung and Adler had not had Freud to compete over, and against, it is questionable whether either Jung or Adler would hold such a high position in psychology today.

Hofstede (1980, p. 43), in a study of the culture of 40 independent nations, found four criteria by which their cultures differed: power distance, uncertainty avoidance, individualism-collectivism and masculinity-femininity. These dimensions appear to have a powerful influence on the 'collective mental programming of the people in an environment'. They are also grounded in our collective cultural history. Americans, for example, tend to exhibit high individualism, small power distance, and weak uncertainty avoidance. That they show these tendencies reflects American history which has placed high value on equality, independence, and willingness to take risks.

This cultural influence is qualitatively different than the social influences mentioned in previous creativity models. For want of a better term, we call it 'cultural embeddedness', because it implies more than a society's norms, values, and mores. It is what defines our reality. In light of this additional component, we are proposing a new model of creativity which not only illustrates the components of creativity, but the creative process as well. In this model, personality and cognitive factors interact with the individual and vice versa. The social environment interacts with the three factors and vice versa; the individual initiates and participates in the creative process. Cultural embeddedness influences not only all of the creative factors but all steps of the creative process.

When, Why and How Innovation Arises

Innovation is creative destruction.

The success of everything depends upon *intuition*, the capacity of seeing things in a way which afterwards proves to be true.

(Joseph Schumpeter)

If creativity can be seen as a process and a product or event, the use of the term innovation in terms of creativity seems to muddy the waters. If one consults the business literature, 'innovation' and 'creativity' appear to be used interchangeably.

Innovation is seen as the panacea for competing successfully in today's global marketplace, but in much of the literature the concept is a vague one. Managers are told they must promote innovation, but they are not given the specifics of how this is to be accomplished. The articles often cite one or two examples of companies that are profiting from 'innovation', and the reader is left to grapple with the mechanics of extrapolating useful information that is transferable to his or her own situation.

In an extensive review of popular and academic business literature, we found that the information provided ranged from the esoteric notion of promoting an innovative organizational climate to concrete steps in creative problem-solving. Given the target audience, some of the information provided is aimed at practical applications. Apart from the confusion over terminology, it appears that the literature may be divided into the following broad categories: the nature of innovation, the individual and creativity/innovation, how to promote innovation within organizations, the political nature of innovation, and enhancing creativity.

Drucker also links innovation with entrepreneurship by noting that entrepreneurs appear to not have a certain kind of personality in common, but a commitment to the systematic practice of innovation. He describes innovation as 'the means by which the entrepreneur either creates new wealth-producing resources or endows existing resources with enhanced potential for creating wealth' (Drucker, 1998, p. 149).

In her study of the longevity of successful pharmaceutical companies, Henderson (1994) found that the companies constantly challenged conventional wisdom and stimulated a dynamic exchange of ideas. 'They focused on continuously refurbishing the innovative capabilities of the organization. They actively managed their companies' knowledge and resources' (Henderson, 1994, p. 102). Gundry et al. (1994) further defines organizational innovation by stating that: "Organizations that encourage employee creativity share certain characteristics: They capitalize on employee attributes, enhance employees' conceptual skills, and cultivate an organizational culture that fosters experimentation and stimulates creative behavior".

Chesbrough & Teece (1996) attack the problem of definition from a different viewpoint. They state that there are two types of innovation. Autonomous innovations are those that can be pursued independently from other innovations. They use the example of a new turbocharger to increase horsepower in an engine, which can be developed without the complete redesign of the engine or the rest of the car. Systemic innovations, on the other hand, are those which must be

accomplished along with related complementary innovations. Redesigning a workflow process in a factory would be an example of a systemic innovation, because it requires changes in supplier management, personnel, and information technology.

The Relationship Between Creativity and Innovation

Learning is formulating intelligence. *Deciding* is implementing intelligence.

Entrepreneurship is organized abandonment. (J. B. Say)

To promote and support innovation within organizations, a corporate culture must be adopted that will accept and defend the vagaries of individual and group creativity. Leaders must ensure that employees believe the expectation that innovation is part of their jobs.

They do this by providing a safe environment, where there is freedom to fail. A high tolerance for failure allows for trial and error, experimentation, and continuous learning (Ahmed et al., 1999).

People, culture, and technology serve as the institutional, market, and socio-economic ‘glue’ that binds, catalyzes, and accelerates interactions and manifestations between creativity and innovation as shown in Fig. 3, along with public-private partnerships, international R&D consortia, technical/business/legal standards such as intellectual property rights as well as human nature and the ‘creative demon’. The relationship is highly non-linear, complex and dynamic, evolving over time and driven by both external and internal stimuli and factors such as firm strategy, structure, and performance as well as top-down policies and bottom-up initiatives that act as enablers,

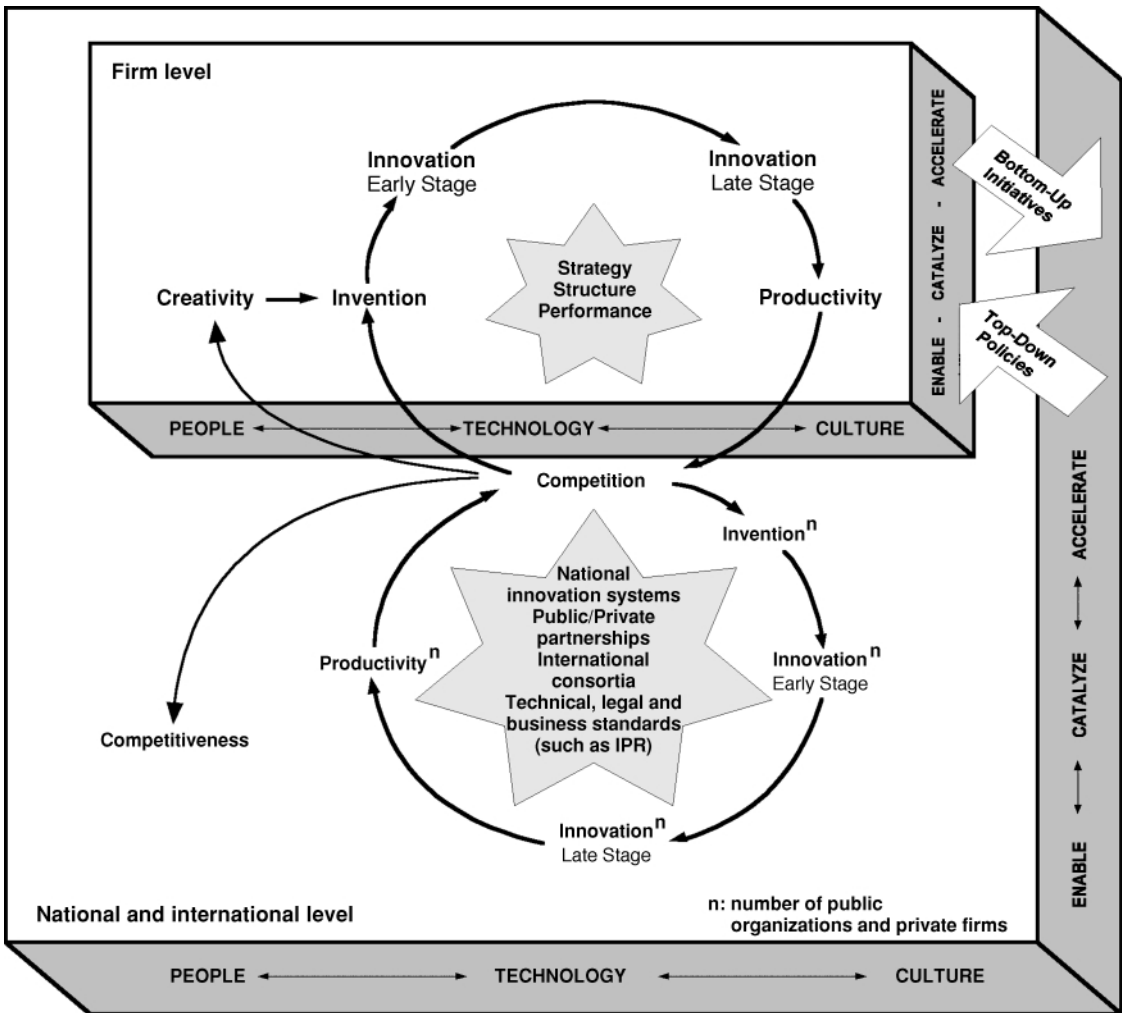

Figure 3. CIC linkages: A system dynamic approach.

catalysts, and accelerators for creativity and innovation that leads to competitiveness.

C.III. Creativity, Innovation and Competitiveness: Concepts and Empirical Findings from the Public and Private Sectors

Leaders in learning organizations have the ability to conceptualize strategic insights, so that they can become public knowledge open to public debate and improvement

(Peter Senge, *The Fifth Discipline*, 1990, p. 356)

Creativity is the result of inspiration and cognition, the liberation of talent in a nurturing and even provocative context and it is mostly an intensely private and individualistic process—it operates at the *micro* (individual) level (see Fig. 4). Innovation is a team effort and takes place at the *meso* (group/organizational) level, as it needs to combine the blessings of creativity

with the fruits of invention and the propitiousness of the market conditions—timing, selection, and sequencing are important as well as ‘divine providence’, obsession and clairvoyance. Competitiveness is the edifice resting on the pillars of creativity, invention, and innovation and it materializes at the *macro* (industry/market/national/regional) level (see Fig. 4).

We are inspired from the Nobel-prize-winning discovery of *the double helix* as nature’s fundamental scaffold and evolutionary competence, to elucidate and articulate the nature and dynamics of the inter-relationship between and among creativity, innovation and competitiveness and their evolutionary pathways. We attempt to do that by means of the *Creativity, Innovation and Competitiveness Double Helix (CIC2Helix)* (Fig. 4) in which one strand represents the flow and record of creativity and the other that of competitiveness. At any point along their evolution, these two strands are linked by the value-adding chain

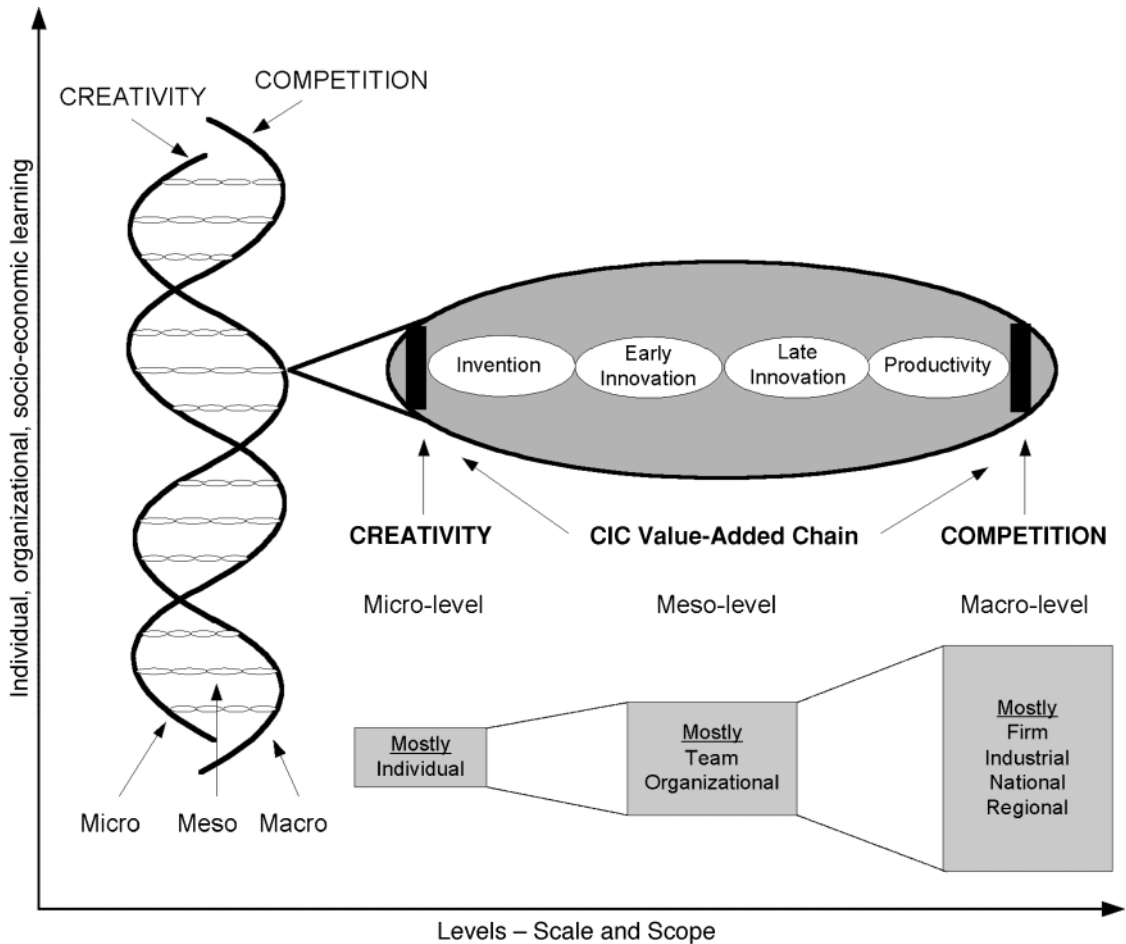

Figure 4. The CIC spiral and value-added chain.

of creativity, invention, early-stage innovation, late-stage innovation, productivity, competitiveness (*CI3PC value-adding chain*). This chain serves as the catalyst and accelerator of *social, economic, organizational and individual learning and meta-learning* which allows for the CI2C Helix to continue evolving by enhancing and advancing the effectiveness of generated knowledge and the efficiency of knowledge transmission and absorption. In so doing, *knowledge economies of scale and scope* are attained at increasingly higher levels, allowing for more to be accomplished with less, faster, cheaper and better. These gains are manifested in diverse ways at the micro, meso and macro levels, namely higher standards of living, more competitive firms, more robust economies, and accelerated and more sustainable development trends.

We further attempt to shape and corroborate our perspectives with field research questionnaires that were responded to by public and private sector managers from a number of countries around the world (see Appendix), dealing with issues related to drivers, critical success and failure factors and measures of creativity, innovation and competitiveness.

Our overall findings from talking to practitioners from the public, and the private sector, point to the following main challenges that encompass as well potential opportunities for growth and development if innovation and creativity is allowed to blossom:

- Failure of imagination (where the policy makers and managers fail to envision the future and confront the present).
- Failure of courage (where the decision makers are too afraid to confront real challenges and as a result, they shy away from critical reality checks).
- Fear to succeed (where the decision makers and other stakeholders are individually or institutionally hesitant to embrace the potential and changes of success—either consciously or subconsciously and thus undermine or undercut their own efforts).
- Fear to fail (where the policy makers and managers are so concerned with failure and fail to realize that one can not avoid risk but that one can only manage it as best possible; as a result, they end up mis-managing risk and engendering processes and trends that lead to failure even when not necessary).
- Too short term focus on earnings (the ‘tyranny of the marketplace’ often precipitates decisions that are poor from a mid- to long-term perspective and only serve as short-term expedients). In the case of the public sector, the equivalent case is that of politicians that only care about or are forced to focus only on winning the next elections.
- Strategic versus Tactical choices and actions (as a result of all the above-mentioned ‘pathologies’ of decision-making, tactical choices trigger actions that

often preempt or impede strategic choices and actions).

We further organize and present our findings by key themes:

Theme 1: Key dimensions of Innovation and Creativity.

Theme 2: Drivers of Innovation—Catalysts and Inhibitors.

Theme 3: A glimpse of the current situation in several countries—Challenges and Opportunities.

• **Theme 1: Key Dimensions of Innovation and Creativity**

In the public and private sectors, innovation can be understood as a way of rethinking and reshaping government, repositioning public service/public organizations, managing/leading the change process, restructuring programs and service delivery, redesigning and improving service delivery for citizens, redesigning accountability frameworks and performance measures and revitalizing public service providers and private firms (see Table 1).

Based on the responses we received from public and private sector practitioners from a number of countries, *innovation* is seen as encompassing the following attributes with the most important ones listed first:

- Inventing something new.
- Seeing something from a different perspective.
- Introducing changes.
- Improving something that already exists.
- Spreading new ideas.
- Performing an existing task in a new way.
- Generating new ideas only.
- Following the market leader.
- Adopting something that has been successfully tried elsewhere.
- Attracting innovative people.

• **Theme 2: Drivers of Innovation**

As we can see from Figs 1, 5 and 6, there are a host of internal and external enablers, catalysts, and accelerators of innovation since it is a complex, non-linear, and interactive process with human, technological and cultural underpinnings. Our empirical findings are reflected in these figures and are further discussed below.

According to the empirical findings, there are factors that act as catalysts or inhibitors for creativity, innovation and competitiveness in the public and in the private sector:

Catalysts

- (1) Leadership, vision, strategic plan (with the right goals). Relative organizational autonomy and certain degree of authority to innovate.
- (2) Innovation/creativity rewards system in place.

- (3) Protection of intellectual property rights (IPR).
- (4) Propitious organizational environment for converting tacit ideas and knowledge into explicit proposals for improvement: open and frequent communication and dialogue, strategic rotation between different functions and technologies and access to information (Nonaka & Takeuchi, 1995).
- (5) The right mix of people and esprit de corps manifested in well-functioning teams.
- (6) Sense of urgency (if you feel you're up against it, as happens frequently in the private sector, you become very innovative and competitive).
- (7) One innovates when in need or 'necessity is the mother of invention': review of innovation experiences in governments during the last 25 years shows that innovation occurred in almost all of the cases in an environment of financial scarcity and even crisis (Glor, 2001).
- (8) Willingness of governments to innovate—for that, motivation is required in both, central and front line government officials and management.
- (9) In the private sector, supportive management willing to take risks and encourage fresh thinking. Public officials and private managers with enough time to formulate and implement innovation initiatives.
- (10) Government support for R&D and incentives for investment in R&D such as R&D tax credit.
- (11) Availability of risk capital including angel investment and venture capital.
- (12) Compromise between the political and economic power and existence of social control.
- (13) Innovation networks and clusters such as: existence of educational institutions of higher learning, think tanks, training programs and technical teams, existence of institutions that act as conveners of networking events, collaboration among different countries and institutions in international collaborative R&D projects.
- (14) Diversity of people and free flow of ideas (generation of widely divergent views, challenging of assumptions, testing of hypotheses,

compensation for cultural or intellectual myopia).

Inhibitors

- (1) Resistance comes from the elites in that elites are inclined to screen out innovations whose consequences threaten to disturb the status quo, for such disruption may lead to a loss of position for them (Rogers, 1995).
- (2) Much innovation fails due to resistance to change: failure of courage and failure of imagination can prove to be formidable deterrents of innovation.
- (3) Sense of 'comfort': why should I push myself and disturb convenient routines; conservatism in its multiples forms, e.g. 'don't change the established path' syndrome, 'no risk policy', 'no non-proven alternatives', 'don't skip the line'.
- (4) Lack of courage in government officials to face opposition, fear of losing support from the electorate and accompanying lack of long-term vision (focus only on short term gains), instability and high turnover of public officials in their positions.
- (5) Lack of courage by Chief Executive Officers and the Board of Directors in the private sector, to embrace change or take a long-term view, pressure from stakeholders to increase earnings per share in the short term, fear of losing support from stakeholders if they do not respond to the short-term pressure for results, frequent turnover and little time to formulate and implement long-range growth initiatives (Perel, 2002).
- (6) The way innovation is introduced is an important determinant and predictor of its likelihood of success: more incremental innovations have a lower impact on hierarchical power relationships and as a result, are confronted with smaller resistance and inertia than more radical ones. The 'dangerous innovations' that are resisted the most, are those of a disruptive and restructuring nature, rather than those that will only affect fine-tune the functioning of the system (Christensen, 1997).
- (7) Rigidity of hierarchical structures and lack of management for results; instability in the rules of the game (arbitrariness, favoritism), corruption and lack of transparency; poverty and political

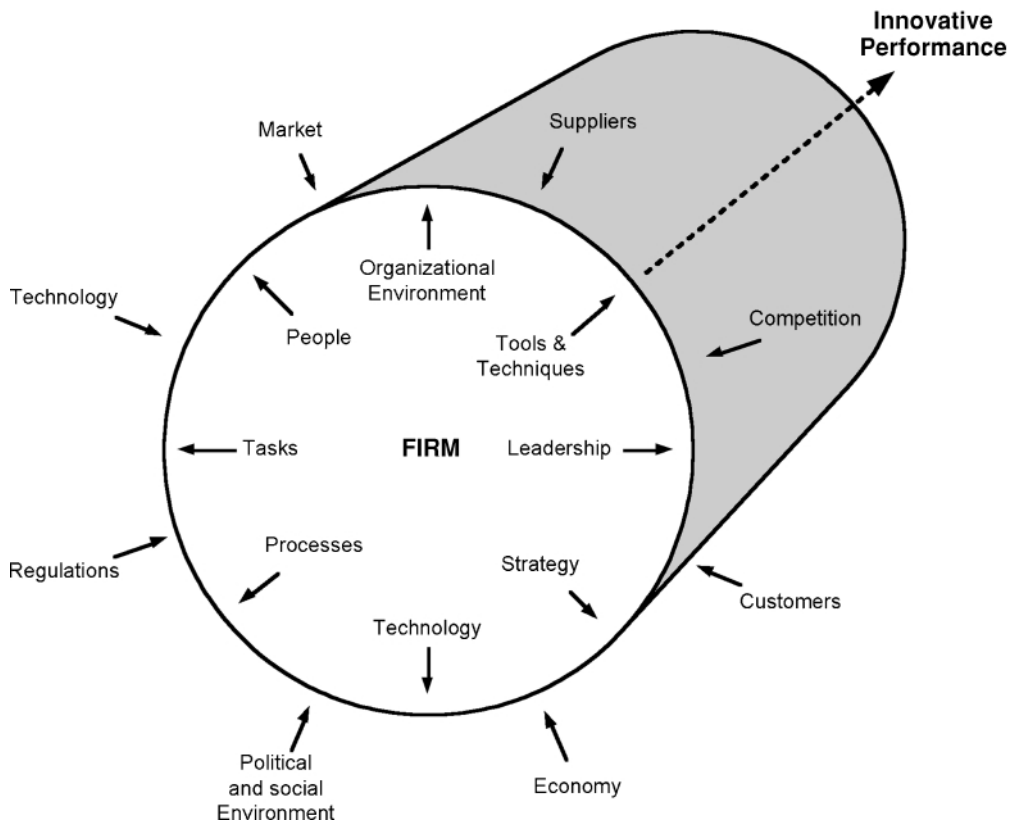

Figure 5. Factors affecting innovative performance.

struggle; centralized bureaucracies, top-down policies and government control for the sake of control.

• **Theme 3: A Glimpse of the Current Situation in Several Countries—Challenges and Opportunities**

Our findings show that there are several major challenges and potential opportunities associated with innovation and creativity-supporting initiatives and policies. Intrinsic in this is the role as well as the successes and failures of the Multilateral Development Banks (MDBs). There are also challenges and opportunities facing the private sector, emanating from the high and increasing rates of technological change, globalization, intensity of rivalry, and dilution of national franchises:

- (1) There is great potential for creativity, innovation and competitiveness at the individual level, but there is a lack of public policies to foster and take advantage of this capacity.
- (2) In some countries, government policies, while providing no direct financial assistance, were invaluable in providing a market for product development and subsequent sales opportunities.
- (3) Usually in developing countries, policies are generated top-down without any consensus, debate or agreement with civil society. The main emphasis is control. There are no channels for participation and formulation of a bottom-up policy. In this regard, the Congress is not even a representative body of the civil society. Also, there is no transparency, nor accountability.
- (4) In some European countries there is an urgent need for stronger links of education and research with the real economy, and integration into the European research and innovation system.
- (5) In many countries the private sector is regarded as more competent in terms of creativity, innovation and competitiveness than the public sector. The public sector seems to be paralyzed because of norms and regulations that block development. The political indecisiveness affects all the economic activities and makes economy sluggish.
- (6) Universities are excellent, shining examples of public sector environments that fuel creativity and innovation.
- (7) Many countries have not fully tackled in a way that policy and practice merge into a single unified outcome. Most of the examples cited in relation with this type of cooperation has occurred in pockets throughout the public sector with the initiative being taken by individuals, rather than through organizational planning.
- (8) The major challenge is for less developed countries because of lack of adequate capacity and infrastructure necessary to transform vision into action and lack of a continuous and stable dynamic that foster creativity, innovation and competitiveness.
- (9) Most developing countries still think in state-centered terms. Public sector too dominant, too prone to doing wrong things for political or even personal reasons. Private sectors are disorganized; companies have poor management and strategic planning skills. Public and private sectors do not collaborate enough; they often play the blame game. Governments policies often help the politically powerful rather than expose firms to competitive pressure in order to build strength to compete on a global basis.
- (10) Overall, in developed as well as in developing countries, no specific, explicit and systematic measurements for creativity, innovation and competitiveness seem to be undertaken. Usually, social and economic performance indicators are considered as proxies to measure performance in this field.
- (11) Multilateral Development Banks (MDBs), although traditionally dominated by paradigms and ideological postures that resist debate and change, and therefore, creativity and innovation, have independently and also in collaboration, launched numerous initiatives to further promote competitiveness and higher levels of development in their borrowing member countries.

Lately, the advances of Internet technology and high speed connectivity have allowed member countries to exchange vital information to participants in various programs and projects, promoting distance learning in a modern and cost effective manner. However, more work is needed in MDBs to measure their effectiveness in terms of fostering creativity, innovation and competitiveness at the national and regional levels.

Recommendations for Action based on Field Study

To learn one must be humble.

(James Joyce, *Ulysses*)

We compile and categorize thematically below, the responses of the public and private sector practitioners we collected via our field research to provide the foundation for recommendations to practitioners and a roadmap for future research.

The Role of the Public Sector in Promoting Creativity, Innovation and Competitiveness (CIC)

The role of public sector innovation is decisive as catalyst and accelerator of social and economic development. Public sector CIC promotion can lead to better, more efficient and cost-effective ways of managing public sector operations and social welfare functions; it can as well help improving market functioning in competitive environments.

The opportunity cost for the public sector not promoting the creation of a more competitive environment is enormous, since the social and economic costs associated with obsolete or outmoded ways of conducting and managing business are substantial, especially in less developed economies.

The role of the government in a developing country is much more critical, as often the private sector has no ways and means to raise venture capital. Therefore unless the government steps into the vacuum there is very little chance that the innovations will ever see the light of day.

Usually, less developed countries lack adequate capacity and infrastructure necessary to transform vision to action; whereas in industrial countries these conditions are met to a greater extent. The public sector can act as a catalyst to CIC in developing countries for it can promote/assume works in areas where the private sector finds inadequate profit incentives for engagement.

The *modus operandi* of the public sector can be a function of the degree of market development, its functions and the demand for public/private sector services. A well-developed public infrastructure should ideally allow for CIC promotion from both public and private sector entities.

Government active support for innovations is essential in developing countries due to the political and economic system inadequacies that might disturb innovative technology initiatives in public or private sector.

The challenge is to have reasonable ways for the science developed in the public sector to migrate to commercialization when warranted, without the public sector becoming effectively competitors with the private sector. The public sector should not be operating as competitor to private sector entities, crowding out entrepreneurial initiative.

The public sector requires more aggressive policies to foster creativity in its own public management, promote the innovation within the government and raise its own competitiveness in the process.

• **The Public Sector could promote CIC in several ways**

- (1) Creating an environment which supports CIC. It includes issuing policies, norms and regulations that enable CIC; giving awards and incentives

like tax breaks, insurance and other favorable conditions to take advantage of international experience; providing effective stimuli to research and scientific development through investing resources adequately.

- (2) Using the purchase power of the government (around 30% of Gross National Product in Latin American countries) to foster competitiveness (besides efficiency and transparency).
- (3) Building social safety nets for those that fail when seeking to invent, as well as support mechanisms for those that need additional support to invent/innovate.
- (4) Acting over those market failures, where the private sector can not act alone because of lack/asymmetry of information or problems of scale. In this regard, the promotion of non-traditional exports or subsidies to technological innovation in small and medium enterprises could be cited as examples.
- (5) Trying to commercialize research generated by the public sector, e.g. from National Aeronautic Space Administration, federal laboratories, or Department of Defense.
- (6) Building an efficient innovation system, the main areas of focus are related to research and innovation networks, innovation and technological transfer programs (scientific and technological parks), innovative SMEs and improved capacity of economy to absorb R&D achievements.
- (7) Making available resources for fundamental research. These monies do create an environment that is less inclined to be driven by economics and be very focused on 'pure' science.

Public-Private Sector Partnerships to Promote CIC

In developed countries where markets are functioning more efficiently private sector participation in ICC is more pronounced. Besides, partnership arrangements between public/private sector are as such as to allow a higher degree of private sector participation in certain operations/areas despite the relatively higher level of competitiveness and/or lower profit margins (in these countries, private firms often have an incentive to engage in partnerships with the government for other reasons such as to acquire a larger market share, or just for marketing, advertisement and promotion). Moreover, in developing countries with less stable socio-economic and/or political structures concerns over government's credibility often act as a deterrent for private sector participation

Some areas in the private sector require support from the public sector to improve creativity, innovation and competitiveness. However, it seems that what the private sector needs, more than public/private sector partnerships, is a more competitive and transparent public procurement process (to fight corruption) and

incentives for university/industry as well as domestic/foreign, public/private sector partnerships.

Support new projects and initiatives in the private sector (i.e. research in applied sciences or manufacturing technological development, etc.). In the last case, there is the possibility of partnerships between public and private sector but, only in those areas in which the private sector is weak and in those areas really innovative.

Support for new projects and initiatives in the private sector (i.e. research in applied sciences or manufacturing technological development, etc.) through public/private partnerships is desired mainly in those areas in which the private sector is lacking innovative capacity and creative competence and especially for those areas where discontinuous innovations (potentially disruptive in nature) are the main pursuit.

Description of criteria to identify potential initiatives/projects to conform partnerships between public and private sector, criteria and process for selecting the candidates in the private sector, and conditions in which public venture capital should be involved:

Criteria for identifying potential initiatives/partners

- (1) Government priority areas.
- (2) Potential practical application and benefit for society and/or economy.
- (3) Low cost or profitable project.
- (4) Long term project.
- (5) Candidates with probity and enough financial means.
- (6) Willingness to change.
- (7) Competitive spirit.
- (8) Futuristic vision.
- (9) Complementary experience and resources.
- (10) A good record of accomplishments.
- (11) Their contribution to innovation.
- (12) Expertise and market access.

Process

- (1) This is a very important and yet paradoxical process, to pick a winner there is almost an element of gambling that comes into play, yet the public sector has a responsibility to the community not to gamble with public funds.
- (2) The process would need to involve the community and the business sector in order to ensure that it was transparent. The rules and procedures would also have to be extremely clear as would the involvement of any public official. This would in particular be extremely critical should the product progress to the next stage where venture capital would be involved.
- (3) An 'Experts Committee' (EC) could be established for selection, oversight and evaluation. A 'Quality Assurance' Committee/Group could complement the functions of the 'EC' to review the quality/

progress at a later stage once relevant works have been initiated. Financing arrangements are always particular to the specific operations in question.

The Role of the MDBs in Promoting CIC

The role of MBDs in supporting public and private sectors innovation is decisive. MDBs could:

- (1) promote the formulation of national policies and action plans for CIC with short and long term goals, with challenging but feasible objectives; train and stimulate the staff responsible of implementing projects and activities in private and public organizations; allocate the needed resources and tools for performing the appropriated actions, and provide continuous technical assistance and supervision;
- (2) create the conditions to foment a climate where innovations in developing nations could be brought to fruition;
- (3) help developing countries get the underlying economic and regulatory policies right so that conditions to encourage new ventures and innovation can work within the private sector;
- (4) share global best practices with developing nations. Strengthen the private sector institutions so that business can make a greater contribution to policy decisions;
- (5) contribute to eliminate trade barriers that affect the developing countries and destroy the possibility of any innovative development;
- (6) disseminate information, knowledge and successful experiences on CIC among member countries;
- (7) promote CIC through agreements and treaties and incorporate them in the policies for development.

To be able to contribute much more effectively to promote CIC, MDBs should:

- (1) incorporate CIC in its own management. It is necessary that MDBs are co-responsible (with the countries) for the results of its cooperation. This responsibility should be measured in terms of national development and citizens' wellbeing in the target countries;
- (2) be organizations more creative and more innovative, less rigid and less bureaucratic;
- (3) support the governmental projects in which the government holds strong leadership and ownership of the plan. In other words, no financial support should be provided to the government that has no independent ownership of development ideas or sustainable leadership;
- (4) give more flexibility to the countries in finding their better path to development (no predefined magic formulas);
- (5) being more accountable for their achievements in terms of national productivity and competitiveness.

Conclusions and Future Research

The empires of the future are the empires of the mind.

(Sir Winston Spencer Churchill)

In this chapter, we have attempted to address the following issues concerning for-profit and not-for-profit entities:

- (a) when, how, and why creativity and innovation occur;
- (b) how and why creativity triggers innovation and vice versa; and
- (c) what are the connections and implications for competitiveness of the presence or absence of creativity and innovation using empirical findings from both the public and private sectors.

We combine literature sources (including those of the authors) as well as field interviews to enrich our chapter with current academic and practitioner insights on the practice and implications of creativity and innovation from the perspective of competitiveness.

We believe that *competitiveness is a product and a function of creativity and innovation stocks and flows* that are determined and modified through diverse types, ways and means of learning (top-down, bottom-up, by doing, by analogy, by succeeding, by failing, trans-national, domestic, via skills exchanges, technology-leveraging, partnerships, etc.) as well as individual cognition and inventiveness (*the 'when', 'how', and 'why' of creativity and innovation*) (see Figs 6 and 7).

In Fig. 6, we show the participatory and synergistic interaction between the public sector, the private sector, and key institutions for collaboration like universities, research institutions and Non-Governmental Organizations (NGOs) in building strategic alliances towards the objective of higher levels of competitiveness in developing countries. In this context:

- governments are accountable for establishing a stable and predictable political and macroeconomic environment, issuing transparent policies and enforcing legal and property rights, facilitating cluster development, creating a business environment with low transaction costs, and supporting and giving incentives to creativity and innovation;
- enterprises have to mount competitive strategies, develop networks and clusters for achieving efficiency (social capital), increase the intensity of their technological effort (more resources for R&D), build new capabilities and skills (human and intellectual capital) and develop a modern infrastructure. Suppliers of physical and service inputs and infrastructure have to meet international standards of costs, quality and delivery;
- universities and research institutions have to align curricula to business needs and craft public and private partnerships to develop new capacities and

skills in public and private sectors. NGOs should serve as enablers, catalysts and accelerators of public and private partnerships.

The *top-down institutional learning* complementing *bottom-up entrepreneurial learning* act as enabler, catalyst, and accelerator of economic development and convergence across developed and developing countries as well as cross-pollination and transfer of technology and best practices across developed and developing countries as well as public and private sectors, universities and research institutions and NGOs (see Figs 3 and 6).

We find from our field research that innovation and creativity are becoming increasingly important for public sector reforms as well as private sector survival and prosperity, given the current challenges and opportunities facing public and private sectors around the world. Some of the challenges and opportunities facing the public sector with serious implications for the private sector as well, encompass the following:

- (a) shrinking budgets and shifting demographics with ageing populations;
- (b) the higher-rent-yielding tax base of knowledge workers attaining increased mobility;
- (c) increased pressures for accountability and transparency driven by privatization, globalization, and an increasingly informed and sophisticated voter base;
- (d) increased pressures on and from the private sector to become more competitive, demanding in return a more competitive public sector;
- (e) and last but not least the role of the Multilateral Development Banks and especially the International Monetary Fund which are relentless in demanding gains in efficiency and transparency in public sector policies, structures and practices.

Competitiveness is also a way of *looking back* as it reflects the past achievements of creative genius and innovative energy as well as shaping the future by providing the foundation and skeleton for emerging private and public sector endeavors. Moreover, at the present, the manifestations of creative and innovative endeavor serve as auguries of the *emerging horizons* of socio-economic and institutional development and learning which further interact with individual learning and creativity in an never-ending spiral process (see Figs 5, 6, and 7).

We also find that creativity and innovation do not always lead to enhanced competitiveness (at least in the short- to medium-term) (Carayannis, 2001a, 2001b, 2002).

All in all, our foray into the domain of creativity and innovation as they relate and impact competitiveness has identified many areas of interest that warrant further focused research to better understand and more

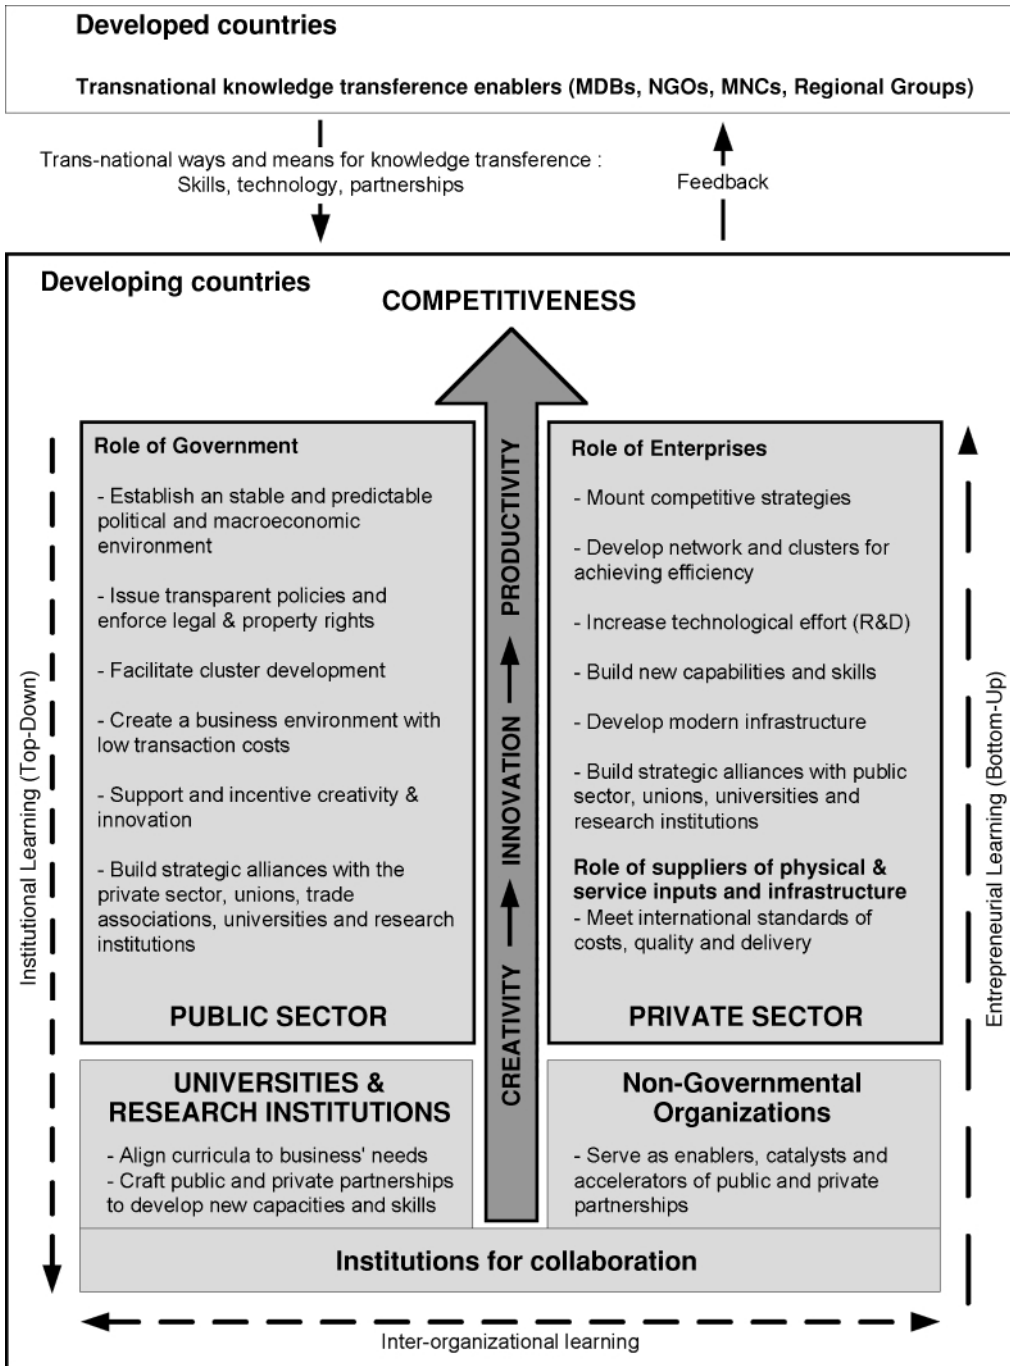

Figure 6. CIC learning and institutional linkages.

clearly exemplify and articulate the key drivers and dimensions (content, process, context, impact) of creativity and innovation and the role of learning in this process (Carayannis, 2002). In particular, we feel that it

would be useful to empirically map the nature and dynamics of learning and meta-learning along the CIC2Helix (Fig. 5) regarding both the public and the private sectors.

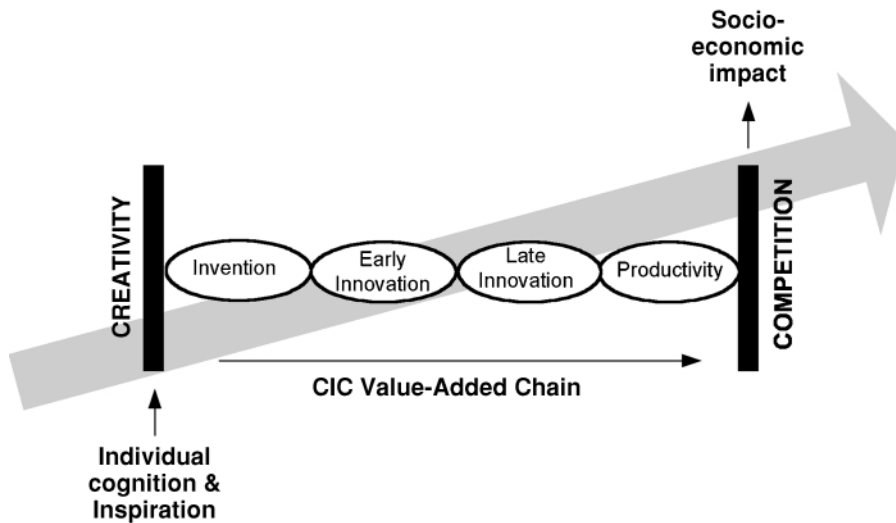

Figure 7. CIC value-added chain.

A better understanding of such processes could result in enhancing and advancing the effectiveness of generated knowledge and the efficiency of knowledge transmission and absorption. In so doing, *knowledge economies of scale and scope* could be attained at increasingly higher levels, allowing for more to be accomplished with less, faster, cheaper and better (Carayannis, 1998a, 1998b, 1999a, 1999b, 2001a, 2001b, 2002).

These gains can be manifested in diverse ways at the *micro, meso and macro levels* (see Fig. 5), namely higher standards of living, more competitive firms, more robust economies, and accelerated and more sustainable development trends (see Figs 5, 6 and 7). Indeed, one could identify both a challenge and an opportunity for private and especially public sector policy makers and managers with regards to the risks and possibilities inherent in the three figures we refer to. Specifically, Figs 5, 6 and 7 capture and reflect upon a combination of dynamic, complex and powerful forces at play: human cognition, individual creativity, organizational productivity, and national competitiveness as well as institutional inertia, political shortsightedness, and market as well as government failures. Understanding how to better manipulate and leverage those forces can result in spectacular results (to some extent, success stories in socio-economic development such as Singapore and South Korea may be cases in point), while attempting to work against those forces and trying to suppress them can lead to dangerous and unsustainable regimes of poverty and autocracy. Providing rewards and incentives to foster creativity and innovation and even rewarding failure may be a strong enabler, catalyst and accelerator for creativity and competitiveness.

In our other chapter on discontinuous and disruptive innovations, we continue our study and analysis of the nature and dynamics of the relationship between creativity and innovation and when, how and why quantum leaps in creative destruction occur following the Schumpeterian line of reasoning (Schumpeter, 1934, 1942).

Appendix I: Field Research Questionnaire

Questions: Please respond by return email within ten days of receipt and email your responses to: caraye@gwu.edu

- (1) Do you think that there is a role for public sector in fostering creativity, innovation and competitiveness?
- (2) According with your experience, what are the main factors that act as catalysts or inhibitors for creativity, innovation and competitiveness in the public and in the private sector?
- (3) What is your definition of ‘innovation?’
 - Inventing something new []
 - Generating new ideas only []
 - Improving something that already exists []
 - Spreading new ideas []
 - Performing an existing task in a new way []
 - Following the market leader []
 - Adopting something that has been successfully tried elsewhere []
 - Introducing changes []
 - Attracting innovative people []
 - Seeing something from a different perspective []
 - Other (please, define) []
- (4) What kind of benefits are expected when public sector plays an active role in promoting creativity, innovation and competitiveness?
 - Benefits to government/public sector []
 - Benefits to society []
 - Profit []
- (5) How could the public sector measure the benefits of fostering creativity, innovation and competitiveness?
- (6) To foster creativity, innovation and competitiveness, should the public sector play a rather passive role (formulating policy, enabling legislation and regulations) or should the public sector play a more active role in new ventures that foster creativity, innovation and competitiveness?
- (7) Should the public sector foster creativity, innovation and competitiveness from outside (by partnering and/or supporting private sector in new ventures) and/or from inside (by developing its own initiatives)?
- (8) How the public sector should select the winners in the private sector for partnering or receiving support in projects and programs promoting creativity, innovation and competitiveness? What should be the criteria? How should be the process? In what stage of the process a venture capital should be involved?
- (9) How does the current policy in your country impact in creativity, innovation and competitiveness?
- (10) Do you see any difference in the role of government/public sector with respect of creativity, innovation and competitiveness in developed VS developing countries?
- (11) Do you measure and benchmark creativity and/or innovation in your organization and, if yes, how?
- (12) Do you benchmark creativity and/or innovation in your organization to that other organizations and are they public, private or both?
- (13) Would you consider the public or the private sector more competent in terms of creativity and innovation, and why?
- (14) What examples could you mention to describe the dynamic of creativity, innovation and competitiveness in your organization/country?
- (15) What should be the role of the Multilateral Development Banks in supporting creativity, innovation and competitiveness in developing and developed countries?

Innovation Tensions: Chaos, Structure, and Managed Chaos

Rajiv Nag¹, Kevin G. Corley² and Dennis A. Gioia¹

¹ *Smeal College of Business, Penn State University, USA*

² *College of Business Administration, University of Illinois, USA*

Abstract: This chapter presents a framework for understanding the tensions that underlie an organization's ability to manage innovation effectively in the face of a turbulent competitive environment: (1) the fundamental tension between the desire for *structure* and need for creative *chaos*, and (2) the on-going tension between *technology-push* and *market-pull* approaches to innovation. We explore the nature and boundaries of these tensions and characterize them as four distinct 'innovation contexts'. Using one high-technology organization's struggle as an example, we discuss the notion of 'managed chaos', a concept that helps understand the role of innovation in the maintenance and change of an organization's identity.

Keywords: Innovation; Chaos; Structure; Organizational identity.

Introduction

Over the course of the last generation, innovation has progressed from being a 'nice to have' to an 'ought to have' to a 'must have' in many organizations. Quantity and quality of innovation have gone from mainly being performance yardsticks in R&D departments and new product development teams to becoming the *raison d'être* for many of the organizations in which R&D departments and NPD teams are housed. The rapid advance of technology is the root cause of this shift, of course, and the need for increased follow-on technological innovation has been the widespread response. We now see a trend in which more and more organizations are treating innovation as a 'critical to have'—i.e. as a survival imperative.

This trend is perhaps most evident in those industries most violently buffeted by technological change and technological competition (where staying on the bleeding edge is itself a business imperative). Yet, the writing on the wall suggests that this heretofore localized trend is quickly spreading to a much wider domain. Business executives in such contexts can no longer assume that they are primarily competent managers of the status quo or shepherds of incremental change. Instead, they need to assume a considerably more complicated role that places a premium on maintaining the dynamic balance between efficiently managing resources to increase shareholder value and

effectively innovating to remain competitive and insure survival.

A theoretical focus on this dynamic balancing act highlights several significant internal tensions associated with innovation, especially in high-tech organizations and industries. Perhaps most evident is the key tension between the creation of stable organizational mechanisms to exploit a particular business model and the subsequent destruction of those same mechanisms and models to cope with the ever-changing requirements of a highly competitive environment (March, 1991). Given the acceleration of the latter process over the last decade, understanding these innovation tensions becomes paramount for understanding the survival and growth of high-tech companies in the modern age.

Innovation most often has been studied by examining the implementation of creative ideas within an organization (Amabile, 1988)—usually the implementation of ideas that are not necessarily new to a given domain, but are new or innovative to the focal organization itself (Ford, 1995). In our view, however, this approach does not adequately account for the most dynamic aspects of organizational innovation. In particular, it does not account for the internal tensions arising from a turbulent competitive environment. The successful exploitation of known technologies requires the creation of stable organizational mechanisms that

enhance the level of coordination. Such mechanisms require much lower levels of flexibility and risk-taking than the creative exploration, development, and implementation of new technologies (which also tend to engender a great deal of turmoil within an organization). When exploitation and exploration processes are necessarily juxtaposed, as they now so frequently are, a predictable tension arises.

We characterize this juxtaposition as a tension between *structure* and *chaos* (a set of provocative first-order labels used by informants in one of our research projects, but which arguably have application to a much wider domain in the study of innovation). Structure/chaos tension makes the nature of organizational innovation different for exploitative approaches and explorative approaches to organizational well-being and survival. Furthermore, and importantly, this is not an either-or choice for most organizations, but rather a continuous dialectic that is closely linked to changes in the organization's environments.

Exploring an essential feature of this structure/chaos tension reveals a different sort of innovation tension, one that emerges as the organization attempts to balance the tendency to become a more inwardly oriented *'technology push'* organization versus the need to become a more externally responsive *'market pull'* organization. A pure technology push approach is characterized by internal creative processes that are focused on designing and developing cutting-edge technology as a basis for advancement and achieve-

ment, with the organization pushing the technology into the marketplace without first identifying a market need. A pure market pull perspective, on the other hand, focuses less on the cutting-edge advancement provided by a technology and more on the technology's ability to fulfill a need in the marketplace that will result in sales and revenue as technology creation and development is pulled by market demand. We believe that this technology push/market pull dichotomy captures a common tension in many contexts involving innovation, perhaps especially in R&D groups and high-tech organizations devoted to R&D. Furthermore, we have found that this technology push/market pull tension implicates an organization's very identity and affects strategic issues such as positioning within the marketplace and relationships with key stakeholders.

In this chapter, we extend traditional notions of organizational innovation in high-tech companies and industries by examining the implications of juxtaposing these two tensions. We argue that organizational structure/chaos and technology push/market pull tensions are a defining part of current organizational practice and, therefore, need to be more closely examined to further our understanding of modern innovation processes. When these two tensions are arrayed in a 2x2 matrix (see Fig. 1), each of the resulting four cells represents a distinct context in which organizations can attempt to nourish innovative practices (Structure-Push, Structure-Pull, Chaos-Push, and Chaos-Pull). We explore the specifics of each of

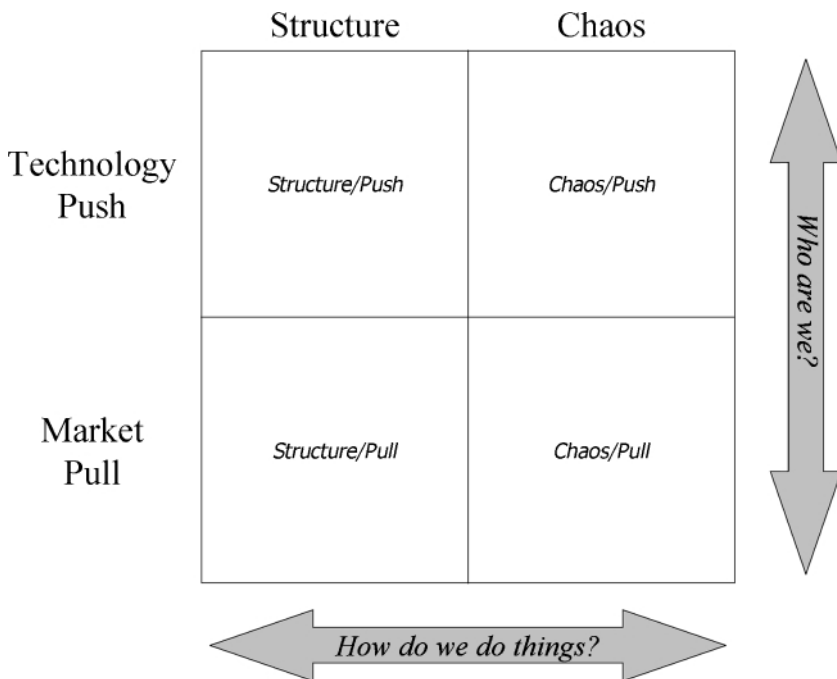

Figure 1. Juxtaposing the two innovation tensions.

these ‘innovation contexts’ and discuss managerial practices necessary to facilitate innovation within each cell.

Additionally, to account for the dynamic environments with which organizations must cope, we examine the issues and implications involved in movement among the different innovation contexts. It is no longer feasible to think of an organization sustaining its innovative practices within a static world. Consequently, organizations must assume that their innovative contexts are in flux and, therefore, must conduct their innovation efforts under changing circumstances. We examine this new state of affairs by considering what it takes to manage these tensions in a way that transitions from one cell to another are not only possible, but also effective. To demonstrate the relevance and usefulness of this framework, we present a case example of one organization’s attempt to manage these tensions and its movement across cells. Our analysis highlights the issues faced by managers, as well as the implications of these tensions for organizational survival and growth.

We conclude our discussion of these innovation tensions with the explication of a model that articulates the main challenges faced by organizations driven to make innovation a vital part of their strategic efforts. Dealing with these challenges inevitably raises fundamental questions about an organization’s identity. The key feature of this model is the notion of ‘managed chaos’, a concept that suggests a way to manage these tensions by surfacing and questioning basic assumptions about the role of innovation in the maintenance or alteration of organizational identity. We posit that managed chaos is exercised not just by destabilizing existing organizational structures and routines, but also by reconsidering innovation’s *raison d’être* in many high-tech companies. We suggest that by working towards a state of managed chaos, an organization can maximize the potential found in the intersection of the structure/chaos and technology push/market pull tensions of organizational innovation.

The Fundamental Tensions of Organizational Innovation

Before delving into the complexities involved with understanding the dynamic aspects of organizational innovation, it is first necessary to understand each tension better and to explore the details of each of the four ‘ideal contexts’ that arise from their juxtaposition. We begin by examining the Structure-Chaos tension in more depth, followed by the Push-Pull tension.

Structure-Chaos Tension

Organizations are composed of individuals who bring together divergent skills and resources that need to be integrated to achieve a common goal. This working premise is as complex as it is simplistic and obvious. Lawrence & Lorsch’s (1967) dimensions of differ-

entiation and integration contain an elemental dialectic that challenges the very act of organizing. The complexities of any modern organizational environment require functional differentiation and division of labor. Each function/department specializes in managing its own part of the environment. To do so, each function/department needs the autonomy to frame the nature of its sub-environment and develop the necessary organizing mechanisms and structure to deal with it.

Uncontrolled differentiation, however, can result in an organization’s sub-units pulling away from each other by pursuing their own independent agendas. To reign in the different sub-units, an organization needs to develop integrating mechanisms that impose a common sense of purpose and some standard operating procedures on the sub-units. Traditionally, the top management of an organization plays the integrative role by setting up control systems and creating the context for the development of a common organizational culture. These integrative mechanisms, however, can result in excessive centralization of decision-making and loss of local flexibility. This problem is exacerbated in turbulent environments, where the need for fast and frequent differentiation to face changing external complexities must co-exist with the integrative need to work together with the rest of the organization (c.f. Brown, Corley & Gioia, 2001).

Another dialectic that is fundamental to organizing is the need to achieve a workable balance between current efficiency and future effectiveness. In other words, organizations face two divergent modes of existence—one that is built on the successful exploitation of existing technologies, markets, and products, and the other that is built on a continuous exploration of new technologies and market opportunities. Successful exploitation of a specific technology requires an organization to focus on the selection, execution, and implementation of a limited set of technologies and/or business models to maintain a stable equilibrium (March, 1991). Thus, a successful exploitative strategy would necessitate the creation of stable organizational structures and routines that persist over an extended period of time (Nelson & Winter, 1982). Organizational resources and energies are focused on maintaining stability and predictability in internal and external environments. Although new ideas might emerge, these are most likely aimed at improving the existing technology and enhancing the efficiency of the current organizational structure and processes.

An organization engaged in exploration follows a diametrically opposing approach, however. Its strategy and structure are characterized by variation, experimentation, uncertainty, and risk (March, 1991). Organizational resources and energies are focused on bringing new data into the organization, turning it into useful information, and putting it to use with other organizational knowledge for the creation of new

structures and processes. Change is treated as a natural part of the organization's culture, while routines (to the extent that they exist) are often focused on facilitating such change. Explorative organizations often can take the form of 'organized anarchies' (Cohen, March & Olsen, 1972) that have unclear technologies and unstructured decision-making processes characterized by solutions looking for problems.

These two elemental rivalries—'differentiation versus integration' (Lawrence & Lorsch, 1967) and 'exploitation versus exploration' (March, 1991)—most affect the design of an organization, especially where innovation is at issue. An organization that focuses on stable technologies and predictable routines and mechanisms to reconcile or resolve these rivalries represents, in our terms, an emphasis on '*structure*'. An organization that focuses on the proactive search for new technologies and employs inventive mechanisms and decision-making styles to reconcile these rivalries represents an emphasis on '*chaos*'. Although this structure-chaos dichotomy might be somewhat of an oversimplification, it provides a useful conceptual basis for examining different approaches to organizing for innovation.

Push-Pull Tension

Although structure-chaos tensions are vital for understanding the organizing process, they alone cannot provide an explanation for the most common difficulties organizations face in trying to become innovative. In practice, the tension between 'technology push' and 'market pull' orientations tends to be more fundamental and to present the more difficult challenge for effectively managing organizational innovation—mainly because the technology push, market pull issue more strongly implicates organizational identity. Although the structure-chaos tension could be described as raising questions about 'how' things are done in an organization, the push-pull tension might be best characterized as provoking questions about 'who' the organization thinks it is—which is obviously a more deeply-rooted and central issue.

In high-tech companies, tension emerges as organizations attempt to balance the tendency to become an inwardly oriented 'technology push' organization (one that values creative and innovative technological invention over practical relevance and marketability) against the need to become an externally responsive 'market pull' organization (one that values developing technological inventions to meet market needs). The notion of technology push presumes the precedence of technological innovation for its own sake, often on the assumption that new technologies can create a new market if one does not exist. If an organization sees itself as a 'technology company' (and many high-tech companies use this label as part of their self description), the tendency to focus on basic research or innovative product development can be overwhelm-

ingly strong ('It's who we are as a company!'). Then, if the organization wants to profit from the technology it develops from this strong internal (and identity-consistent) focus, it must actively push the technology out into the marketplace and try to discover or develop a market need.

Alternatively, the notion of market pull is characterized by technological design and development focused on serving an identified need or filling a niche in the market (thus the idea of the market 'pulling' the technology out of the organization). In this case, the organization brings its technical resources and capabilities to bear on a market problem to be solved. Innovative capacity is directed toward the creative solution of externally identified needs. The organization does not need to spend as much time or as many resources selling the technology, but also most likely has less discretion in designing and developing the specific aspects of the technology itself.

The Organizational Identity Issue

As noted, the difficulty for the organization in adopting a push versus pull orientation is found in the strong ties this tension has to the organization's identity. Organizational identity can be thought of as the shared theory that members of an organization have about who they are as a collective (Stimpert, Gustafson & Sarason, 1998), or as the perception of the organization held by insiders that helps to answer the question 'Who are we as an organization?' (Gioia, Schultz & Corley, 2000). If key members of the organization see their identity as being a collection of top-tier scientists dedicated to the production or advancement of scientific knowledge, then the notion of market pull, or 'science in the name of profits', is a tough sell and difficult to implement. Likewise, if the members of the organization are at heart business-oriented and see profit-generation as the driver of R&D decisions, the notion of 'science for science's sake' seems not only foreign, but downright dangerous for the organization's survival. A further difficulty might arise because often the organization is split in its desires, with top echelons of the organization being more market pull oriented and the lower echelons being more technology push oriented (e.g. managers versus scientists/engineers)—a case where an organization might be said to have 'multiple identities' (Pratt & Foreman, 2000).

In principle, neither pure state appears particularly healthy, especially over time. Pure technology push might lead an organization to be renowned for the technological advancement of the field, but it can endanger the company's chances at survival (especially if there is inadequate internal marketing expertise). Pure market pull, on the other hand, can result in better business standing and more profits, but might easily relegate the company to the status of a 'technology reactor', always behind the curve in terms of advancing technologies that can capture the markets' interest

(especially when the timeline for patents is considered). Thus, some sort of middle range approach would seem to be most effective, because an organization able to balance this tension would be able to take advantage of the benefits on both aspects of the tension. Because technology push/market pull tension is so closely linked with organizational identity, however, the inertial pressures pushing an organization away from the center and toward one end of the dichotomy can be great.

Juxtaposing the Tensions

Figure 1 provides a graphical representation of four prototypical innovation contexts that arise by arraying these two tensions in a 2x2 matrix. The horizontal dimension represents the tension between *Structure* and *Chaos*, or how an organization answers the question ‘How do we do things?’ The vertical dimension represents the tension between *Technology Push* and *Market Pull*, or how the organization answers the question, ‘Who are we?’ Of course, Fig. 1 represents an oversimplified visualization of the tensions underlying organizational innovation. The bifurcations

between Structure/Chaos and Technology Push/Market Pull represent prototypes, whereas many organizations might find themselves straddling these extremities. To emphasize the details of these underlying tensions, however, we present a graphical description of the pure states (details in Fig. 2), along with a brief description of each innovation context.

Chaos, Structure, and Technology Push

As noted earlier, technology push involves an organization developing technologies and products without expressed consideration of immediate or specific market requirements. The tensions involved in managing structure/chaos tradeoffs within a technology push orientation is one that has implications for the breadth and flexibility of the R&D agenda and ensuing organizational mechanisms. A technology push R&D environment favoring a chaos approach is characterized by apparently haphazard endeavors focused on solving a loosely-articulated scientific problem. There is usually a high level of ambiguity as to what research questions need to be asked and how the likely solutions are to be generated and pursued. The search for

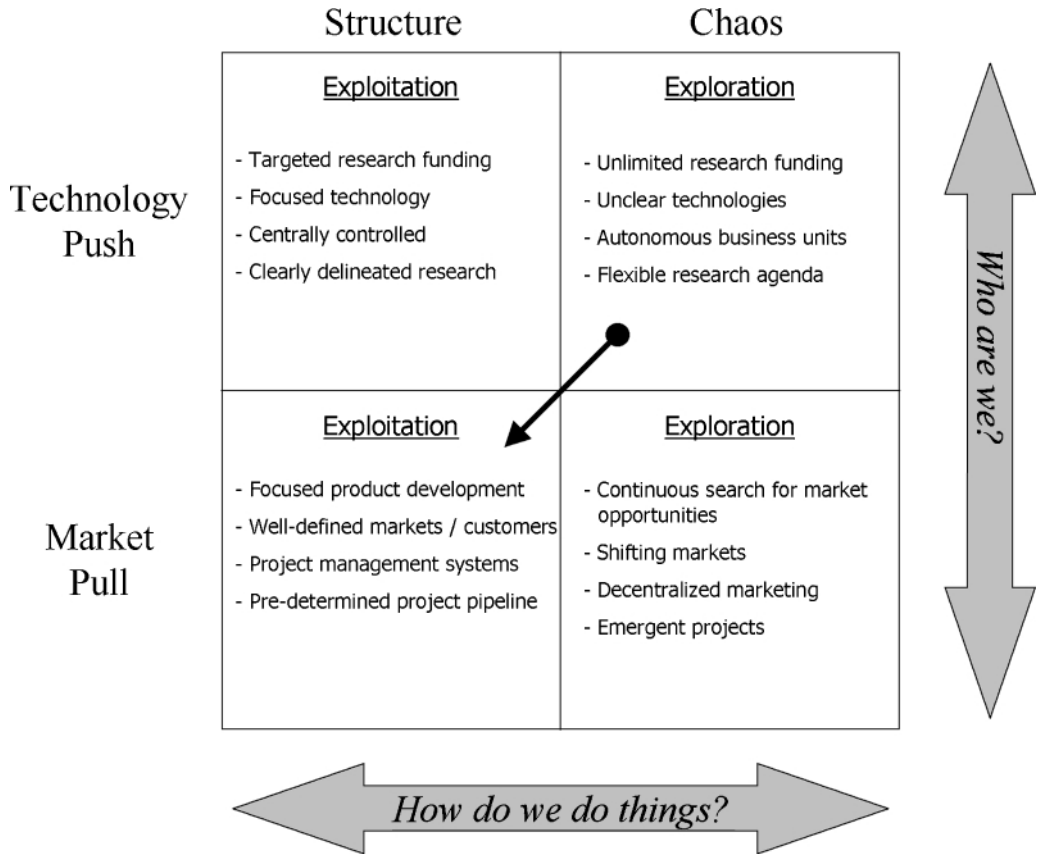

Figure 2. Inchoate’s underlying assumptions and change path.

scientific breakthroughs is often serendipitous and is aided by an enhanced employee autonomy and decentralization of decision-making. Typically, adequate research funding is available to pursue a wide range of technological approaches. Politics, however, can be fierce, as autonomous units vie for the funding and attention from the best technology people.

A technology-driven organization that favors a structured approach is one that usually channels its funding and efforts into specific technologies. This focused technology push can arise for historical reasons ('this what we are good at' or 'this is what we do here'), for external reputation reasons ('this is what we are known for'), or even for prestige reasons ('this is what will bring us visibility'). The focal technologies, however, often involve long term projects where centrally controlled processes and procedures ensure that resources are applied to the right efforts at the right time. Close controls and monitoring are usually in place to guarantee that projects maintain efficiencies, possibly to the detriment of the groundbreaking discovery that a less focused process might produce.

Chaos, Structure, and Market Pull

The other aspect of the vertical dimension in Fig. 2 represents the market pull orientation. A market-driven organization is one that seeks to get closer to its customer's needs, forecast changes in the market, and stay ahead of the competition by pre-empting the moves of other players in the market (Day, 1999). In short, the organization is externally aligned to the changing requirements of the market. As depicted in Fig. 1, a market pull orientation can be accompanied either by chaos or structure, but with different outcomes.

In a turbulent external environment, a market driven organization that favors a chaos approach engages in a continuous search for new market opportunities. The internal organization is characterized by a continuous emergence of new commercial ideas that vie with each other for top management support. The marketing orientation is most often decentralized across the organization and the senior management encourages independent initiatives. The organization typically does not adhere to specific markets for a long term but engages in a continuous search for new and unexplored markets that might require completely different business approaches and technological expertise.

A market-driven organization that favors a structured approach is one that successfully positions itself in one or more markets and follows a leadership strategy. The emphasis on structure is meant to derive efficiencies from cross-pollination of creative ideas and commercial opportunities. The emphasis on structure also provides a certain amount of direction and predictability to the organization's developmental projects. Such an organization creates integrative mechanisms (Lawrence & Lorsch, 1967) in the form of well-defined

and widely-disseminated reporting systems and project appraisal mechanisms. These systems in turn provide an opportunity for the transfer of insights and learning from one part of the organization to the other. Structure enables a market-driven organization to successfully exploit product ideas and to maintain a healthy stream of creative initiatives contemporaneously. It thus able attempts to capitalize on the efficiency benefits of exploitation and the creative advantages of exploration.

Changing Innovation Contexts: A Case Example of Structure/Chaos, Push/Pull Innovation Tensions

Although examining the four 'prototypical' innovation contexts provides some insight into better understanding organizational innovation in high-tech companies, this static representation does not go far enough. Because modern organizations face rapidly changing competitive environments and fast paced technological shifts, different innovation contexts are often required to help cope with these changes. Therefore, in addition to understanding the contexts themselves, it also is necessary to understand some of the issues and implications of organizations moving among these innovation contexts. To help highlight these issues and implications, we employ a demonstrative case analysis of one organization's attempts to move within the innovation tension grid.

Innovation and Change at Inchoate Inc.

In this section, we examine the ways in which Inchoate Inc. (a pseudonym), effectively managed the innovation tension between structure and chaos, but struggled in trying to manage the innovation tension between technology push and market pull. It was Inchoate's difficulties in managing this more fundamental tension that characterized its problems as it attempted to adapt to changes in its competitive environments. We acquired access to the organization as a group of researchers interested in understanding the links between organizational identity, change, and innovation. During a span of six months, we carried out extensive one to two hour interviews with top executives and senior managers, and analyzed various secondary data sources such as the organization's intranet, internal corporate communications, and reports in the external media. Before examining the details of Inchoate's change experiences, it is helpful first to present an overview of its history and some of the more significant changes it underwent leading up to our study, because tracing Inchoate's historical trajectory is important to understanding its current innovation tensions.

Historical Roots

Inchoate Inc. began as a dedicated research laboratory of a large American electronics firm over a half century ago, flush with funds to do basic scientific research. It

maintained that status until the mid-1980s, when its parent company was acquired by another large technology conglomerate that already had an R&D division, whereupon Inchoate was reconstituted as a freestanding R&D corporation wholly responsible for its own strategic direction and performance. While studying the organization, we found that the structure/chaos tensions faced by Inchoate Inc. were evident early in its history, even if they might be more prominent today. What has changed most dramatically for Inchoate is the nature and scope of its business and the level of turbulence in the external environment that is in direct conflict with its institutional heritage. During its time as the R&D division of its parent company, Inchoate's key human resources were composed almost solely of talented scientists and engineers. In those early years, they were focused on carrying out basic scientific research and developing innovative technologies in the fields where its parent company competed. During this initial period, the emphasis on the type of research alternated between basic research and applied research. Despite these fluctuations, though, the research arm continued to be inwardly oriented, with its research agenda defined either by the application requirements of the parent company or by the top management's visions of the future of science.

The next distinct period in the company's history, spanning the 1950s and 1960s was a time when the emphasis on basic scientific research gained clear ascendancy over applied research. During this period, the research arm ventured into uncharted scientific areas that broadened its knowledge base and allowed its scientists to create new fields through their discoveries. The subsequent period in the early 1970s, however, saw a return to the application of technologies for solving problems for the manufacturing divisions of the parent corporation. In the late 1980s, when the parent corporation was acquired by a conglomerate that already had its own R&D division, Inchoate was spun off as an independent entity. The spinoff agreement stipulated that Inchoate would receive five years of (progressively decreasing) funding to help establish itself as an independent technology company. At the end of this period, Inchoate's scientists and engineers would lose access to the former parent's funds for basic research, as well as the closed, well-defined environment fostered by a parent corporation. As the weaning period wound down, Inchoate Inc. had to redefine itself as a freestanding organization, open to market and environmental forces, and responsible for seeking its own revenues and funds for further research.

The newly found independent status was a watershed in Inchoate's evolution. Suddenly, the same scientists and engineers whose main job for years had been to work on projects that excited their intellectual desires and aspirations were now forced to search for external clients and be sensitive to the needs of the

market. Funding for projects could now come only from Inchoate's own success at developing products and ventures. Only if a proposed project was deemed to have potential for market success would its own top management approve explorative funding. Science-for-science's-sake was no longer a criterion for funding. Scientists were asked not only to think of the technological and scientific implications of their work, but also the marketing, development, and distribution implications of any ideas they were pursuing. The organization began hiring market-savvy people with business development backgrounds to join project teams and help ensure that the scientists were focusing their efforts on technologies that could be turned into marketable products. Top management pointedly characterized this shift as one that moved Inchoate from being a 'technology push' to a 'market pull' organization.

This change, and the tensions it produced, plainly tapped a much more fundamental dialectic than the historical tension between structure and chaos. Up until the late 1980s, the challenge for Inchoate's precursor (the research arm) was to manage its irregular changes among basic research (an activity that demanded an unfettered and chaotic internal environment to facilitate serendipitous explorations in science and technology) and applied research (which required a periodic focus on more structured and orderly processes). From the early 1990s, however, this 'traditional' dialectic was compounded by the need to transform from a new technology-generating orientation into a market-responsive orientation—a transformation that represented a profound shift in the organization's identity.

Identity change at Inchoate

It is important to emphasize that most of Inchoate's key employees (including most members of the top management team) were scientists and engineers trained to carry out trailblazing research without previously having to think about revenue streams and cost efficiencies. Their only major constraint had been an occasional emphasis on focused applications of technology for meeting specific requirements of the parent corporation's manufacturing division. We believe that this state of affairs is, in principle, common to many high-tech firms, who often tend to hire mainly for technical expertise and then find themselves confronting environments that demand more business acumen.

During our involvement with Inchoate, we found that it had had great difficulty giving up this orientation, despite the demands of sometimes merciless markets, and despite the very real possibility that the organization might not survive *unless* a market pull orientation could be adopted. This difficulty in adapting is directly traceable to the legacy of the organization and the people who constitute it. The research scientists, as well as the top management

members (who rose from the scientific research ranks), are predominantly university-trained researchers, whose main reason to work in an organization like Inchoate is to engage in creative research that satisfies their intellectual curiosities and justifies their superior training. To this day there is still greater value in the company for scientific brilliance over commercial viability (and thus also a strong value for a more chaotic approach to discovery and innovation).

Inchoate engendered and exacerbated this chaos in a different way by creating many independent business units based on loosely defined technology areas. High autonomy granted to the business units meant they could chart their own research agendas and hire their own research staff, although the central organization had broad control over profitability. This approach led to the creation of what senior executives described as ‘stovepipes’ out of the business units; i.e. there was no evident integration of resources and even little evident sharing of knowledge across the units. The only distinct prior effort to structure the technology push orientation in Inchoate that we found was a focus on licensing of technologies to the government and other companies. The licensing process required the development of organizational mechanisms that would enable the protection of Inchoate’s intellectual property and allow its appropriation. We also found no evidence that the licensing department of Inchoate, which is the organization’s intellectual property repository, has played a significant role in the creation and dissemination of knowledge from the intellectual property to the business units. For all these reasons, we classify the initial state of Inchoate (at the inception of their intended transformation) as being in the Chaos-Technology Push quadrant of Fig. 2.

The removal of virtually unlimited research funds as part of their (not necessarily welcome) independence led Inchoate into an era where it had to seek out new revenue sources that would fund future research agendas. To do that, Inchoate faced a new reality of listening to customers in the market who were not necessarily looking for brilliant technology but solutions to their specific problems. The change from ‘creators of technologies’ to ‘marketers of solutions’ has been a tough one for Inchoate’s scientists and engineers. It has demanded that they change their long-held views on how research should be carried out. More importantly, it has brought into their laboratories an unpredictable and dynamic element—the forces and vagaries of the market.

Inchoate’s top management, in its efforts to transform the organization into a market-driven organization, tried to impose a ‘structure’ approach to displace the existing ‘chaos’ approach. This distinction is especially important when viewed in the light of the starting point of this transformation (technology push/chaos) to its intended outcome (market pull/structure). Inchoate instigated this intended transformation by

bringing in a new group of senior professionals who were not scientists and engineers, but rather people who knew market trends and who had business development, rather than technological skills. These senior managers were brought in to design and implement systems that would bring a high level of predictability to the research and developmental projects and ensure that they had commercial viability and revenue potential. Inchoate also adopted a novel structural initiative that employed two person teams made up of a technological specialist and a business development professional. These teams would champion research projects that had market potential and satisfied specific needs of customers.

Innovation, Change, and Inchoate’s Problems

The bold arrow in Fig. 2 depicts Inchoate’s path of intended transformation. The attempted change was not just in ‘how’ activities were carried out in the organization (structure/chaos) but also ‘who’ the organizational members thought they were (technology push/market pull). Throughout its history, Inchoate and the earlier research arm managed to shift between basic and applied research while still maintaining the essential character of the organization as based in scientific and technological excellence without much regard to the commercial utility. The change from technology push to market pull, however, required a redefinition of the fundamental character of the organization and its people. This is the elemental intersection of tensions that Inchoate’s top management did not succeed in managing, even though they were able to recognize it.

Inchoate’s lack of success in their transformation attempt can be ascribed, at least in part, to the adoption of a change in innovation strategy that tried to take a direct leap from chaos/technology push to structure/market pull. Inchoate’s problems with the hoped-for change were hindered because the change effort implicated two tensions simultaneously (both the ‘how’ and ‘who’ dimensions). The end result of the change effort was that although Inchoate was able to adopt a number of structural mechanisms to enhance the commercial viability of its research projects, it could not transform its fundamental organizational identity from technology push to market pull, thus rendering most of the structural changes ineffective.

Innovation as Managed Chaos—The Reverse ‘Z’

The model presented in Fig. 3 highlights the key challenges faced by organizations that are driven by the simultaneous need to innovate and to alter their identities to accommodate dynamic innovation contexts. These challenges, as previously noted, are exacerbated in high turbulence environments where the bases for competitive leadership and survival constantly shift (a condition that now arguably applies to many R&D firms and high-tech industries). In this

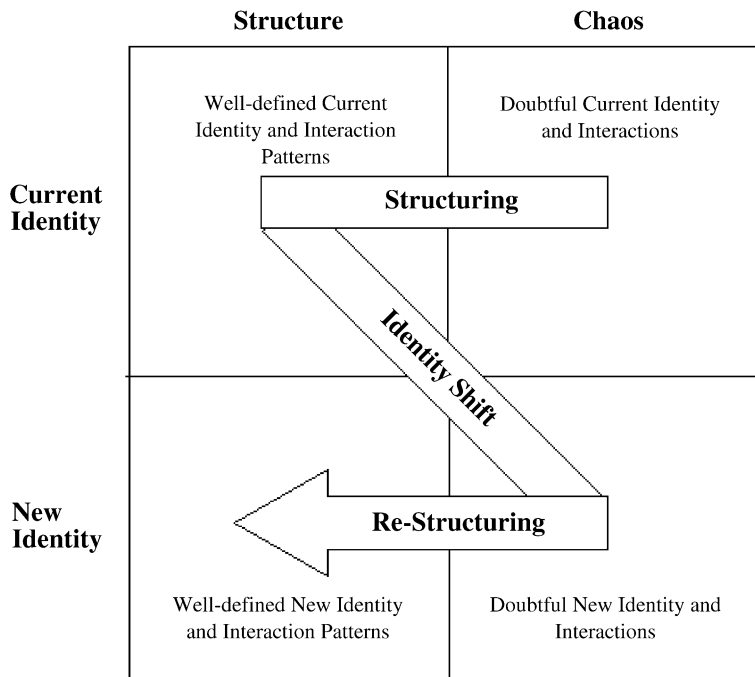

Figure 3. Managing the innovation tensions via managed chaos.

final section we attempt to enlarge our conceptual understanding of the link between organizational structure and organizational identity in the changing contexts of innovation by employing a ‘structuralist’ lens (Giddens, 1984). The underpinnings of structuration theory provide a useful general framework for analyzing issues arising from shifts within the innovation tension grid because of its focus on how social actors continuously and reflexively create and recreate social structures. The key insight from structuration theory is that the interactions among actors serve the dual roles of forming the basis of social structures while also creating the means for changing those structures.

In brief outline, the process occurs as follows: Initially there is ambiguity among organization members concerning appropriate modes of thought, action, and interaction. Over a period of time, however, actors’ interactions coalesce into structured patterns governed by rules that in turn both reflexively constrain and yet also enable further action. Structuration, or *structuring* (to highlight its inherent dynamism), can be viewed as a process by which patterns of interaction between members of a collective or an organization attain a rule-like ‘objectivity’, and these rules (which form the basis of the organization’s structure) in turn delimit the behavior of the very organizational members who created them. Yet, rules and structured patterns can be reconstituted on an on-going basis via thought and

action to create revised structures (Nag, 2001). Thus, organizational structures are, by nature, fluid and continuously being shaped by organizational members, even as those structures act to constrain and guide organizational behavior.

The idea of structuration, therefore, provides a link between our previously discussed notions of chaos and structure. Most organizations start with ill-defined activities and nebulous goals and, over a period of time, develop relatively stable and temporally persistent coordinating mechanisms that can be discerned as their structures. However, these structures can be disturbed by environmental jolts (such as the one faced by Inchoate Inc. and many other modern high-tech companies), bringing about a state where the organization’s activities and goals are again infused with ambiguity and are better characterized as chaotic. In highly turbulent environments, then, a shift can occur, from a somewhat stable conception of ‘organizational structure’ to a more dynamic view of ‘organizational structuring’ to better capture the interplay between present chaos and prior structure. In Fig. 3, this notion is captured in the two horizontal ends of the reverse ‘Z’ that represent the dynamic process of structuring/restructuring, linking the states of structure and chaos.

Although the concept of structuring provides a link between chaos and structure, it still leaves us searching for a similarly useful fulcrum to track the second tension between technology push and market pull.

As noted before, we view this tension as more fundamental because it relates more directly to the organization's identity. Scholars of organizational identity typically define identity as organizational members' collective understanding of features presumed to be central, enduring, and distinctive for the organization (Albert & Whetten, 1985). However, recent theoretical conceptualizations of organizational identity view it as less enduring and more flexible in character than previously presumed (Corley, 2002; Gioia, Schultz & Corley, 2000). These views highlight the mutable character of an organization's identity as it continuously interacts with perceptions of the organization held by entities external to the organization. Although the labels used to describe organizational identity may remain stable during normal periods of incremental change, the meanings underlying those labels nonetheless tend to change over time as the organization attempts to adapt to changes in its external environments. In this manner, organizations enjoy the benefits arising from a sense of stability around answers to the question 'who are we?', while still finding it possible to adapt to fluctuating environments.

Extending this notion of an adaptable organizational identity to our innovation grid, we contend that an organization's identity develops and evolves contemporaneously with its structure. The process of structuring, which leads to the institutionalization of interaction patterns, can also lead to a crystallization of organizational identity attributes, especially in the labels used to describe the organization's core attributes. Although structure and identity might develop out of interactions between organizational members, however, the latter exists at a more fundamental and tacit level. Therefore, it is likely that an organization will respond to external changes, even dramatic environmental jolts, merely by changing its structures, without realizing a corresponding need to change its identity. That is, a horizontal movement in the innovation grid (illustrating a change in structure) might seem like an appropriate response to competitive pressures in one's industry, but might not be successful without a corresponding vertical movement (illustrating an identity change), as well. Thus, we posit that the structure-chaos tension and the more fundamental push-pull tension implicating an identity change need to be seen as mutually interlinked and recursive processes that should be carefully identified and managed by organizational leaders.

For us, the notion of *'managed chaos'* captures this sense of simultaneously managing necessary changes in organizational structure and organizational identity to cope with changing innovation contexts. Some scholars have focused on the importance of viewing chaos as a reality of organizations in highly dynamic industries and have prescribed continuously evolving and flexible organizational structures and systems to

maintain an inherent instability (Brown & Eisenhardt, 1998; Nonaka, 1988; Schoonhoven & Jelinek, 1990). The notion of managed chaos extends this thinking by recognizing that it is necessary to surface and then challenge the present organizational assumptions underlying how the organization sees itself before structural changes can have a lasting impact.

The reverse 'Z' symbol encapsulates a plausible prescription for attaining managed chaos in the face of turbulent environments that force organizations to manage the interlinked tensions between chaos, structure, and organizational identity. In illustrating this notion of managed chaos in Fig. 3, we have replaced the first-order concepts of 'technology push' and 'market pull' with the labels 'current identity' and 'new identity' to help generalize beyond those organizations dealing with the push-pull tension. Other identity-related tensions exist beyond the push-pull tension and it is important to illustrate how the managed chaos model also applies to them.

After analyzing Inchoate's experiences, we concluded that its problems stemmed fundamentally from top management's attempts to change it from technology push to market pull through structural changes only (for example, bringing in a new team of business development professionals). That is, Inchoate failed to realize that the change it was undertaking involved more than just changing its internal structures; it also required a corresponding change in its identity. As depicted in Fig. 2, the new business development team tried to take Inchoate directly from a technology push/chaos mindset to a market pull/structure mindset. The technology push/chaos mindset of Inchoate was emblematic of the organization's longstanding inward focus on pure technology research and lack of formal structures to develop a specific set of technological ideas for commercial success. The new business development team tried to implement project evaluation processes that were meant to ensure the market relevance and commercial viability of the research projects carried out by Inchoate's scientists. This change, however, remained only superficial in nature. There was strong evidence for this phenomenon in the organization members' comments during the process of change. We found that in spite of having made structural changes towards the espoused market-pull transformation, the organizational members nonetheless continued to use identity adjectives that were reminiscent of their technology-push character.

Gioia et al. (2000) have argued that despite using the same identity labels in the face of incremental change, nonetheless, there can be subtle changes in the meanings and actions underlying those labels, which can create an adaptive instability in organizational identity that facilitates organizational change. Certainly, under conditions of incremental change the subtleties involved in maintaining familiar labels while underlying meanings and actions change can be quite

useful in managing non-disruptive change. This line of thinking, however, can be modified and extended to account for more radical change. Inchoate's experiences suggest that deliberate changes in actions and structures (in the face of severe environmental jolts) might augur for a more pronounced change in identity labels themselves in order to execute transformative change. Changes in actions, structure, meanings and labels are likely to be necessary to produce managed chaos under such conditions.

Inchoate failed to unearth, and change, the basic assumptions accompanying the technology push paradigm. It failed to realize that to become a market pull company, Inchoate and its members had to change important aspects of their identity and fundamental assumptions underlying the nature of their business. Thus, the fact that they attempted a direct leap across the grid instead of the more steadying movement found in the reverse-Z model of managed chaos ultimately stymied the change effort, to the dismay of top management and the change champions.

Conclusion

Overall, on the basis of our recent research, we have concluded that to better understand effective innovation practices we need to expand the conceptualization of the dynamics involved in organizational innovation. We have identified two dimensions that apply to many high-tech firms and industries. Those dimensions focus on the tensions and tradeoffs involved in: (1) how an organization pursues innovation (ranging from very structured to relatively chaotic processes); and (2) how an organization conceives its identity (in terms of technology push versus market pull orientations). The intersection of these dimensions suggests four prototypical contexts, each with different requirements for managing innovation processes. Furthermore, the framework developed in Fig. 3 acknowledges that environmental shifts can and do demand changing innovation assumptions and practices. Changes in the modern environment have produced an inordinately complex innovation-management challenge—one that might be addressed by adopting a 'managed chaos' approach.

The concept of managed chaos suggests that organizations facing turbulent environments need to exhibit flexibilities in both structure and identity. The linkage between these two basic notions is an important fulcrum for understanding the tensions of managing organizational innovation in contemporary organizations. The reverse 'Z' model of managed chaos presented here beckons managers to proactively evaluate the organizational change initiatives in terms of their implications for both the emergent organizational structure and the organization's identity. A corresponding change in an organization's identity is essential for the new structure to make sense to the organizational

members. If structure is the tool to achieve organizational objectives then identity is the lens by which organizational members look at themselves and the world outside. This hitherto underdeveloped relationship between 'How we do things' and 'Who we are' is an important dialectic that forms the crux of managing innovation in the face of extreme turbulence.

Involvement in Innovation: The Role of Identity

Nigel King

Department of Behavioural Sciences, University of Huddersfield, U.K.

Abstract: The impact of innovation on organizational members has been examined in various ways. However, relatively few studies have addressed how innovation processes shape people's work-related identities (and vice versa). This chapter argues that the concept of identity is useful for considering the relationship of the person to the organization in the context of innovation. It evaluates the potential contributions of Social Identity Theory and Constructivist/ Constructionist accounts of identity to this area. Finally, it presents data from case studies of innovations in the British health service to illustrate the value of an interpretive approach to identity and innovation.

Keywords: Innovation; Identity; Functionalism; Postmodernism; Interpretivism.

Introduction

Innovation has been a prominent research topic in work and organizational (w/o) psychology for over two decades, and as such can claim many successes. It has, for example, shown how organizational structures can impede or facilitate innovation (Miles & Snow, 1978); it has highlighted the problems that often occur through autocratic leadership and the refusal to devolve decision-making power (Bass, 1985, 1999a, 1999b; Kanter, 1983); it has demonstrated the key role that climate and culture can play in shaping the innovative performance of teams and organizations (Nystrom, 1990; West & Anderson, 1992). This is not to say that we now have definitive answers to the key questions in such areas—on the contrary, they remain the foci of debate, as new and competing ways of explaining the phenomena are advocated. What we *do* have is a sense of a vigorous, constructive discussion capable of clarifying and refining our understanding, and offering managers and practitioners potentially valuable insights into the what is happening in their own organizations. In some areas, though, there has been a paucity of theoretical and empirical research and as a result a failure to properly address important real-world issues. For example, there has been a much greater focus on the processes by which new ideas are generated and adopted in organizations, and much less on the implementation and routinization of change (Kimberly, 1981; King & Anderson, 2002). I will argue in this chapter that

another major area of neglect has been the involvement in the innovation process of organizational members *other* than those with direct managerial responsibility for it. After a critical overview of the relevant literature, considering the likely causes of this neglect, I will propose that occupational identity is a useful concept to utilize in developing our understanding of involvement in innovation. I will illustrate this point with examples of current and ongoing research into innovation in primary health care settings in the United Kingdom. Finally, I will conclude by drawing some implications for future research and practice.

Defining Innovation

Before turning to the main theme of this chapter, it may be useful to consider how innovation should be defined. The difficulty of defining innovation has long been recognized, and while there is consensus that novelty is a central feature of innovation, a range of positions are proposed regarding the degree of novelty (absolute or relative?), the scale of changes which 'count' as innovations, and the way innovation should be distinguished from related concepts such as creativity and organizational change (Kimberly, 1981; King & Anderson, 2002; West & Farr, 1990; Zaltman et al., 1973). Nicholson (1990) argues that any attempt to define innovation objectively is undermined by the fact that the phenomenon is intrinsically relative and subjective—how innovative a new product, process or

procedure is depends on the perspective of the observer. He likens this to an audience at a jazz concert; what may sound like novel and creative improvisation to one member, may be recognized as derivative and unoriginal by another. This position is congruent with the central arguments of the present chapter, in terms of its advocacy of non-positivist approaches to the study of innovation. I would therefore claim that the question of ‘what is innovation?’ is not one to be answered in the abstract prior to commencing research, but should itself be a key focus of innovation research.

Involvement in the Innovation Process: Overview of the Literature

In identifying it as a neglected topic within innovation research, I am not suggesting that writers have thought organizational member involvement to be of no great importance. On the contrary, many of the common recommendations from innovation research are based on assumptions about organizational member responses to, and participation in, change; from Lewin’s (1951) early work on democratic leadership styles to the literature championing transformational leadership (Howell & Higgins, 1990). The rationale for promoting participative leadership styles, for example, is that these will result in members feeling a greater sense of ownership in innovations, reducing the likelihood of resistance (e.g. Kanter, 1983). Similarly, arguments for risk-tolerant climates and cultures are based on a recognition that fear of the consequences of failure can inhibit individual and team propensity to innovate (e.g. West, 1990). The problem is that most of this literature has either treated organizational member involvement as a black box (between the ‘inputs’ of structure, leadership, resources etc. and the ‘output’ of innovation), or has reduced its complexities to the single issue of ‘resistance’. Exceptions include a relatively small number of studies that have sought to understand innovation involvement as a meaning-making process, related to values, relationships and inter-group dynamics (e.g. Meston & King, 1996; Symon, 2000).

Resistance to Change

The literature in this area has long been driven by a strong practical concern to offer reliable advice to organizations on how to overcome resistance (e.g. Kotter & Schlesinger, 1979; Lawrence, 1969). While this applied focus is in many ways commendable, too often it is associated with a set of unacknowledged assumptions that can result in a very blinkered view of the processes involved. First, work on resistance is often infused with the kind of ‘pro-innovation bias’ discussed by Rogers (1983), which portrays innovation in general as a ‘good thing’ and thus resistance as ‘bad’. Second, the research agenda is commonly dominated by the concerns of senior management, who

control the researcher’s access to the organization, and in some cases may have directly funded the research. Finally, there is also a bias in much of the literature towards pluralistic models of change (as Glendon, 1992, notes) which recognize that different groups in an organization will have different perspectives on innovations, but assume that if the process is managed effectively, all parties can benefit from positive outcomes.

The result of this combination of biases is to make questions such as ‘how can organizations best overcome resistance to innovation?’ appear neutral and non-contentious. I would argue on the contrary, that applied to any particular example this question is almost inevitably controversial and politically-charged. As with the concept of innovation itself (e.g. Nicholson, 1990), what counts as resistance depends on one’s perspective (Aydin & Rice, 1991; Burgoyne, 1994). Thus a group of staff perceived by managers to be willfully resisting change may see themselves as struggling to do the best they can with increased demands, or attempting to make sense of unclear aims and expectations. Managers may believe that an innovation is clearly for the general good, and thus interpret opposition as irrational intransigence; staff may view it as inevitably producing winners and losers in terms of power, status and/or material rewards. The very notion that resistance *should* be overcome becomes dangerous if one accepts that some innovations may have a socially malign impact. If an administrative innovation in a hospital was putting patient safety or confidentiality at risk, would we feel comfortable in advising managers on how to overcome the resistance of doctors and nurses?

It is not my intention here to dismiss as irrelevant the bulk of previous research for exhibiting the biases I have noted above. There is much valuable work showing, for example, the contingencies that managers should consider when adopting a change-management strategy (Kotter & Schlesinger, 1979), or the key role of two-way communication in minimizing resistance (Plant, 1987). My point is rather that by failing to recognize the unspoken assumptions behind their work, researchers provide a very partial view of the way organizational members respond to, and are involved in, innovation. This needs to be complimented by research taking different perspectives which move away from the ‘overcoming resistance’ framework in their conceptualizing of involvement in the innovation process.

Meaning-Making in the Innovation Process

Rather than locating organizational members’ reactions to innovation on a dimension of resistance—acceptance, a small but growing number of researchers have focused on the ways in which they construct their responses, and the purposes such constructions serve (e.g. Bouwen & Fry, 1996; King, Anderson & West,

1991; Whetten & Godfrey, 1999). Although this research comes from a variety of theoretical perspectives, much of the empirical work uses a qualitative methodology, because of its suitability for examining meaning-making in specific contexts. One example of this kind of research is a study I carried out with Carolyn Meston (Meston & King, 1996), looking at the introduction of a staff training innovation (National Vocational Qualifications, or 'NVQs') in a residential care home for older people. We used a grounded theory methodology which seeks to build a theoretical account of a particular phenomenon through detailed qualitative analysis (Strauss & Corbin, 1990). This 'bottom-up' approach to the development of theory is in contrast to the traditional 'top-down' perspective of positivist social science. Data were gathered by participant observation over a six month period, supplemented by semi-structured interviews with key informants. The grounded theory model developed from our analysis is shown in Fig. 1. As can be seen, personal values in the workplace, and the extent to which individuals felt a need for peer group approval, were important factors shaping the way members of staff evaluated the innovation and responded to it in specific situations. To take one example; Michael (a Care Assistant) strongly values his social relationships at work, but also gains great satisfaction from a sense of doing his job well. These values pull him in two directions in his responses to NVQs. He perceives the peers whose company and esteem he values as largely hostile to the innovation, but at the same time he personally can see the benefits of the new training for quality of care. The result is that the responses he exhibits to NVQs vary markedly depending on which of his colleagues he is working alongside on a particular shift.

A different perspective on meaning-making processes in relation to innovation comes from scholars drawing on ideas from social constructionism. This tradition has developed most strongly in European Social Psychology, and is centrally concerned with the way our social reality is constructed through the everyday use of language. It eschews any attempt to 'explain' social phenomena in terms of such internal psychological factors as 'beliefs', 'attitudes', 'personality traits' and so on. In terms of empirical research, it utilizes a range of methods—most prominently discourse analysis (e.g. Burman & Parker, 1993)—which seek to show in fine detail how language operates in particular texts to construct particular versions of social reality. (See Burr, 1995, for a good overview of the differing strands of social constructionist theory). René Bouwen and colleagues have argued that organizational innovation can be seen as 'a joint conversational event where new configurations of meaning are constructed' (Steyaert, Bouwen & Van Looy, 1996, p. 67). They use the term 'logics' to refer to the different stances organizational members may take

towards an innovation, as encapsulated in their talk about it (Bouwen, De Visch & Steyaert, 1992). Using interviews from case studies of organizational innovations, they show how old and new logics compete within participants' accounts; for instance, in one Flemish high-tech company, an established 'academic', research-oriented logic is challenged by a 'commercial' customer relations-based logic in the wake of innovations introduced by a new, entrepreneurial management (Steyaert et al., 1996).

A different social constructionist approach is taken by Symon (2000), who examines the use of rhetoric in the construction and justification of responses to innovation. The case she considers is the introduction of a networked PC system in a British public sector organization. The professional staff (referred to as 'inspectors') utilize a range of rhetorical devices to justify their opposition to the innovation. They construct an identity for themselves as technically expert, and as the staff group who best understand the business of the organization (they use the metaphor of working 'at the coal face'). This provides legitimacy for their criticisms of the position of IT specialists who are championing the innovation. They also turn the main argument of proponents of the change on its head—that far from saving resources, it will waste them, in the form of the valuable time of professional staff who will be expected to do their own typing as one of the consequences of the new system.

Qualitative research focusing on meaning-making in responses to innovation has begun to make apparent the complex ways in which organizational members may be involved in innovation processes (Symon, Cassell & Dickson, 2000). When we look closely at individual cases it becomes clear that traditional quantitative methodologies such as attitude surveys present a static and rather superficial view of the way people are affected by and involved in innovation attempts. As such, they can only provide a partial view of why organizational members respond as they do, and offer little insight into how their responses are formed. For critics of qualitative approaches (e.g. Morgan, 1996), their principle limitation is that through their insistence on the over-riding importance of context, they are unable to draw generalized conclusions about organizational innovation, which may serve as the basis for recommendations for practice. I will return to this issue in the concluding section of the chapter.

Innovation and Identity

As the previous section shows, researchers have begun to move towards a more rounded and context-sensitive view of involvement in organizational innovation (Bouwen & Fry, 1996; Carrero, Peiró & Salanova, 2000; Meston & King, 1996; Symon, 2000). Longitudinal research examining the development of particular innovations over time has also helped highlight the complexities of the process, underlining the

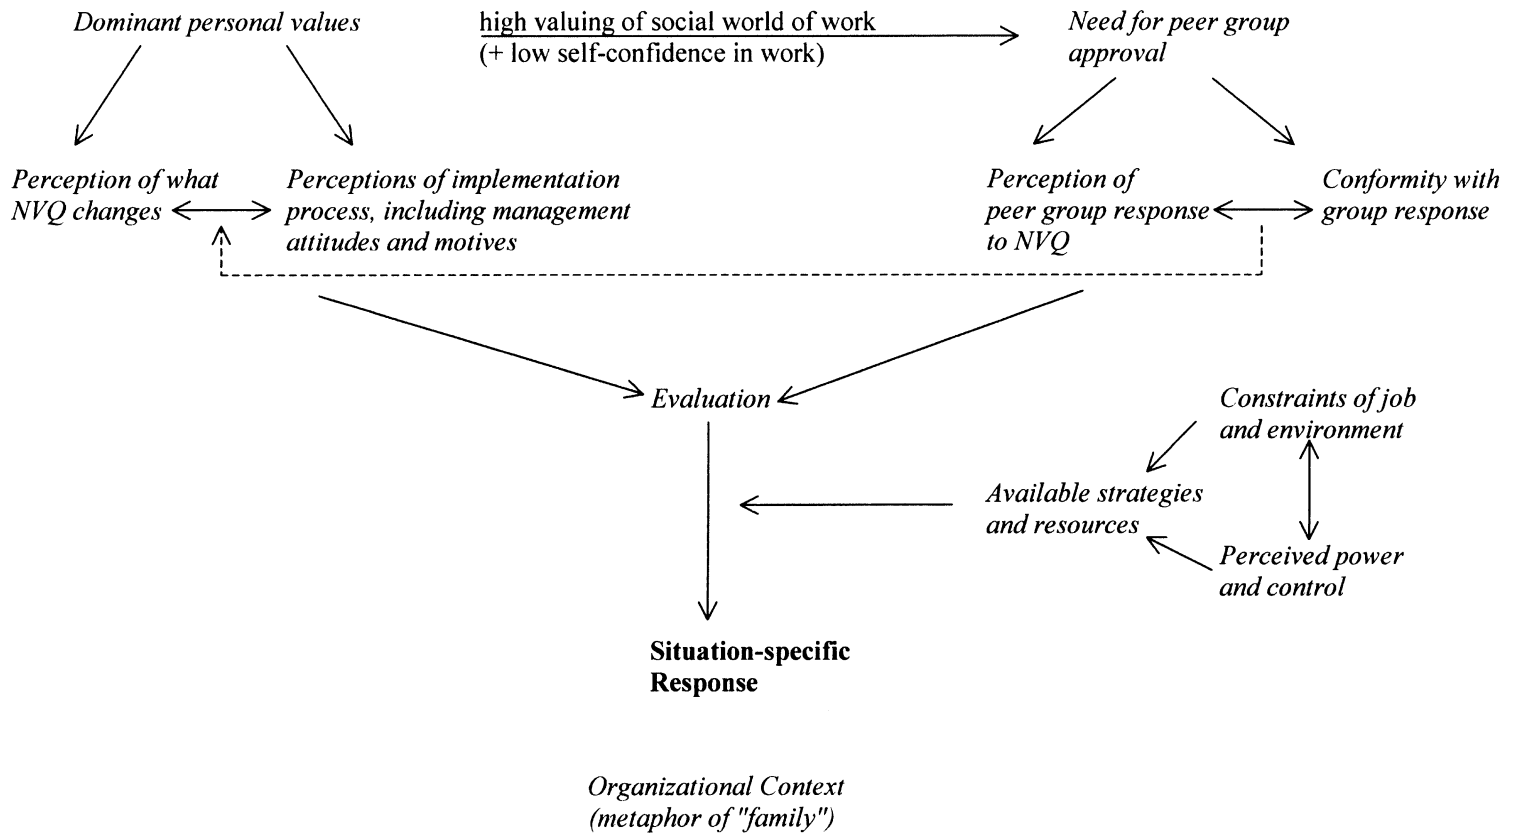

Figure 1. A grounded theoretical model of responses to the introduction of a training innovation at 'Hazel Hill' nursing home.

Reproduced by kind permission of the authors and *Psychology Press*, from Meston, C. M. & King, N. (1996). Making sense of 'resistance': Responses to organizational change in a private nursing home for the elderly. *European Journal of Work and Organizational Psychology*, 5, 91–102.

inadequacies of simple, uni-dimensional understandings of member responses; the Minnesota Innovation Research Program (MIRP) is the most important example of this kind of work (Van de Ven, Polley, Garud & Venkataraman, 1999). I want to argue here that to further develop our understanding in this area, a focus on issues of identity construction and change should play a central role.

Relevance to Innovation Research

Identity is a key concept in Social Psychology and Sociology, and one which is utilized in a variety of ways to address a range of issues in those disciplines. Du Gay, Evans & Redman (2000) argue that ‘the term ‘identity’ often provides only simple cover for a plethora of very particular and perhaps non-transferable debates’ (p. 2); it is therefore likely that any attempt to provide a universally-acceptable definition will be in vain. For the purposes of this chapter I will propose a broad working definition, taking *identity* to refer to a person’s relatively enduring sense of who they are. Two points of elaboration are required here. Firstly, I assume identity to be intrinsically social; one can only have a sense of oneself through a sense of how one relates to others—be they specific individuals and groups (friends, family, workmates and so on), or wider social categories (such as gender, class or ethnic group). Secondly, in saying that identity is relatively enduring, I am not implying that there is necessarily anything essential about it. Whether there are essential and universal aspects to identity is a question of vigorous debate amongst different theoretical traditions, such as psychoanalysis (Frosh, 1989), social constructionism (Burr, 1995), symbolic interactionism (Blumer, 1969), and many others (Du Gay et al., 2000).

Despite its prominence in the social sciences generally, the concept of identity has received relatively little attention in work and organizational (w/o) psychology. This is beginning to change now, for example through the recognition that studying diversity at work inevitably means studying identities (Nkomo, 1995). I would contend that the field of organizational innovation and change—and especially the topic of organizational member involvement in innovation processes—is a particularly fruitful one in which to employ it. This is principally due to the fact that innovation and change commonly have a strong impact on work-related identities. The nature of this impact is highly varied. Because innovations often result in changes to work roles and practices, people may feel their occupational identities to be under threat, and thus may adopt a resistant stance—as was the case for the ‘inspectors’ in Symon’s (2000) study, cited above. Innovations may also surface tensions between different aspects of identity; Michael’s ambiguous response to NVQs in Meston & King’s study (1996) (*op cit*) may be interpreted as resulting from a conflict between his

peer group identity and his occupational identity as a caring, competent Care Assistant. Finally, people may reconstruct their identity in response to organizational innovation, a process exemplified in Steyaert et al’s (1996) (*op cit*) depiction of the shift from old to new ‘logics’ in the course of change implementation.

Approaches to Identity and Innovation

In the recent edited volume ‘Identity in Organizations’ (Whetton & Godfrey, 1998), Gioia (1998) distinguishes three main types of theoretical approach to the area, which he describes as ‘lenses for understanding organizational identity’; functionalist, postmodern and interpretivist. I will use the same categories to review the main theories which have been, or could be, applied to issues of involvement in innovation processes.

1. Functionalism: Social Identity Theory

One of the most influential theories in Social Psychology over the last two decades has been Social Identity Theory, as devised by Henri Tajfel (1978) and developed by writers such as Turner (Turner, Hogg, Oakes, Reicher & Wetherell, 1987), Hogg & Abrams (1988), and Brewer (1991). The theory states that in order to make manageable the huge amount of social information available to us, we rely on a cognitive process of categorization to simplify it. Because we are motivated to view ourselves in a positive light, we seek ways of comparing the groups we identify with (‘in-groups’) favourably with those we do not identify with (‘out-groups’). Note that the theory sees identity as plural, but with different identifications being salient in different circumstances. For example, a person’s identification as a supporter of a particular soccer team may be unimportant at work, and therefore not serve as a basis for in-group/out-group comparisons. In contrast, when attending a match, the supporter identity will be highly salient, and ‘superiority’ over the opposing team’s supporters is likely to be symbolized in colourful verbal exchanges between the groups.

Social Identity Theory has had its greatest impact in w/o psychology in the area of diversity (see Jackson & Ruderman, 1995, for several examples). It is equally applicable to the study of involvement in and responses to innovation. There are many situations in which the nature of group identifications is likely to influence how people respond to innovations. The effectiveness of change agents, for example, may depend on the extent to which they are seen as representing a disliked or distrusted out-group by staff in a position to effectively undermine an innovation attempt. Innovations may make salient inter-group distinctions which had previously been unimportant, by seeming to benefit some groups at the expense of others, raising the likelihood of inter-group conflict focused on the innovation. Equally, innovations may stimulate people to change their identifications, in order to maintain a positive evaluation of the in-group. Social Identity

Theory can thus provide a well-developed framework for studying involvement in innovation, allowing predictions to be made and tested about organizational member responses.

Despite these strengths, some important criticisms of Social Identity Theory have been made, which are pertinent to its application to the area of organizational innovation. Hartley (1996) has pointed out the substantial differences between the kinds of groups used in most experimental studies and the groups that exist in work organizations. Experimental groups are, for example, lacking in history, untroubled by internal power and status issues, expect no long-term consequences as a result of their actions and decisions, and are usually composed of schoolchildren or students. She argues that the effects on identification produced by the most trivial manipulations of categorization in such experimental groups may well not occur in work groups where history, power, status, and anticipations of future consequences are likely to be highly salient to members. She also suggests that there is a need to distinguish between 'group identification' which may be relatively transient and open to change, and 'social identity' which is more enduring and resistant to change.

2. Postmodern Critique: Social Constructionist Perspectives on Social Identity

Hartley's warning against assuming that effects produced in experimental groups will be found in real-world ones raises the issue of the extent to which group context shapes social identity processes. Because Social Identity Theory proposes a universal social-cognitive mechanism of categorization as underlying social identity formation, it is open to the criticism that it underplays the extent to which the context of a group influences the nature of social identifications within it. Social constructionist critics emphasize that identities are constructed (and reconstructed) through everyday interactions, drawing on the discourses of the person's society and culture to achieve particular ends in particular contexts. One consequence of this is that identities are more shifting and unstable than Social Identity Theory suggests, as people use them for differing purposes—even in the course of a single interaction (Potter & Wetherell, 1987). To give a hypothetical example relevant to the topic of this volume; a middle-manager might in the course of a conversation with her superior identify herself with the traditions of the company at one point, and as an enthusiast for innovation at another. The apparent conflict between 'traditionalist' and 'innovator' identities does not imply she is being intentionally deceitful; it simply reflects the multiplicity of identities, which are available to this individual.

A further social constructionist critique of Social Identity Theory focuses on the role of argument and persuasion in identity construction. Michael Billig

(1987) contends that Social Identity Theory presents a model of identification processes which is rather mechanistic, operating as a kind of 'bureaucratic filing system' in which a particular ready-formed identity is retrieved or disposed of according to the prevailing social contingencies. In contrast, Billig (1987) claims that identity formation and change occurs chiefly in the context of dialogue and argument; we discuss, challenge, debate each others' identifications in a two-way process through which both sides' identities may shift.

Social constructionist approaches to identity have played an important part in drawing attention to the role of everyday interaction in the forming and reforming of identities. This has been recognized even by some influential adherents of Social Identity Theory such as Abrams & Hogg (1992), though they insist that there is still a need to understand the identities apparent in talk in terms of underlying cognitive mechanisms. Other critics who are more sympathetic to social constructionism's rejection of universalism and cognitivism are troubled by its tendency to 'lose the person' in its accounts (e.g. Crossley, 2000) and to deny the possibility of personal agency.

3. Interpretivism: Symbolic Interactionist and Phenomenological Approaches

Symbolic interactionism (Denzin, 1989) and phenomenology (especially phenomenological psychology; Giorgi, 1970; Moustakas, 1994), though distinct and broad traditions, share common features in the way they theorize identity. Like social constructionism, they argue for identity to be understood in context, and emphasize its location in everyday interactions. They are, however, less exclusively focused on the minutiae of language use and stress the importance of understanding the personal and collective projects that people engage in. Looking at an occupational group such as lawyers or doctors, for example, interactionists have examined how they have organized themselves in order to achieve the status of 'profession', and at how individual members of the group take on values and develop their careers in a way that enables them to become recognized as successful 'professionals' (Macdonald, 1995). Although interactionist and phenomenological writers do not see identity as in any sense fixed, they tend to represent it as less fluid and shifting than do social constructionists. Biography (individual experience) and history (collective experience) constrain the ways in which identity can be formed just as the immediate social context does (Denzin, 1989; Moran, 1999).

Within this tradition, Butt (1996, 1998, 2001) has developed an approach to identity which has much to offer to the study of organizational member involvement in innovation. He presents an interpretation of Kelly's (1955) Personal Construct Psychology (PCP) as a phenomenological theory, also drawing strong parallels with G. H. Mead's interactionism (Butt,

2001). PCP states that each person has their own unique set of constructs, representing the common ways they perceive themselves and their world. Constructs are usually seen as cognitive entities located within the individual (e.g. Mancuso, 1996). In contrast, Butt (2001) emphasizes that construing should be seen as a form of social action, and constructs therefore located principally in our interactions with others. Furthermore, he supports the view of the phenomenological philosopher Merleau-Ponty (1962) that we generally do not stop to reflect before acting; rather, that most of our engagement with the world is 'pre-reflective'.

Organizational innovations commonly disrupt the patterns of social interaction through which, according to Butt (2001), our identities are constructed. As a result, organizational members may be drawn to deliberate upon aspects of identity, which are usually taken for granted and not the subject of reflection (i.e. normally remain pre-reflective). Precisely how any one member construes the implications of organizational change for their identity at work is neither the result of purely individual cognitions nor is it determined by social structural forces. Instead, it is mediated by their personal construct system, which—though unique to each person—will inevitably reflect the constraints of a particular organizational and professional/occupational context. Butt (2001) uses the example of fashion to illustrate how context moulds and limits personal agency;

Our personal constructs do not arise in a vacuum, but in the context of the social constructs which surround us. Just as it is difficult to choose clothes which are not manufactured and on offer, so we cannot easily be a particular man or woman that is not sketched out in our culture (p. 90).

Burr & Butt (1997) have used this approach to examine personal change at work following role change from shopfloor worker to Supervisor, a situation which has some parallels with that of innovations that result in role change. In the next section of this chapter I will provide an outline of research from this perspective looking directly at how organizational members respond to innovation and change.

Innovation and Identity in a Primary Health Care Setting

In the British National Health Service (NHS), most patients' initial access to healthcare is through the primary care system. This consists principally of community-based General Medical Practitioners (GPs) and the teams of other health professionals employed by or attached to their Practices, including Community Nurses and a range of therapy services. Most incidences of ill-health are dealt with within the primary care system, with only a minority being referred on to specialist secondary care in hospitals. Primary care is

an especially fruitful area for the study of innovation and identity for two main reasons. Firstly, over the last decade or so it has been subject to an unprecedented series of radical policy, organizational and practice changes, instigated by successive Conservative and Labour governments (e.g. Department of Health, 1989, 1998, 2000). Secondly, the work force consists of several professional groups with strong—and in the case of medicine and nursing, long-established—identities, which are likely to be challenged by the recent and current macro-level changes in the sector. Particularly challenging is the increased emphasis on multi-disciplinary collaborative working, both amongst different health care professions and between the health and social care sectors (Burch & Borland, 2001; Poxton, 1999). (Note that in the U.K., social care is the responsibility of Local Authority Social Services departments).

The Primary Care Research Group at the University of Huddersfield has been involved in evaluating a number of multi-disciplinary service innovations (e.g. King, Roche & Frost, 2000; King & Ross, in press). I would like to draw on data from two of these ongoing projects to illustrate how identity (defined from an interpretivist position) can be a valuable concept in understanding organizational members' experiences of and involvement in innovation processes. Both innovations were concerned with the provision of care outside of the normal working daytime hours, and were led by Community Nursing services; however, to function effectively both required good collaboration with social services staff, with other primary health care professions, and with the secondary care sector. I will provide some brief background to each innovation, before focusing on some specific points relating to identity. Pseudonyms for places and people will be used throughout, to protect confidentiality.

Case One: Fast Response Service, Buckton

Buckton is a large city in the north of England, with a population of around half a million which includes a substantial ethnic minority population (especially from the Indian sub-continent, but also Afro-Caribbean and Eastern European). It encompasses several significant areas of high deprivation. The Fast Response Service was set up in 1998 to provide short periods (up to two weeks) of support for patients in their own homes during episodes of acute illness. A major aim was to prevent admission to hospital in cases where this was not medically imperative, but without a service like the FRS would be necessary because of a lack of support in the home. The lead role in the service was played by District Nurses (community nurses with a specialist post-registration qualification); they oversaw the provision of care in the home (for up to 24 hours per day) by Health Care Assistants (who are not professionally trained). Many of the patients receiving the service were already receiving support from social services;

those who were not at the time FRS went in often needed to do so once discharged. Because of these issues of co-ordination and hand-over between services, social service managers were closely involved in the development of FRS. It should be noted that the boundaries of community nursing and social services teams within the city were not co-terminous at the time of the study.

Case Two: Out of Hours District Nursing Service, Spilsdale

Spilsdale is a borough in the north west of England, covering a mixture of urban, suburban and rural areas. Almost half of its 200,000 population live in the main town, Wigglesworth, which has a sizeable ethnic minority (like Buckton, predominantly from the Indian sub-continent) and some areas of high deprivation. The more rural parts of the borough comprise a number of small towns and villages, some relatively isolated and all with a strong sense of local identity. The Out of Hours District Nursing Service (OHDNS) was set up to address the lack of night-time and weekend District Nursing cover. As with the FRS, the introduction of the new service had important implications for co-ordination with social services, and close liaison between the two was planned, as well as with medical out of hours services. Unlike Buckton, Spilsdale's community nursing and social service boundaries were co-terminous.

Method

In both cases a qualitative methodology was used to examine the experiences of staff involved in the service innovations. The principal data collection method used was focus groups, supplemented by individual interviews. While a wide range of primary care, secondary care and social services staff were included, for the purposes of this chapter we will concentrate on the two main professional groups concerned; District Nurses and Social Workers. Summary details of participants from these professions are given in Table 1, below. All interviews were transcribed and analysed thematically, using the 'template' approach (King, 1998). For fuller details of the methodology see King & Ross (in press).

Identity Issues in the Two Service Innovations

As noted earlier, interpretivist views see identity as constructed in the interactions we undertake in our everyday lives, though inevitably also shaped by wider historical and cultural forces. The interactions of professional nurses and social workers are strongly related to the roles associated with the two groups. In our case studies the innovations impacted on professional identities because they led to perceptions or anticipations of changes to professional roles and the relationships with colleagues and patients/clients associated with them. I want to highlight below three ways in which this was manifest: in experiences of role uncertainty, in perceptions of role erosion, and in perceptions of role extension.

1. Role Uncertainty

In the two cases, some staff from both professions complained about uncertainty and confusion surrounding their roles in the wake of the innovations. Very often it was not the new service *per se* that caused difficulty; rather it was a whole range of changes, both local and national, of which the FRS and OHDNS were particular instances. This is typified by a comment from Abbie, a social services team leader in Spilsdale;

It's very confusing. I know there are a lot of things coming up, new initiatives. Everybody is left with their heads spinning and thinking 'where does that fit into that?' I think we need to be sure who's doing what, and how we access it, and who provides what!

Role uncertainty was not inevitably seen as a threat to valued aspects of professional identities (though in some instances it could be), but it was often associated with perceptions that identities were in some degree of flux. The following two sections show how this mutability could be interpreted in quite different ways, even by members of the same professional group in the same innovation case.

2. Role Erosion

A number of participants described perceptions of 'role erosion'; that valued aspects of their role were being lost because of national and local changes in primary

Table 1. Participants in the two primary care innovation studies.

Innovation example	Management of service	Community Nursing staff	Social Services staff
Buckton City Fast Response Service	1 focus group (n=6) 1 individual interview	2 focus groups (n=5, n=7)	3 focus groups (n=3, n=3, n=4)
Spilsdale Out-of-hours District Nursing service	1 focus group (n=2)	5 focus groups (n=7, n=3, n=5, n=5, n=9)	4 focus groups (n=3, n=12, n=7, n=5)

health care and/or social care. These perceptions could colour their responses to the particular changes we were focusing on, leading to a suspicious stance even where the innovation itself did not appear to offer any real threat to their role. Often, the 'other' professional group were blamed for this erosion, potentially making collaboration in new services more difficult;

Don't get me on about Social Services! I just feel totally out of my role. They have skimmed off the top, I feel left with the odd jobs (Julie, District Nurse: Spilsdale).

This perception of role erosion was shared by some of the community nursing managers. Sheri, Co-ordinator for the Out-of-hours scheme in Spilsdale, and a qualified District Nurse herself, expressed anxiety about the way further developments in the service might impact on her staff;

I do worry—it does concern me the way they've always been devalued really and undermined umm and its like, you know, to give you (an example) to do with the out of hours or 24-hour District Nursing—at the moment the Trust are looking at developing a sort of crisis intervention team in addition to the 24-hour District Nursing service—but that is going to be led from the hospital . . . and so you are going to have staff who don't have the District Nursing qualification assessing patients in the community to decide whether or not its appropriate for their care to be maintained at home, or whether they need to go into hospital, or into the intermediate care bed or discharged from hospital out into the community—well, you know in my opinion that should be a role for—that is for a trained District Nurse really.

Perceptions of role erosion related to service changes were probably more prominent amongst District Nurses than Social Workers. This may reflect the fact that nursing is a more developed profession than Social Work, with a generally more positive public and media image; they thus may have more to lose if new collaborative arrangements alter the boundaries between the two professions.

3. Role Extension

In direct contrast to those participants who felt their professional identity was threatened by role erosion were those who construed organizational changes as enhancing or extending their roles. In these cases, staff showed a willingness to redefine what it means to be a District Nurse or a Social Worker;

We do things now that we wouldn't have done 20 years ago, it's a progression—things are still changing—it's exciting really (Tina, District Nurse: Spilsdale).

Note that the above quote is from the same professional group in the same case as the previous example of perceived role erosion. This illustrates an important point in interpretive approaches, although the construction of identities is strongly shaped by immediate and wider social contexts, it is also personal—reflecting the particular pattern of relationships and experiences of an individual professional. Divergences in interpretations of what organizational innovations imply for identities are therefore to be expected. However, in defining identity as a personal and social construction, we must be wary of slipping back towards an individualistic account which reduces social context to a set of 'external variables' having a secondary influence on essentially individual processes of identity formation (Social Identity Theory's emphasis on cognitive mechanisms of categorization is an instance of this). The person does not and cannot exist independent of their social context, even though she is not simply determined by it. In relation to our innovation examples, this was evident in the way that public perceptions of the two professions limited the scope for identity change; for example, Social Workers pointed out that many service users expected certain care tasks to be carried out by a uniformed nurse, and were uncomfortable with any redefinition of traditional roles and boundaries.

Conclusion

I have argued in this chapter that the involvement of organizational members (other than senior managers and other key decision-makers) in innovation processes is a neglected research area. There is a considerable amount of work on resistance to change, but this presents a rather partial and restricted view of organizational members' experiences. In responding to this neglect, I have proposed that the concept of identity is a particularly useful one to employ. I have outlined some of the main theoretical approaches to identity and illustrated my favored interpretivist position with examples from current research in a British Primary Healthcare setting. I want to conclude by suggesting future directions for research and practice in the area of identity and involvement in innovation.

Implications for Research

The particular interpretivist approach to identity an innovation that I have advocated, has two main strengths as a basis for further research. First, it emphasizes the need to examine organizational member involvement in the context of specific innovations and specific organizations. This is in keeping with other important developments in related areas of organizational research, such as the attention to the detail of innovation processes in the Minnesota Innovation Research Program (Van de Ven et al., 1999), or the arguments for sensitivity to context in research on work group diversity (Triandis, 1995). Second, it

recognizes the essentially social nature of human beings, but also accepts that within bounds the individual organizational member has scope for a distinctive personal construal of an innovation. This approach therefore avoids the individualism of Social Identity Theory, and the denial of personal agency inherent in Social Constructionism.

In terms of an agenda for empirical work, the immediate need is for more interpretivist case studies of innovations from a widening range of types of organization. As more such material is published, fruitful areas for attention in future studies will become apparent. In the work on collaboration between health and social services in progress at Huddersfield, for example, our findings so far have led us towards a more fine-grained examination of the dynamics of personal relationships in the context of organizational change. From this we hope to gain a deeper understanding of the way professional identity is constructed in the everyday working lives of our participants, resulting in the kind of widely-varying perceptions of innovation and change that we noted above ('role erosion' versus 'role extension').

So far I have discussed identity in terms of the way organizational members perceive themselves. The concept can, however, be applied at a different level, to examine the way the organization as a whole sees and presents itself. As Fiol, Hatch and Golden-Biddle (1998) state;

An organization's identity is the aspect of culturally embedded sensemaking that is self-focused. It defines who we are in relation to the larger social system to which we belong (p. 56).

Identity understood at this level is also relevant to organizational member involvement in innovation. Significant organizational innovations very commonly involve cultural change (whether intended or not), impacting on the identity of the organization. Member responses to innovation will be shaped by the nature of the relationship between personal identities and the changing organizational identity. For instance, where there is perceived to be an incongruity between the organizational identity and the professional/occupational identities of members, the result could be hostility, obstructiveness, or feelings of disempowerment and disengagement. Future research could usefully begin to examine these kinds of relationships between different levels of organizational identity.

Implications for Practice

Interpretive research into identity and innovation does not seek to produce general theories, which explain experience and behavior regardless of context. For some critics, this makes such work of limited value for informing practice. I would contend, however, that interpretive studies can make a strong contribution to practice, in several ways. Most directly, they can

provide powerful insights for the organizations in which the actual research is carried out; insights not available to less contextually-informed approaches. They can also achieve transferability to other settings, through 'naturalistic generalization' (Stake, 1995), as I have argued elsewhere;

The transferability of findings is based on the recognition of parallels between the research setting and other contexts, and must be on the basis of the reader's own understanding of other cases. This process must be facilitated by the researcher describing the setting, methodology and findings in sufficient depth to give the reader a strong grasp of the nature of the research context—what is commonly referred to as 'thick description' (Geertz, 1973) (King, 2000, p. 595).

Rather than seeing the reluctance to make generalizations as a weakness, I would view it as a useful corrective to the tendency in the innovation and change literature towards over-generalized prescriptions for managers (e.g. Kanter, 1984; Peters & Waterman, 1983). The one piece of general advice I am comfortable in giving is that innovation leaders should take into account the identities of organizational members when planning and implementing change. Interpretive research cannot tell them how to resolve specific issues in specific circumstances—that must be based on their own knowledge of their organization and its members. What it can do is sensitize them to areas, which may be of significance and warrant careful scrutiny.

To conclude, it is not my purpose here to claim that only the interpretive approach can advance our knowledge of organizational member involvement in innovation—although I do see it as having considerable strengths, as I hope I have shown. I would like to see growing emphasis on this area from a range of theoretical perspectives, because it is through dialogue and debate between different positions that we sharpen our concepts and enrich our understanding. Identity is, of course, not the only concept of relevance to this area, but it is one which is centrally important and which up to now has been largely overlooked by w/o psychologists investigating innovation.

Managers' Recognition of Employees' Creative Ideas: A Social-Cognitive Model*

Jing Zhou and Richard W. Woodman

Department of Management, Mays Business School, Texas A&M University, USA

Abstract: The recognition and support of employee creative ideas is a crucial component in organizational creativity. In this paper, we explore a social-cognitive approach to explaining the conditions under which a manager is likely to consider an employee idea as creative. Our model posits that the manager's 'creativity schema' dictates recognition of creative ideas in the work setting. This creativity schema is influenced by personal characteristics of the manager, by aspects of the manager's relationship with the employee, and by a number of organizational influences. Implications of this approach for research and for practice are discussed.

Keywords: Creativity; Creativity schema; Organizational creativity; Creative ideas.

Introduction

Employee creativity plays an important role in the survival and growth of organizations (Amabile, 1988; Staw, 1984; Woodman, Sawyer & Griffin, 1993). Recognition of this dynamic has led to an increasing research interest in understanding what contextual or organizational factors facilitate employee creative performance (e.g. Amabile, Conti, Coon, Lazenby & Herron, 1996; George & Zhou, 2002; Oldham & Cummings, 1996; Shalley, 1995; Shalley & Oldham, 1997; Tierney, Farmer & Graen, 1999; Zhou, forthcoming (a); Zhou & Oldham, 2001).

Management support and encouragement have consistently been shown to have main or interactive effects in promoting employee creativity (Madjar, Oldham & Pratt, 2002; Oldham & Cummings, 1996; Scott & Bruce, 1994; Tierney, Farmer & Graen, 1999). However, we know relatively little about what factors influence when and why an idea, event, behavior, or outcome is considered creative from a manager's perspective. To fully understand the nature and dynam-

ics of management support for creativity, we first need to understand the factors that determine the recognition (or non-recognition) of employee creativity.

In this chapter, we will develop a conceptual model designed to explain the recognition of creative ideas in the work setting. We posit that a manager's creativity schema provides a useful heuristic to explain the recognition of behavior, events, ideas, and outcomes as creative. We develop a social-cognitive model to identify and describe the personal characteristics, work relationship factors, and organizational factors associated with the formation and use of such schema.

Conceptual Background

Employee creativity may be defined as the generation of novel and useful ideas (Amabile, 1988). We embed this individual creativity within the broader issue of organizational creativity which may be defined as the creation of a valuable, useful new product, service, idea, procedure, or process by individuals working together in a complex social system (cf. Woodman et al., 1993). Within the context of organizational creativity, three assumptions make research on managers' recognition of employee creative ideas particularly meaningful. First, employees seldom produce creative ideas in social isolation. Creative performance is as much of a social process as a cognitive process (Amabile, 1983). Second, employees typically do not generate creative ideas overnight. Instead, there is a

* Earlier versions of this paper were presented at 'The 21st Century Change Imperative: Evolving Organizations & Emerging Networks' Conference, Center for the Study of Organizational Change, University of Missouri-Columbia, June 12-14, 1998, and the Academy of Management Annual Meetings, Chicago, 1999.

process by which a novel and useful idea gets developed and refined (Basadur, Graen & Green, 1982; Rogers, 1983; Wallas, 1926). This process is likely to involve interaction, communication with others, and is often subject to evaluation and feedback from others (Amabile, 1996; Shalley & Perry-Smith, 2001; Zhou, forthcoming (b)). To the extent that managers are important elements of the social environment in organizations, their reactions may have substantial influence on the creative idea generation process. Third, whether an idea or event is creative is not completely objective. Individuals attach meanings and interpretations to ideas or events. Thus, the degree to which an idea, event, or outcome is creative is, to a very real extent, subjective. What one person sees as a creative idea another person may or may not agree with.

There has always been a subjective, social dimension to the judgment of creativity. As defined above, creativity implies, at a minimum, an assessment of two dimensions; novelty and usefulness. These dimensions are sometimes further broken down into component sub-dimensions (e.g. MacCrimmon & Wagner, 1994), but these are the two most commonly accepted dimensions of creativity and will suffice for our purposes here. In terms of measurement, novelty has traditionally posed less of a problem than usefulness. Novelty or originality is a (sometimes) simple matter of counting and comparing. (Although lacking the knowledge base to accurately recognize novelty could, of course, be a constraint.) The dimension of usefulness, however, has proven to pose the most tricky construct validity issues. At some level of abstraction, it seems impossible to assess the value or usefulness of a product, idea, outcome, and so on without a *judgment* about such value or usefulness. We see this most clearly in the world of art. What one person regards as an attractive, valuable painting for example, another individual may view as without merit. At first, it might seem that the usefulness criterion would be less daunting in judging creativity in the organization. A newly invented product is useful if people buy it; a newly created process is useful if it is more efficient than the process it replaces, and so on. However, at the 'idea' stage, usefulness depends very much upon a judgment about a future state of value. Also, an idea judged as creative (both novel and potentially useful) by one manager may leave another unmoved. Indeed, Epstein is so vexed by the problems plaguing the usefulness criterion that he avoids altogether the language of creativity when dealing with 'generative phenomena' (his preferred term). 'Behavior called creative by one group might be harshly judged by another' (Epstein, 1990, p. 139). Epstein even argues that, due largely to these judgmental disagreements, the creative product may ultimately provide a poor index for measuring or understanding the creative process. Nevertheless, we wish to focus on a particular type of

creative product in this chapter; specifically, the creative idea and the factors that influence managerial recognition of the idea as creative.

Csikszentmihalyi goes much further than most observers when he argued that "... creativity is not an attribute of individuals but of social systems making judgments about individuals" (1990, p. 198). In his systems view of creativity, Csikszentmihalyi conceptualizes creativity as the result of the interaction among three sub-systems: a domain, a person, and a field (Csikszentmihalyi, 1990, 1996). It is within the 'field' sub-system that judgments concerning creative ideas, behavior, and outcomes are made. Within the work setting, the manager would appear to be a crucial component of Csikszentmihalyi's 'field'. In sum, we view the manager as a key actor in the social system that 'makes judgments' about the creativity of individual employees.

Recognition of Creative Ideas

What is the most useful way to understand or to explain managerial recognition of creative ideas? In this chapter, we will argue that creativity schema dictate managers' recognition of a creative idea. In this section, we will: (a) describe the nature and potential function of a creativity schema; (b) identify personal characteristics that are associated with the formation of a creativity schema; (c) identify aspects of the manager's relationship with the employee that are related to the specific dimensions of the manager's creativity schema; and (d) identify the organizational influence factors that are related to the specific dimensions of the schema. Because we are still at a very preliminary stage of developing a social-cognitive perspective of managers' recognition of creative ideas, we emphasize presenting new research ideas instead of empirical support. In addition, in identifying the variables that affect the formation and utilization of a creativity schema, we shall attempt to be illustrative rather than exhaustive.

Figure 1 displays the hypothesized linkages between creativity schema and the personal, relationship, and organizational influences factors that are associated with the schema. An important aspect of the model shown in Fig. 1 should be noted at this point. We see a critical difference among these three categories (i.e. personal, relationship, and organizational) in terms of their relationship to the schema. Specifically, we posit that personal characteristics of the manager are related to, or help to explain, the *formation* of creativity schema. In contrast, the dyadic relationship and organizational influence variables help to explain how the schema is *utilized* in judging the creativity of the employee's idea. In each category, however, we will propose relationships to specific dimensions of the schema. In developing our propositions, we will specify the nature of the association (i.e. a positive or a negative relationship) whenever possible. In some

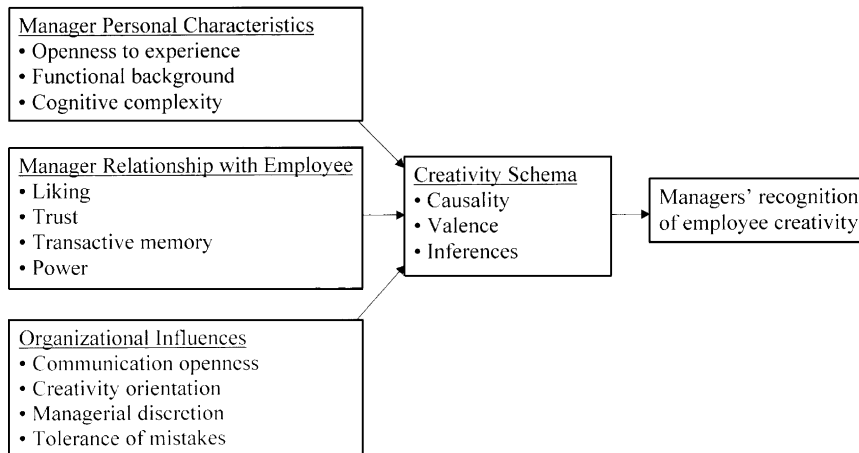

Figure 1. Managers' Recognition of Employee Creativity: A Social-Cognitive Model.

cases, however, the nature of the relationship between the variables is difficult to predict given the current state of our knowledge. Also, it is possible in a few instances that the directionality of the relationship might vary across situations. (Potential moderators are not explored in this paper.) In these cases, we choose to make a more general statement concerning the relationship.

Creativity Schema

Fiske & Taylor define a schema as a “cognitive structure that represents organized knowledge about a given concept or type of stimulus. A schema contains both the attributes of the concept and the relationships among the attributes” (1984, p. 140). In essence, a schema is a mental representation of an external target that helps the individual to make sense of the target in a simplified and organized way.

Previous theory and research in social cognitive psychology and organizational change suggests that a schema concerning a specific target can be meaningfully thought of as including three components; causality, valence, and inferences (e.g. Lau & Woodman, 1995; Markus & Zajonc, 1985; Taylor & Crocker, 1981). Causality refers to the aspect of a schema that maps the sequential relations between events. It enables individuals to make causal attributions and to understand the connections between causes and effects. For a creativity schema, causality provides managers with some explanations concerning where the creative idea has come from, why it has been produced, and how it fits in the particular context within which the employee and manager work. Valence refers to the significance of the target idea or event. For a creativity schema, valence allows the manager to decide whether the idea produced by the employee is significant and meaningful. Finally, inferences allow the individual to

predict what is going to happen in the future, and how likely these events or outcomes are to take place. This component in a creativity schema allows the manager to make inferences about whether the focal idea can be successfully implemented, and what the consequences of implementation are for the organization and for the manager.

Although little research has been conducted to examine the role of schema on managers' recognition of creative ideas generated by employees, previous research in organizational change sheds light on the construct validity of this concept. For example, Lau & Woodman (1995) investigated the content and development of change schema. Using both qualitative and quantitative data-collection methods across three different samples, they found that the measurement of change schema had satisfactory construct validity. Also, empirical work has successfully employed the change schema construct to explore changes in organizational culture and further demonstrated the construct validity of change schema as well as the utility of a cognitive approach to measuring culture change (Lau, Kilbourne & Woodman, 2003). In addition, theory and research, in general, has supported the notion that a schema has the function of directing an individual to make sense of an external target or event. Further, a schema can be useful for explaining or understanding an individual's possible attitudinal and behavioral reactions to the target or event (e.g. Markus & Zajonc, 1985; Schank & Abelson, 1977; Taylor & Crocker, 1981).

Formation of Creativity Schema: Relationships to Personal Characteristics

As shown in Fig. 1, we posit that three variables concerning the focal manager's personal characteristics are related to the formation of a creativity schema.

While we are prepared to argue for the likely importance of these three personal characteristics, we certainly are not suggesting that these individual differences are the only ones associated with the components of a creativity schema.

The first of these, openness to experience, is one of the Big Five personality dimensions (e.g. McCrae & Costa, 1985, 1999). It captures intellectual curiosity, imagination, aesthetic sensitivity, and wide interests, among other traits (John & Srivastava, 1999). Individuals scoring highly on the openness to experience dimension tend to seek and enjoy varied experiences for their own sake. Scratchley & Hakstian (2000–2001) found that openness to experience (operationalized as openness to change, openness to risk, and openness to ambiguity) was positively correlated with divergent thinking and could be used to successfully predict managerial creativity (operationalized as devising new ideas, work methods, and modes of operation useful to the organization). George & Zhou (2001) found that individuals high on openness to experience were the most creative when provided with positive feedback and when performing heuristic (as opposed to algorithmic) tasks. They concluded that openness to experience may support creative behavior when the situation allows for the manifestation of the possible influence of the trait. In addition to the production of new ideas, by extension openness to experience could be related to the recognition of new ideas as well. Thus, it appears that managers who are more open to experience would be more likely to perceive an idea to have high valence. Thus, we posit:

Proposition 1: Openness to experience is positively related to the valence component of creativity schema.

A second variable that might be related to creativity schema is the manager's functional background. This background is an indicator of the type of knowledge he or she possesses with regard to the domain of the proposed creative idea. Amabile (1988) identified 'domain-relevant skills' as being important for creativity. By extension, knowledge and skills relevant to the domain of some proposed idea could also be a factor in the recognition and appreciation of an idea as being novel and valuable. Functional background also results in a manager's selective perceptions of ambient stimuli (e.g. Dearborn & Simon, 1958; Waller, Huber & Glick, 1995). That is, the cognitive map derived from experience in a particular functional background directs a manager's attention to certain events in the surrounding environment, and to certain attributes of the creative idea. Functional background would appear to be associated with how the manager makes sense of why an idea might be developed, how it fits into the employee's work, whether the idea is significant in this context, and whether or not it is likely to be successfully implemented. Therefore, we suggest:

Proposition 2: Functional background is related to all three components—causality, valence, and inferences—of creativity schema.

A third individual difference construct that may be related to the formation of creativity schema is captured by the broad notion of cognitive complexity. Research has identified a number of cognitive abilities that are related to creativity (Hayes, 1989; Woodman et al., 1993). For example, the cognitive ability of divergent production, consisting of processes of fluency, flexibility, originality, and elaboration, has long been considered as a cognitive key to creativity (Guilford, 1984; Mumford, 2000–2001). Interestingly, with regard to the *recognition* as opposed to the production of creative ideas, the cognitive ability of convergent production or thinking may be more critical. Whereas divergent thinking might allow the individual to find or produce numerous original ideas, it is convergent thinking that allows the individual to select from among the ideas those that might be most useful or valuable. Runco (1999) explores the role of critical thinking in creativity and his conclusions suggest that this aspect of cognitive functioning might be crucial for the recognition of the value of an idea, particularly when the idea is one among many. In a similar vein, Hogarth (1987) suggested that the ability to reason and to understand the causality of events was a crucial component of creativity. In general, we would expect managers with higher cognitive complexity (with the attendant cognitive abilities implied by that construct) to be better able to process the complex information that might be needed for judging an idea as creative. Specifically, we expect:

Proposition 3: Cognitive complexity is positively related to the causality and inferences components of creativity schema.

Utilization of Creativity Schema: The Role of Relationships

Four variables in our model concern the dyadic relationship between the focal manager and the employee who has generated the creative idea (see Fig. 1). The first of these, liking, refers to the extent to which the manager has positive affect toward the employee (e.g. Judge & Ferris, 1993; Tsui & O'Reilly, 1989). Previous research showed that when a manager liked an employee, the manager tended to respond more positively to him or her, for example by giving higher performance ratings (e.g. Cardy & Dobbins, 1986; Judge & Ferris, 1993). Although we know of no research directly focused on the relationship between liking an employee and the response to ideas produced by the employee, related evidence concerning the relationship between liking and manager assessments and responses in general suggests that liking might be related to the creativity schema components of valence and inferences. When a manager likes an employee, he

or she is more likely to think positively about the employee's ideas, believe such ideas are meaningful and significant, and also judge that the idea is likely to be successfully implemented. Therefore, we propose:

Proposition 4: Liking is positively related to the valence and inferences components of creativity schema.

Trust is another important variable that defines the quality of the relationship between a manager and an employee. Following Mayer, Davis & Schoorman (1995), trust is defined as "the willingness of a party to be vulnerable to the actions of another party based on the expectation that the other will perform a particular action important to the trustor, irrespective of the ability to monitor or control that other party" (Mayer et al., 1995, p. 712). Because any potentially creative idea is accompanied by some degree of uncertainty, and is, as previously discussed, somewhat subjective, whether or not the idea is congruent with other aspects of the job and work setting, as well as its significance and consequences are subjected to the manager's personal interpretations. If the manager trusts the employee, he or she should be more likely to favorably interpret questions and issues surrounding why the employee has produced the idea, the meaning and significance of the idea, and the consequences that may stem from implementation of the idea. In sum:

Proposition 5: Trust is related to the causality, valence, and inferences components of creativity schema.

Wegner and his colleagues (e.g. Wegner, 1986; Wegner, Erber & Raymond, 1991) maintain that transactive memory is a system of encoding, storing, and retrieving information that is shared by more than one person. This is an intriguing concept with potential implications for understanding the utilization of creativity schema from the perspective of the dyadic relationship between a manager and her subordinate. When a manager and an employee have developed this memory sharing system, they have knowledge about each other's memories, and have shared responsibility that could enable one person to remember something the other might not (Wegner et al., 1991). Due to the potential utility of transactive memory, a manager having such a relationship with an employee should have a good understanding of the causes, nature, and consequences of the ideas produced by the employee. Therefore, we posit:

Proposition 6: Transactive memory is related to the causality, valence, and inferences components of creativity schema.

A final aspect of the dyadic relationship between the manager and the employee that could impact managerial recognition of employee creative ideas is captured by the notion of relative power in the relationship (Hellriegel, Slocum & Woodman, 2001; Kramer &

Neale, 1998). The ability of one actor in this dyad to influence the other could range from the manager having all of the power, with the employee being virtually powerless to a relationship where power is more balanced between the actors, to, at the other extreme, the employee having strong ability to influence the manager while the manager has little ability to influence the subordinate. This latter scenario seems the least likely of the three. One might speculate that a balanced relationship (regardless of the source or reasons for that balance) might be the one where the manager is most likely to focus on the 'merits' of the creative idea in judging it. It seems conceivable that the circumstance where the manager's power is dramatically stronger than the employee's power might result in a tendency for the manager to be less willing to acknowledge the potential value of any employee's idea, creative or not. In any event, we expect that the relative power positions characterizing this dyadic relationship may influence managerial recognition of employee creative ideas. Thus:

Proposition 7: The relative power of the manager in relation to the employee is related to all three components of creativity schema.

Utilization of Creativity Schema: The Role of Organizational Influences

Finally, as shown in Fig. 1, we hypothesize that four organizational influences are related to creativity schema. The first of these factors, communication openness, refers to the extent to which there are open channels of communication in the organization. A significant body of research on organizational innovation supports the notion that the availability of information is a crucial variable in the creative process (Damanpour, 1991; Kanter, 1988; Payne, 1990). This work further suggests that constraints on information and communication have a negative impact on creativity. When a manager can openly and freely exchange ideas and acquire information, he or she is more likely to understand how an idea produced by an employee is related to other aspects of the job that the employee is doing, and how the idea might be related to the work performed by other employees across various jobs and organizational functions. As such, the manager may also have a better understanding of the meaning and significance of the proposed idea. Finally, the manager is also likely to have a better and richer understanding of whether the idea can be implemented, and the likely consequences of this implementation. Thus, we propose:

Proposition 8: Communication openness is related to all three components of creativity schema.

The second variable in the organizational influences category is creativity orientation. In general, the 'climate for creativity' has long been considered a

crucial component in fostering creative behaviors and outcomes (cf. Amabile, 1983, 1996). It would seem to be intuitive that when an organization is oriented toward finding, promoting, and supporting employee creativity, a manager is more likely to see the significance of the idea generated by the employee, and is more likely as well to believe that the idea has a good chance to be successfully implemented. Therefore:

Proposition 9: Creativity orientation is related to the valence and inferences components of creativity schema.

The third variable in this category is managerial discretion. This discretion reflects the extent to which the focal manager has control over many operational and production related issues such as, choices of projects, work procedures, outcome criteria, and timelines. Greater autonomy, in general, allows for an exploration of alternative methods for completing work. An increase in experimentation, in turn, appears to be related to more creative outcomes (Amabile, 1996; Shalley, 1991; Zhou, 1998). By extension, it seems logical that the greater the discretion a manager has, the more likely that he or she is to believe that the implementation of the idea and its consequences are predictable and manageable. Thus:

Proposition 10: Management discretion is positively related to the inferences component of creativity schema.

Finally, tolerance of mistakes refers to the extent to which the organization's reward policy, practices, and culture encourage risk-taking and forgive innocent mistakes committed in the course of trying to accomplish the organization's tasks. In such an organizational culture, producing and implementing new and useful ideas would typically be well regarded and valued. Evidence supports the notion that creative behavior and outcomes are enhanced when risk-taking is both encouraged and supported, particularly by an absence of punishment (Amabile, 1988; Burnside, 1990; Nystrom, 1990). When there is a tolerance for mistakes made in the pursuit of organizational goals, the focal manager may be more likely to feel confident and comfortable about new ideas proposed by employees. In other words, organizational tolerance of mistakes may be related to the component of the manager's creativity schema related to the consequences of the idea. That is:

Proposition 11: Tolerance of mistakes is related to the inferences component of creativity schema.

Discussion and Suggestions

In summary, the focus of the model shown in Fig. 1 and developed here has been to explore the key role of the manager in the judgment and recognition of employee creativity. A social-cognitive approach to understand-

ing the manager's role in the creative process in organizations suggests several implications for organizational research and management practice.

Implications for Research

In terms of our model in Fig. 1, there are a number of implications for needed research as well as further theory development. While the dimensionality of schema (causality, valence, and inferences) has been supported by previous research (e.g. Lau & Woodman, 1995), it will be important to develop and demonstrate the construct validity of a measure of *creativity* schema. Further, we have posited only a limited number of personal characteristics of the manager that might be related to the formation of creativity schema and hence to the recognition of employee creativity. It seems reasonable to suppose a much larger list of possibilities in this regard. In addition, it could well be that greater explanatory power could be added to the socio-cognitive model shown in Fig. 1 by including specific characteristics and behavior of the employee generating the creative idea. For example, an obvious aspect of the employee's behavior that could impact the recognition of creative ideas would be past employee performance. That is, an idea generated by an employee with a history of exemplary performance might be likely to be judged as creative. At the other extreme, an employee with a checkered past in terms of job performance might more readily have his ideas dismissed or ignored by his manager or supervisor.

Finally, in terms of theory development, we have proposed a model in the most straightforward manner possible, i.e. that manager personal characteristics, characteristics of the dyadic relationship between manager and employee, and organizational influences are viewed as 'antecedent conditions' to managerial recognition of creativity. Research may show that a more complex configuration provides greater explanatory power. For example, some contextual variables (e.g. organizational influences) may well moderate the relationship between personal characteristics and managerial recognition.

There is some recent research on organizational creativity that can inform theoretical development of the model represented by Fig. 1. In addition, our perspective may contribute to the further development of several on-going lines of inquiry. For example, Shalley, Gibson & Blum (2000) investigated the degree to which work environments were structured to complement or be congruent with the 'creativity requirements' (i.e. level of creative behavior) required by a particular job. Among other notions, they posited that the level of creativity required in a job was positively associated with organizational support. While they showed only partial support for this hypothesis across a series of potential relationships, the hypothesis would seem to capture a crucial dynamic. In terms of our posited relationships, it would be valuable

to know to what extent managerial recognition of employee creativity represents an important component of 'organizational support'. Further, the creative requirements of a specific job represent another explanatory variable that could be added to our model. It is logical that managerial recognition could be more important in situations where the jobs have a relatively high 'creativity requirement' than in situations where it is less important for employees to engage in creative behavior.

Organizational support for creativity was posited by Zhou & George (2001) to interact with job dissatisfaction and continuance commitment to predict creativity. Continuance commitment refers to employees being committed to their organizations not because of affective attachment or identification with the organizations' values and goals, but because of necessity (e.g. not being able to find jobs elsewhere) (Allen & Meyer, 1996). They found that, employees with high levels of job dissatisfaction and continuance commitment were more likely to exhibit creativity when perceived organizational support for creativity was high. In terms of our model, the findings from the Zhou & George study are potentially related to both the manager-employee set of variables as well as the organizational influences antecedents. Their work suggests that our straightforward diagramming of these explanatory variables, as we discussed earlier, may be far too simple. The potential for interactions among these variables across levels of analysis is very real.

Another line of inquiry with implications for our social-cognitive model is represented by the investigation performed by McGrath (2001). In a study of 56 new business development projects, she found that organizational learning was more effective when the projects were operated with high degrees of autonomy. Learning effectiveness, as operationalized in this study, is related to exploration behaviors leading to creativity and innovation. This line of inquiry suggests that the managerial discretion variable, which we include as an important component of organizational influences on managerial recognition, may be a particularly important explanatory variable. Research is needed to isolate the potentially crucial role of autonomy and discretion in the perception of employee creativity. Here again, possible interactions between autonomy and variables in our model seem likely.

Finally, a theoretical perspective advanced by Unsworth (2001) suggests yet another potentially useful avenue in developing research to explore our model. Unsworth recently suggested that treating creativity as a unitary concept has hampered development of a richer understanding of organizational creativity. Unsworth advanced a matrix of 'creativity types' consisting of the following categories; expected creativity (required solution to discovered problem), proactive creativity (volunteered solution to discovered problem), responsive creativity (required solution to

specified problem), and contributory creativity (volunteered solution to specified problem). These types differ along dimensions of driver (why engage in the creative process?) and problem (what is the initial state triggering the need for creativity?). Unsworth (2001) posits that there may be important and interesting differences in factors contributing to creativity and the creative process itself across these categories. In terms of the model in Fig. 1, an interesting research question concerns whether the classes of antecedents would vary with the type of creativity involved (e.g. would the important organizational influences vary across types?). Further, might managers in general, regardless of the constellation of antecedents, more readily recognize some types of creativity than others? Of course, the construct validity of Unsworth's creativity categories has yet to be established.

Implications for Practice

The major approach taken organizationally in terms of utilizing knowledge about creativity in the work setting has probably been through training programs. While results are somewhat mixed, in general a number of studies have shown positive results from attempting to 'train' employees to be more creative. As mentioned earlier, divergent thinking has long been considered a cognitive key to creativity. Thus, training programs have frequently targeted divergent thinking when attempting to improve the creative performance of employees and managers (e.g. Basadur, Graen & Scandura, 1986; Basadur, Wakabayashi & Graen, 1990). The widely-used training programs designed to improve the ability of groups and teams to brainstorm creative solutions to problems and/or teaching individual decision makers to engage in 'lateral thinking' (i.e. looking for alternative ways to define and understand problems) also fall into the divergent thinking arena conceptually (Ripple, 1999). A second approach has been to target creative performance related to a specific domain, for example strategic planning (cf. Wheatley, Anthony & Maddox, 1991). Based on the logic developed in our paper, a potentially fruitful arena for creativity training might be to focus this activity on enhancing the ability of key managers and decision makers to recognize creativity when they see it. Such creativity training would have the advantage of a relatively specific focus, might have wide-spread applicability across a large number of individuals of varying cognitive abilities, personalities, attitudes, and values and thus could be instrumental in helping to foster the supportive climate and acceptance considered important for organizational creativity.

Harrington (1999) suggests the crucial importance of the environmental context for creative behavior. There is a tradition of research in the psychological sciences that has focused on the effect of the environment on the creativity of gifted individuals. In general, opportunities to learn and create, ready access to needed

information, the presence of a supportive social system including appropriate rewards for creative behavior, and the like are considered to be instrumental for creativity. Research on the 'climate for creativity' has been successfully extended into organizations (e.g. Amabile, 1996; Isaksen, Lauer, Ekvall & Britz, 2000–2001; Tesluk, Farr & Klein, 1997). As one example of this body of work, Tesluk et al. (1997) identified a supportive organizational culture, the utilization of appropriate goal-setting and rewards for creativity, a host of organizational characteristics (e.g. design features, human resource practices and policies), and socioemotional support as being particularly crucial in fostering individual creativity in the workplace. In sum, we have reasonable insight into many of the contextual factors (both at the organizational level and the group level) that can enhance organizational creativity and, conversely, inhibit it (cf. Woodman, et al., 1993). Based on the approach represented by the model of Fig. 1, and consistent with the systems view of creativity advanced by Csikszentmihalyi (1996), we argue that managerial recognition of creative ideas should be considered a crucial component of the necessary organizational climate, socioemotional support, appropriate reward structure, and so on needed for organizational creativity. Woodman (1995) has long argued that the high-payoff strategy for managers in terms of impacting creative behavior and outcomes in the work setting is to learn how to design, and to manage, the context affecting creativity, rather than focusing on attempting to directly manage either creative persons or the creative process. To this argument we would now add the notion that the manager needs to learn how to manage herself in terms of the ability to identify, nurture, and reward creative ideas when they appear.

Concluding Comments

We have argued that the managerial recognition of employee creative ideas can be meaningfully explained by an examination of the manager's creativity schema. This schema is influenced by personal characteristics of the manager, by the relationship that exists between the manager and the employee who creates the idea that will be judged by the manager, and by certain organizational or contextual influences that characterize the particular work setting. We have proposed a number of relationships between these sources of explanatory variation and the causality, valence, and inferences components of the manager's creativity schema.

Certainly, our proposed social-cognitive model has a number of limitations. We have made no attempt to address the exact process through which a manager's creativity schema is developed. Further, we have made no attempt to specify how much time might be needed for the formation and development of the schema. Pettigrew, Woodman & Cameron (2001) have argued

strongly that notions of time need to be incorporated into theory development concerned with *any* change processes in organizations. The model developed here would fit that broad context and will eventually need to include the dimension of time. An additional limitation concerns the explanatory variation included in Fig. 1 or, more to the point, the variables that have been omitted. The model could be expanded in several ways as was noted above.

Despite the obvious limitations at this point of theory development, the proposed model has the potential to make important contributions to organizational creativity research. To the extent that management support is crucial in fostering employee creativity, then understanding the initial conditions for management support—how and why managers might recognize an idea as creative—would seem to be a valuable line of inquiry. This approach has the potential to broaden our understanding of how to foster employee creativity. Creative idea generation is an ongoing process in organizations, and managers' recognition of and responses to potentially creative ideas put forth by employees may affect whether these ideas will be accepted, nurtured, and implemented.

Venture Capital's Role in Innovation: Issues, Research and Stakeholder Interests

John Callahan and Steven Muegge

Department of Systems and Computer Engineering and Eric Sprott School of Business, Carleton University, Canada

Abstract: The purpose of this chapter is to review the role of venture capital in innovation. The chapter begins with the history and current state of venture capital. We also describe the process of venture capital financing and how it relates to the innovation process. Then, we review the research literature related to venture capital investment decision-making, the venture capital-entrepreneur relationship, and the fostering of innovation by venture capital. Finally, using a stakeholder perspective, we outline the usefulness of current research for different stakeholders and call for more qualitative, longitudinal research that contributes better stories and richer data on variable interrelationships.

Keywords: Innovation; Venture capital; Research.

Introduction

The purpose of this chapter is to provide a review of the role of venture capital in the innovation process. Excellent reviews of the investment issues of venture capital already exist (Gompers & Lerner, 2001a, 2001b). There are no reviews, however, that focus on venture capital's role in innovation. The present chapter aims to fill this gap.

Innovation is an ancient activity in human history. The pace of innovation, however, has accelerated significantly in the last 50 years (Agarwal & Gort, 2001). Innovation is now commonly regarded as the basis for competitive advantage between enterprises and between whole communities (Porter, 1990). Venture capitalists make high-risk equity investments in new entrepreneurial ventures. Innovation by venture capital financed start-ups is felt by many to contribute significantly to modern economic development. The fall of 2002, as this chapter is being written, is actually a good time to ask about venture capital's role in innovation and economic development. The last 15 years provide a complete up-and-down cycle.

There are many natural sources of conflict between venture capitalists and entrepreneurs. As equity investors, venture capitalists want the companies in which they invest to be successful. There are many versions of 'success', however, in any situation as complex as building a new company. For the founding team of

entrepreneurs, successful innovation can be the creation of a company of which they can be proud, that provides a good living, and may provide real equity value at some time in the future. This process might take 10, 15, even 20 years and still be successful. Entrepreneurs are normally not diversified—their entire fortunes will be tied up in their companies. On the other hand, a venture capitalist will have a reasonably diversified portfolio of a dozen or more investments. Moreover, for the venture capitalist, success is very specific and clear cut. A VC invests only with the prospect of realizing real equity value through a liquidity event like acquisition or an initial public offering—generally within a period of five to seven years (Lerner, 1994). The conflicts that naturally exist in this relationship are captured by a quote from an article in an online engineering journal (Tredennick, 2001):

VCs know how to deal with engineers, but engineers don't know how to deal with VCs. VCs take advantage of this situation to maximize the return for the venture fund's investors. Engineers are getting short-changed.

In reviewing the role of venture capital in innovation, we cover the management issues and the research to date. Our focus is on independent venture capital firms but we also review corporate venturing for comparison.

The chapter begins with an overview of venture capital—its history and current state. We then describe the process of venture capital financing and how it relates to the innovation process. Next we review the research literature related to venture capital investment decision-making and the venture capital-entrepreneur relationship. We also ask the question again using the research literature—does venture capital foster innovation? We find that the jury is out on this question. Finally, using a stakeholder perspective, we outline the usefulness of current research for different stakeholders and call for more qualitative, longitudinal research that contributes better stories and richer data on variable interrelationships.

Overview of Venture Capital

Venture capital (VC) is a specialized form of financing, available to a minority of entrepreneurs in attractive industries. Many venture capital success stories have become household names—Amazon, Cisco, Compaq, eBay, Federal Express, Intel, Lotus, Netscape, Sun Microsystems, and Yahoo all received VC funding. Venture capital is not exclusive, however, to the technology sector. The growth of Staples, Starbucks, and TCBY—all ‘brick and mortar’ retailers with innovative business models—was also fueled by venture capital investment. In the words of VC researchers Paul Gompers & Josh Lerner (2001b, p. 83):

No matter how we look at the numbers, venture capital clearly serves as an important source for economic development, wealth and job creation, and innovation. This unique form of investing brightens entrepreneurial companies’ prospects by relieving all-too-common capital constraints. Venture-backed firms grow more quickly and create far more value than nonventure-backed firms. Similarly, venture capital generates a tremendous number of jobs and boosts corporate profits, earnings, and workforce quality. Finally, venture capital exerts a powerful effect on innovation.

In addition to funding, venture capital investors (venture capitalists, or VCs) can provide specialized knowledge of a particular industry, experience successfully growing a business from start-up to publicly traded company, and access to a network of contacts that may include seasoned managers, partners, and customers. The venture capitalist brings terms, controls, expertise, and financial strength that helps form a well-managed and well-financed company that is more likely to succeed. In exchange, the venture capitalist demands a preferred equity share of the new venture, along with favorable upside and downside investment

protections.¹ The founding entrepreneurs relinquish equity and agree to contractual restrictions intended to protect the venture investment. In doing so, the founders give up exclusive ownership of the whole pie for the possibility of owning a small slice of a much larger pie, when the firm is taken public or acquired.

Venture capitalists are able to effectively exit their investments only at a liquidity event—an initial public offering of stock (IPO) on a public stock exchange, acquisition of the firm by another firm, or bankruptcy. The IPO is the most lucrative result for all investors (Cumming & MacIntosh, 2002), so in principle, the interests of the founders and venture capital investors align in this regard.

Joseph Schumpeter (1934) first proposed that small entrepreneurial firms are most likely to be the source of most innovation. Modern research supports the notion that large established firms have great difficulty managing innovations that fall outside of their previous experience, including *architectural innovations* (Henderson & Clark, 1990), *competency-destroying innovations* (Tushman & Anderson, 1986), and *disruptive technology* that changes the basis for competition in an industry (Christensen, 1997). Established firms may partially overcome these limitations through *ambidextrous organizational structures* (Tushman & O’Reilly, 1997), *radical innovation hubs* (Leifer et al., 2000), and *corporate venturing* programs that emulate venture capital (Chesbrough, 2000). Nonetheless, new firms would appear to have some natural advantages at realizing some innovations.

Innovation in small firms is difficult to finance because of four fundamental problems (Gompers & Lerner, 2001b):

- (1) high uncertainty;
- (2) information asymmetry;
- (3) intangible soft assets;
- (4) sensitivity to volatile market conditions.

High uncertainty is a fundamental trait of innovation that no amount of study or due diligence can entirely eliminate. The future is not only unknown, it is unknowable (Christensen, 1997). *Information asymmetry* refers to the large information gaps possible between innovators and investors. Because of their particular specialized expertise, innovators are likely to have a superior understanding of their innovation,

¹ According to Zider (1998) and Kaplan & Stromberg (2000a), these restrictions may include preferred and convertible securities to ensure that VCs are paid first if the firm is liquidated, anti-dilution constraints, prevention of early liquidation by entrepreneurs, mandatory redemption rights to force liquidation by VCs, restrictions on the sale of assets, restrictions of sales of stock that would alter ownership, non-compete and vesting provisions that make it expensive for the entrepreneur to leave the firm, and loss of control rights if the firm performs poorly.

while investors are likely to have a superior understanding of financing. *Intangible soft assets* include patents and trademarks, human capital, and future opportunities. The real value of these assets is difficult to measure; they may have great value to a particular owner, but negligible value to others. The value and liquidity of innovative firms is highly *sensitive to volatile market conditions*. During an economic boom, it may be relatively easy and lucrative to complete an IPO of a promising firm on the public stock markets; in a depressed market, it may be impossible.

These four fundamental problems make it difficult for many entrepreneurs to raise high levels of funds through traditional debt financing.² Venture capital fills this void by providing high levels of funding to opportunities with high uncertainty and large information asymmetries—in other words, ventures that may not otherwise have been funded.

Venture capital is neither available nor necessarily desirable to all entrepreneurs. Most start-ups do not employ venture capital, nor would they be attractive candidates for venture funding.³ The vast majority of entrepreneurial start-ups are sole proprietorships in the service industry with limited opportunity for growth (Bhidé, 2000, p. 13). Venture capitalists do not fund laundries, family-run restaurants, or hair salons.

Some founding entrepreneurs that would qualify for venture funding may prefer to *bootstrap*—self-finance from personal savings, debt, and re-invested revenue. A number of significant Fortune 500 firms, including such technology notables as Hewlett-Packard,⁴ Microsoft,⁵ and Dell,⁶ have grown to dominate their industries without early venture capital funding. In each example, the original founders retained significant ownership and control of their innovation.

² Qualification for a bank loan, for example, may require tangible collateral and agreement to a fixed repayment plan. As the perceived risk of the investment rises, the terms of the financing would become more expensive and restrictive.

³ Bhidé (2000) reports that only 5% of 1989 *Inc. 500* companies start with VC funding, while 80% bootstrap with modest funds. The *Inc. 500* is a compilation of the fastest growing privately held companies in the United States.

⁴ HP was founded in 1938 and taken public in 1957—an interval of 19 years. It achieved Fortune 500 status in 1962. In contrast, the typical VC-backed company that went public between 1984 and 1994 did so in just five years (Venture Capital Journal, February 1995, p. 45).

⁵ Microsoft was founded in 1975 and taken public in 1986. In 1975, personal computers were restricted to a small number of hobbyists; neither founder had management experience, and both had dropped out of college. Microsoft did accept some late-stage funding prior to IPO, although Bhidé (2000, p. 164) suggests that this decision was motivated by the desire to improve the legitimacy of the IPO to institutional investors rather than a need to raise capital.

⁶ Dell was founded in 1984, taken public in 1988, and achieved Fortune 500 status in 1992, all without venture capital financing.

Venture capital emerged in the United States in the years following World War II (Gompers & Lerner, 2001a). In 1946, founders from the Massachusetts Institute of Technology and Harvard Business School partnered with local business leaders to establish American Research and Development (ARD), the first true venture capital firm. ARD invested in emerging companies seeking to commercialize wartime technologies. ARD was a publicly traded closed-end mutual fund.⁷

Many early venture capital organizations were organized as closed-end funds or Small Business Investment Companies (SBICs).⁸ In 1958, the first venture capital limited partnership was formed (Draper, Gaither & Anderson). Limited partnerships became more prevalent throughout the 1970s and 1980s, and are now the most common venture capital structure. Unlike mutual funds, limited partnerships are exempt from American Securities Exchange Commission (SEC) regulations, including exacting investment disclosure requirements.

Until 1979, investment in limited partnership venture capital funds was restricted to a limited number of institutions and wealthy individuals. In that year, changes to U.S. Department of Labor regulations opened up venture fund investment to pension funds, a rich new source of capital to fuel new growth.

Venture capital is not equally available to entrepreneurs in all countries. The U.S. venture capital pool remains the largest in the world by either absolute size or relative comparison to other economic data. In 1995, the ratio of the venture capital pool to the size of the economy was 8.7 times higher in the United States than in Asia, and 8.0 times higher in the United States than in continental Europe (Gompers & Lerner, 1999a, p. 326). In 2001, 62% of global private equity⁹ was invested in North America, 21% in Western Europe, 12% in Asia Pacific, 2% in the Middle East and Africa,

⁷ A closed-end fund is a mutual fund whose shares are issued initially and subsequently trade on an exchange much like common shares. Because of their liquidity, securities regulation did not preclude them being marketed to average investors—this fact led to brokers too commonly selling them to investors not really suited to their high risk (Gompers & Lerner, 2001a).

⁸ The SBIC program was set up by the American federal government to encourage the development of venture capital for innovation after the shock of the Soviet launch of the Sputnik satellite in 1957. The program, however, was badly designed and the organizational form is no longer significant (Gompers & Lerner, 2001a).

⁹ Statistics on global private equity are more widely available and better standardized than international venture capital statistics. Private equity includes venture capital, buyout funds, mezzanine debt funds, and special situation funds. Venture capital is a substantial component of private equity. In the United States in 2001, the \$59.7B pool of private equity included \$41.9B of venture capital.

and less than 1% in Central and Eastern Europe (PricewaterhouseCoopers, 2002). Table 1 ranks the top twenty countries for disbursements of private equity investment.

Table 1. Global private equity investment (2001).*

Rank	Country	Investment (US\$B)
1	USA	59.7

Timing is significant—the supply of venture capital money and the willingness of venture capitalists to invest are strongly dependent on the state of the equity markets and other market forces (Sahlman, 1990b). Over the long run, the pool of venture capital, and venture disbursements to portfolio firms, have grown significantly (see Fig. 1). Disbursements from U.S. venture funds have grown from just over US\$1B in 1981 to nearly US\$42B in 2001, a compound annual growth rate of nearly 19%. The cyclical fluctuations can be very large—disbursements in 2000, the peak year for venture capital, exceeded US\$100B. While U.S. 2001 venture capital investment declined sharply from 2000 levels, 2001 was still the third-highest disbursement year in the history of the industry, trailing only the two exceptional preceding years. Internationally, the recent declines were less precipitous, with Canadian disbursements declining 27% in 2001 compared to the 65% decline in the United States. Periods with a rapid increase in capital commitments favor the entrepreneur, with less restrictive partnership agreements, larger and more frequent investments in portfolio firms, and higher valuations for investments (Gompers & Lerner, 1999a, p. 326). Periods of decline reduce the supply of VC money and favor the venture capitalist.

At the time of this writing, the technology industry is in a downturn following an exceptional period of record fundraising, IPOs, and acquisitions. Technology spending by businesses, the target customer base of many technology ventures, is in decline. Market

evaluations of technology firms are low. Based on data from the first three quarters, U.S. disbursements in 2002 are expected to further decline from 2001 levels. Such 'boom and bust' cycles are not new. VC disbursements previously declined in the late 1970s, and again in the mid-1980s. Figure 2 expands the ten-year period between 1982 and 1991 to illustrate the depth and duration of the previous disbursement decline.

Despite impressive long-term growth, venture capital remains a very small fraction of the total equity markets. Gompers & Lerner (1999a) estimate that in the United States, there are a hundred dollars of publicly traded equity for every dollar of venture capital.

Venture capitalists strongly favor particular high-growth, technology industries. Tables 2 and 3 show the distribution of U.S. venture capital investment across industry classification.¹⁰ In 2001, nearly three-quarters of total venture capital disbursement dollars went to firms in only six of the seventeen industries classifications: *software* (20%), *telecommunications* (15%), *networking and equipment* (14%), *retailing and distribution* (10%), *biotechnology* (8%), and *Information Technology services* (7%). The retailing and distribution category includes traditional 'brick and mortar' retailing as well as Internet businesses; the other five categories are exclusively technology industries. In the

most recent data available at the time of this writing, 55% of U.S. venture capital investment was awarded to Internet-related businesses, including E-commerce, Internet software, services and tools, hardware, and infrastructure.¹¹

These tables also demonstrate the short-term trends common in venture capital investment. As an example, consider the retailing and distribution category. During the height of the dot-com boom of 1999 and early 2000, the fraction of venture money invested in retailing rose from typical levels of 5–10%, to 23% and 18% respectively, as venture firms invested heavily in e-commerce. In 2001, the fraction of venture investment in retailing had returned to 10%.

According to Zider (1998):

The myth is that VCs invest in good people and good ideas. The reality is that they invest in good industries. Regardless of the talent or charisma of individual entrepreneurs, they rarely receive backing from a VC if their businesses are in low-growth market segments.

Tredennick (2001) summarizes this differently:

Vcs either all fund something or none of them will. If you ride the crest of a fad, you've got a good chance of getting funded. If you have an idea that's too new and different, you will struggle for funding.

¹⁰ The seventeen industry classifications are defined by the PricewaterhouseCoopers/Venture Economics/National Venture Capital Association MoneyTree Survey.

¹¹ From the MoneyTree survey, Third Quarter 2002, \$2464.1M of 4475.9M total VC investment in Q3 2002 was disbursed to Internet-related businesses.

Venture capitalists strongly favor particular geographical regions. Figure 3 shows the distribution of U.S. venture capital by state. In the United States, venture capital investment is strongly concentrated in Cal-

ifornia (particularly in Silicon Valley, Orange County, and San Diego) and Massachusetts (particularly near Route 128 that circles Boston). In the third quarter of 2002, these two states together represented over half of

Figure 3. Venture capital investment by region (U.S. only).

all U.S. venture capital investment.¹² There appear to be two closely related factors to explain geographical clustering.

First, venture capitalists tend to invest close to home. In the United States, venture capital firms are highly clustered in California and Massachusetts.¹³ Lerner (1995) reports that over half the venture-backed firms in a biotechnology sample had a venture director with an office within 60 miles of their headquarters. Powell et al. (2002) reports that more than half of all U.S. biotech firms received locally based venture funding between 1988 and 1999.

Second, regions with large venture capital activity develop *agglomeration economies* that further favor

¹² From the birth of the VC industry, venture capital has favored California and Massachusetts. In the third quarter of 2002, California and Massachusetts respectively captured 41% and 11% of U.S. venture capital investment. In the late 1960s, Silicon Valley and Route 128 had similar levels of both high-tech employment and venture capital investment; today, Silicon Valley has significantly outpaced Route 128. For a history and analysis of regional advantage, see Saxenian (1994).

¹³ Nearly 40% of U.S. venture capital firms qualifying for the 2002 MoneyTree Survey had head offices in either California or Massachusetts (251 of 668 VC investment firms). Ten more firms had offices in the New England area close to Massachusetts.

venture capital through a virtuous circle of improved process efficiency. Intermediaries familiar with the workings of the venture process, particularly lawyers, accountants, and real estate brokers, reduce the transaction costs associated with forming and financing new firms (Gompers & Lerner, 1999b).

Each venture capital firm has a style and character unique to itself (Nesheim, 2000, p. 187). Firms differ from one another by reputation, age, experience of the general partners, preference for lead or follow-on investment, and their record of past success. Many choose to specialize in a particular industry (such as telecommunications or biotechnology), or a particular funding stage (seed, early or late-stage investments). A few firms can boast of significantly higher performance. According to Nesheim (2000, p. 180), while approximately 60% of funded firms go bankrupt, several VC partners claim to have one-third to one-half fewer bankruptcies per portfolio company. The IPOs of firms backed by VCs with strong reputations attract higher quality underwriters and are more widely held by institutional investors (Megginson & Weiss, 1991).

The Venture Capital Investment Cycle

In the dominant limited partnership form, a venture capital firm sets up one or more separate investment funds as limited partnerships. The firm becomes the

general partner in these funds and then sells units of interest in these funds to limited partners (wealthy individuals, pension funds and corporate investors).¹⁴ The VC firm manages these funds as a general partner. A condition of limited partnership is that the limited partners play no role in managing the funds. When opening a fund, a VC firm will specify both a subscription target and an investment policy for the fund.

Limited partners pay VCs annual ‘carrying’ or management fees generally between 1% and 3% of the their investment. Once a fund is terminated (usually within ten years), the general partner receives ‘carried interest’ of around 20% (Gompers & Lerner, 1999b) of the capital gains realized by the fund over its lifetime with the limited partners receiving the rest. It is only at fund termination that the limited partners realize liquidity on their investment. A VC firm opens and terminates different funds, some appealing to retail investors and others to institutional investors, on a regular basis.

Note that VCs do not participate directly in losses although losses certainly lead to a loss of future business. Bhidé (2000, p. 144) argues that this asymmetry leads VCs to take excessive risk in their investments.

Insiders in the companies in which VCs invest, have tacit knowledge of their opportunities that is very hard to make available to outsiders. Because of information asymmetries and the related lack of ‘efficient pricing’, venture capital investing is very labor intensive. VC firms do not handle the volume of invested funds regularly handled by fund managers of liquid established stocks. \$100 million is large for a VC firm, whereas funds over a \$1 billion are common for liquid investments. As a result the fees charged to investors by VCs are correspondingly higher (Lerner, 1995; Sahlman, 1990a, p. 508).

Once the venture capital firm has received money from subscription to a fund, it sets about investing the funds. This process of raising money, and then placing it, creates a time lag that has given venture capital firms significant difficulties in recent years. Firms raised funds during good years for investing, and then when markets turned down in 2000 and 2001 they did not have good opportunities in which to invest. As a result, many firms had significant ‘overhang’ during this period. Some even returned funds to investors—a very costly proposition.

The investor returns on a venture capital fund are typically generated by a small fraction of their investments. One study of venture capital portfolios reported that about 7% of investments accounted for

more than 60% of the profits, while fully one-third resulted in a partial or total loss (Bhidé, 2000, p. 145). Such skewed returns across the portfolio have been an attribute of venture capital investing throughout the history of the industry. ARD, the first professionally managed VC firm, generated over half of its annualized rate of return from a single \$70K investment in Digital Equipment Corporation (out of total investments of \$48M).¹⁵

Venture Capital’s Role in New Venture Financing

When thinking about venture capital’s role in innovation, keep in mind the relatively small percentage of innovative start-up companies that use venture capital during their development.

The Financing Sequence

For those start-up companies that do have business models that require significant up-front expenditures on product/service development and business infrastructure creation, the normal sequence of equity financing is as follows:

(i) Personal funds of the entrepreneurs

The entrepreneurs who start a company are the first to invest in the company. This may be a significant amount in the case of a company started by entrepreneurs successful from previous ventures. Normally, the amounts raised this way will be tens of thousands of dollars. This equity will likely include personal debt raised by these individuals that is invested in the start-up as equity. It may include ‘sweat equity’ in the form of under-compensated work. This type of initial investment can extend to employees as well. The proposition becomes: ‘If you think that a job here is attractive, you should want to invest in the opportunity’.

(ii) Friends and family funds

A new venture will seldom be able to proceed to raise equity investments from organized sources if it is not able to raise equity from the friends and family of the founding entrepreneurs. The ability to go to friends and family and convince them to invest is regarded as a sign of commitment by the founding entrepreneurs to a real, quality opportunity. The family and friends round is again likely to be in the tens of thousands of dollars range.

(iii) Angel investors

Angels are wealthy individuals who invest their own money (Fenn & Liang, 1998). They are often entrepreneurs who have been successful in the

¹⁴ A typical distribution of limited partners includes pension funds (50%–60%), endowments and foundations (20%–30%), other financial institutions (6%), and high net worth individuals (4%). Source: Venture Economics.

¹⁵ The twenty-five year annualized rate of return from 1946 to 1971 was 15.8%. Excluding the DEC investment, the annualized rate of return would have been 7.4% (Bhidé, 2000, p. 162).

same area of business as that in which they invest. Angels often keep a low profile in their communities, not wanting to be pestered by start-ups looking for money, but preferring to find investment opportunities through their personal business networks. They usually invest between \$100K and \$500K. Although seldom organized, there are exceptions including the Band of Angels in Silicon Valley, Zero Stage Capital in New England and Purple Angel in Ottawa, Canada.¹⁶ Many more firms receive funding from angels than from venture capitalists, but the level of funding is much lower (Freear & Wetzel, 1990).

Angel investment is important to a start-up for more than the risk capital that angels provide. They often have deep knowledge of the industry and of the entrepreneurs that drive them. As a result, they bring credibility and contacts with their investments. Start-ups that have been financed by angels have a much greater success rate in attracting subsequent venture capital. In a recent questionnaire survey study, Madill et al. (2002) found that “57% of the firms that had received private investor financing also received financing from institutional venture capitalists; only 10% of firms that had not received angel financing obtained venture capital”.

(iv) Venture capital

The minimum amount invested in a venture by organized venture capital companies is generally over a million dollars. On the high side, VC investments up to \$100 million are possible.

VC investments are very commonly *syndicated*—there will be a lead VC that organizes a group of VC firms to invest in a start-up (Lerner, 1994). For example, when the computer security company, Zero Knowledge, went to the venture capital market for financing in 1999, they had serious discussions with 10 venture capital firms in both Canada and the United States. In the end, they raised \$12 million in equity from three American firms: Platinum, Aragon and Strategic Acquisitions.

VC investments are also commonly *staged*, so that multiple rounds of venture capital investment may be required to take an early-stage firm to liquidity (Gompers, 1995). Each funding round is negotiated at the current valuation of the firm, and dilutes the ownership of existing investors.¹⁷

¹⁶ The Purple Angel partners are former executives of Nortel Networks. Purple was the corporate color of Bell-Northern Research, the Nortel research and development subsidiary, until the mid-1990s.

¹⁷ Venture capital investors commonly demand anti-dilution protections on their investments, shifting this burden to founders and other investors.

Staging is a control mechanism that allows VCs to monitor the progress of firms and maintain the option to abandon under performing projects.

Venture capital firms supply many other things to a new venture in addition to financing. Very commonly they bring a deep knowledge of the technologies and markets, and as a result can add significant value in terms of business model and marketing strategy. Some VCs have large networks of contacts—with other investors, customers, potential partners, and managers. These contacts can be of great value to a new venture. Investment in a start-up by a prestigious VC also brings credibility in both the financial and product markets.

(v) Merchant bank financing

As a startup grows and proves its business model, investment risk can decrease. At this point the need for capital can increase substantially. Under these circumstances, a start-up can look to institutional investors called ‘merchant banks’ for financing. Investments at this stage are called late stage venture capital or mezzanine financing. Merchant banks have large amounts of funds available to them, and the lower risk and likely shorter horizon until liquidity of late stage venture financing can be attractive to them. They generally invest in the form of debt, sometimes convertible to equity. As debt investors, one of their principal concerns is that the company has the cash flow to service the debt.

(vi) Liquidity

Venture capitalists look to a liquidity event like divestiture (i.e. acquisition by another company) or an initial public offering (IPO) to cash out. As a result, a venture capital backed new venture must plan and work towards such a liquidity event from the start if they wish to raise venture capital.

In some cases, venture capitalists may exercise control rights to force bankruptcy of an under performing venture. This may allow the VC to recoup some investment through ownership of preferred shares that are paid out before common shares.

The investor view of this financing sequence is shown in Fig. 4, which is an adaptation of the funnel model commonly used in new product innovation management (Wheelwright & Clark, 1992, 111–132).

Opportunities arise out of ideas at the ‘fuzzy front end’ of innovation. Many opportunities enter the funnel; few exit to sustained profitability. The timing in the diagram is meant to be descriptive of common patterns. The line segment marking the timing of venture capital investment is dotted at both ends to indicate the variable entry points of venture capital

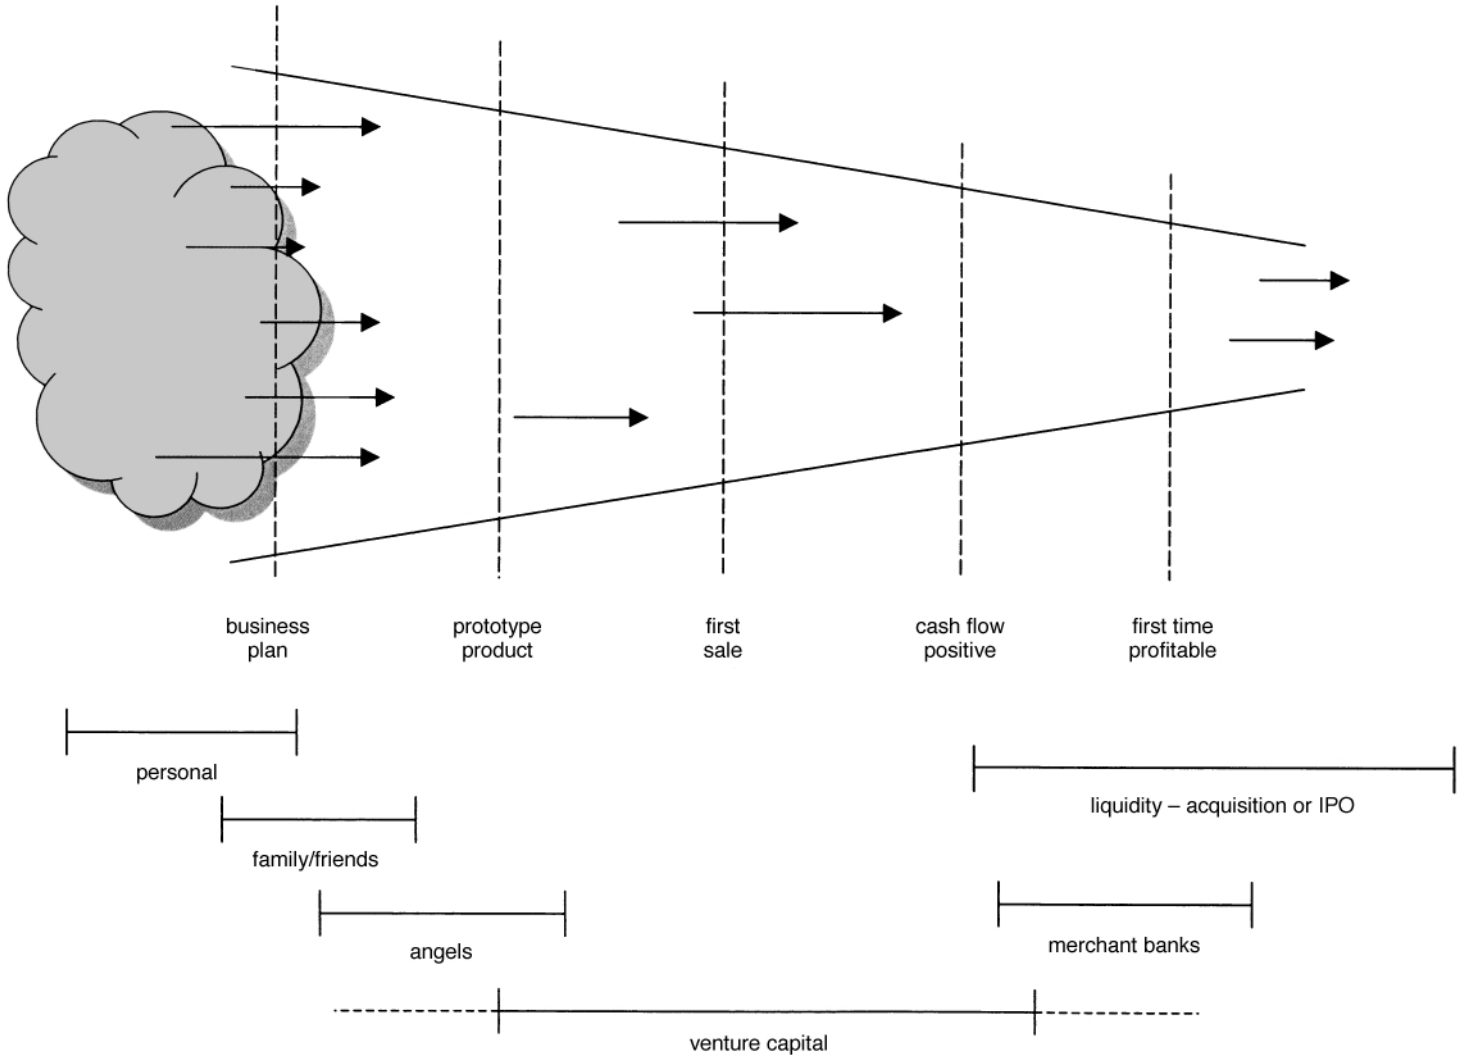

Figure 4. The venture capital investment process.

during different investment eras: for example, very early in 1998 and 1999, and much later in 2001 and 2002.

New venture opportunities emerge from the 'fuzzy front end' propelled by the drive, and personal funds, of the entrepreneurial team. As they enter the funnel, opportunities proceed through standard milestones such as having a business plan, having a prototype of their product or service, making a first sale, becoming cash flow positive, and reaching profitability. At each stage, a portion of these opportunities fail—the narrowing of the funnel represents the attrition of opportunities. Early stage investors regard success as having an opportunity exit the funnel through a liquidity event, at which time they can cash out. Very few startup ventures ever reach a VC satisfying exit like divestiture or IPO.

The Venture Capital Investment Process

Table 4 outlines the main stages of a model of the venture capital investment process (Tyejee & Bruno, 1984). The model was developed on the basis of a questionnaire survey of 87 U.S. VCs and comments received from managers of seven of them. Tyejee and Bruno make an important point about their results:

The diversity of the responses, both in content and style, demonstrates the heterogeneity in practices of different venture capital firms. This heterogeneity cautions against too rigid a specification in any model describing venture capital management.

Tyejee & Bruno's model was corroborated by Sweeting (1991) for U.K. venture firms.

Venture capital firms are interested in learning early about potential investments, and use their personal networks to locate such opportunities. In rare instances, a venture capitalist may become involved in the development of a new venture before it is ready for investments of the size and type appropriate for VCs. More commonly, however, the deals seek out VCs, who often maintain a high profile in their investment community—spending significant amounts of time at business events and conferences. The timing of VC financial entry into an opportunity can depend greatly on the supply of and demand for good opportunities by VCs. During the bubble years of 1998 and 1999, very early entry—before real sales—was the norm. Since the bubble burst in 2000, many VCs have been investing more conservatively and later in the opportunity development cycle.

VCS refer to 'deal flow' to describe the flow of investment opportunities that they see. Deal flow is the lifeblood of a VC firm. Because they normally see so many business plans, they have tough filters to control their workload. Of the business plans that they see, they finance only a very small percentage (Nesheim, 2000). Just reading a business plan can take hours, and VCs can receive hundreds per month. Some VCs do not accept any unsolicited business plans. They do take seriously, business plans brought to them by personal contacts and individuals that they know and trust (Shane & Stuart, 2002). This is one of the reasons that angel investment can be so important for a new venture intent on raising venture capital. A well-connected angel can personally introduce the founding entrepreneurs and their business opportunity to potential VC investors (Fenn & Liang, 1998).

Table 4. A processual model of U.S. venture capital fund activity.

Stage	Features
I. Deal origination	<ul style="list-style-type: none"> • Most deals are referred by third parties. • Referrals by other VCs are often invitations to join syndicates. • VCs are rarely proactive in searching out deals.
II. Deal screening	<ul style="list-style-type: none"> • Most frequently used screening criteria are: technology and/or market; stage of financing.
III. Deal evaluation	<ul style="list-style-type: none"> • Decision to invest based upon expected return compared with level of risk. Factors considered include: <ul style="list-style-type: none"> Market attractiveness Product differentiation Management team capabilities Protection of business from uncontrollable factors, e.g. competition, product obsolescence.
IV. Deal structuring	<ul style="list-style-type: none"> • VC funds use a wide range of approaches. An aim can be to help motivate managers to perform. • Price can be determined by: quality of opportunity; past experience with similar deals and so on.
V. Post-investment activities	<ul style="list-style-type: none"> • Venture funds provide management guidance and business contacts. • Representatives of venture funds normally sit on boards of operating businesses; they assist with development of business strategy. • Venture fund representatives can act as 'sounding boards' for operating business management.

Source: Sweeting (1991, p. 603).

VCs screen deals initially based on such factors as investment stage, investment size, industry sector and geography. If a deal gets through this screening, the first questions asked of the entrepreneurs driving an opportunity are of the form, “So what? Who cares? Why you?”¹⁸ In other words: What is the core of the opportunity and why is it important? Who are the customers and what value is the start-up going to provide to them? And, what competitive advantage does the start-up bring to the table that will ensure that they can make money with the opportunity? Subsequent discussions elaborate on these themes. The decision criteria that VenGrowth uses in evaluating opportunities are the following: people, market, customer traction, competition, product idea, technology and timing. Other VC firms may have somewhat different criteria, but the core elements—experienced managers,¹⁹ proprietary products, minimum investment thresholds, and extensive due diligence—are fairly uniform across VC firms (Bhidé, 2000). The research on venture capital deal evaluation is surveyed in a later section.

If a VC is still interested in investing after reviewing the company’s business plan and talking with the principals, the VC will issue a term sheet to the company. This term sheet outlines what the VC sees as the basis for a financing deal. If the company accepts the term sheet, then *due diligence* by the VC begins in earnest on the company, the entrepreneurial team, and the opportunity. During this period of due diligence, the company is normally restricted from ‘shopping the deal around’ to other investors—in a sense, acceptance of the term sheet gives the VC an option to invest. This due diligence period can last several months, and is always a period of high stress and high cost in terms of management attention for the company.

Valuation of a startup, required as part of any deal, is a complex task (Timmons, 2001, Ch. 14). Quantitative models are used—multiples of sales, discounted multiples of future earnings, comparison with previous and concurrent deals, previous valuations at angel seed rounds—but many of the factors are qualitative. Qualitative factors focus on the match between what is required to be successful and the strength of the core management team, and of future market and technology trends.

Structuring the deal is the last stage before closing the investment. A good deal structure is one in which the goals of the VCs and of the entrepreneurs are

aligned to the greatest extent possible. Important considerations include the equity share allocated to each party, the investment instruments used, and the staging of disbursements to the company.

The investment instruments used in VC deals have changed over the last few years. In the past, it was usual for VCs to purchase common shares of the companies in which they invested. They became investors on the same level as the founding entrepreneurs, family and friends, and angels. In the last few years, VCs have taken to insisting on convertible preferred shares and the senior liquidation rights that come with them (Kaplan & Stromberg, 2000a). These shares generally have minimum conversion values of two to three times the original sums invested. This means that when a liquidity event occurs, the VCs get paid before the common shareholders at a minimum payout that is a multiple of their initial investment. These are very tough terms.

When a deal has been signed, the start-up firm gets a check for the initial ‘tranche’ of the VC funds to be invested. It is rare for the full deal amount to be paid in one lump sum.²⁰ As part of the contract, the start-up must meet defined milestones to get successive tranches of the deal. These milestones take a variety of forms such as product development events, hiring key personnel, and meeting sales targets.

VCs are very active investors. Commonly, they participate as active members of the board; recruiting management and key technical personnel; developing business strategies; monitoring the company’s performance; and facilitating subsequent financing rounds (Kaplan & Stromberg, 2000b). VC firms have even been known to function much like the chief financial officers of their client companies if these companies do not yet have adequate internal financial controls and competencies. This is usually short lived, however, and a VC will actively aid in recruiting such competencies for a company. VC-financed firms are more likely and faster to professionalize by adopting stock option plans and hiring external business executives, such as a vice-president of sales, or an external CEO (Hellman & Puri, 2000b).

As stated earlier, VCs will only invest in an opportunity if there is a good likelihood of some liquidity event within their five to seven year investment horizon.

Corporate Venturing

Corporations have also experimented with funding innovation directly through corporate venturing programs that seek to emulate the venture capital industry. The popularity of corporate venturing appears to rise and fall in approximately ten-year cycles with the

¹⁸ These questions have actually been copyrighted by an Ottawa consulting company, Reid-Eddison.

¹⁹ There is a saying in the venture capital community that ‘the three important things about a deal are people, people and people’. A variation on this is that ‘the five most important things about a deal are people, people, people, market and product’. Good people will find good opportunities, and more importantly, be able to execute on them.

²⁰ This was not the case during the Internet and dot.com ‘bubble’ when VCs commonly paid out the full amounts of an investment stage in one check.

venture capital industry and the broader equity markets (Block & MacMillan, 1995). Activity peaked in the late 1960s (Fast, 1978), mid-1980s (Yost, 1994) and late 1990s, declining again each time at the next market downturn (Chesbrough, 2000).

Corporate venturing includes 'intrapreneurship' programs to incubate and spin-off new entrepreneurial firms from within the corporation, as well as corporate venture capital funds (CVC) that invest corporate money directly in external start-ups in exchange for equity and control rights.

Examples of corporate venturing programs include *Xerox Technology Ventures* (1989–1995) documented by Hunt & Lerner (1995), Chesbrough & Smith (2000), and Chesbrough & Rosenbloom (2002); the *Lucent New Ventures Group* documented by Chesbrough & Socolof (2000); and the *Nortel Networks New Business Ventures* program (1997–1999), documented by O'Connor & Maslyn (2002), Leifer et al. (2001) and Hyland (2002).

Corporate venturing can provide favorable returns when compared to the returns from independent venture funds. During its eight-year lifetime, the \$30M XTV fund invested in over twelve ventures, delivering capital gains of \$219M. Hunt & Lerner (1995) estimate that \$175M returned to Xerox, suggesting a 56% internal rate of return compared to a mean net return of 13.7% by independent VC funds over the same time period. Nonetheless, the program was discontinued,²¹ underscoring the significant challenges of fostering entrepreneurship within large corporations.

Chesbrough's (2000) survey of the corporate venturing literature identifies several specific challenges that these initiatives face, including *adverse selection*, *resource allocation conflicts*, *conflicts of interest* between the new venture and parent sponsor, and potential *conflict of objectives* between financial and objectives.

Von Hippel (1977) identified the problem of adverse selection. Over time, the best performing ventures either spin-off or migrate to other divisions, leaving the corporate venturing organization with the under performing ventures. Fast (1978) noted that managers of established businesses can view successful corporate ventures as threats which compete for scarce resources. Rind (1981) explored possible conflicts of interest within new venture organizations between the success of the parent sponsor and the success of the new venture. The sponsor may constrain the marketing options of the new venture in order to prevent competition with existing businesses. Siegel & MacMillan (1988) explored the potential conflict between two frequently cited rationales for new venture businesses. *Strategic* investments seek to

exploit the potential for additional growth latent in the parent sponsor—in other words, improve the performance of existing businesses. *Financial* investments aim to create additional revenue and profit in the new venture itself. According to Siegel et al., parental intervention to align the venture with strategic interests reduces the autonomy of the new venture, and likely reduces financial performance.

Chesbrough (2000) proposes that corporate venture structures and venture capital structures have some significant differences. Compared to venture capital, corporate venturing provides weaker incentives for success, weaker financial discipline on the downside (i.e. slower to terminate under performing ventures), internal (rather than external) monitoring, and constraints on the discovery of alternative business models (Chesbrough & Rosenbloom, 2000). Potential advantages include longer investment time horizons (unconstrained by the fixed lifetime of a VC fund), larger scale of capital investment, management of strategic complementarities, and the retention of group learning. Chesbrough argues that for corporate venturing to succeed and persist through the less exuberant market cycles, it must leverage these potential advantages to deliver strategic benefits to the sponsoring firm.

Von Hippel (1977) showed that corporate ventures were more likely to succeed when the parent firm had significant prior experience in the target market. Experience with the technology, however, did not correlate to increased likelihood of success. Athey & Stern (1997) introduced *complementarity*—the notion that corporations can benefit from closely related activities. Research suggests that intrapreneurship and CVC programs are both more effective when investing in businesses that are closely related to the core competencies of parent. In a comparison of VC and CVC investments, Gompers & Lerner (1999c) found that corporations may be able to select better ventures using information from their related businesses and provide greater value to those firms once the investments are made. CVC programs without a well-defined strategic focus have less investment success and less stability than well-defined programs. Likewise, the successful investments of the Xerox Technology Ventures program were concentrated in industries closely related to corporate parent's business (Hunt & Lerner, 1995).

Venture Capital Decision Criteria

Early venture capital studies established that venture capitalists make investment decisions based on analysis of financial fundamentals rather than intuition or 'gut feel' (Pence, 1982). Subsequent work has made progress towards elucidating the details of this process.

MacMillan et al. (1985) conducted a frequently referenced study on the decision criteria of U.S.

²¹ For an analysis of the motivations behind this decision, see Hunt & Lerner (1995).

Table 5. Opportunity evaluation criteria.

Criteria	Percent
Capable of sustained effort	64
Thoroughly familiar with market	62
At least 10× return in 5–10 years	50
Demonstrated leadership in the past	50
Evaluates and reacts well to risk	48
Investments can be made liquid	44
Significant market growth	43
Track record relevant to venture	37
Articulates venture well	31
Proprietary technology	29

venture capital firms. The criteria most frequently rated are shown in Table 5.

The quality of the people is the most important factor; six of the top ten criteria in Table 5 relate to characteristics of the founding entrepreneurs. Experienced founders significantly increase the attractiveness of a venture (Bhidé, 2000). Having people on the team that ‘have done it before’—that is, who have previously built a start-up opportunity to create shareholder value—is regarded very positively by VC investors.

Other considerations include the size and accessibility of the total available market, the growth rate of this market, customer traction, and the technology of the product. Customer traction is highly valued and paying customers are best. VCs typically bring in resident or contract technical experts to evaluate the product design and technology. They also interview prospective customers.

Kaplan & Stomberg (2000b) analyzed investment memoranda and subsequent status reports from ten VC partnerships for 58 investments in 42 portfolio companies. Their results confirm that VCs expend a great deal of time and resources evaluating and screening transactions. VCs explicitly consider the attractiveness of the opportunity (market size, strategy, technology, customer adoption, and competition) and risk. Management risk is cited in 60% of sample investments, most often related to a need to complete the team with seasoned executives. Management risk is correlated with contract restrictions (particularly voting and board seats) and cash flow restrictions based on performance. The early appraisal of the management team was related to subsequent performance; in particular, portfolio companies with strong management teams were more likely to go public.

Shane & Stuart (2002) studied the social capital of company founders. New ventures with founders having direct and indirect relationships with venture investors were more likely to receive venture funding and less likely to fail. They conclude that founder social capital represents an important endowment for early-stage organizations. Either the venture capital decision

criteria are partially subjective or they objectively place value on established relationships beyond that observed in previous studies.

Shepherd & Zacharakis (2002) suggest that research into decision aids can potentially improve the venture capital decision process, decision accuracy, and speed up the acquisition of expertise. This is a promising avenue for future research.

The Venture Capitalist—Entrepreneur Relationship

There has been a significant amount of research done on the venture capitalists entrepreneur relationship.²² Frequent calls are heard for more since the area is one of great importance (Sapienza & Korsgaard, 1996; Steier & Greenwood, 1995). The theoretical frameworks used for most of this research have come from economics—for example, agency theory and incomplete contracts.²³ These economic theories focus on the natural conflicts that exist between investors and entrepreneurs, and remedies based on factors such as governance structure, restrictive covenants, stage disbursement of funds and investor oversight (Giudici & Paleari, 2000).

The usual application of agency theory to the venture capitalists—entrepreneur relationship models the venture capitalist as the principle and the entrepreneur as his agent. Once the venture capitalist invests in a new venture, he or she is interested in financial success that results in an early liquidity event such as acquisition or IPO. The entrepreneur shares this objective to a certain extent but has other interests as well such as compensation, management perks, career, survival of the business, and building the business beyond liquidity.

Just differences in risk exposure can lead to significant agency type conflicts. Venture capitalists are relatively well diversified as investors; entrepreneurs are not. Based on financial theory, this means that venture capitalists are concerned with systematic risk related to the market as a whole, whereas entrepreneurs are concerned with the total risk of their investment in their venture. Callahan & Sharp (1985) show analytically that this difference in risk exposure leads to growth objectives that differ between entrepreneurs and venture capitalists.²⁴ As part of their model,

²² (Bhidé, 2002; Baker & Gompers, 1999; Bratton, 2002; Gifford, 1997; Gompers, 1999; Gompers, 1995; Gompers & Lerner, 1996; Jog et al., 1991; Kaplan & Stromberg, 2001, 2002; Lerner, 1995; MacMillan et al., 1989; Steier & Greenwood, 1995; Sahlman, 1990; Sapienza & Korsgaard, 1996; Sweeting, 1991; Sweeting & Wong, 1997.)

²³ The first important article on agency theory was Jensen & Meckling (1976). See Hart (2001) for recent review of the agency theory literature. See Hart & Moore (1990) for an introduction to incomplete contracts.

²⁴ Callahan & Sharp’s simple analytic argument is excerpted and shown in Appendix A.

Callahan & Sharp also show that conflicts between entrepreneurs and venture capitalists are likely to arise over such issues as managerial compensation and perquisite consumption. Jog et al. (1991) showed these conflicts to exist empirically using a questionnaire survey of Canadian VC partners.

The book, *The Venture Capital Cycle*, by Gompers & Lerner (1999) contains excellent examples of research on the venture capitalist—entrepreneur relationship based on agency theory. In Chapter 7, Why are Investments Staged?, they conclude that VCs stage their investments in new ventures because of a concern that entrepreneurs with inside information will continue spending investor money even when faced with losing prospects because they stand personally to lose salary, perks, and reputation. In Chapter 8, How Do Venture Capitalists Oversee Firms?, they examine the role of VCs as directors of their portfolio companies. They conclude that the representation of VCs, unlike outside board members, increases around the time of CEO turnover.²⁵ They also find that geographic proximity is important for VC board members. In Chapter 9, Why Do Venture Capitalists Syndicate Investments?, they find that established VCs syndicate with each other in first round financing. In subsequent rounds, they involve less-established VCs. They attribute these results to the uncertainty in the first round—having another established VC also willing to invest is an important decision factor. They also find support for the contention that syndication is a way around the unfair information advantage that would accrue to the lead VC in subsequent rounds, that will probably demand syndication because of amounts of money required, if they go in alone at first.

Procedural justice theory provides another theoretical framework for Sapienza & Korsgaard (1996) to examine entrepreneur—investor relations.²⁶ They carried out two studies: a simulation study using students and a survey questionnaire study of VC partners. Their principle conclusion is that ‘timely feedback promoted positive relations between entrepreneurs and investors’. They suggest that entrepreneurs yield a level of control and share information so that investors will eschew monitoring, and trust and support the entrepreneurs. This suggestion is congruent with advice that comes from agency theoretic analyses of the venture capitalist—entrepreneur relationship.

Game theory also provides a different perspective on the venture capitalist—entrepreneur relationship. Cable & Shane (1997) use a prisoner's dilemma

approach to develop a number of testable hypotheses that emphasize the cooperative alternatives to mutual value creation by venture capitalists and entrepreneurs. This perspective builds on Timmons & Bygrave's (1986) finding that “an ongoing cooperative relationship between entrepreneur's and venture capitalists is more important to the performance of the venture than the provision of venture capital itself” (Cable & Shane, 1997, p. 143). Cable & Shane (1997, p. 168) maintain that:

Modeling venture capital relationships as a principal-agent problem appears unduly restrictive given the potential for opportunistic, non-cooperative actions by venture capitalists as well as entrepreneurs. For example, while the agency approach focuses on venture capitalists' adverse selection problem when evaluating entrepreneurs, an adverse selection problem also exists for entrepreneurs since they must locate venture capitalists who can provide complimentary managerial experience, access to relevant networks, and legitimacy.

Two recent empirical papers (Schefczyk & Gerpott, 2001a; Schefczyk & Gerpott, 2001a) have referenced Cable and Shane's paper but do not build specifically on their hypothesis structure.

Shepherd & Zacharakis (2001) emphasize the necessity of a balance between trust and control in the venture capital—entrepreneur relationship. They propose that the entrepreneur can

build trust with the VC (and vice versa) by signaling commitment and consistency, being fair and just, obtaining a good fit with one's partner, and with frequent and open communication.

They regard their study as a counter weight to economic approaches like agency theory in which control is emphasized.

Venture Capital and Innovation

Does venture capital foster innovation? There are three popular arguments:

- (1) venture capital unleashes innovation. VCs free innovative firms from capital constraints and add genuine value that helps them become successful;
- (2) venture capital is neutral to innovation. VCs identify the best new ventures, and are the intermediary gatekeepers for funding;
- (3) venture capital stifles innovation. VCs back only conventional ideas. Unconventional innovative ventures are screened out as too risky, and never receive funding.

The research to date is inconclusive. The jury is still out on this very important question.

The venture capital research is clear in one regard—VC-backed firms are more successful than non-VC backed firms, both before and after IPO. Venture-

²⁵ A similar conclusion is drawn by Gabrielson & Huse (2002).

²⁶ Procedural justice theory (Lind & Tyler, 1988) examines the impact of the *process* of decision-making on the quality of exchange relationships. See De Clercq & Sapienza (2001) for a theoretical application of both agency and procedural justice theories to venture capitalist—entrepreneur relationships.

backed firms bring product to market faster (Hellman & Puri, 2000b), ‘professionalize’ earlier by introducing stock option plans and hiring external business managers (Hellman & Puri, 2000a), time IPOs more effectively to the market (Lerner, 1994), and have higher valuations at least five years after IPO (Gompers & Brav, 1997). Venture-backed IPOs pay lower fees and are less under priced. (Megginson & Weiss, 1991).

Causation, however, is more difficult to establish. Do venture capitalists add value that makes it more likely for their portfolio firms to succeed, or are they simply good at picking winners?

Research suggests that VCs do have some impact on their portfolio firms. Hsu (2000) compares a group of VC-backed start-ups with a control group of start-ups that obtained government funding through the U.S. Small Business Innovative Research (SBIR) program, which does not impact ownership or governance. The study concludes that venture capital changes the path of funded projects, by altering the commercialization strategy and making the firm more sensitive to the business environment.

Other studies imply that there are limitations to the value added by VC influence. Ruhnka, Feldman & Dean (1992) investigated the strategies employed by 80 venture capital firms to deal with the ‘living dead’ investments in their portfolios—ventures that were self-sustaining but failed to achieve levels of growth or profitability necessary for attractive exits such as IPO or acquisition. Venture managers were able to achieve a successful turnaround or exit in 55.9% of living dead situations, regardless of the age of the VC firms, their size, or the relative availability of investor personnel for monitoring investees. From the invariance of this result, the authors argue that that causal factors are outside VC control.

Some promising recent work supports the notion of a causal link between VC and innovation. Kortum & Lerner (2000) investigated trends in patent rates as a measure of innovation. Statistical analysis showed that the rate of U.S. patent filing was correlated with early-stage venture capital disbursements, when controlling for corporate research and development expenditures. In particular, the rate of patent applications declined during the 1970s and early 1980s while corporate research and development spending increased steadily. The rate of patent applications steadily increased after 1985, following the rapid rise of early-stage venture capital disbursements in the late 1970s and early 1980s.

Some anecdotal accounts, however, present a different picture. According to Tredennick (2001), venture capitalists and their technical experts actually favor very conventional and proven ideas: “If you step too far from tradition, (the VC) will not understand or appreciate your approach . . . Just as Hollywood would rather make a sequel than produce an original movie,

VCs look for a formula that has brought success”. According to Bhidé (2000):

VC-backed entrepreneurs face extensive scrutiny of their plans and ongoing monitoring of their performance by their capital providers. These distinctive initial conditions lead them to pursue opportunities with greater investment and less uncertainty, rely more on anticipation and planning and less on improvisation and adaptation, use different strategies for securing resources, and face different requirements for success.

Both accounts suggest that the venture capital process may actually screen out the most significant innovations in favor of minor variations of what has come before.

Other research suggests that venture capitalists frequently engage in ‘herding’—making investments that are very similar to those of other firms—or what Tredennick (2001) calls ‘riding the crest of a fad’. Devenow & Welch (1996) show that a variety of factors can lead to investors obtaining poor performance. Social welfare may suffer because value-creating investments in less popular technology areas may have been ignored.

During the Internet and dot-com ‘bubble’ of the late 1990s and early 2000, many startup ventures received large disbursements of very early venture capital funding. Since the collapse of the bubble, anecdotes have emerged describing the destructive effects of such large amounts of early money. The business model of a startup venture is like an untested hypothesis—the real test is making a profit from paying customers. Availability of early money can hide problems in a business by delaying such a test. Some very early stage startups redefined success in terms of financing—achieving the first (or the next) venture capital investment round. Bootstrapping, the creation of a significant business without significant outside financing, is again becoming popular because of the relatively limited supply of venture capital money—and it may not be a bad development. Important bootstrapped success stories include household names like Dell, Gillette, Heinz, HP, Mattel, Nike, Oracle, UPS, and Walt Disney.

The differences between bootstrapped and ‘big money’ startups are summarized in Table 6. Bootstrapping forces focus on cash flow and the immediate needs of customers in niche addressable markets. Freed of cash flow constraints, big money startups can try for highly engineered product ‘home runs’ with a view of striking it rich and cashing out. Big money allows for significant compensation packages, so the personal sacrifice of principals can be very low. When one reads about big money startups, the news all too often centers on their financing progress rather than success with real customers.

Table 6. Differences between bootstrap and big money startups.

	Bootstrap	Big Money
Cash	earn it	other people's
Initial focus	customers	exit
Product	incremental	fully featured
Markets	niche	\$1B
Org. Structure	fluid	rigid
Time Horizon	near term	long term
Media Profile	low	high
Personal Sacrifice	high	low

Source: Presentation by Ken Charbonneau, Partner, KPMG, Ottawa, Carleton University, *Magic from a Hat* entrepreneurship lecture series, November 11, 2002.

In conclusion, venture capital would appear to at least help bring innovation to market. However, the selection process may not always identify and fund the most significant innovations, and especially in times of abundant supply, there may be disadvantages to 'big money'. Over all, venture capital may be a positive force to drive innovation—but the jury is still out.

The substantial body of financial and econometrics research offers few insights on innovation. More work is needed to specifically isolate and disentangle the influence of venture capital from that of other market forces, and relate that influence to innovation and the public good. Anecdotal accounts from seasoned practitioners and observers on possible limitations and drawbacks of venture financing remain untested with accepted research methods.

As Zider (1998) states:

The (venture capital system) works well for the players it serves: entrepreneurs, institutional investors, investment bankers, and the venture capitalists themselves. It also serves the supporting cast of lawyers, advisers, and accountants. Whether it meets the needs of the investing public is still an open question.

Stakeholders and Research

Research on the role of VCs in innovation is carried out because there is a market for it. Researchers are producers. Consumers—the stakeholders in the output—are varied. They include entrepreneurs, venture capitalists, investors, policy makers, and researchers themselves.

Entrepreneurs need guidance on how to:

- approach VCs so as to maximize their chances of getting a good deal;
- appraise and judge VCs one from another;
- negotiate and structure equity investment deals;
- structure the participation of VCs on their boards and manage this participation subsequently;

- maintain control of their companies as they accept outside ownership;
- negotiate and work with VC set milestones;
- get through a liquidity event like an acquisition or an IPO effectively.

VCs are interested in how to:

- find good opportunities;
- screen and appraise good opportunities;
- negotiate and structure equity investment deals;
- support and control client companies;
- terminate client company relationships.

Investors need help in how to:

- judge the investment records of VC firms;
- appraise VC competencies in specific fields of investment;
- appraise the risk/return potential of VC investments;
- negotiate investment terms and covenants.

Policy makers include government officials and participants in quasi-government bodies such as the U.S. Federal Reserve Bank. They need guidance in how to:

- set tax policy;
- regulate investor access to VC funds;
- support VC activity that increases entrepreneurial value creation.

Researchers and educators, mainly in universities, want:

- research tools;
- interesting testable hypotheses;
- theories for creating new testable hypotheses;
- theories for explaining and teaching.

We can see that the interests of these consumer stakeholder groups are not the same.

Most research relevant to the role of venture capital in innovation follows the normal cycle of positivist scientific inquiry developed in the natural sciences: description of some phenomenon; theorizing that results in interesting, testable hypotheses; data gathering based on the hypotheses; hypothesis tests; and then renewed theorizing. Another approach to theory building is qualitative methods (Bailyn, 1977; Schall, 1983). Researchers using this methodology gather large amounts of text data, often interview transcripts, and then analyze the data for generalizable wisdom. They do not build theory in terms of testable hypotheses. Qualitative theory building and theory testing are closely interrelated—rather than being rigidly distinct as in positive theory building and testing. A variant of qualitative method based on case studies (Yin & Campbell, 2002) is used in the initial, descriptive stage of positive theory building.

Most large sample hypothesis tests are cross-sectional. They gather and analyze data on cases at a point in time. As a result there is little evidence of

interrelationships between variables in each case. Such interrelationships are investigated across cases using multivariate statistical methods like regression. Qualitative methods can be used more easily to gather longitudinal data on a case over time. Then variable interactions within a single case can be investigated. Qualitative longitudinal data gathering, however, is very resource intensive. Processual research (Dawson, 1997; Hinings, 1997; Pettigrew, 1997; Woiceshyn, 1997) is one specific form of qualitative analysis.

The total effort of a research study is usually constrained by the availability of some resource like time or money. Given such a constraint, there is a natural trade-off between the number of cases in a sample and the amount of information gathered for each case. When testing hypotheses, it is normal to gather small amounts of very specific data on a large number of cases. Hundreds, even thousands, of cases about which little is known. When using case studies to develop theory rather than test it, large amounts of information are gathered on a very small number of cases. Research studies with one case can be published (Steier & Greenwood, 1995). Nested studies of several cases are more rigorous (Yin & Campbell, 2002) but are rare since they are very resource intensive. Qualitative studies tend to lie between these two extremes—tens of cases with significant amounts of data on each one.

These different research approaches can be complementary, but they appeal to stakeholders in different ways. Investors, policy makers and researchers can be satisfied with averages because they are interested either with long run effects or with large numbers of situations. The covariance-based techniques of large sample statistics can satisfy them. This is not true of entrepreneurs and venture capitalists. A typical entrepreneur would only be involved in a few startup ventures in his or her entire lifetime. Entrepreneurs deal with particular, specific, negotiated situations. They create new ventures, and are seldom interested in averages. In fact, they quite explicitly do not reference their situations to the average. Even venture capitalists deal with few enough investments that they do not really trust in averages or the law of large numbers to assist them. Both entrepreneurs and venture capitalists, as is common for business decision makers, test theories against their experience and intuition rather than using large scale statistical methods. Research must work to assist these decision makers to improve their intuition.

There is a striking lack of research on the role of VCs in innovation that provides rich insights into specific situations, and that can form the basis for effective theorizing as a result. Steier & Greenwood (1995) provide a notable exception. They document in detail the experiences of a single entrepreneurial new venture in the deal structuring and post-investment stages of venture capital involvement. Another is the

Zaplet Inc. case study by Leonard (2001). Leonard describes how the lead VC, Vinod Khosla, played an atypically active—even dominant—role in reformulating the business strategy and management structure of a very early start-up. There is a need for the equivalent of the studies by Burns & Stalker (1994, originally published in 1961) and Poole et al. (2000) that have been carried in innovation. Consider even the book, *Startup*, by Kaplan (1994). The book is a breathless, first person account of the story of GO Corporation, a start-up that tried and failed to develop and commercialize a hand held computer operated with a pen instead of a keyboard in the early 1990s. The book is not research—but the chapter on financing (Kaplan, 1994, pp. 59–81) contains more information useful to an entrepreneur than does the MacMillan et al. (1985) VC decision investment model referred to earlier.

We do not pretend that this call for more qualitative, processual research, and with it better stories, is new.²⁷ It does seem particularly important in the area of venture capital's role in innovation.

Financial Data Sources

The financial and economic data for this chapter was taken from the following sources: global private equity from PricewaterhouseCoopers (2002); venture capital investment in the United States from the *PricewaterhouseCoopers/Venture Economics/National Venture Capital Association MoneyTree Survey*, available online (<http://www.pwcmoneytree.com>), *Venture Economics* (<http://www.ventureeconomics.com>), and the *National Venture Capital Association (NVCA)* (<http://www.nvca.com>); venture capital investment in Canada from *Macdonald and Associates* (<http://www.canadavc.com>); venture capital investment in Europe from the *European Venture Capital Association* (<http://www.evca.com>); venture capital investment in Asia from the *Asian Venture Capital Journal* (<http://www.asiaventure.com>).

Appendix Entrepreneurs and Venture Capitalists: Differences in Growth Objectives

Excerpted from Callahan & Sharp (1985)

The Problem

The typical entrepreneur is not diversified; as far as financial risk is concerned he has most of his personal fortune and human capital in the new venture. As an active manager, he receives a salary and fringe benefits from the company during its start-up and initial stages.

The typical venture capitalist is well diversified financially. Unlike the entrepreneur, he has a financial, rather than a personal relationship with the company. The venture capitalist is interested in the overall performance of a portfolio of investments. He is not an active manager, nor does he want to be involved in day-to-day management. He exerts control by constraint through protective covenants and membership on the board of directors. The typical venture capitalist

receives no immediate cash flow from an investment but rather is interested only in capital gains.

The points of conflict between the entrepreneur and the venture capitalists are twofold:

- (i) the amount of salary and fringe benefits consumed by the manager/entrepreneur; and
- (ii) the growth rate of the company, resulting from strategy decisions that affect growth such as products and markets, pricing and the relative focus or diversification of the company.

We outline a model that illustrates how these two conflicting points of interest arise in a natural and logical way given the differences in diversification of the entrepreneur and the venture capitalist, and the fact that the entrepreneur receives salary and fringe benefits as a manager.

The Model

The complete model comprises three sections:

The Basic Valuation Model

The basic valuation model used is an adaptation of the capital asset pricing model of Stapleton (1971). The basic idea behind Stapleton's model is that the present value of an uncertain cash flow can be considered as the certainty equivalent of the value of the cash flow discounted to the present value at the risk free rate. Stapleton further argues that in a capital asset pricing model world this certainly equivalent is a linear function of the expected value and the standard deviation of cash flow.

In Stapleton's notation, DV is the discounted value operation using the risk free rate. Thus if C is some uncertain cash flow anticipated at time n and I is the risk free rate

$$DVC = C/(1+i)^n \quad (1)$$

The present value of C for a diversified investor is

$$E(DVC) - S \cdot R_{CM} \cdot \sigma(DVC) \quad (2)$$

where R_{CM} is the correlation between C and the return on the market (as defined in the capital asset pricing model) and S is a market determined risk aversion factor. In a sense, $R_{CM} \cdot \sigma(DVC)$ is the relevant risk measure for a diversified investor since he is concerned only with systematic risk, being able to eliminate unsystematic risk through diversification. For an undiversified investor though, the relevant risk factor is $\sigma(DVC)$ and the present value of C is

$$E(DVC) - S\sigma(DVC) \quad (3)$$

We shall assume that the company goes public after n periods and that both entrepreneur and venture capitalist can (but do not have to) wind up their positions at this time. We also assume that the net value of the company at this time, V, increase with the average growth rate, g, of the company. This is a weak

assumption implicit in most conceivable company valuation models.

The Entrepreneur Model

We assume that the manager/entrepreneur receives a periodic wage, w, that is not random. It is possible to consider a random wage, or one that is performance related, but that would add little to the analysis. We further assume that the entrepreneur owns a portion α of the equity of the company and that α remains constant. Then the present value of the entrepreneur's claims on the company, V_1 , is a function of g and w given by

$$V_1 = V_1(g, w) \quad (4)$$

$$= w \cdot \{[(1+i)^n - 1]/i\} + \alpha \cdot \{E/(1+i)^n - S \cdot \sigma/(1+i)^n\} \quad (5)$$

$$= w \cdot \{[(1+i)^n - 1]/i\} + \{\alpha/(1+i)^n\} \cdot \{E - S \cdot \sigma\} \quad (6)$$

where E and σ are the mean and standard deviation of V respectively and the relevant risk for the entrepreneur as an undiversified investor is the total risk.

The Venture Capitalist Model

The present value of the venture capitalist's claim on the company, V_2 , is given by

$$V_2 = V_2(g, w) \quad (7)$$

$$= \{(1 - \alpha)/(1+i)^n\} \cdot \{E - S \cdot R_{VM} \cdot \sigma\} \quad (8)$$

where R_{VM} is the correlation between V and the return on the market as a whole given that the venture capitalist is a diversified investor.

The Analysis

Taking partial derivatives we have

$$\partial V_1/\partial w = \{[(1+i)^n - 1]/i\} + \{\alpha/(1+i)^n\} \cdot \{1 - S \cdot \partial\sigma/\partial E\} \cdot \partial E/\partial w \quad (9)$$

$$\partial V_1/\partial g = \{\alpha/(1+i)^n\} \cdot \{1 - S \cdot \partial\sigma/\partial E\} \cdot \partial E/\partial g \quad (10)$$

$$\partial V_2/\partial w = \{(1 - \alpha)/(1+i)^n\} \cdot \{1 - S \cdot R_{VM} \cdot \partial\sigma/\partial E\} \cdot \partial E/\partial w \quad (11)$$

$$\partial V_2/\partial g = \{(1 - \alpha)/(1+i)^n\} \cdot \{1 - S \cdot R_{VM} \cdot \partial\sigma/\partial E\} \cdot \partial E/\partial g \quad (12)$$

We assume that

$$\partial E/\partial w < 0 \quad (13)$$

i.e. the higher the wages paid to the entrepreneur the lower the expected terminal net value of the company. By virtue of our assumption that a higher growth rate increases the expected terminal value of the company, we also have

$$\partial E/\partial g > 0 \quad (14)$$

We shall examine the extent to which the objectives of the venture capitalist and entrepreneur are congruent by considering whether a wage (w) and growth rate (g) exist that simultaneously optimize V_1 and V_2 . Because the power of the venture capitalist at the stage of venture capital financing of the company is usually greater than that of the entrepreneur, we start with the venture capitalist's point of view.

Now the venture capitalist wants values of w and g such that

$$\partial V_2/\partial w \geq 0 \text{ and } \partial V_2/\partial g \geq 0$$

i.e. such that from (11) and (12)

$$\begin{aligned} \partial E/\partial w \leq 0, \{1 - S \cdot R_{VM} \cdot \partial \sigma/\partial E\} \leq 0 \quad \text{and} \\ \{1 - S \cdot R_{VM} \cdot \partial \sigma/\partial E\} \geq 0 \end{aligned}$$

or

$$\partial \sigma/\partial E = 1/\{S \cdot R_{VM}\} \quad (15)$$

In all probability, R_{VM} will be small so that the optimal value of E for the venture capitalist will be large.

For the entrepreneur, if we set

$$\partial \sigma/\partial E = 1/\{S \cdot R_{VM}\}$$

we have from (9)

$$\begin{aligned} \partial V_1/\partial w = \{[(1+i)^n - 1]/i\} + \{\alpha/(1+i)^n\} \\ \cdot \{1 - 1/R_{VM}\} \cdot \partial E/\partial w > 0 \end{aligned} \quad (16)$$

and from (10)

$$\partial V_1/\partial g = \{\alpha/(1+i)^n\} \cdot \{1 - 1/R_{VM}\} \cdot \partial E/\partial g < 0 \quad (17)$$

In other words, when the entrepreneur's wage and growth rate of the company are set at values that are optimal for the venture capitalist, the entrepreneur wants a higher wage and a lower growth rate for the company.

As can be seen there is no prospect of simultaneous optimization of V_1 and V_2 . The values of the growth rate and wage that optimize the venture capitalist's value, V_2 , certainly do not optimize the entrepreneur's value, V_1 .

Equations (16) and (17) present the entrepreneur's view of the dilemma. Equation (16) merely confirms the intuition that the entrepreneur is better off with a higher wage. Equation (17) conceals a little more. Venture capital is most likely to be used as a method of financing for companies in new and innovative industries. There is a case for arguing that the earnings of such industries, unrelated as they are to the mature industries whose earnings represent the bulk of the market index, will show an unusually low correlation with the market index. It is plausible then that the term $1/R_{VM}$ is much greater than 1 so that the term $\{1 - 1/R_{VM}\}$ is considerably less than zero. In other words the optimum growth rate as seen by the venture capitalist is way above that perceived by the entrepreneur as ideal. At a growth rate that appears attractive to the venture capitalist Eq. (17) shows that the value to the entrepreneur is decreasing rapidly.

Encouraging Innovation in Small Firms Through Externally Generated Knowledge

Edward Major¹ and Martyn Cordey-Hayes²

¹ *Bedfordshire Police Force and Middlesex University, U.K.*

² *Cranfield University, U.K.*

Abstract: This chapter examines the conveyance to small firms of externally generated knowledge. Successful innovation requires firms to draw on multiple sources of knowledge. Many small firms take little note of external sources, thus restricting their potential innovative base. We develop the concepts of *knowledge translation* and the *knowledge translation gap* to illustrate why so many small firms fail to access externally generated knowledge. Findings from research into U.K. small firms and national innovation schemes show how intermediary organisations can be used to bridge the knowledge translation gap. Implications follow for government innovation schemes, for intermediaries and for small firms.

Keywords: Innovation; Small firms; External knowledge; Knowledge translation; Intermediaries.

Introduction

The rise to prominence of the field of knowledge management (see Farr, Sin & Tesluk, 2003) gives witness to the centrality of knowledge in fostering innovation. Knowledge underlies innovation. It is the precursor, in many ways the lubricant, of innovation. Firms need knowledge to build innovative potential.

Innovation is 'the introduction of novelties' or 'the alteration of what is established by the introduction of new elements or forms'.¹ It thus concerns introduction and progression rather than invention. Innovation has been adjudged the main determinant by which commercially successful organisations derive competitive advantage (Tidd, Bessant & Pavitt, 1997). Successful innovation must involve several parties. A knowledge source is needed to support the innovating party (i.e. to provide the new invention/idea). Innovation within a firm might be based on knowledge held by that firm. Even so, the source of the knowledge contributing towards an innovation may be separated from the actual innovating party. Alternatively, the innovating firm might need to go to external sources for

the knowledge it needs. In this case the distance between knowledge source and innovating party is increased. For successful innovation, knowledge needs to be successfully conveyed. The conveyance, or transfer, of knowledge forms a third element in the process, between the knowledge source and the innovating party. This chapter considers the conveyance into small firms of externally generated knowledge. It thus compliments Hadjimanolis's study (2003) of the internal and external barriers to innovation that firms face. Understanding this conveyance process has implications both for the presentation of government innovation schemes and policy initiatives and for the small firms themselves.

The chapter begins with a brief discussion of the barriers to innovation in small firms (the innovating party). Consideration then turns to the knowledge sources contributing to innovation. Sources of externally generated knowledge are emphasized, including government innovation schemes and policy initiatives. The concept and models of knowledge transfer provide the basis for examination of the conveyance of external knowledge. The chapter develops knowledge transfer into a model of knowledge *translation* that enables a clear understanding of the conveyance process to be built. Findings are then reported from research into

¹ As defined in the Oxford English Dictionary, Oxford University Press, 1933, reprinted 1978.

small firms and innovation schemes in the U.K. Applying the knowledge translation model to this research reveals how intermediary organizations can be used to reach different *types* of small firms. Implications are drawn for the conveyance process itself, for government innovation schemes and policy initiatives, for intermediaries and for small firms. Recommendations are made which are aimed at enhancing the flow of externally generated knowledge, therefore encouraging successful small firm innovation.

Barriers to Innovation in Small Firms

Statistics show that in 1999, 99.8% of all U.K. businesses employed less than 250 people. These small and medium sized enterprises (SMEs) accounted for 55% of national employment and 51% of national turnover. The 0.2% of businesses rated as *large* contributed less than half of the nation's employment and turnover (Department of Trade and Industry, 2001). Other developed economies are similar. Storey (1994) records that businesses with less than 500 employees account for between 62% and 91% of national employment in all member states of the European Community. Figures for Japan and the United States are of the same order (Small Business Administration, 2000; Storey, 1994). Whichever way they are looked at, small firms make an immense contribution to wealth and employment.

Innovation is favored by the small firms' advantages of flexibility and reduced bureaucracy. But their innovative potential is hampered by inherent problems not faced by large firms. Rothwell & Zegvelt (1982) identify four weaknesses particular to small firms. First, limited manpower restricts their ability to perform competitive R&D. Small firms are likely to have a much lower proportion of their personnel, possibly none, concerned exclusively with R&D than large firms (Storey, 1994). Many small firm personnel have more than one role. Second, small firms have limited time and resources to devote to external communications. This limits the information base from which decisions can be made. Low in-house employment of specialists restricts communication and network formation with outside sources of expertise (Rothwell, 1991). Third, is excessive management influence. Small firms are much more prone to domination by a single manager or team that may use inappropriate skills or strategies. Fourth, small firms can have difficulties raising finance. Financial barriers to innovation in small firms are variously reflected as a lack of capital (Garsombke & Garsombke, 1989; Keogh & Evans, 1999) and unfavorable bank policies on credit (Hadjimanolis, 1999). Small firms of course are varied and different, as will be shown below. Their inherent weaknesses (and advantages) will be present to varying degrees.

Sources of Externally Generated Knowledge

The traditional way for a small firm to build its knowledge base is to generate knowledge internally. Firms use formal and informal research and development to grow their internal knowledge. In this internal process, research may be considered the knowledge source and development the means of conveyance to the firms' innovation centre (its decision-makers). Internally generated knowledge has the advantage of close proximity to the firm's decision-makers. By definition it lies within the firm's boundaries. Of course, close proximity does not ensure that internal knowledge will have any impact. It also suffers from Rothwell & Zegvelt's (1982) first weakness, limited manpower to devote to internal R&D.

By concentrating on internal R&D many firms neglect the role of externally generated knowledge. Small firms, with their limited resources are particularly prone to neglecting external knowledge. They are disadvantaged when compared to larger competitors who may be able to dedicate specific resources to examining external knowledge sources. Woolgar, Vaux, Gomes, Ezingard & Grieve (1998) present a framework showing the environment surrounding a small firm. Their 'SME-centric universe' (Fig. 1) gives the basis for a categorization of a firm's external knowledge sources.

The Immediate Business Environment

Small firms interact most often and most closely with their immediate business environment: their customers and suppliers, and to a lesser extent their competitors. Research has shown that customers and suppliers, the *supply chain*, are always the most extensive and important external contacts that a firm has (Moore, 1996; Woolgar et al., 1998). Customer feedback is a constant source of external information, and therefore potentially usable knowledge. Suppliers can be a major source of component and production knowledge. Competitors, through their behavior, can be a further significant source of knowledge.

Intermediaries

Beyond the immediate business environment, a small firm will have communications with trade associations, colleges and schools, TECs (training and enterprise councils) and consultants, will read the trade press and may attend exhibitions. Other organizations within the business support community can be added: Chambers of Commerce, innovation and technology centres, small business agencies such as the U.K.'s Business Links and USA's Small Business Development Centers, professional institutes and research associations. Here, all of these organizations are grouped under the collective term *intermediaries*. Often a firm's intermediary contacts will be very cursory, where they can provide only a minor source of external knowledge. As

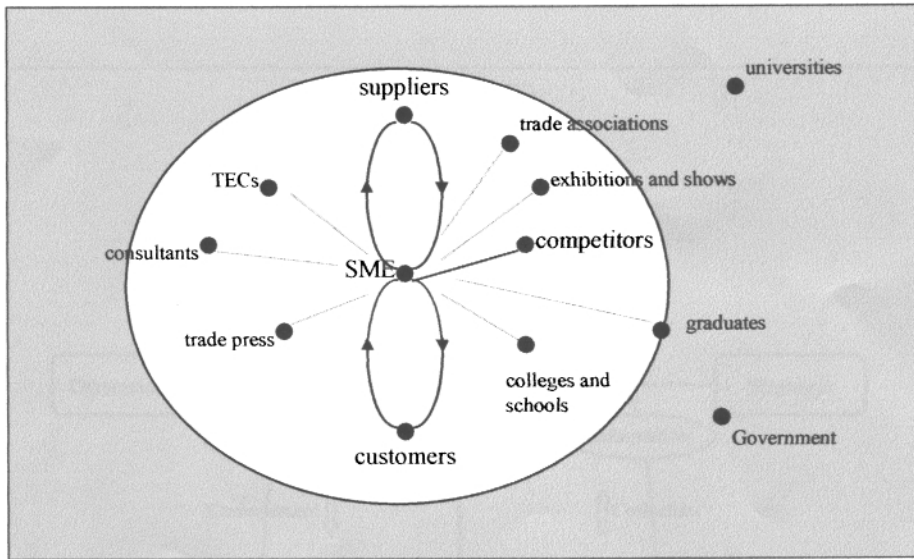

Figure 1. Woolgar et al.'s SME-centric universe.

Source: Woolgar et al. (1998), page 578.

will be seen intermediaries have a significant role to play in conveying externally generated knowledge.

Universities and Outside Research

In Woolgar et al.'s (1998) framework, universities fall well outside of a small firm's focus of attention. Universities are repositories of knowledge and expertise, but partly due to the problems considered above, many small firms have no significant contact with them. Evidencing the differences between small firms, Woolgar et al. (1998) found that those that did have well-developed links with universities had a greater appreciation of external knowledge sources than had those lacking such links.

Governments; Policy Initiatives and Innovation Schemes

Governments, like universities, generally fall beyond a small firm's normal sphere of attention. Governments try to influence small firms through business services, innovation schemes and policy initiatives. The U.K. Government's Small Business Service (SBS) is organized: to help small businesses realize their potential, to enhance small business performance through world class business support, to promote small business enterprise across society and to provide high standard, value for money service (Department of Trade and Industry, 2001). In the USA, the Small Business Administration (SBA) provides financial, technical and management assistance to help Americans start, run and grow their small businesses.

As an example of a national policy initiative, recent years have seen many governments running national *Foresight* programs. These are structured programmes taking a forward look to identify and prepare for emerging trends in markets and technologies in the medium to long term. Foresight activities aim to:

- (a) identify events and seek opinions in order to prioritize future events;
- (b) contribute to the development of a well-informed support environment for resource allocation and funding prioritization; and
- (c) promote cooperation between actors from different fields so as to incorporate a variety of viewpoints (Cabello et al., 1996).

The U.K. Government's national Foresight program was initiated in 1993 to identify emerging technological trends and market opportunities. When applied to individual firms, Foresight is about generating and growing the capabilities to envision and look forward, enhancing the firms' future innovative potential. Government schemes and initiatives have a poor implementation record. For example despite substantial communicative effort, the U.K. Foresight program has had minimal effect on U.K. firms (Major & Cordey-Hayes, 2000a). The small firms' inherent problems discussed above compound the difficulties of distance. Government initiatives and innovation schemes lie outside of the firms' normal sphere of attention in much the same way as the government itself. Many small firms are simply not aware of support services and initiatives.

External Networking

The final external knowledge source is a method rather than a location. An inquisitive manager will search the external knowledge sources, be they in the immediate business environment, intermediaries, universities or government schemes and initiatives. Through this external networking he or she will be better positioned to access new externally generated knowledge.

Conveying External Knowledge

Hadjimanolis (2003) notes that information and knowledge must be transferred throughout a firm, for the firm to learn from it. But externally generated knowledge lacks the advantage of close proximity to the firm's decision-makers. Unlike internally generated knowledge it must first be brought into the firm's internal sphere before it can be used. The growing subject of *knowledge transfer* informs our understanding of how externally generated knowledge is conveyed to the small firm.

The Concept of Knowledge Transfer

The concept of knowledge transfer derives from the field of innovation (Gilbert & Cordey-Hayes, 1996). Knowledge transfer is the conveyance of knowledge from one place, person, ownership, etc. to another (Major & Cordey-Hayes, 2000b).

Any transfer must involve more than one party. There has to be a source (the original holder of the knowledge) and a destination (where the knowledge is transferred to). When used to describe movement of knowledge, the term *transfer* is perhaps inappropriate. As defined, it implies that for the transferred item to be gained by (conveyed to) the destination it must be lost by (conveyed from) the source. But as an intangible asset, knowledge does not necessarily have to be given up by one party to be gained by the other. The framework developed below proposes alternative terminology that more accurately describes the process.

Models of Knowledge Transfer

Research into knowledge transfer has focused on separating the overall transfer from source to destination into comprehensible sub-processes. Trott, Seaton & Cordey-Hayes (1996) develop an interactive model of technology transfer describing four stages in the knowledge transfer process: for inward technology transfer (knowledge transfer) to be successful, an organization must be able to:

- (1) search and scan for information which is new to the organization (*awareness*);
- (2) recognize the potential benefit of this information by associating it with internal organizational needs and capabilities (*association*);
- (3) communicate these to and assimilate them within the organization (*assimilation*); and
- (4) apply them for competitive advantage (*application*)

Non-routine scanning, prior knowledge, internal communication and internal knowledge accumulation are key activities affecting an organization's knowledge acquisition ability (Trott et al., 1996). These findings correspond with those underlying Cohen & Levinthal's (1990) *absorptive capacity*, the ability of an organization to recognize the value of new information, to assimilate it and to commercially apply it.

In addition to the works of Trott et al. (1996) and Cohen & Levinthal (1990), the knowledge transfer literature includes frameworks and models by Cooley (1987), Slaughter (1995) and Horton (1997, 1999). Two streams of models can be distinguished: Node models describe nodes, discrete steps that are each gone through. Process models describe knowledge transfer by separate processes that are each undertaken. Node models are presented by Cooley (1987), Slaughter (1995) and Horton (1997). Cooley discusses *information systems* in the context of the information society:

Most of such systems I encounter could be better described as *data* systems. It is true that *data* suitably organized and acted upon may become *information*. *Information* absorbed, understood and applied by people may become *knowledge*. *Knowledge* frequently applied in a domain may become *wisdom*, and *wisdom* the basis for positive *action* (Cooley, 1987, p. 11).

Cooley thus raises a progressive sequence of five nodes. He conceptualizes his model as a noise-to-signal ratio. The signal being transmitted (i.e. conveyed) is subject to noise, but as the information system moves from data towards wisdom, noise is reduced and the signal increases. Knowledge acquiring organizations will find low-noise wisdom more useful than high-noise data.

Slaughter (1995) presents a four-node *hierarchy of knowledge*, which he uses to describe a *wise culture*. He uses the same first four terms as Cooley (1987):

- (1) *Data*; raw factual material;
- (2) *Information*; categorized data, useful and otherwise;
- (3) *Knowledge*; information with human significance;
- (4) *Wisdom*; higher-order meanings and purposes.

Slaughter's descriptions indicate how stages further up the hierarchy are subject to less noise, and are more useful to knowledge acquiring organizations. Data, information and knowledge are stages on the path to wisdom.

While Cooley (1987) and Slaughter (1995) set their models in a macro-context, Horton (1997) focuses on industry on a micro-scale. In the specific context of the printing industry, but with wider applicability, she describes an *information value progression*. This progression again starts with data and finishes with wisdom, with information and knowledge as inter-

mediate steps. Cooley (1987) describes data as objective, calculative and subject to noise. Horton (1997) agrees; data is hard, objective and low order, as well as being low value, voluminous and contained. At the other end, wisdom is subjective, judgmental and less subject to noise (Cooley, 1987). By Horton (1997) it is subjective, soft and high order, as well as high value, low volume and contextualized.

Similarities are seen in all three models described, despite their contextual differences. Horton (1997) however adds another intermediate step. This is the node of *understanding*, between knowledge and wisdom. Understanding:

is the result of realising the significance of relationships between one set of knowledge and another . . . It is possible to view the ability to benefit from understanding as being wisdom (Horton, 1997, p. 3).

Understanding thus results from knowledge but precedes wisdom. Table 1 compares the three node models. With wisdom a result of understanding and the basis for positive action, the models are mutually supportive. A six-node scheme of knowledge transfer is formed.

Process models are presented by Cohen & Levinthal (1990), Trott et al. (1996) and Horton (1999). Trott et al.'s (1996) four processes of inward technology transfer, awareness, association, assimilation and application, are described above. Horton (1999) presents a three-phase process model of successful foresight. Phase one is a *collection, collation and summarization* phase. Information is collected from a wide range of sources, collated to give it structure, and summarized into a manageable form. Knowledge generated from stage one needs *translation and interpretation*, the elements of phase two. Translation puts the information in an understandable language. Interpretation is organization specific. It is about determining the meanings and implications of the translated information. Translation and interpretation is the most crucial step in the process, where most of the value is added. But it is also poorly understood, having few theoretical techniques. Phase three comprises *assimilation and commitment*. Understanding generated in phase two needs to be assimilated by decision-makers. If changes are to result commitment to act is needed. It is only at this point that the value of the whole three-phase process can be realized and judged.

Table 1. Node schemes of knowledge transfer.

Model	node 1	node 2	node 3	node 4	node 5	node 6
Cooley	data	information	knowledge	N/A	wisdom	action
Slaughter	data	information	knowledge	N/A	wisdom	N/A
Horton	data	information	knowledge	understanding	wisdom	N/A

Trott et al. (1996) and Horton (1999) both refer to an assimilation process; the means by which ideas are communicated within the organization (Trott et al., 1996), or by which understanding is embedded in the organization's decision-makers (Horton, 1999). Assimilation then is a process of internal communication. Horton's assimilation process is in the same phase as commitment. By separating these out, Horton's commitment becomes correlated with Trott et al.'s subsequent process of application. Commitment to action is equivalent to the process of application for competitive advantage. By similarly separating Horton's phase one, collection becomes analogous to Trott et al.'s first process of awareness. The collection of data is a central means for an organization to become aware of new opportunities. Similarly, Horton's collation and summarization can together be compared to Trott et al.'s association. Collection and summarization of information is equivalent to the process of associating the value of the information to the organization. This leaves Horton's second phase, translation and interpretation, with no direct analogy. The comparison suggests analogy with a process not explicitly stated by Trott et al., the process of *acquisition*. This may be described as the process by which an organization draws knowledge into itself, which it can then assimilate. Viewed from within the organization this is a process of acquisition into itself. Viewed from outside it is a process of translation of knowledge from one place to another. It should be noted that the term *acquisition* as used here refers to a discrete part of the overall process of drawing knowledge into the knowledge acquiring organizations. The term *knowledge* similarly has an overall meaning (as in the phrase knowledge transfer) as well as referring to a discrete node in the overall knowledge transfer process.

Trott et al. (1996) and Horton (1999) can now be related to Cohen & Levinthal (1990). Cohen and Levinthal describe *absorptive capacity* as:

the ability of a firm to *recognize* the value of new, external information, *assimilate* it, and *apply* it for commercial ends (Cohen & Levinthal, 1990, p. 128).

These recognition, assimilation and application steps correspond to Horton's (1999) collation, assimilation and commitment. Again there is no explicit provision for the translation and interpretation process. Neither is

Table 2. Process schemes of knowledge transfer.

Model	process 1	process 2	process 3	process 4	process 5
Horton	collection	collation summarization	translation interpretation	assimilation	commitment
Trott et al Cohen and Levinthal	awareness N/A	association recognition	N/A N/A	assimilation assimilation	application application

there an initial collection process. However the positions of these can be filled without upsetting the basic model. Horton (1999) presents the only model to clearly distinguish the translation and interpretation phase, supporting her contention that this phase is poorly understood. Table 2 compares the three process models. A five-process scheme of knowledge transfer is formed.

Knowledge Translation

A Framework for Knowledge Translation

From showing correspondences between models within the two streams, it becomes possible to build an integrated framework, a *framework for knowledge translation*, combining both nodes and processes. The term *knowledge translation* brings a subtly different perspective than the term *knowledge transfer*. The word translation has a dual meaning. It can refer to movement from one place to another place, much the same as the word transfer. It can also refer to putting something into an understandable form, as in the second phase of Horton's (1999) process model. Both meanings are appropriate to the context here: Knowl-

edge translation is both the movement (or transfer) of knowledge from one place to another, and the altering of that knowledge into an understandable form.

Horton's work (1997, 1999) provides the key to integrating the knowledge transfer models. Her guide to successful foresight (process model; Horton, 1999) makes use of her information value progression (node model; Horton, 1997):

Each phase (in the process model) creates greater value than the previous one as the outputs move up the information value chain from information through knowledge to understanding (Horton, 1999, p. 5).

Thus Horton's four nodes are connected by her three phases. Looking simultaneously at the expanded node and process schemes in Tables 1 and 2, the five processes fall neatly between the six nodes. Figure 2 illustrates this, combining the contents of Tables 1 and 2 into a single combined framework for knowledge translation. The initial node is raw data. The first process is to collect this into information. The second process is collation and summarization of this information into knowledge. Knowledge is the end point of

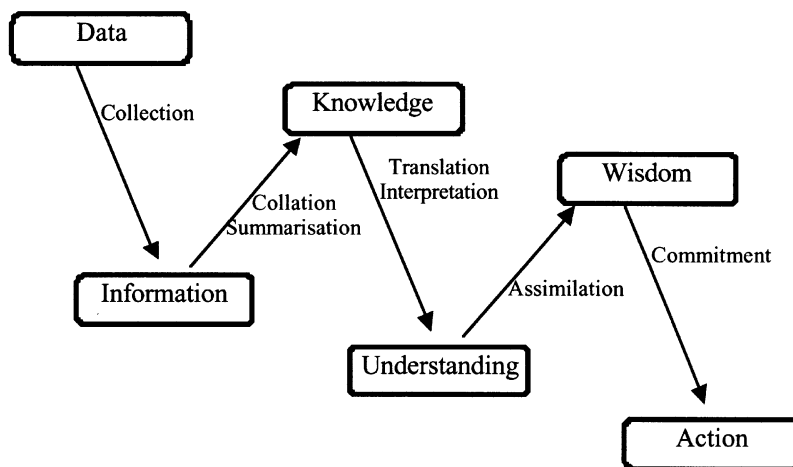

Figure 2. Combined knowledge translation framework.

Source: Expanded from Horton (1997, 1999).

Horton's (1999) phase one. The third process exactly follows Horton's (1999) phase two; the translation and interpretation of knowledge into understanding. Understanding is then assimilated within the organization into wisdom, from which a commitment to positive action can follow. The processes in this integrated framework are the ways of reaching the successive nodes.

Figure 2 presents a complete system of knowledge translation. This completeness may be misrepresentative of extant knowledge transfer or translation schemes. For example, the U.K. national Foresight program has been incomplete in its intent to encourage a forward thinking culture within industry (Major & Cordey-Hayes, 2000a). It is possible that not every process in the scheme will always be fully conducted, thus restricting the overall flow of new ideas that can lead to innovation. The latter processes of assimilation and commitment take place mainly within the destination organization (Cooley, 1987). Early stages might be carried out by an outside body, perhaps the source of the data or information. Collection of data and collation of information can be performed on a macro-scale by government innovation schemes and policy initiatives (as was done by the U.K. Foresight program). This leaves the middle process less clear, and possibly incomplete. This is the notion of the *knowledge translation gap*. For a complete and successful knowledge translation process this gap must be bridged. This implies a role for parties other than the source and destination organizations; i.e. for some outside intermediary organization. Attention is thus turned to the intermediaries, introduced as an external knowledge source in Section 4, above. The knowledge translation gap conceptualizes the barriers to external

learning identified and discussed by Hadjimanolis (2003).

Characteristics of Knowledge and the Knowledge Translation Framework

Before turning in earnest to the role of the intermediaries, some consideration of the characteristics of knowledge is needed to complete the groundwork. Major & Cordey-Hayes (2000a, 2000b) show how knowledge can be characterized along two perception-dependant dimensions. Whether internally or externally generated, firms want knowledge in a discrete and concrete form. To make decisions they want something tangible that can give them operational knowledge. Distant external sources such as universities and governments, as well as government innovation schemes and policy initiatives, are perceived to be intangible and strategic. Distinctions are being made according to the tangibility and the temporal nature of knowledge. Along one dimension, knowledge can be either *concrete* (i.e. tangible) or *abstract* (i.e. intangible, or tacit). A product can be characterized as exhibiting tangible knowledge, while a process exhibits intangible, or tacit, knowledge. Along the second dimension, knowledge can be either *strategic* (i.e. long-term, for overall direction setting) or *operational* (i.e. short-term, decision-making knowledge, for route finding within the overall direction).

These characteristics of knowledge can be illustrated by a two dimensional framework. Figure 3 shows the abstract/concrete distinction along a vertical axis and the strategic/operational distinction along a horizontal axis. Four regions are defined within this framework. The firm's decision-makers want knowledge in Region A; concrete information to help them make decisions.

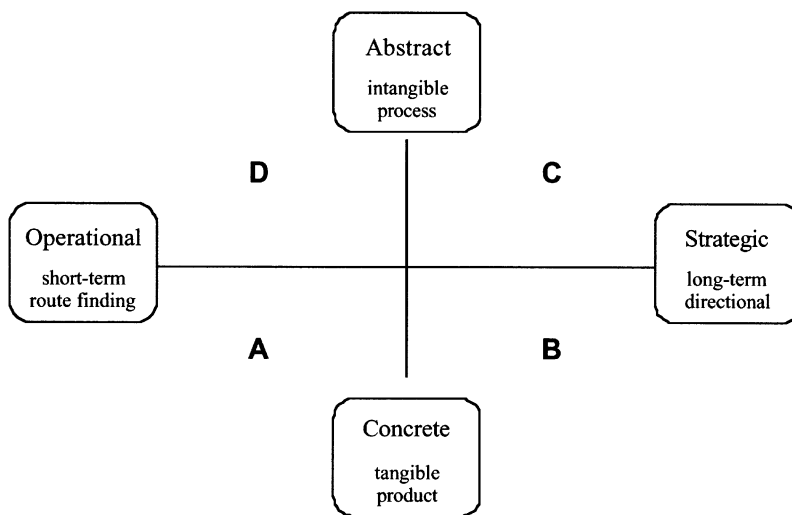

Figure 3. Characteristics of knowledge.

They want a tangible product giving them operational knowledge. External knowledge sources such as universities and government innovation schemes are perceived to be in Region C; their distance makes them intangible; their subject matter outside of the firm's operational needs and therefore strategic. Where specific outputs are produced, such as the reports of the U.K. Foresight program, a scheme or initiative might be regarded as being in Region B; it is still long-term, but has a perceived product in the form of reports that can be read. Region D represents an area of tacit knowledge, unwritten rules, processes and procedures that contribute to a firm's short-term decision-making culture.

The two-dimensional framework in Fig. 3 gives another context in which to view the framework of knowledge translation developed above. Research shows that firms view internally generated knowledge in concrete and operational terms (Major & Cordey-Hayes, 2000a, 2000b). They want discrete and tangible knowledge to enable them to take immediate actions. In the terminology of the knowledge translation framework they are using their internally generated knowledge as wisdom, from which they take actions. Where they seek externally generated knowledge, most firms do so to add to this stock of short-term, tangible knowledge. Certain firms take a much longer-term view. Forward-looking, future orientated firms have a fuller perspective of knowledge acquisition. Their

internal *processes* (the term processes itself signifying their greater appreciation of the abstract dimension) for acquiring external knowledge show them to be reaching much *farther back* through the nodes and processes of the knowledge translation framework. They seek knowledge that they can translate into understanding within the company, which gives an informed base for the wisdom underlying their actions. Even farther back they may seek the basic uncollated information that underlies knowledge.

Action is concrete, and, almost by definition, short-term. Wisdom, in the sense of firms' requirements, is also concrete and operational (though less short-term than action). Action and wisdom, the final two nodes of the knowledge translation framework fall within Region A in Fig. 3. It follows that the remaining nodes and processes of the knowledge translation framework can be located on the two-dimensional characterization of knowledge. The nodes and processes from the combined knowledge translation framework (Fig. 2) can be superimposed onto the dimensions of knowledge (Fig. 3). Figure 4 shows the resulting integrated conceptual framework for knowledge translation.

Action and wisdom are concrete and operational. At the other end, data is also concrete. It is a tangible product (hard and objective according to Cooley (1987) and Horton (1997)). However, because it lacks codification or an operational context it is strategic. As data is collected and collated into information and knowl-

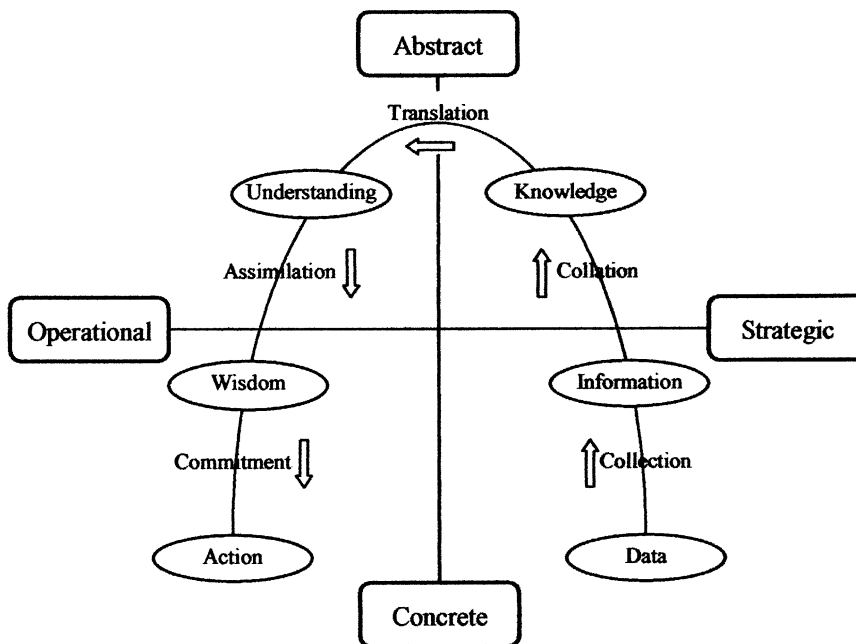

Figure 4. Integrated conceptual framework for knowledge translation.

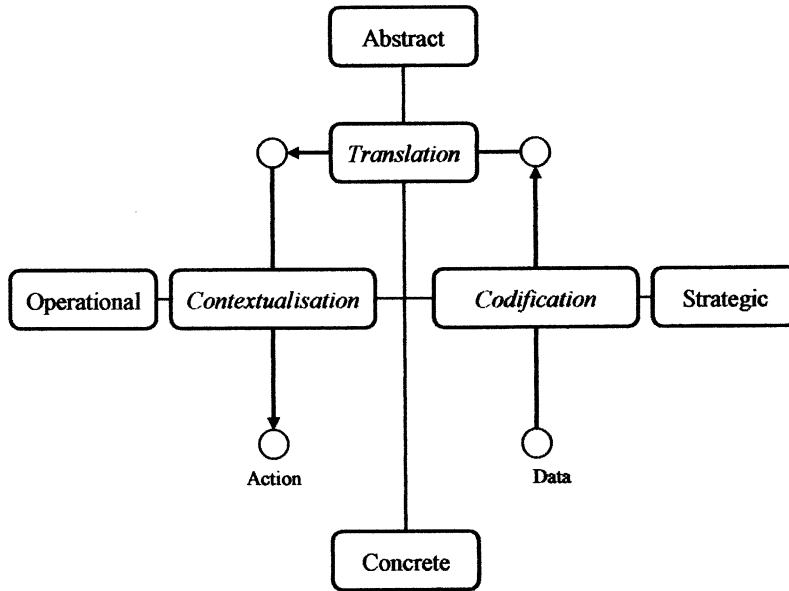

Figure 5. Codification, translation and contextualization phases.

edge, its immediate tangibility is reduced. Information is softer, less tangible, than data. Knowledge is less tangible still. While information may be talked about in product terms, knowledge is regarded more as an abstract process. The translation and interpretation phase brings the system into the operational frame of an individual firm (as the knowledge receiver), reaching a level of internal understanding. Abstract understanding, given a context through assimilation becomes tangible wisdom, the basis for commitment to action. The sequence of elements in the combined knowledge translation framework moves through the quadrants defined by the two dimensions of knowledge in the order BCDA. Concrete and strategic data must be taken and transformed through abstract elements before they can emerge as concrete and operational wisdom.

The sequence can be summarized into movements between the quadrants. Moving from quadrant B to quadrant C (strategic-concrete to strategic-abstract) is a process of *codification*. Combining the collection and collation processes, this extracts abstract meanings from the data. Quadrant C to quadrant D (strategic-abstract to operational-abstract) remains the *translation* process. This process brings externally generated knowledge into the organization's sphere, generating internal understanding. Finally, a *contextualization* process, moving from quadrant D to quadrant A (operational-abstract to operational-concrete), extracts wisdom and promotes action. This is the result of putting the understanding into the organization-specific context. These three summary *phases* equate to Hor-

ton's (1999) three phases of successful foresight. They are shown in Fig. 5.

The Role of Intermediaries in Knowledge Translation

Bridging the Knowledge Translation Gap

The previous section introduced the knowledge translation gap to describe how the overall knowledge translation process can be incomplete. In terms of Fig. 5, the codification of externally generated knowledge can be carried out by an outside body, perhaps the knowledge source itself (e.g. government as the source of a national innovation scheme). Contextualization occurs within the knowledge destination (the small firm in the present context). As suggested certain (forward-looking, future orientated) firms reach back through the knowledge translation framework to carry out the translation phase (and possibly also the codification phase) themselves. Most firms though face the possibility of a gap in the translation phase, and therefore a barrier in their access to externally generated knowledge. Some other body is needed to bridge the gap between the firm and the knowledge source. An organization fulfilling an intermediary role can translate and interpret external knowledge into a form in which receiving organizations can then contextualize it.

Intermediaries were introduced in Section 3. In broad terms, an intermediary organization is any body coming between the knowledge source and the destination (fulfilling the role of an agent in principle-agent

theory). In these terms, organizations within the business support community are intermediaries. Business support agencies such as Chambers of Commerce and small business support organizations might therefore be able to fulfil this role. Industry based bodies; trade and research associations and professional institutes, are potentially well positioned to supply an intermediary service to their industries. Even universities, not previously considered as intermediaries, might bridge the gap through their specialist knowledge. Intermediaries provide a ready, extant system for connecting knowledge sources to knowledge receivers.

Categorizing Intermediaries

The roles of intermediaries are poorly understood. Previous studies expressed the somewhat muddled and amorphous perception of the business support community (Center for Exploitation of Science and Technology, 1997; Woolgar et al., 1998). Major & Cordey-Hayes (2000a) distinguish three categories of intermediary, according to the prime function they provide for their industrial clients. First are *signposters*. These are first-point-of-contact organizations. They point to sources of advice, guidance and expertise, rather than answer problems themselves. In the U.K. Training and Enterprise Councils (TECs), Business Links and Regional Technology Centers (RTCs) all signpost firms to a body appropriate to the query. Small Business Development Centers (SBDCs) and the Office of Technology perform a similar function in the U.S. Second are *facilitators*. These give advice and guidance to client firms to help them to help themselves. Trade associations' central information provision role is a facilitating function. Some industrial research associations (RAs) have a membership body of industry clients much as trade associations. These membership-based RAs (MRAs) play a similar information provision, facilitating role. Chambers of Commerce facilitate regionally, by encouraging networking between firms in a common locality. Third are *contractors*. These are specialist sources of expertise offering direct help on specific issues. University research, non-membership RAs (NMRAs) and professional institutes (through personal memberships) are prime sources of such expertise. When viewed as a continuum, patterns emerge within these three intermediary functions. On moving from signposters, through facilitators to contractors there are longer-term intermediary-client relationships, increasing involvement with client firms' operations, an increasing large firm focus and a corresponding increasing difficulty of small firm involvement.

Intermediaries then have a central role in bridging the knowledge translation gap and thus in the conveyance to small firms of externally generated knowledge. The next section shows how this bridging role can be exploited to reach the small firms.

Intermediaries and Conveyance to Small Firms of Externally Generated Knowledge

Categorizing Small Firms

Major & Cordey-Hayes's (2000a) research leads to a categorization of small firms. They propose that small firms be ordered according to the *futures orientation* of their culture and attitude. Firms with a strong futures orientation have the ability to reach back to the translation and codification processes of the knowledge translation framework (Fig. 5) to acquire externally generated knowledge, which can then contribute to their innovative potential. Four themes describing the boundary activities and network orientation of a sample of U.K. small firms were studied (Major, Asch & Cordey-Hayes, 2001; Major & Cordey-Hayes, 2000a) to identify the attributes that contribute to small firms' futures orientation. The key theme was awareness and perception of the U.K. Foresight program and the concepts it is promoting, and the use of such concepts as a regular part of their business. High awareness, accurate perception and regular use suggest a greater appreciation of long-term issues (i.e. a strong futures orientation). Such firms are able to reach out to obtain the type of knowledge that Foresight provides. Remaining themes were: (1) firms' relationships with intermediaries; (2) the importance of external networking between firm personnel and people in outside organizations; and (3) firms' reliance on their supply chains as a knowledge source.

Three distinct groups of firms emerged, 10% of the small firms sampled had a strong futures orientation. These are *strategic* firms, with a highly *involved* approach to their future. They are characterized by high and ongoing awareness and accurate perception of Foresight, and regular use of Foresight concepts predating their knowledge of the U.K. Foresight program. Their futures orientation puts them ahead of what the Foresight program can provide, and some have been giving the program the benefit of their own experience. These firms have many contacts with intermediaries, but only a select few, typically with trade and research associations and universities, are deep and ongoing. These few intermediaries are important sources of external knowledge. Outwardly focused personal attitudes underpin these firms' foresight knowledge and futures orientation. Correspondingly, external interpersonal networking was found to be highly important. However, reliance on supply chains was not important. Customers and suppliers (the supply chain) are always a firm's most extensive contacts (Moore, 1996; Woolgar et al., 1998), but for the involved, strategic firms they are not a significant source of externally generated knowledge. 70% of the small firms sampled had a weak futures orientation. Their attitude is *reactive* or *uninvolved*. These firms have little or no awareness of Foresight or its concepts. Their intermediary contacts are all at a level where they can

have little impact as external knowledge sources. External networking has a low importance, driven out by concentration on the present. Completing the contrast with the *involved* firms, supply chains are their most important external knowledge source. But reliance on these tangible, short-term operational management relationships tends to drive out use of longer-term external knowledge sources. Between the two extremes, 20% of the small firms sampled were distinguished with intermediate characteristics. These firms know about Foresight and are aware of the importance of their future, but lack prior involvement with Foresight concepts. Their intermediary contacts are more selective and more useful external knowledge sources than in uninvolved firms, but lack the depth and selectivity of involved firms. The importance of external networking and reliance on the supply chain also consistently rate between involved and uninvolved firms. These are *open*, or *responsive* firms. They are open to the future, but need a stimulus to generate response and action. Compared to the involved firms open firms know what is needed, but only the involved firms can actually do it.

Targeting Small Firms—Small Firm-Intermediary Interactions

Dissemination of the U.K. Foresight program took no account of the differences between small firms. Communicating Foresight to *involved* firms, who already have a futures-orientated culture, is like *preaching to the converted*. For *uninvolved* firms futures-orientated policy initiatives are so far outside of their normal sphere of attention as to be essentially unreachable. The present, they perceive, requires their full attention. Communicating with these firms would require great expenditure of effort simply to be heard, let alone be listened to. It is proposed that the most effective audience for futures oriented initiatives like Foresight is the *open* firms. Openness means that they will listen, lack of prior involvement means that significant impacts may result. Combining management or organizational changes with a well-targeted innovation scheme or policy initiative could be the stimulus an open firm needs to become an involved firm.

Major & Cordey-Hayes's (2000a, 2000b) research shows that only a small portion of an innovation scheme or policy initiative's potential audience will respond so as to fulfil its aims. The most important outcome of the research in terms of conveyance of government schemes and initiatives was a model developed to show how intermediary organizations can provide the method to target this priority audience. Intermediaries interact with small firms as part of their regular operation. The research revealed strong patterns in how small firms use intermediaries to build up their internal knowledge and to enhance their awareness and acquisition of externally generated knowledge

(Major & Cordey-Hayes, 2000a). *Involved* firms were found to get this support from *contractor* organizations, *open* firms from *facilitators*, and *uninvolved* firms (at a minimal level) from *signposters*.

Figure 6 illustrates these relationships between small firms and intermediaries. The vertical axis ranks small firms by their futures orientation. *Involved* firms, with a strong futures orientation rank higher than *open* and *uninvolved* firms with moderate and weak futures orientation respectively. The horizontal axis ranks the intermediary organizations by the signposter-facilitator-contractor categorization. In describing the small firms-intermediaries relationships, the model shows that a move up the small firms' futures orientation scale is accompanied by a move along the intermediaries functions scale. *Involved* firms use their extensive contacts at universities, and to a lesser extent NMRAs and professional institutes, for their specific research expertise. Knowing where to look, they do not need to be signposted. Already having access to important external knowledge sources, they do not need a facilitator. *Open* firms are open to the desire for futures involvement but lack the *facility*. Links with trade associations and MRAs and links with chambers of commerce give them access to externally generated knowledge on industry and regional bases respectively. With this access, these firms too are in no need of signposting. *Uninvolved* firms use trade associations and chambers of commerce for their present-orientated representational roles, but have little desire to access external knowledge that can lead to innovation. Lacking the intermediation of the facilitators they require the basic guidance of signposters, Business Links and RTCs in the U.K., SBDCs and the SBA Office of Technology in the U.S., to point them towards external knowledge sources.

Implications and Recommendations

Implications for Innovation Schemes and Policy Initiatives

Figure 6 gives the basis for engaging intermediaries to target small firms. Though generated primarily from study of the Foresight program, the mechanism that the model describes is generic; it describes relationships, rather than a single policy initiative. Foresight is simply a *package of knowledge*, the conveyance, or translation of which the model is guiding. It plays no part in the conveyance, or translation mechanism itself. The mechanism can therefore be applied to translation of other schemes and initiatives of a similar nature to the Foresight program.

Engaging intermediaries brings schemes and initiatives closer to the small firms, overcoming some of their inherent resource problems. Increasing the distance between policy-makers and firms, reduces the effects of firms' mistrust of government and government's limited understanding of the firms' situations.

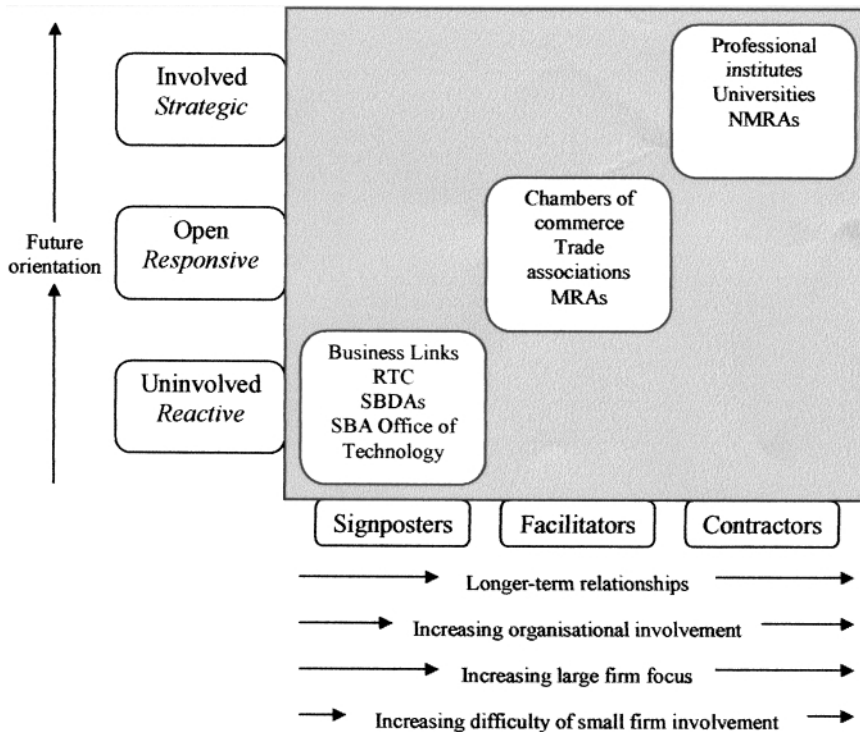

Figure 6. Relationships between small firms and intermediaries.

Compared with policy-makers, intermediaries hold greater understanding of, and are more trusted by, small firms, and have more dedicated resources to deal with them. In principle, all that is required is for the policy-maker to select the organizations that deal appropriately with the specified target audience. The previous section suggested that for Foresight, the priority target audience should be *open* firms. But whichever target group a policy initiative deems the priority, the generic nature of the model indicates which intermediaries to engage. The U.K. Foresight program has started to recognize the value of intermediaries. The *Foresight associate program* engaging intermediaries to bring the benefits of Foresight to their spheres of influence, is a welcome development, but the predominance of professional institutes among the associates (Office of Science and Technology, 2000) does not fully reflect the recommended targeting of open, responsive firms.

Implications for Small Firms

The theory and models developed in this chapter should encourage small firms to strengthen their links with intermediaries. Stronger links could increase the small firms' exposure to externally generated knowledge, be it from the intermediary itself or through

greater access to innovation schemes and policy initiatives, with consequent benefits to the firms' innovative potential.

The previous section linked small firms' futures orientation (with its effect on future innovation) to the type of intermediary they have dealings with. Involved firms' futures-orientation accompanies their deep links with contractors. Encouraging open firms to deepen their contractor links may stimulate them towards an involved attitude. Similarly, encouraging greater use of facilitators in uninvolved firms could stimulate a more open attitude.

This chapter has made recommendations for the conveyance of externally generated knowledge to small firms. The processes within the firms whereby that knowledge is manipulated to generate innovation and competitive advantage fall beyond the scope of the present chapter. This theme is taken up in the literature on organizational learning (see Gilbert & Cordey-Hayes, 1996; Vickers & Cordey-Hayes, 1999).

Implications for Intermediaries

Intermediaries have been shown to have a central role in the conveyance to small firms of externally generated knowledge. They should thus be encouraged to perform this role, working with government innovation

schemes and other knowledge sources, bridging the knowledge translation gap to increase the innovative potential of their small firm contacts.

Conclusions

This chapter has considered the conveyance into small firms of externally generated knowledge. It started by presenting the barriers to innovation in small firms and the sources of internally and externally generated knowledge potentially available. From the concept of knowledge transfer a framework of knowledge translation has been developed. The derived notion of the knowledge translation gap explicitly illustrates why so many small firms fail to reach external knowledge sources. The chapter has proposed that intermediaries can be the bridge that is needed to cover the knowledge translation gap. Understanding how intermediaries can be used to convey externally generated knowledge to small firms brings implications and recommendations for government innovation schemes and policy initiatives, for intermediaries and for the small firms, all of which will encourage and enhance successful small firm innovation.

Linking Knowledge, Networking and Innovation Processes: A Conceptual Model

Jacqueline Swan, Harry Scarbrough and Maxine Robertson

IKON (Innovation, Knowledge and Organizational Networks) Research Centre, Warwick Business School, University of Warwick, U.K.

Abstract: Innovation is frequently cited as a major reason for the emergence of network structures. However, although network structures have been studied extensively, relatively little research has examined the diverse roles played by networking processes in innovation. This chapter develops a conceptual model that relates specific kinds of networking, to particular episodes of innovation (invention, diffusion, implementation) and to processes of knowledge transformation. The operation of the model is illustrated through three case examples, each focusing on a different innovation episode. These are used to illustrate interactions among processes of networking, innovation and knowledge transformation.

Keywords: Innovation; Knowledge; Networking; Networks; Invention; Diffusion; Implementation; Knowledge transformation.

Introduction

Innovation may be defined as: “the development and implementation of new ideas by people who over time engage in transactions with others in an institutional context” (Van de Ven, 1986, p. 591). Networking—as a social communication process—is thus recognized as playing a central role in innovation. Freeman (1991), for example, observes that many studies since the 1950s have noted ‘the importance of both formal and informal networks, even if the expression network was less frequently used’ (p. 500). Encouraging innovation is frequently cited as the major reason for developing network forms of organization. Despite this observation, relatively little research has focused explicitly on the links between networks and innovation (Oliver & Ebers, 1998). Moreover, research that does address links between networks and innovation tends to look at the impact of network structures—social processes of networking receive relatively little attention (Pettigrew & Fenton, 2000). This chapter looks, therefore, at the roles and implications of networks for innovation focusing, in particular, on processes of networking.

The chapter begins by using existing theory and research to develop a conceptual model linking networking with innovation processes. Innovation is presented here as an episodic *process*, encompassing

the design and development (invention), spread (diffusion) and implementation of ideas that are new to the adopting unit (Clark, 1987; Van de Ven, 1986). Recognising the limits of stage models of innovation, these episodes are seen as iterative, recursive and ultimately conflated, not as linear and sequential (Clark & Staunton, 1989; Etlie, 1980). For example, pivotal modifications built into the design of the innovation during implementation may feed back into its diffusion (Fleck, 1994). Previous studies have tended to separate these different aspects of innovation and to focus on discrete episodes (i.e. either invention or diffusion or implementation—Wolfe, 1994). However, this chapter attempts to outline a more holistic model of the links between networking and innovation by tracking the roles of networks and social networking activities across the entire innovation process, and by noting how these roles may vary across different episodes.

This model is developed and illustrated by contrasting the role of inter-organizational networking (the case of a professional association) in *diffusing* technological innovation with that of intra-organizational networking (the case of a consultancy firm) in *inventing* scientific innovation for clients. It then illustrates how these different kinds of networks coalesce when *implementing* operations management

technology (the case of a manufacturing firm). The aim of the chapter is to use these examples to explore the roles played by different kinds of network and social networking activities at different points across the whole innovation process.

This focus on the links between networking and innovation processes highlights an area, which is comparatively under-researched and under-theorized in the literature (exceptions being the work of Alter & Hage, 1993; Oliver & Leibeskind, 1998; Rogers, 1983). Although explanations of the emergence of network structures frequently cite, as reasons for these structures, the industrial change and market turbulence associated with product and process innovations, relatively few studies go on to address the performative role of networks in developing or promoting such innovations (Oliver & Ebers, 1998). In contrast, our study, not only highlights that role, but also suggests that innovation is closely, reciprocally and systematically intertwined with the creation and maintenance of networks (see also Gibson & Conceicao, 2003; Major & Cordey-Hayes, 2003). The argument for this view is based, firstly, on the development of a theoretical model which draws on research in this area, and, secondly, on the empirical study of network effects in widely differing innovation processes. In concise terms, the development of the argument is based on two key propositions. Namely, that a processual view of networks is as, or more, relevant to innovation studies than the conventional structural view (Pettigrew & Fenton, 2000; Wolfe, 1994) and second, that innovation is better characterized not as the production of physical artefacts but as flows and combinations of knowledge and information (Major & Cordey-Hayes, 2003; Nonaka et al., 2003; Tidd, 1997). These propositions are elaborated further below.

Network Structures and Networking Processes

Networks have been analyzed in a variety of ways and through different theoretical lenses (Alter & Hage, 1993; Ebers & Jarrillo, 1997; Grandori & Soda, 1995; Oliver & Ebers, 1998). However, in many discussions a distinction is made between *structural* characteristics or forms of networks and the *processes* involved in developing and sustaining networking relations (e.g. Alter & Hage, 1993). Existing work (cf. Ahuja, 2000; Powell et al., 1996) linking networks with innovation tends to focus on the former. Networks are viewed principally in functional terms as structured channels through which information is communicated and knowledge is transferred. Hansen (1999), for example, develops a contingency model linking network structures (in terms of the strength of network ties) to forms of knowledge transfer (in terms of relatively complex/tacit or simple/explicit forms). From a detailed empirical study of product innovation in a large electronics company he concludes that networks characterized by strong ties are most effective for the

transfer of tacit knowledge and weak ties for transfer of explicit knowledge.

Structural perspectives tend to see networks as an intermediate organizational form which lies somewhere between markets and hierarchies. A distinction is also made between inter and intra-organizational networks with much of the networking literature focusing on the latter (e.g. Alter & Hage, 1993; Ebers, 1997; Grandori & Soda, 1995; Jarrillo, 1993). Grandori & Soda (1995, p. 184), for example, define networks as 'modes of organizing economic activities through inter-firm co-ordination'. Such modes of organizing—i.e. network structures—are, it is argued, important for innovation because they allow for more open and/or extensive exchange and transfer of knowledge and information across firms.

This emphasis on the relatively formal and persistent relationships between firms usefully highlights the structural implications of *networks* in innovation. However, it tends to downplay social processes of *networking*, including the creative role of actors and agents and the importance of interpersonal and informal relationships in developing, creating and sustaining networks (Ebers, 1997). The emphasis on networks as structures for knowledge and information exchange, then, tends to overshadow the social processes through which these structures emerge and develop and the intentions of the actors involved. It also tends to downplay the performative role of networks in actually creating, defining and shaping the knowledge and information that is exchanged.

In contrast, our chapter builds from this earlier work but aims to develop a framework that will address the role of networking processes, not just structures. This underscores the importance of both structure *and* agency in the innovation process. This is not to downplay the importance of structural accounts but merely to give more serious attention to social processes of networking in innovation. In keeping with recent work that has highlighted the importance of 'social capital' (Nahapiet & Ghoshal, 1998), this chapter reveals how the development of the innovation process is intertwined with the creation and maintenance of social networks over time.

Networking involves the active search and development of knowledge and information through the creation and articulation of informal relationships within a context of more formal intra- and inter-organizational structural arrangements. Networking processes are critical for innovation precisely because they span structural forms rather than being contained within them. For example, they occur not just within network structures but also within hierarchies and markets. Networking is also self-sustaining and self-energising—one contact leads to, or precludes, the development of other contacts. Unlike the search routines highlighted in classical organization theory (Cyert & March, 1963), networking is wayward and

emergent, being driven more by interest and opportunity, or by chance ‘accidental encounters’, than by the rational needs of a particular decision-making process (Kreiner & Schultz, 1993). It is also important for innovation because it involves the liberal sharing of knowledge and information and an open-ended outlook on collaboration (Kreiner & Schultz, 1993).

This processual view of networks has important implications for the analysis of innovation. First, it highlights the need to set aside static, institutional explanations of network development in order to recognize their emergent, formative qualities (Ebers, 1997). Where a structural view refers to persistence, stability and established relationships, a processual view denotes the need to examine the role, in innovation, of the sometimes fragile and exploratory activities based on embryonic contacts and half-formed relationships. Second, this approach suggests that the conventional separation between inter- and intra-organizational networks overstates the effect of more-or-less settled organizational boundaries and under-estimates the networking activities that are directly subversive of such boundaries. For example, in innovation projects networking among actors from different organizations (such as that between project managers and consultants) may be as close or closer than networking among actors from within the same organization. Thus inter and intra-organizational boundaries may become blurred as those involved may come to identify more with the innovation process and their role in it than with their own organization.

The pervasiveness and importance of social networking processes in creating and defining the role of networks in innovation is underlined in this chapter by three case examples. This extends the relevance of the network concept beyond the question of structural form to the wider issue of the ‘organizing methods’ or the ‘social practices of organizing’ (Knights et al., 1993) which are applied to socio-economic activity.

Innovation and Networking

Structural perspectives conceptualize networks as diffusion channels through which new ideas are spread from innovators to adopters (e.g. Abrahamsson, 1991; Ebers & Jarrillo, 1997). In contrast, the processual view presented here not only addresses diffusion, but also seeks to analyze ways in which networking processes exert shaping effects on the character and design of the knowledge and innovations diffused. The role of intermediaries (business support agencies, trade associations, professional institutes, universities etc.) in the translation of knowledge relating to innovation is also highlighted by Major & Cordey-Hayes (2003). During the diffusion of innovation, certain features technologies may be highlighted, and others downplayed, depending of the kinds of networking activity

involved and the vested interests of those concerned (Swan et al., 1999a). For example, in the mid-1980s Manufacturing Resources Planning (MRP2) was heavily pushed by technology suppliers in the USA via their engagement in a variety of networks, including professional associations. This became the dominant technology design for production management, even though other options existed at the time (e.g. *Just In Time*—Newell & Clark, 1993). This links the diffusion of innovation more closely to its design and implementation and suggests a much closer examination of the interactions between networking activities and knowledge flows than is usually the case with more structural accounts. In helping to understand these interactions two existing processual accounts are worthy of closer attention—those of Kreiner & Schultz (1993) and Ring & Van De Ven (1994).

Kreiner & Schultz’s (1993) study of informal university-industry networks in the R&D environment proposes a multi-stage analysis of network formation. The first stage of this process is ‘discovering opportunities’ which is activated by the accidental encounters and exploratory trust-building of a ‘barter economy’. This stage leads on to ‘exploring possibilities’ where initial ideas are tested and validated and projects materialize. The final stage—‘consummating collaboration’—is where projects are enacted through a ‘crystallized network of collaboration’. The Kreiner and Schultz model contains some important insights into the links between networking and innovation. For example, they note that in the initial stages of idea generation, the concept of knowledge exchange or ‘know-how trading’ (von Hippel, 1988) fails to explain the promiscuous sharing of ideas seen amongst their R&D actors. This leads them to question the assumption that the act of sharing knowledge diminishes its value to the owner. Rather, when knowledge consists of ‘loose ideas and inspirations’ (p. 197), the immediate value of the knowledge being shared is low, but the potential gain from combining it with the knowledge of others is high.

A further implication of the Kreiner & Schultz model is that the process of networking has a joint outcome. While networking creates knowledge (in this case R&D knowledge), it also crystallizes new network relationships that then act as a ‘centre of gravity’ for further networking and research. In short, networking creates path dependencies in the production and diffusion of knowledge by providing space for new network relationships. It is important to note, however, that such path dependencies do not impose rigid search behaviours on network participants. Kreiner & Schultz (1993) suggest that innovation derives from the ‘*blending of ideas, knowledge, competencies, experience and individuals*’ (p. 200), but that this blending usually happens in unplanned and emergent ways. The importance of ‘accidental encounters’ in the Kreiner & Schultz (1993) study underlines the central importance

to innovation, particularly in the nascent phases, of informal, opportunistic inter-personal relations in network formation. This need to recognize the role of personal and informal dimensions of networks and networking in innovation is further echoed and amplified in the work of Ring & Van De Ven (1994) who seek to develop a socio-psychological account of networking processes.

The Ring & Van De Ven (1994) model is presented as a counterpoint to conventional analyses of networks, contrasting, for instance, the importance of perceived trust and equity with the usual emphasis on transactional efficiency. This approach leads them to propose a cyclical model of network formation encompassing four distinctive socio-psychological activities—negotiations, commitments, executions, and assessments. This model shows some important similarities with the Kreiner & Schultz (1993) analysis. First, it is process-based—network structures are seen as an outcome of networking processes. Second, it is recursive—networking interactions closely resemble the path-dependencies noted by Kreiner & Schultz (1993). Third, it highlights the importance of exploratory trust-building interactions as the catalyst to network formation. Fourth, Ring & Van de Ven (1994) also highlight the tensions between formal organizational structures, networking activities, and innovation, focusing in particular on the tensions created between organizational roles and personal interactions, with narrowly defined roles limiting the scope for networking and innovation.

Innovation and Knowledge

The important role played by networking highlighted in these studies, underscores the need to revise our understanding of innovation. Traditional views have tended to emphasize the creation and distribution of physical artefacts—ideas are invented, distributed as physical artefacts, and then implemented in firms (Clark, 1995; Rogers, 1983, 1995). This artefact-based model is increasingly challenged, however, by the growth of the service sector and the rise of knowledge-based products and processes (reflected in the growth of the consultancy industry). In this context, innovation is better conceptualized not as a materially-constituted entity but as a particular transformation of knowledge and information (Macdonald & Williams, 1992; Nonaka et al., 2003). This 'knowledge-based' view of innovation moves us beyond the linear assumptions of the artefact-based model and highlights the complex and recursive interactions that filter and shape the innovation from inception through to end-use.

One implication of this 'knowledge-based' view of innovation is the significance attached to networks as the means through which knowledge is elicited, translated and (re)combined to produce innovation. However, an emphasis on networking suggests that such networks are not passive channels for the transfer

of knowledge but are also implicated in its active (re)production and appropriation (Alter & Hage, 1993; Clark, 2000). This further differentiates the processual view from the so-called 'entitive approach' of the artefact-centred model (Hosking & Morley, 1990). Entitive perspectives treat innovation as an object or thing which is invented and diffused, more or less unchanged, from one adopter to another. In contrast, the knowledge-based view, not only suggests that innovation involves complex interactions between different groups and constituencies, but also that these interactions have a shaping and filtering effect upon the innovation itself. In short, during innovation, knowledge and information is both communicated and transformed by the network of social actors.

Taking this further, the different 'episodes' within the innovation process (invention, diffusion and implementation) can be characterized as involving distinctive shifts in the ways knowledge is constituted (see also Major & Cordey-Hayes, 2003). The episode of invention, for example, may be characterized in terms of the (social) *construction* of knowledge (Bijker et al., 1987). Here, loose ideas shared through interpersonal networks may crystallize into new forms of work practices or products. In contrast, the diffusion episode is associated more closely with the *commodification* and *communication* of knowledge (Rogers, 1983). This episode requires that knowledge be made more explicit and codified in order to be translated to a wider social constituency. Diffusion involves, then, the progressive *objectification* or 'black boxing' of knowledge, such that its communication and distribution ceases to be dependent on the particular tacit understandings and social context of its creators, but is transformed into more explicit, generic and therefore, more widely portable forms (Scarbrough, 1995). In contrast, again, the episode of implementation relies on the *appropriation* of knowledge within firms (Clark, 1987). Here generic, objectified ideas about new work practices, technologies or products need to be applied to the specific context of the adopter by customizing and adapting them to local requirements. This involves unpacking knowledge from its objectified state and fusing it with local and often tacit knowledge of the organization (Fleck, 1994).

A Model to Link Innovation, Knowledge and Networking

The discussion so far has outlined the importance of networking in innovation by conceptualizing innovation as a process that involves flows and combinations of knowledge and information occurring through networks and networking. This suggests that a conceptual model that is able to link networking processes and innovation could be useful. However, the different knowledge requirements of different episodes of the innovation process also suggests that any model to link innovation and networks needs to be able to relate

specific types of networking activities to particular episodes within the innovation process.

A number of different perspectives have been applied to this issue. As noted, many writers adopt a structural approach, which sees the creation of networks as a consequence of the failure of market and hierarchical forms to adequately regulate certain kinds of transactions (Casson & Cox, 1997; Grandori & Soda, 1995; Poire & Sabel, 1984; Powell et al., 1996). However, there are important limitations to this analysis. First, it emphasizes the functional characteristics of organizational and institutional structures over the agency of groups and individuals. Yet, by focusing on agency, it is clear that networking relationships may occur, for example, within markets and hierarchies and so these may be complementary, rather than competing, forms (Holland & Lockett, 1997). Second, the emphasis on individual transactions is a poor characterization of the rich social interactions involved in the transfer and exchange of knowledge. For example, Kreiner & Schultz (1993) note the inappropriateness of an exchange perspective to the R&D environment. This suggests that the potential creation of new economic benefits from the innovation—as opposed to the distribution of existing benefits—may help to lower some of the transactional barriers to the communication and exchange of knowledge (Lazonick, 1991). Third, the economists' concerns with the problems of costing and exchanging knowledge tend to gloss over social concerns to do with the legitimation of knowledge (Casson & Cox, 1997; Williamson, 1985). Before knowledge can be effectively diffused and implemented (for example, as a new form of 'best practice'), it has to be accepted as legitimate by the relevant social group. Therefore, social and institutional mechanisms of validation are also critical.

The social validation of knowledge involves establishing the credibility, the essential 'rightness' of what is proposed. In a technological context a variety of institutional networks may perform this function including, importantly, professional associations, trade associations, policy making bodies and so forth (Major & Cordey-Hayes, 2003; Swan et al., 1999a). Hence, the networks which facilitate the communication and exchange of knowledge often, simultaneously, provide the means of its validation. Persuasion and co-optation through networking activities, rather than exchange seem, then, to be key (Callon, 1980). Thus, even objectified forms of knowledge—emerging technologies, for example—will depend for their acceptance on the underpinning validation supplied by industry standards, relevant professions, and adoption of 'best' practice by 'leading' firms (King et al., 1994). Inter-organizational networks that help to communicate such standards will be crucial.

Taken together, these points suggest that networking activities are particularly suited to the dynamic and unstructured flows of knowledge associated with

innovation processes. Networking operates within and across markets and hierarchies. It helps to address the transactional 'stickiness' of knowledge by promoting trust and stimulating value creation through innovation. At the same time, it also serves as means of validating knowledge by enrolling network partners. Thus, networks serve both to disseminate and to transform knowledge. Taking these arguments together suggests that a model of the role of networks in innovation should incorporate the following features:

- (1) It should recognize that the roles of networks vary across episodes involved in the innovation process.
- (2) The importance of knowledge transformation (involving construction, communication and exchange) should be highlighted.
- (3) Both structural *and* processual dimensions of networks should be incorporated.
- (4) It should recognize the changing role of personal sense-making and trust-building activities in the evolution of networks through networking activities.
- (5) Path-dependency of both the innovation process and network formation should be included.
- (6) The implications of different kinds of knowledge for the roles played by networks should be addressed.

A model that encompasses the theoretical points above and relates different episodes of the innovation process to networking activity is presented in Fig. 1. This focuses on the interplay between the three critical dimensions identified in the discussion above—networking activity, knowledge attributes, and the episodic innovation process. However, unlike the existing models outlined above (e.g. Kreiner & Schultz, 1993), Figure 1 attempts not just to describe the interplay between these different elements, but also to compare different innovation episodes in terms of the different kinds of networking involved.

Mapping these complex interactions in this schematic way requires a number of theoretical caveats and qualifications. For example, the relationships between the different episodes of the innovation process must be seen as operating in a non-linear, recursive fashion (Clark & Staunton, 1989; Fleck, 1994). At the same time, while the character of networking is broadly correlated with the relative codification of knowledge (global, inter-organizational networks serving to disseminate more codified knowledge, for example), it is also important to acknowledge the continuous interplay between the ways in which knowledge is created and exchanged. Although Fig. 1 suggests that the dominant forms of knowledge transfer may vary from one episode to another, the overall scope and direction of the innovation process will reflect these co-dependencies. It follows from this discussion that

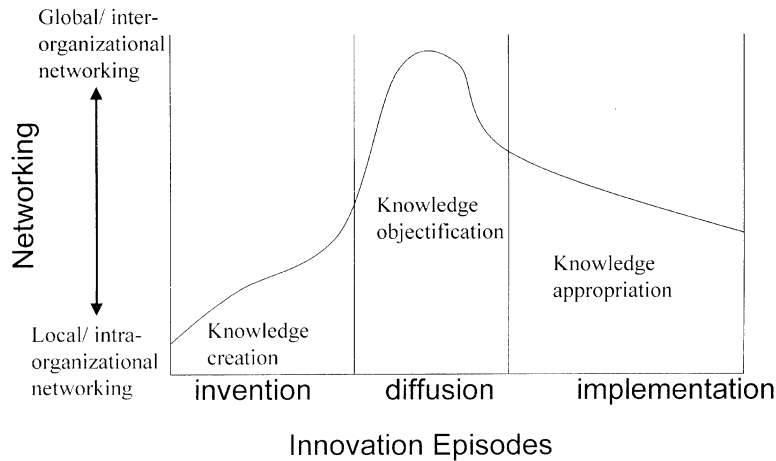

Figure 1. A model linking networking, knowledge and innovation.

the curve outlined in Fig. 1 defines the interaction between networking and innovation, not only in terms of the distinctive characteristics of networking in different episodes (e.g. inter- or intra-organizational), but also in terms of its extent or *scope*. This is denoted in Fig. 1 by the area encompassed within the curve during the different episodes. The constituent elements and assumptions of this model are characterized as follows:

Invention

During this innovation episode, the focus is on the social construction and creation of new knowledge through an exploratory and highly personalized process of networking among a fairly narrowly defined social group who have relevant tacit knowledge and interests. This is referred to in Fig. 1 as ‘local intra-organizational’ networking in order to reinforce the point that networking activities may cut across organizational boundaries. However, the advantages of physical proximity for interpersonal networking, means that networking within the firm would be likely to be especially crucial.

During this episode informal, interpersonal networking seeks to identify potential network participants who possess information and expertise that could be relevant to the development of new products or services. This networking will typically be wayward and emergent, with initial loose contacts quickly generating stronger ties as individuals come to realize that they have some common interest. ‘Accidental encounters’ may be important here (Kreiner & Schultz, 1993). Formal or informal coalitions (e.g. project teams) are assembled on the basis of (uncertain) expectations of reciprocity and trust and a willingness to share knowledge (Ring & Van de Ven, 1994). These expectations are generated through repeated social

interaction but may also be signalled by contextual cues. For example, membership of a particular organization or profession may imbue incumbents with expected expertise (Meyerson et al., 1996). A key role of social coalitions and teams is in the testing and interpretation of knowledge—what Ring & Van De Ven (1994) term ‘sense-making’. The emphasis here, then, is on the sharing and creation of knowledge, rather than on the exchange of information or artefacts. Because outcomes are uncertain, economic considerations will be secondary to interpersonal, trust-based interactions.

Diffusion

During the diffusion episode, the emphasis shifts to the objectification and communication of knowledge through more global, inter-organizational networks. Ideas, now crystallized as new technical artefacts, products or services, become commodities that can be exchanged. Here the primary role of networking is to broadcast knowledge to legitimize particular inventions or new ideas (or old ideas repackaged) so that they become accepted and adopted by the wider community. For example, particular templates for technology design may be promoted to the wider community as new forms of ‘best practice’.

Diffusion thus involves a social process of formal and informal information exchange among members of a social system (Rogers, 1983, 1995). This process is unequal and may be conflictual. For example, different groups of ‘change agents’ (such as salespeople, consultants, firms) may aggressively and opportunistically promote the adoption of particular ideas or artefacts where it is in their interests to do so (Swan & Newell, 1995). New ideas may also be diffused through the ‘weak ties’ linking different social groups (Granovetter, 1973; Hansen, 1999). ‘Boundary spanning’ individuals (e.g. key consultants) play a role

in this diffusion process, involving themselves in a wide range of broader inter-organizational networks and translating ideas developed through this networking into locally applicable or organizationally useful solutions (Tushman & Scanlan, 1981). Thus, boundary spanning individuals act as 'knowledge brokers', helping to overcome social and organizational barriers (Aldrich, 1999).

Particular inter-organizational networks may also play a brokerage role in providing opportunities for members from different social communities to meet and interact. Professional associations, for example, allow links to develop between practitioners working in industry, academics, consultants and technical specialists, thereby promoting knowledge flows within a particular professional knowledge domain (Aldrich & von Glinow, 1992). At the same time, market structures create distinctive incentives towards the commodification of knowledge. Some networks (e.g. with technology suppliers) will act as distribution channels for pre-packaged knowledge and ideas (Scarbrough, 1995).

The distributed nature of networks in this episode may enforce a reliance on surrogate indices of the validity and legitimacy of the knowledge being diffused. One such surrogate may be found in the professional ethos and credentials of the networks through which knowledge is communicated. For example, professional groupings such as professional institutes and trade associations may be seen as more 'impartial' communicators of the 'state of the art' than organizations with more naked commercial interests. As we will see, this assumption is not always justified—professional networks may well be colonized by actors with commercial interests—but it may help to explain the importance of professionalized networks in communicating knowledge.

The usefulness of inter-organizational networks in legitimizing and diffusing knowledge is not without consequences for innovating firms. Such networks also exercise a shaping effect upon the range of technological options available to such firms. For example, DiMaggio & Powell (1983) argue that the greater the interconnections among firms within a particular community, the greater the tendency for 'isomorphism' to occur—for example, through mimetic, normative or coercive processes—that leads firms to resemble one another. Hence networks for diffusion may paradoxically allow new ideas to diffuse more widely but, at the same time, place tighter constraints around the particular ideas that will be considered legitimate within the community. Again, social agency is important here—by engaging in diffusion networks, particular constituents (or agents) can influence further processes of invention and implementation. For example, Rogers (1983) describes how the Dvorak design keyboard—a more efficient alternative to the existing Qwerty—was effectively precluded by core con-

stituents (e.g. manufacturers and teachers) with vested interests in maintaining the status quo.

Implementation

This episode refers to the local appropriation of new ideas as organizationally-specific solutions. Often innovations cannot be adopted by organizations as 'off the shelf' packages. Rather, they represent multifaceted 'bundles' of knowledge that require modification and reconfiguration to adapt them to specific technical and organizational contexts (Clark, 2000). In implementation episodes, the deconstruction and re-construction of knowledge comes to the fore. Generic, objectified ideas floated through global, inter-organizational networks need to be appropriated by blending with ideas about specific organizational problems and context (Clark, 1987). The customization, during implementation, of standardized software packages diffused by technology suppliers through global inter-organizational networks so that they meet local user requirements, is a good example of the knowledge appropriation involved in implementation (e.g. Robertson et al., 1996).

Here networking is more purposeful, as those with interests in implementing specific solutions use networking to mobilize the information and resources (including political and social resources) that will be required. With many kinds of implementation, local intra-organizational networking again becomes important as new generic ideas are interpreted and blended with existing local, often tacit, knowledge and as project owners attempt to generate the commitment needed from the relevant social groups (Fulk, 1993). Thus inter- and intra-organizational networks may converge during implementation—weak inter-organizational ties for information search combine with strong intra-organizational ties required for the formation of project teams.

Figure 1 depicts these episodes of invention, diffusion and implementation as unfolding recursively over time through the medium of networking. Local, intra-organizational networking clusters around the intensive episodes of invention and implementation, where tightly integrated knowledge and information flows are required. New relationships are forged on the basis of reciprocity and the development of trust—the kind of 'barter economy' described by Kreiner & Schultz (1993). Then, in diffusion, networking is extensively rather than intensively oriented and emerges around the dissemination of more explicitly objectified knowledge flows. Relationships are more structured than emergent, and are more explicitly transactional or market-based (Scarbrough, 1995). Issues about the value of what is being diffused are resolved through more institutionalized forms of legitimation and validation.

The remainder of this chapter operationalizes and further develops this model using case examples of invention, diffusion and implementation. These brief

Table 1. A summary of networks, networking and knowledge transformation during episodes of the innovation process.

Innovation Episode	Dominant networks	Features of the networking process	Role of networks	Knowledge transformation
Invention: <i>Universal Consulting Case Example</i>	Local intra-organizational —strong ties within consultants' firm Local inter-organizational —strong ties between consultants and clients Mainly interpersonal networking	Wayward and emergent: formation of many strong ties and some weak ties	Coalition building around new ideas and clients projects	Knowledge created, socially constructed from loosely structured, ambiguous and novel ideas into new products/services
Diffusion: <i>Professional Association Case Example</i>	Global inter-organizational —many weak ties across firms via professional association —relatively strong ties between MRP2 consultants and professional association Mainly informational networking plus interpersonal for an active minority	Opportunistic and conflictual: primarily through many weak/indirect ties and few strong ties	Brokerage, broadcasting and legitimation of new technology as 'best' practice Selective promotion of knowledge (e.g. in the form of technology design templates)	Knowledge objectified, commodified and communicated using material artefacts and 'best practice' methodologies
Implementation: <i>LiveCo Case Example</i>	Local intra-organizational —strong ties among project team Local inter-organizational —formal relationship between team and IT consultant Global inter-organizational —weak ties with other firms, professional association, IT vendors. Intra/inter-organizational boundaries blurred Mainly interpersonal networking plus formal, client/consultant relationship	Purposeful, intentional: primarily using weak ties for information search coupled with strong ties in project team	Exchange of required information and resources (including political and social)	Knowledge appropriated (unpacked and reconfigured) into workable applications in specific context by combining objectified knowledge with local (often tacit) knowledge

case 'vignettes' are taken from our earlier empirical studies of innovation and networking. The first focuses on the role of local, intra-organizational networking within a scientific consultancy generating inventions for clients. The second case examines the ways in which global inter-organizational networking made possible by a professional association can serve as a vehicle for the diffusion of innovation in the area of operations management. The third case examines how the knowledge diffused via global networks is appropriated *in situ* with that constructed via local networks during the implementation of operations management technology in a particular manufacturing firm. The links between networks, knowledge and innovation episodes identified in these cases are summarized in Table 1. The comparison between them also allows

further analyzes of the relative value of different forms of networking in different episodes of the innovation process.

Case Example 1: Universal Consultancy—The Role of Networks in Invention

This case example is based on longitudinal research at the 'Universal Consultancy' organization (see Robertson & Swan, 1998 for details). Universal was founded in 1986 by a charismatic, highly successful individual and, over time, had grown from a handful of consultants, to an organization employing 150 consultants at its main headquarters and a further 110 on an associate basis in the U.S., Japan and Europe. The organization is a laboratory-based, business and technology, consulting and investing company specializing in the

invention of novel scientific products and services, which are sold to clients in the form of Intellectual Property Rights (IPR).

All consultants in Universal were educated to Ph.D. level within their respective scientific subjects and many were considered 'world' experts. The emphasis was on inventing new products and services by consultants combining their different areas of scientific knowledge with a keen commercial awareness (i.e. characteristic of the 'symbolic analyst'—Reich, 1991). The overall ethos of the firm (vehemently defended by the founder) was that sustainable competitive advantage was to be achieved through innovation and that this depended on the effectiveness of the skill base. Universal's competitive advantage was based, then, on its ability to *rapidly* develop inventions in line with client requirements. This capability was maintained and supported by the method of working that relied heavily on the local, intra-organizational networking activities of consultants.

Consultants were allocated across seven divisions reflecting broad specialisms (e.g. applied science, IT, engineering) but these existed purely for administrative purposes. In general, formal structures were quite deliberately opposed—the overriding emphasis being, instead, on maintaining a non-hierarchical (with the exception of the founder), egalitarian approach to organizing. Divisions were created, merged and disbanded over time in a reactive manner, premised on market opportunities and consultants were reallocated accordingly. Consultants would come together in self-forming teams for the duration of projects, regrouping as new projects and personal interests demanded. The approach to organizing was typical of the 'ad hoc-racy'—an organizational form considered to stimulate innovation (Mintzberg, 1983)—and work organization was described as 'fluid'. Everyone, including the Founder, was actively involved in project working. Project working was to be largely unconstrained by organizational (hierarchical or divisional) boundaries. The 'modus operandum' was intensive, local, intra-organizational networking, mobilized around the inventions being worked on at any point in time. Inter-disciplinary working across divisions was encouraged and valued—indeed many consultants had chosen to work at Universal because of its emphasis on cross-disciplinary working and informal work practices.

As the organization grew it became necessary to consider mechanisms that would sustain networking across divisions. One mechanism introduced was based on individual performance targets set within a loose financial control system. Personal revenue targets (PRTs) were established by the Board yearly and performance was monitored monthly. Given the emphasis on egalitarianism, the same monthly PRT applied to all consultants. This meant that Divisional targets were directly related to the number of consultants within each division. Personal (and therefore

Divisional) revenue was generated by consultants getting themselves involved in a project and receiving a share of the project revenue (decided through negotiation with the project leader). To get involved in new projects—and so meet Divisional targets—consultants were expected, and encouraged, to actively engage in intra-organizational networking. This intra-organizational networking allowed them to market their own expertise so it could be spotted and exploited. Although this local networking was mainly intra-organizational, it also extended to the client base. Over time then, as the organization grew, local inter-organizational networking expanded as consultants created and built their own client base. Market opportunities were discovered through a dual process of trust-building and exploring possibilities for invention with clients and consultants in other divisions, in a manner reminiscent of the university-industry R&D networks described by Kriener & Schulz (1993).

Project leaders and project team members were not formally allocated at Universal. Rather, they emerged during the proposal stage of a project. Typically the project leader was the consultant who was seen to have generated the market opportunity via his or her local networking. At the project proposal stage, the potential gain of combining knowledge with others was high—'know-how' trading (von Hippel, 1988) and the promiscuous sharing of ideas within the intra-organizational network was common (Kreiner & Schulz, 1993). Project leaders were also expected to be fair in their assessment of individual consultants' likely contribution. This helped to generate trust-based relations and perceptions of equity and so sustained and strengthened the intra-organizational network (Ring & Van de Ven, 1994).

In short, a micro-economy for knowledge existed at Universal—the PRT system demanded that individuals' knowledge be made 'visible' and traded within the organization. This micro-economy facilitated informal and interpersonal intra-organizational networking necessary to sustain invention. This networking, in turn, encouraged the social construction and creation of knowledge in projects and also enhanced the individual consultants' own knowledge base. This expanding knowledge base then further advanced the internal 'marketability' of the individual consultant. Given the absence of structurally-defined roles and responsibilities, there was an overriding emphasis on social relations—these being governed by a psychological, rather than a legal or employment-based, contract. These are defining characteristics of co-operative networking relationships (Ring & Van de Ven, 1994).

When project work began it was characterized by the exchange of tacit and explicit knowledge (Nonaka & Takeuchi, 1995) among consultants. Some client input was necessary, particularly at the early stages, but because of the consultants' high levels of scientific expertise, knowledge creation relied more heavily on

intra-organizational networking activity. This intra-organizational networking was based mostly on interpersonal contact, for example, through face-to-face informal 'brainstorming' sessions. Many consultants also spent a considerable amount of time travelling so e-mail was also used intensively. However, the limitations of electronic communication, and the advantages of face-to-face interaction for creating knowledge were recognized (and referred to, often) by consultants. The successful conclusion of project work occurred when the knowledge that had been created through this intra-organizational networking activity became objectified and communicated to the client, for example in the form of a new IPR.

The Universal case highlights the ways in which the dynamics of local and intra-organizational networking, driven by an internal 'market for knowledge', could promote coalitions around new ideas and projects, and collaborative efforts to innovate, even amongst a group of workers that were (as in this case) highly individualistic. This intra-organizational networking was mostly informal and interpersonal and emerged around the inventions themselves. It was supported by the social context, in particular a strong egalitarian culture and an efficient information (e-mail) system. These kind of intensive informal interpersonal networking activities generated social mechanisms (e.g. the formation of trust, establishing reputation, negotiation of responsibilities, collaborative working and so forth) that were important for further invention. Given the nature of the work (and workers) involved, these mechanisms would have been much more difficult, if not impossible, to achieve through more formal means.

Case Example 2: A Professional Association—The Role of Networks in Diffusion

This section examines the relationship between the networking engendered through a particular professional association, and its role in the diffusion of technologies for operations management (for details of the empirical work see, Newell & Clark, 1993; Swan & Newell, 1995; Swan et al., 1999a). The association is the Institute of Operations Management in the U.K. The IOM, like its American Counterpart—the American Production and Inventory Control Society (APICS)—comprised members from different occupational sectors (e.g. manufacturing, consultancy, software and hardware suppliers, academics) and market sectors (e.g. pharmaceuticals, automotive, food and drink). This association therefore played a 'brokerage' role, operating as an extensive (or 'global') network that generated a large number of 'weak ties' across individuals from different organizations (Aldrich & von Glinow, 1992). Weak ties have been identified as important for the diffusion of innovation because they allow ideas to spread across social communities and allow firms to encounter ideas that

are not bounded by the usual norms of their particular sector (Granovetter, 1973; Rogers, 1983).

The primary aims of the IOM were: first, to keep members who work in industry up to date with new developments in operations management; and second, to enhance the professional profile of careers in operations management (these have traditionally afforded relatively low status in the U.K.). To achieve these aims, the IOM organized a formalized program of events (e.g. journals, conferences, seminars, and company presentations) aimed at broadcasting information about new technological solutions to members. It also organized educational qualifications in an attempt to provide a clearer career path for those working in operations management.

Members who actually attended formal meetings also had opportunities to meet informally and discuss new ideas. The professional association thus created an arena in which knowledge and ideas relating to innovation could be exchanged both through formal and informal networking. However, although opportunities for informal, interpersonal networking existed, only around 20% of members actively exploited these by attending events on a regular basis. The passive majority just read, or scanned, the information that was transmitted through the association's journals—their networking was informational (contact with information) rather than interpersonal (contact with other members). The role of the IOM, then, was largely one of broadcasting—it acted as a diffusion network whereby knowledge that had already been created and articulated in explicit forms by the more active members (e.g. in the form of written articles) was broadcast to the relatively passive community.

Because professional associations rely heavily on volunteers, the shape of their activities depends on the interests of those particular social groups who get involved. For example, the IOM depended heavily on volunteers to organize events, write articles for journals, teach on courses and so forth. Technology suppliers (software vendors and consultants) were particularly active in the IOM. They got involved because they saw the professional association as an important global network for marketing their particular technologies. Thus, although they comprised a minority of members (23% as compared to 70% who work as practitioners in manufacturing), technology suppliers were extremely active in articulating the information that the IOM then disseminated to members in industry. For example, the bulk of the information disseminated by two of its key activities—journals and conferences—was written or presented by the much smaller group of technology suppliers (Newell et al., 1997).

One of the most widely known technological developments for operations management is known as 'Manufacturing Resources Planning' (MRP2). The concept of MRP2 diffused widely during the mid-

1980s to mid-1990s, mainly from the U.S. to Europe (Clark, 1987). The early diffusion process was driven by aggressive marketing among suppliers of software and hardware (notably IBM) and also by consultants selling training and education to accompany the introduction of the MRP2 ‘philosophy’ (notably the Oliver Wight Consultancy in the U.S.—Wilson et al., 1994). Market arenas, bolstered by the many problems that firms had experienced in implementing technologies to date, developed and provided incentives and opportunities for the commodification of knowledge associated with MRP2. Technology suppliers played a key role in this—effectively objectifying knowledge about MRP2 in the form of material artefacts (software packages) and tightly prescribed methodologies that could, it was claimed, be used in anywhere. For example, Oliver Wight developed a step-by-step ‘Proven Path’ to successful MRP2 implementation (Wight, 1984). MRP2 was promoted by many as *the* definitive ‘best practice’ for operations management, even though alternative technologies were known at that time (Swan & Newell, 1995). The diffusion process, then, was driven by the commodification and objectification of knowledge. Whilst this was a useful marketing strategy for technology suppliers, it caused problems for users because the objectified MRP2 solutions presented simplified the technology and de-emphasized the need for organizational appropriation (as discussed below—Clark & Staunton, 1989).

In the U.S. and U.K. the professional associations played a critical role in the diffusion of this objectified knowledge about MRP2 in two key respects. First, they acted as global inter-organizational networks for the broadcasting of information about MRP2. As seen, technology suppliers play an active role in shaping the information that these networks disseminate. In this case, a few major suppliers of MRP2 systems (e.g. IBM) took the opportunity to form strong ties with the professional association organizers (e.g. APICS). These resulted in the APICS network being enlisted to help in an ‘MRP2 Campaign’ to disseminate knowledge about the new MRP2 technology to its members (Vollman & Berry, 1985). Further, a global networking arrangement between the IOM and APICS was significant in providing a channel through which best practice ideas originating in the USA could be packaged and diffused to a practitioner community in the U.K. (Clark & Newell, 1993).

Second, the professional association networks played an important legitimizing role—MRP2 became accepted by firms in industry as *the* latest ‘best practice’ in part because communication about it was being broadcast via the professional associations. Whilst information encountered through professional association networks reaches only a subset of the relevant community, it is afforded a very high level of legitimacy and validity. Where close interpersonal trust among members of a network is not present or difficult

to develop, then problems surrounding competing claims to knowledge are solved by trusting your source (Meyerson et al., 1996). If the source is a professional association then credibility is likely to be greater than if the source is a more direct link with a technology supplier. Thus, ideas diffused via the professional association network are likely to be seen by potential adopters as impartial, even though (as seen above) they may have originated in the supply side.

This case illustrates how professional networks in the U.K. and U.S. played both a broadcasting and legitimating role in the promotion of objectified knowledge about MRP2 as a new ‘best practice’ technology design. This role is particularly salient because of the extensive weak ties generated by such network structures. However, because much of the networking activity of members was to do with transmitting information, rather than with developing interpersonal relationships, and because much of this information was shaped by an active supply side with interests in selling technologies, only positive features of the technology that would encourage it to be adopted were communicated. In contrast, the difficulties and complexities associated with the technology and its implementation were heavily downplayed. Thus whilst this inter-organizational networking encouraged rapid diffusion, it also generated potential problems for implementation. These are illustrated in the case that follows.

Case Example 3: A Manufacturing Firm—The Role of Networks in Implementation

This section presents the case of a manufacturing firm, which successfully implemented a new MRP2 system (for details of the empirical work see Robertson et al., 1996). It illustrates how the coalition of global and local networks played a key role in the implementation process.

The case study firm is referred to herein as LiveCo. LiveCo is a large vehicle manufacturer in the U.K. operating to a make-to-order profile. The implementation process in LiveCo began in the late 1980s when a decision was taken by members of the Board to invest in and implement an MRP2 system. At this time the company was facing a financial crisis—sales were declining in all markets due, it was claimed, to LiveCo’s outdated product range. The firm decided to consolidate its manufacturing operations from 14 geographically distributed different sites into one. This major organizational change clearly had a profound destabilizing effect on local networking activity. This to some extent made it easier to develop new local networks specifically in relation to the MRP2 project.

The philosophy behind MRP2 technology is to integrate information used for different aspects of the manufacturing process with wider capacity planning and sales forecasts, so that materials are available when needed without holding unnecessarily high levels of

inventory. Due to this demand for integration, the implementation of these technologies often requires considerable change in both organization and technical practice (Clark & Staunton, 1989). The implementation of MRP2 technologies, then, depends heavily on the context into which they are introduced and require a blending of both technical and organizational knowledge. The notion of a single, generic, 'best' practice with regards to MRP2, promoted (as seen) through diffusion networks, is actually quite misleading when it comes to implementation. Rather, MRP2 technologies need to be (re)configured according to the unique context in which they operate (Fleck, 1994; Swan et al., 1999b). Some researchers refer to this as a process of knowledge *appropriation* (e.g. Clark & Staunton, 1989). The need for organizational integration, in particular, has posed many problems for user firms attempting to implement MRP2 technologies, with examples of failure or partial failure littering the research on implementation (Waterlow & Monniot, 1986; Wilson et al., 1994). LiveCo was perhaps unusual in managing to implement MRP2 technology successfully, achieving both high levels of integration and appropriation of the technology within a relatively short timescale.

LiveCo was structured along traditional hierarchical and functional lines. Because of this, intra-organizational networking might have been expected to be difficult. However, because of the uncertainty surrounding reorganization, formal routines were introduced that demanded that senior managers from all functions would have an input into all major policy decisions, including those concerning new technology. In line with this policy, LiveCo developed a formal cross-functional senior project team to handle implementation (comprising operations management, manufacturing engineering, manufacturing systems, sales and marketing, and logistics). This team met regularly and over an extended period of time, mostly on a face-to-face basis. A crucial feature of implementation in this case, then, was the development of local intra-organizational network, comprising powerful individuals who were engaged in interpersonal networking that transcended functional boundaries. Because individuals in this team were more or less equal in terms of their formal status, regular negotiation took place over project commitments, directions, roles and responsibilities. Thus, the formation of this network comprised many of the social processes highlighted by Ring & van de Ven (1994) as important for inter-organizational networking. This local networking also extended beyond the LiveCo organization to include information systems support from a specialist IT consultancy. This had a long history of working with LiveCo and provided, among other things, a consultant to be a permanent member of the project team. Thus inter and intra-organizational boundaries became blurred during implementation.

Project team members developed an awareness of MRP2 'best practice' via their involvement in a number of inter-organizational networks. For example, members of the project team had heard about MRP2 from reading trade and professional association journals and from software vendors and their publicity materials. As the logistics manager commented '*it was difficult to read or speak to anyone back then without MRP2 being mentioned as the answer to all our problems*'. This manager was also an active member of the IOM and had attended IOM courses and seminars where MRP2 had been advocated. The IT consultant in the team also advocated the use of MRP2 and arranged for the Oliver Wight consultancy to present the MRP2 concept to the board. Thus inter-organizational diffusion networks played a significant role in alerting project managers to generic notions of MRP2 'best practice'.

However, armed with a good understanding of local manufacturing operations developed through their local networks, the project team rejected supplier prescriptions regarding MRP2 'best practice' implementation. They were aware that these prescriptions did not sit comfortably with their particular manufacturing profile. Instead, team members explicitly set out to use their own informal interpersonal contacts in other manufacturing firms (e.g. friends and ex-colleagues) to arrange factory visits to other 'like' companies and to see for themselves what they were doing. These site visits allowed the team to develop an understanding of a broader range of technological design templates for operations management than MRP2. During implementation then, some of these ideas were blended with the MRP2 'best practice' template, with the result being that MRP2 was implemented in a limited capacity for high level planning, whilst detailed shopfloor planning and control was achieved with a combination of in-house software and a Just-in-Time 'Kanban' system. Initial education and training for a broader group of senior managers was then provided by a consultancy specializing in MRP2. However, because project team members were aware that this only offered, as they put it a '*single-point*' solution, they also developed in-house training to show users how knowledge about MRP2 concepts was to be appropriated within the particular operational context of LiveCo.

This case illustrates how knowledge cultivated via intra- and inter-organizational networks may be blended during implementation. A major factor in LiveCo's ability to successfully develop and implement their MRP2 system was that they recognized the limitations of the tightly prescribed and commodified knowledge regarding MRP2. They were thus able to unpack the knowledge gained via inter-organizational diffusion networks and blend this with that gained via local networking activity to implement a system that was appropriate for their specific context. The fact that

implementation team members were from different functions extended local networking activity to cover a broader range of expertise.

Conclusion

If the three cases (summarized in Table 1) are compared in terms of the model outlined in Fig. 1, an insight can be gained into the differing roles played by networks and networking within the innovation process. Thus, the shallow curve that we see in the typical project in Universal reflects a concern with the social construction and creation of knowledge to produce customized client solutions. Although local inter-organizational networks with clients were important for identifying market opportunities, intra-organizational networks among consultants, mobilized by the development of informal, interpersonal, and trust-based relationships, were more important for knowledge creation. This has certain advantages for the invention process. Universal is able to mobilize an extensive knowledge community in which knowledge sharing is relatively open and more or less unaffected by the problems of opportunism seen in market relations. This certainly enhances the speed and responsiveness of the invention process.

Universal Consultancy represents an organization that has managed to create a powerful local networking environment that encourages the sharing of knowledge and information. The ability of organizations to promote such an environment should not be overestimated. Despite Williamson's (1985) claim that hierarchies are generally more conducive to the sharing of knowledge than markets, it is clear that many organizations find it difficult to promote open sharing of knowledge amongst their employees. This is partly due to internal organizational boundaries (e.g. functional departments) but it also reflects the instrumental attitudes that may be fostered by the employment relationship. Put simply, even within a hierarchy, groups and individuals may view knowledge as private property to be hoarded and only grudgingly or calculatedly shared. In this case, the financial performance system developed by the consultancy, as well as the prevailing egalitarian culture, plays a powerful role in fostering the kind of organic, loosely structured sharing of knowledge that is critical in the generation of invention. At the same time, the effective use of email reinforces this by making it possible for knowledge sharing to transcend face-to-face contact.

In contrast, the steeper curve of MRP2 diffusion reflects a much greater concern with broadcasting and legitimation of knowledge and information occurring through the objectification of knowledge. Whereas the intra-organizational networking at Universal permitted a rich, highly interactive and collaborative process of knowledge creation that then generated further innovation, the inter-organizational networking that took place within the structure of the professional associa-

tion network had a more constraining effect on innovation. Certainly, both the objectification of knowledge, as well as the legitimation of selected technologies as 'best', encouraged more rapid diffusion. However, it is also clear that the validating role of the professional association network structure was, to an extent, subverted by the networking activity of technology suppliers. The latter created a pro-innovation bias and biased communication processes in favour of a particular innovation—MRP2—which actually proved much harder to implement in many organizational contexts than it appeared (Clark & Staunton, 1989). During implementation, for example in LiveCo, local inter- and intra-organizational networks needed, then, to be mobilized in order to unpack and reconfigure generic solutions into locally applicable ones.

The model in Fig. 1 allows the ways in which knowledge is organized during the innovation process to be compared across different episodes. This gives it some analytical value that goes beyond purely descriptive accounts of process. The model also attempts—perhaps ambitiously—to weave together innovation, networks and processes of knowledge transformation, and so adding to an understanding of process. However, the model—indeed any model—is schematic. The real complexity and inherent 'messiness' of networking activity during innovation is also captured within the case examples. Finally, comparing these cases has some important implications for further work in this area. In particular, the model that is outlined here is a stylized representation of particular episodes of innovation. It does not address certain important issues, notably the interaction between episodes. If innovation episodes are indeed iterative and recursive as claimed (Wolfe, 1994), then it is also important to understand the nature of these iterations and their relation to networking.

Further research into these areas is certainly called for, especially insofar as it develops a network perspective on the innovation process. In addition, it is also worth commenting on the roles of consultancy firms in the transformation of knowledge and innovation that emerges from these cases. It seems clear, then, from contrasting the case of Universal with the case of the diffusion process, that consultants may play a wide variety of roles, and that their networking activities can act both to expand and constrain innovation. When considering this final point, a major theme of this chapter is highlighted, that is, the need to recognize the diverse roles played by networks and networking alike in the processes of innovation systems.

Acknowledgments

The authors would like to acknowledge Professor Sue Newell, Bentley College, Boston, for her contribution to the empirical work and the Economic and Social

Research Council for supporting the research that informs this analysis.

Managing Innovation in Multitechnology Firms

Andrea Prencipe

Complex Product Systems Innovation Centre, SPRU, University of Sussex, U.K. and Faculty of Economics, University G. D'Annunzio, Pescara, Italy

Abstract: This chapter identifies two major dimensions of capabilities of firms developing multitechnology products: *synchronic systems integration* and *diachronic systems integration*. Within each of these two dimensions, multitechnology firms maintain *absorptive capabilities* to monitor and identify technological opportunity from external sources and *generative capabilities* to introduce innovations at the architectural and component levels. The chapter focuses on a firm's *generative capabilities* and illustrates that a firm's *generative capabilities* enables it to *frame* a particular problem, *enact* an innovative vision, and *solve* the problem by developing new manufacturing techniques. The triad *frame-enact-solve* is argued to be the primary feature of a firm's *generative capability*.

Keywords: Innovation; Multitechnology products; Systems integration capabilities; Generative capabilities.

Introduction

Early research on the management of technological innovation underlined that innovation is a complex multi-actor phenomenon (Rothwell et al., 1974). Innovation is understood as the processes whereby new ideas are commercialized (Freeman, 1972, 1984). Not only do successful industrial innovations require the involvement and co-ordination of all firm's business functions, from R&D, through engineering and manufacturing, to marketing, but also the involvement and co-ordination of external organizations to the firm, such as suppliers (Clark & Fujimoto, 1991; Freeman, 1991; Nonaka et al., 2003; Rothwell, 1992; Von Hippel, 1988). Organizing and managing the innovation process, therefore, span both intra- and inter-firm boundaries (Bessant, 2003; Gassmann & von Zedtwitz, 2003; Katz, 2003; Swan et al., 2003).

The literature on technology strategy has highlighted that several industries are increasingly characterized by multitechnology multicomponent products (Granstrand et al., 1997). Multitechnology multicomponent products have important managerial implications since they intensify the co-ordination efforts for firms developing them. The number of technologies and components is in fact too large to be managed within the firm's

organizational boundaries so that the co-ordination of external sources of components and technologies becomes paramount for the successful development of new products and processes. In other words, the multi-actor nature of the innovation process is exacerbated in firms that develop multitechnology multicomponent products because of the increasing number and relevance of external organizations, such as suppliers, customers, and universities.

Building upon the emerging literature on multitechnology corporations (Brusoni et al., 2001; Granstrand, 1998; Granstrand et al., 1997; Patel & Pavitt, 1997), this chapter identifies the different types of capabilities that firms developing multitechnology products are required to develop and maintain. It proposes a taxonomy that categorizes these capabilities into *synchronic systems integration* and *diachronic systems integration*. Within each category, firms monitor external technological developments (*absorptive capabilities*) and introduce innovative solutions at both the component and architectural levels (*generative capabilities*). The chapter focuses on a firm's *generative capabilities* and argues that *generative capabilities* enables firm to *frame* a particular problem,

enact an innovative vision, and *solve* the problem. The triad *framing-enacting-solving* constitutes the primary feature of a firm's *generative capability*.

The chapter is organized as follows. Based on the theoretical and empirical literature on multitechnology firms and products, the next section introduces two dimensions of capabilities of firm's developing multitechnology products. This is followed by a section that focuses on the firm's *generative* capabilities and attempts to disentangle its primary feature. The final section presents the conclusions.

Multitechnology Firms and Multitechnology Products: The Multiple Roles of Firms' Capabilities

Empirical and theoretical studies on firms' capabilities, although paradoxically in their infancy (given that Penrose pioneered the resource-based approach in 1959), have provided invaluable insights to understand their nature (Dosi et al., 2000) and their role as source of a firm's competitive advantage (Grant, 1998). This section relies on the resource-based research tradition and its more recent evolution known as the capability-based approach, to single out and discuss the role of a firm's capabilities in multitechnology settings. In so doing, it extends the theoretical and empirical research on *multitechnology corporations* (Granstrand & Sjölander, 1990). Granstrand & Sjölander (1990) observed that technological diversification was an increasing and prevailing phenomenon among large firms in Europe, Japan and the U.S. and put forward the concept of the *multitechnology corporation*. A *multitechnology corporation* is a firm that has expanded its technology base into several technologies. Following this line of research, Patel & Pavitt (1997) showed that products, and firms developing them, are becoming increasingly multitechnology. Firms rely on a growing number of specialized bodies of scientific and technological knowledge to develop products.

The concept of a multitechnology corporation rests on the fundamental distinction between products and technologies. A product is a physical artefact made up of components that carry out specific functions and rely on specific yet different technologies. A technology is understood here as the body of knowledge underlying the design, development, and manufacture of the product (Brusoni et al., 2001). In this way, the concept of a multitechnology firm is different from that of multiproduct firm, since 'the development, production, and use of a product usually involve several technologies and each technology can usually be applied in several products. Thus the technology-product connection is not 'one-to-one' (Granstrand & Sjölander, 1990, p. 36). Also as discussed in Grant & Baden-Fuller (1995) and Pavitt (1998), the distinction between product and its underlying technologies is fundamental for theoretical interpretations of the firm and in particular for the definition of its boundaries.

The multitechnology nature of products has significant managerial implications for the firms producing them in terms of the technological capabilities that are required to be developed, maintained, and nurtured over time. In particular, 'make or buy' decisions are critical issues since firms do not and cannot develop in-house all the technologies relevant for product design and manufacturing. Multitechnology firms must increasingly make use of external sources of components and technological knowledge, such as suppliers, through the use of the market or through collaborative agreements, such as joint ventures.

In order to take full advantage of collaborative relations, firms need to be equipped with an adequate and independent set of in-house technological capabilities (Mowery, 1983). Granstrand et al. (1997) found that large firms develop capabilities over a wider number of technological fields than those in which they actually produce, and this number is increasing over time. In other words, firms retain technological capabilities about components whose production is fully outsourced. Specifically, Granstrand et al. (1997) drew some conclusions on outsourcing decisions in multitechnology firms. They distinguished two sets of factors that affect corporate outsourcing decisions: (a) the degree to which the innovation is autonomous or systemic; and (b) the number of independent suppliers outside the firm. On these grounds, they proposed a two-by-two matrix that identifies four cells. Each cell is associated with a different case calling for a particular degree of internal technological capabilities. Granstrand et al. identified four intermediate corporate positions between full integration and full disintegration, where each position is characterized by a different type of technological capabilities, namely exploratory research capability, applied research capability, systems integration capability, and full design capability. For instance, when the number of external sources is low and the innovation is systemic, then companies should maintain a wide range of in-house capabilities, from exploratory and applied research down to production engineering.

Besides the factors identified by Granstrand et al., the type of capabilities that multitechnology firms should develop may depend on the role and the ensuing importance that each component plays within a product. The importance of components within the economics of product, and therefore, of a firm varies greatly according to a number of dimensions, such as their technical features, performances, and costs. Firms conceive *components' hierarchies* in order to identify which are the peripheral and the key components and consequently adjust their technological capabilities (Prencipe, 2003b).

An interesting approach to analyzing the hierarchical role of components in a product has been put forward by Maisseu (1995). Considering three variables,

namely the impact of the component's cost on the cost of the overall system, its influence on the quality of the system, and the technological maturity of the component, he proposed a taxonomy, which identifies four categories. According to this approach, it is possible to determine the relative weight of each component. Thus, components with low impact in terms of quality and cost of the end product and whose underlying technologies are mature are to be considered to be *trivial*. Then, there are *basic components* whose cost is relatively high, while their technologies have reached the maturity stage. *Key components* are those whose characteristics heavily influence the quality of the end product and whose technologies are at the initial stage, but which do not affect the cost of the system to a great extent. Finally, there are the *critical components*. Their influence in terms of cost and quality is relatively high and their underlying technologies are at the initial stage.

It is worth stressing that this approach heavily underlines the issue that components may evolve across the hierarchy over time. Technological change occurring at different levels of the systems may shift the relative hierarchy of components and system-level critical problems. As hierarchies are usually constituted according to a series of 'rules' valid at a given point in time, they can provide predictions as long as the 'rules' remain unchanged. Therefore, a hierarchical taxonomy concerning products made up of many components may be undermined by changes in the underlying component technologies. Evolution may be endogenous in that changes can occur within the system itself, stemming from existing as well as exogenous technological trajectories, that is to say existing technologies can be replaced by new ones or new technologies can be added (Prencipe, 1997).

This may well inform firms' outsourcing decisions. For instance, Pavitt (1998) argued that a critical issue that companies take (or should take) into account when outsourcing components is the rate of change of the underlying technologies and the ensuing *technological imbalances* (Rosenberg, 1976). When technologies advance at different rates then companies should be able to keep pace with them and incorporate changes in their product and their *components' hierarchies*.

Identifying Capabilities in Multitechnology Firms

Drawing on and extending Granstrand et al. (1997), the aim of this section is to single out the diverse roles of firms' capabilities in multitechnology settings. Firms producing multitechnology products develop capabilities to generate new products and processes as well as to integrate externally produced components and co-ordinate the development of new technologies. In multitechnology settings, therefore, a firm's capabilities are not monolithic entities, and do not perform 'one role only', rather they are multifaceted and multipurpose. This is the reason why multitechnology

corporations are important and interesting empirical settings in which to study the roles of a firm's capabilities. Besides R&D, design, and manufacturing capabilities, therefore, we argue that firms producing multitechnology products must develop two main types of capabilities to compete successfully over time (Prencipe, 2003).

Synchronic systems integration refers to the capabilities to define the requirements, specify and source equipment, materials, and components, which can be designed and manufactured either internally or externally, and integrate them into the architectures of existing products. These capabilities are developed and maintained through a deliberate strategy labelled *intelligent customership* that enables firms to gain a better understanding of the underlying technologies of outsourced components in order to control and integrate changes and improvements (Prencipe, 1997). Therefore, *synchronic systems integration* relates to the capabilities to manage evolutionary changes in products and their underlying technologies through the introduction of component-level innovations.

Diachronic systems integration refers to the capabilities to co-ordinate the development of new and emerging bodies of technological knowledge across organizational boundaries in order to introduce new product architectures. Different bodies of technological knowledge relevant to the production of a multitechnology product may be characterized by uneven rates of advance. Firms that develop multitechnology products must keep pace with and, more importantly, co-ordinate uneven technological developments to incorporate them into new products and processes (Prencipe, 2004). Also, firms developing multitechnology products cannot encompass in-house, all the relevant scientific and technological fields. The management of the relationships with and co-ordination of external sources of technologies, such as universities, research laboratories, and suppliers, becomes, therefore, a central task for multitechnology firms (Lorenzoni & Lipparini, 1999). Therefore, *diachronic systems integration* relates to the capabilities required to master revolutionary changes in products and technologies.

Multitechnology firms are required to develop both *synchronic* and *diachronic systems integration capabilities* to pursue both incremental and discontinuous innovations and changes in order to compete successfully. *Synchronic* and *diachronic systems integration* may well constitute the capabilities of the *ambidextrous organization* as identified by Tushman & O'Reilly (1996). Ambidextrous organizations are those capable of competing in mature environments through incremental innovations and in new environments through discontinuous innovations.

Besides integrating and co-ordinating, multitechnology firms monitor external technological developments (*absorptive capabilities*) and introduce innovative solu-

tions at both the component and architectural levels (*generative capabilities*). *Absorptive capabilities* are those required to monitor, identify, and evaluate new opportunities emerging from general advances in science and technology. This is close to the concept of absorptive capacity as put forward by Cohen & Levinthal (1990). *Generative capabilities* are the capabilities to innovate both at the component level and the architecture level (i.e. new paths of product configuration) also independently of external sources. While component-level innovations mostly relate to the synchronic dimension of systems integration, architectural-level innovations refer to the diachronic systems integration. Exploratory research programs play a fundamental role in the introduction of new component technologies as well as new product architectures. *Absorptive* and *generative capabilities* permeate both the synchronic and the diachronic dimension of systems integration (Prencipe, 2004).

The discussion above should be interpreted as a preliminary attempt to categorize the role of capabilities of firms developing multitechnology products. The intention is not to defend the boundaries of a specific category, particularly because there are other dimensions according to which firms' capabilities can be categorized (see, e.g. Granstrand & Sjölander, 1990; Granstrand et al., 1997). The use of the different categories is instead designed to draw attention to the multiple roles that capabilities have in the economics of the development of multitechnology products. The different roles of capabilities of multitechnology firms are discussed at length in previous works. For instance, Brusoni & Prencipe (2001) discussed the impact of modular design strategy on firm's capabilities operating in multitechnology settings. The synchronic and diachronic dimensions of systems integration and their relationships with a firm's corporate strategy are discussed in Prencipe (2003). Systems integration is scrutinized in relation to typologies of products (e.g. monotechnology versus multitechnology) and rate and stage of development of the underlying technologies in Brusoni et al. (2001). Dosi et al. (2003) provided an evolutionary economics interpretations of a firm's systems integration capabilities. Paoli & Prencipe (1999) discussed the role of a firm's knowledge base in multitechnology settings. Building on these previous works, the following section focuses on generative capabilities and attempts to identify its primary features.

Generative Capabilities: Primary Features

In the previous section, *generative capabilities* have been defined as the capabilities to introduce innovative technological solutions both at the component level and the architectural level also independently of external sources. To detail the primary features of *generative capabilities* we rely on the contributions of Dierickx & Cool (1989) on the cumulative nature of a

firm's capabilities and Dosi & Marengo (1993) on the role of a firm's *frame of reference*.

Dierickx & Cool (1989) put emphasis on the building process that affects the accumulation of a firm's capabilities. Although they talked about strategic assets, we argue that their argument holds also for a firm's capabilities. They argued that the common feature of a firm's capabilities is 'the cumulative result of adhering to a set of consistent policies over a period of time. Put differently, strategic asset *stocks* are *accumulated* by choosing appropriate time paths of *flows* over a period of time ... *while flows can be adjusted instantly, stocks cannot*. It takes a consistent pattern of resource flows to accumulate a desired change in strategic asset stocks' (1989, p.1506, original emphasis).

Dierickx & Cool argued that the process of accumulation of *stocks* is characterized by the interplay of the following properties:

- (a) *time compression diseconomies*, ('crash' R&D programmes are often characterized by low effectiveness);
- (b) *asset mass efficiencies* ('success breeds success');
- (c) *interconnectedness of assets stocks* (assets stock accumulation is influenced by the stock of other assets);
- (d) *asset erosion* (all asset stocks decay and need to be maintained); and
- (e) *causal ambiguity* (the process is not deterministic but it is characterized by stochastic elements).

This distinction between *stocks* and *flows* and the features of the building process of firms' capabilities as proposed by Dierickx & Cool (1989) underlines that a firm's capabilities must be painstakingly accumulated over time. Also, the distinction between *stocks* and *flows* underlines the relevance of the accumulated technological capabilities both as a basis for further development and the need for them to be continuously cultivated over time via dedicated investments in experimentation and personnel. Based on Dierickx & Cool, we argue that a firm's capabilities need to be built, cumulated, nurtured, and refined over time. Although the *stock-flow* dynamics captures the relevant features of each type of capability proposed in the taxonomy, as discussed below it is particularly useful to better understand the primary features of a firm's *generative capabilities*.

Dosi & Marengo (1993) argued that a firm's learning processes could not be reduced to mere information gathering and processing. Unlike Bayesian learning processes, where new information is employed to update the probability distribution within a fixed and unchanging *frame of reference*, in the learning processes Dosi & Marengo referred to, the *frame of reference* is continuously updated, constructed, evaluated, and eventually modified. Dosi & Marengo

maintained that “There are fundamental elements of learning and innovation that concern much more the *representation* of the environment in which individuals operate and *problem solving* rather than simple information gathering and processing” (1993, p. 160, original emphasis).

Based on this line of reasoning, we argue that a firm’s frame of reference, and more importantly its continuous renewal, constitute the distinctive base of its learning processes. A firm’s frame of reference is based on its cumulated knowledge and its updating and modification are the result of continuous learning investments. What is fundamental is the *dynamic* that characterizes the frame of reference and its continuous renewal. This dynamic is well captured by the *stock-flow* binomial *à la* Dierickx & Cool. We propose that a *generative capability* hinges on a firm’s frame of reference (i.e. its capability to frame and identify a problem and allocate resources to its solution) and problem solving capability (i.e. its capability to develop a solution to a problem). Also, we contend that the primary features of a firm’s *generative capabilities* are *problem framing*, *vision enacting*, and *problem solving*. Firms build, update, and renew their frames of reference within which they enact an innovative vision to solve problems in turn identified by their frame of reference (their view of the world). The triad *framing-enacting-solving* is clearly inspired by the work of Weick (1969, 1985) on enactment and sense-making.

Framing, Enacting, and Solving in Context: An Example of a Firm’s Generative Capabilities

The development of the first- and second-generation wide chord fan blade by Rolls-Royce Aero Engines discussed in Prencipe (2001) constitutes a good case to explain the deployment and enhancement of a firm’s *generative capabilities*. The in-house technological capabilities accumulated over time by Rolls-Royce constituted the base of its learning processes and gave impetus to virtuous cycles of *framing*, *enacting*, and *solving*. Notwithstanding the failure of the first attempt (the all-composite wide chord fan blade), Rolls-Royce’s conviction about the enormous advantage of the wide chord fan blade supported new investments aimed at developing the radically new technology. Due to the technological knowledge developed over time, Rolls-Royce was able to *frame* the problem (low performing, narrow blade) and *enact* an innovative technological vision (wide chord fan blade).

Borrowing the terms of Dierickx & Cool (1989), the knowledge garnered during the development of the first-generation wide chord fan blade represented Rolls-Royce’s *stock* of cumulated technological knowledge, which was refined and advanced through dedicated in-house investments (*flows*) that led to the development of the second-generation fan blade. While the stock of in-house technological knowledge cumulated during the development of the first generation fan

blade formed the platform for Rolls-Royce’s new technological solution, the dedicated investments in experimentation and personnel enhanced the company’s *generative capabilities*.

The interrelations between first- and second-generation fan blades also provide empirical support to the insights of Dierickx & Cool on the features of the building process of a firm’s capabilities. The success of the second generation built heavily on the first-generation’s success (*asset mass efficiency*). As Dierickx & Cool argued “firms who already have an important stock of R&D know-how are often in a better position to make further breakthroughs and add to their existing stock of knowledge than firms who have low initial levels of know-how” (Dierickx & Cool, 1989, p. 1508).

The second-generation fan blade was not a mere *point extrapolation* of the first-generation, however. It contained several innovative technological features both at the product level and at the process level. The first-generation wide chord fan blade was innovative at the time of its introduction. It was, however, both complex and labour intensive in terms of engineering and manufacturing activities. This called for a fundamental change in design, analysis, and manufacturing processes. Therefore, although the second-generation fan blade development relied heavily on the *stock* of previously accumulated technological capabilities, the company’s *generative capabilities* from the first generation fan blade were not only deployed, but also were nurtured and enhanced via dedicated investments in experimentation and personnel. These investments gave rise to a new virtuous cycle *frame-enact-solve*. The cycle started with the *reframing* of the complex and labour intensive engineering and manufacturing activities of the first-generation blade which led to new design concepts of hollow blades that in turn prompted to laboratory programmes on bonding and forming fabrication processes. Eventually this led to a better understanding of the manufacturing processes (Prencipe, 2001).

Concluding Remarks

This chapter has identified two main dimensions of the capabilities firms developing multitechnology products. *Synchronic systems integration* relates to the capabilities required to specify, buy, and integrate externally-designed and produced components. Firms developing multitechnology products are also required to develop *diachronic systems integration*, that is, the capabilities required for the co-ordination of change across different bodies of technological knowledge as well as across organizational boundaries. *Synchronic systems integration* and *diachronic systems integration* refer to the capabilities of the *ambidextrous organization* as identified by Tushman & O’Reilly (1996). The chapter also argued that firms are characterized by what Cohen & Levinthal (1990) labelled *absorptive*

capabilities related to monitoring, identifying, and evaluating new technologies.

The chapter has then focused on *generative capabilities* needed to innovate both at the component level and the architectural level, also independently of external sources. It proposed that the primary features of a firm's *generative capabilities* are *problem framing*, *vision enacting*, and *problem-solving*. Firms build, update, and renew the frames of reference within which they enact an innovative vision to solve problems that, in turn, are identified by their frame of reference. Following Dosi & Marengo (1993), we argued that *problem framing* is the distinctive basis for organizational learning processes.

This chapter is an attempt towards a better understanding of a firm's capabilities. By considering the multitechnology empirical setting, the chapter proposed a taxonomy to categorize a firm's capabilities according to their roles. The capabilities needed to strategically manage the links with a network of suppliers are paramount for a firm's competitiveness in a multitechnology setting (Brusoni et al., 2001; Lorenzoni & Lipparini, 1999). This chapter has extended this argument and argued that in-house capabilities play an equally important role in building such competitive advantage in a high-technology dynamic environment. The firm's *generative capabilities*, discussed in-depth here, constitute an important dimension of dynamic capability (Teece & Pisano, 1994) that enables a firm to grow (Penrose, 1959).

Innovation Processes in Transnational Corporations

Oliver Gassmann¹ and Maximilian von Zedtwitz²

¹ *Institute for Technology Management, University of St. Gallen, Switzerland*

² *IMD-International Institute for Management Development, Switzerland*

Abstract: If innovation is considered as a process, then the differentiation of the innovation process into two phases creates several benefits. These two phases are, firstly, a pre-project phase fostering creativity and effectiveness, and a secondly a discipline-focused phase to ensure efficiency of implementation. This differentiation enables transnational companies to replicate and scale innovation efforts more easily in remote locations, exploiting both economies of scale and scope. Although the characteristics of these phases are quite distinct, few companies have consistent and differentiated techniques to manage and lead the overall innovation effort specific to each phase.

Keywords: Innovation; International project management; R&D; Creativity; Phase model.

Introduction

If innovation is considered as a process, then the differentiation of the innovation process into two phases creates several benefits. These two phases are, first, a pre-project 'cloudy' phase fostering creativity and effectiveness and, second, a discipline-focused 'component' phase to ensure efficiency of implementation. This differentiation enables transnational companies to replicate and scale innovation efforts more easily in remote locations, exploiting both economies of scale and scope. Although the characteristics of these phases are quite distinct, few companies have consistent and differentiated techniques to manage and lead the overall innovation effort specific to each phase.

Our overarching goal is to show that dividing the overall innovation process into the cloudy and component phases is a simple and easily implementable way to overcome typical communication and managerial problems in international innovation. In this chapter we first summarize earlier phase models of innovation. In this context, we refer to innovation as a company's efforts in instituting new means of production and/or bringing new products or services to market. Next we describe several innovation processes. An innovation process is a cumulative sequence of defined stages and activities leading to an innovation. Recent research, most notably work done in the Minnesota Innovation

Research Program (see Van de Ven, Angle & Poole, 1989; Van de Ven, Polley, Garud & Venkataraman, 1999), shows that innovation is usually unpredictable and difficult to manage with tight controls. The two-phase model we outline in this chapter allows chaotic and random innovation processes to occur in the early innovation phase, and argues for a narrowing and redirection of the creative energy in the first phase during execution and implementation of the initial ideas in the second phase. We then describe tools and systems that help to channel creativity into implementation suited to transnational innovation. Creativity here is understood to be the ability to produce both novel and original ideas appropriate for the task at hand. Transnational innovation is innovation that includes participants of the innovation process from geographically distributed locations, usually in other countries or time zones. We conclude with some implications for managing innovation processes in transnational settings.

Linear and Non-Linear Models of Innovation

Innovation is an inherently complex and unpredictable task. Companies that are driven by meeting financial and operational targets as well as strategic objectives have invented numerous techniques to capture the uncertainty of innovation into a measurable and hence manageable framework.

Pioneering work done by Schumpeter (1911, 1939) and Bush (1945) helped to explain the origin of organized technology development. Building on the notion of *science push*, they described innovation as a linear process from basic research, applied research, and development, through design and manufacturing, to marketing and sales (see Marinova & Phillimore, this volume). Similar models based on a linear logic (e.g. the value-added chain, Porter (1985)) reinforced the concept of a sequential innovation process. Science and technology programs in many Western countries are still based on this pipeline model and are often used to justify the financing of public research and science. This ideology implicitly assumes a causal correlation of research input and innovation output: higher investments in basic research will lead to more innovation and more advanced products.

The linear model has worked well in fields where immediate applicability and practicality was not a determining driver. A well-known example of science-driven innovation is laser technology: the theoretical foundation of this technology was built between 1900 and 1920 by famous scientists such as Max Planck (quantum effect), Niels Bohr (atomic model) and Albert Einstein (conventional sources of light emit a spontaneous photon radiation). Scientific research on laser technology itself took place in the 1950s, and the first successful laser device was constructed by Theodore Maiman in 1960. Today's applications are widespread: cutting, drilling and welding of materials; distance and gas measuring; telecommunications; and medical technology.

In the 1960s, a new paradigm emerged based on the empirical work of Schmoockler (1966) in patent statistics. Innovation was found to be determined more by *market pull* than by the classical science push. This model also assumes a linear causal innovation sequence, but in this case a market demand is what triggers innovative activity in the preceding functions. This model enhanced the position of marketing: R&D (research and development) departments and new product development teams were assigned reactive roles to develop products according to given specifications.

The market-driven model has given companies a tool that aligns internal processes according to measurable output, thus greatly increasing the role of R&D as a strategic element in achieving, building and expanding market dominance. For instance, AT&T strongly pushed transistor development at Bell Labs because telephone companies demanded smaller and more convenient switching technologies. Hippel's (1988) lead user concept, further underscored the importance of capable users, and customers, as a source of innovation. Lead users are technologically savvy customers with an urgent need for improved products who could serve as trendsetters in an emerging market. Hilti, a leading construction technology supplier,

applied the lead user concept and easily halved R&D costs and time-to-market (Hippel & Herstatt, 1991).

Both the science push and the market pull approaches are linear sequential models. Only the initial source of innovation is different. However, several studies since the late 1970s have shown that innovation processes are seldom linear processes triggered by a single source—either scientific potential or market need—but rather *random processes* that are more complex and uncertain than the linear model assumes (e.g. Cohen, March & Olsen, 1972; Tushman & Anderson, 1986).

Van de Ven and colleagues (1989, 1999) have undertaken several longitudinal studies consisting of thousands of single observations, and assembled ample and rich evidence that innovation is inherently a chaotic process. The description of 3M's Cochlear Hearing Implant innovation journey (detailing more than one thousand events of the 3M innovation effort, see Van de Ven et al., 1999) is well documented and underlines how difficult it is to predict consequences from decisions to actions to outcomes.

Managers and organizations, however, assume a certain degree of predictability and cause-and-effect relationships in innovation and often introduce structured management schemes to increase the stability and coherence of their efforts. Linear models were improved by integrating science push and market pull into non-sequential *feedback models*. Regardless of the trigger of innovation, several complete feedback loops ensure that both science and market inputs are recognized and implemented. For instance, Roy (1986) described innovation as a cyclic process in which technological opportunities, invention, knowledge production and market demands were linked together. Later, Kline (1985) and Kline & Rosenberg (1986) introduced the *chain-linked model*. This model describes five paths of innovations. Some of these paths are linear and follow the invention to development to production to marketing sequence, while other paths are based on several feedback loops, i.e. reiteration to early-stage innovative activity. A major implication of their model is that the market remains a significant driver of innovation and that science-driven innovation is relatively rare, yet should not be totally neglected.

In the 1980s, several integrative approaches to R&D management pioneered by Japanese companies (e.g. the 'rugby'-approach, which advocates a team rather than a relay approach to product development) became popular under the umbrella of simultaneous or concurrent engineering. These approaches focused on overlapping innovation sub-phases, mainly in product development and manufacturing (see e.g. Liker, Kamath, Wasti & Nagamachi, 1995; Nishiguchi, 1996). Based on these interlaced models of innovation, i.e. innovation processes with overlapping sub-phases, *interaction models* were developed that emphasized the

principle of interaction itself as an important source of innovation (see e.g. Durand, 1992; Schmoch, Hinze, Jäckel, Kirsch, Meyer-Krahmer & Münt, 1995). They explain innovation as the result of intense, continuous interaction of both individual and institutional protagonists, and communication becomes a key factor in innovation processes. Nonaka & Takeuchi (1995), who introduced the rugby-approach of R&D management noted above, focus on knowledge creation and sharing as the central determinants of corporate success, and consider innovation almost as a byproduct of knowledge management (see also Nonaka & Ahmed, 2003).

Over the past decades, compliance with ISO requirements has led to highly disintegrated and ineffective R&D phase concepts and the illusion that all critical innovation factors can be measured and structured. At the same time, engineers and developers have requested more creative freedom and fewer administrative chores, particularly in the early phases of innovation. Although it is now accepted that innovation processes are non-linear, managers need normative models that reflect the need for clear, unified processes throughout the organization. In the following section we compare process models that attempt to combine both linear and non-linear approaches to innovation.

Normative Models of Innovation Processes

In R&D management practice it is very rare to find clearly distinguishable and predetermined project phases executed exactly according to a predefined schedule. Although systems engineering offers some help in structuring the R&D process into linear sequential project phases, R&D managers are generally not successful in implementing these methods in the innovation process. However, there are some frameworks that guide the design of innovation processes in a company.

Classical phase segmentation and process orientation (as in modern management theory) have been combined in the *stage-gate process* (see Cooper, this volume; Cooper & Kleinschmidt, 1991; O'Connor, 1994; for transnational innovation: Gassmann, 1997). Every step—or 'stage'—necessary to complete a particular project task is linked to the next by a 'gate' at which decisions for the continuation of the project are made. Unlike milestones, gates are more flexible in terms of time, date and content. Gates allow a deliberate parallelization of phases as well as their recombination or adaptation to new requirements. At each gate the R&D project is analyzed and reviewed in its entirety, often including some competitor intelligence (i.e. evaluation of similar R&D projects by competing firms), as well as external market and technology developments. The number of stages and gates needs to be adapted to industry and project requirements. Ex-ante agreements serve as guidelines for the collaboration of project participants.

The *loose-tight concept* also plays a central role in the design of R&D processes (e.g. Albers & Eggers, 1991; Wilson, 1966). According to this concept, the success of the project depends on the degree of organization during the R&D process. In the early stage of a project, the organization should be designed loosely; towards the conclusion of the project, it should become more and more rigid and tight. The varying degrees of R&D project organization are imposed by constraints in time: Although creativity and idea generation are highly important in the early stage, the management concern shifts to efficiency and project implementation on schedule in the later stage.

The stage-gate process is successful in areas and industries dominated by market-pull innovation. Further indications for applying the stage-gate process are innovations in existing markets (e.g. transfer of product development competence); new applications of existing products and services (e.g. relaunch of an adapted product in a new market); high costs of product development and market introduction (e.g. initial product releases); and limited uncertainty in terms of expected innovation (e.g. incremental innovation). Most of today's industries and well-managed R&D processes rely on the stage-gate process to some extent.

In industries or projects where the science or technology push is the dominant driver of innovation, stage-gate processes are too rigid and slow. Innovations that are triggered by a technological invention with unknown market potential need different processes and techniques to succeed. Under these circumstances, the *probe-and-learn process* is more appropriate. This process has been described from a number of angles, including marketing and discontinuous innovations (e.g. Lynn, Morone & Paulsen, 1996), product development and experimentation (e.g. Thomke, 1995; Wheelwright & Clark, 1992) and technology strategy (e.g. Iansiti, 1998).

Traditional market research methods are based on the 'law of big numbers'—the more customers who want a new feature or product, the more valuable it is. These methods often do not work in technology-driven innovation, as target markets do not yet exist. More anticipatory and exploratory market research methods are needed, such as scenario techniques (pioneered by Royal Dutch/Shell, see Shoemaker, 1995), Delphi studies (see Best, 1974; Dalkey & Helmer, 1963), Beta-customer test groups (see Kottler, 2000) and lead user workshops (Hippel, 1986, 1988). Successful examples of this kind of innovation are 3M's Post-it, Corning's optical fiber technology, Netscape's Navigator and Schindler's LiftLoc system.

Many innovation projects in New Economy companies (i.e. those with mostly Internet-based products and services) have been characterized by a high degree of uncertainty in terms of market fit (see e.g. Trott & Veryzer, 2003). An example of an e-innovation that

followed the probe-and-learn process is ICQ (pronounced 'I seek you'). The term was coined by four avid young computer users—who established Mirabilis, a new Internet company, in July 1996 in Tel Aviv, Israel—to describe a new way of communicating over the Internet. Although millions of people were connected to one huge worldwide network—the Internet—they recognized that these people were not truly interconnected. The missing link was a technology that would enable Internet users to locate each other online on the Internet and create peer-to-peer communication channels in an easy and simple manner.

They developed a crude prototype first, and offered it free of charge on the Internet in November 1996. Still a very sketchy product, it was full of flaws and lacked important functionalities. However, based on online feedback from users and rapid prototyping techniques, they continued to fine-tune the first version. Three months after the launch, ICQ customer base reached 350,000 users; after an additional three months this number stood at 850,000. Even at this stage the product was continually refined and adapted to new user needs (e.g. the introduction of a 'I am busy' state in order to prevent communication bottlenecks). However, there was no clear product strategy.

Fourteen months after first introducing the product, Mirabilis had 8 million subscribers and handled 1.3 million users a day. Although the company operated with heavy losses, the market value increased in expectation of even higher subscription numbers. Eventually, AOL acquired Mirabilis in mid-1998 for \$287 million in cash and renamed it ICQ. By November 2001, ICQ had 120 million users.

ICQ is perhaps a forerunner of product development in an increasingly international and online-based world. Two observations can be made:

Even established industries develop products with more and more online content. In addition, simulation, virtual reality and communication tools based on broadband information and communication technologies (ICT) allow research, development and design to integrate users, scientists and engineers in virtual teams around the world. Greater density of information and greater geographical dispersion are two important factors in the design of modern innovation processes.

Generally, there is only a vague idea about the eventual product design at the start of a development project. Project members differ greatly in their understanding of project objectives and methodologies. By communicating their ideas during the conception of the project, project members create shared knowledge and understanding. In the early phases of a project, tacit or implicit knowledge is transformed into explicit knowledge. But designing and generating product design drafts and specification lists must be done and decided on as a team. Knowledge sharing and know-how transfer is hampered not only by geographical separation but also by epistemological and cultural barriers.

Stage-gate, loose-tight and probe-and-learn processes were developed when most R&D was carried out in one location by one team. However, the typical development team at the beginning of the 21st century is becoming transnational in nature (Boutellier, Gassmann & Zedtwitz, 2000; Gassmann & Zedtwitz, 1997). Probe-and-learn processes also appear to work well in web-based settings and can thus be transposed to dispersed team settings. Nevertheless, distance—and thus problems of different time zones—and culture impose barriers and further imperfections on the innovation process (see e.g. Hadjimanoli, 2003). Would it be possible to combine some of these process models and adapt the result to a truly transnational innovation process framework?

Cloudy-to-Component Process for Modular Innovations in Multinational Companies

What is the Cloudy-to-Component Process?

Companies that undertake more than just application engineering and engage in fully fledged R&D will need to split their innovation process into two phases: the 'cloudy' phase and the 'component' phase. More differentiated phase concepts are commonly accepted and applied in industrial R&D, but they suffer from the strictly sequential execution of project phases and are therefore often impractical in transnational innovation projects. The highly structured stage-gate process can easily become bogged down in bureaucracy and rigidity; the probe-and-learn process can lead to unplanned trial-and-error development and unproductive chaos.

Our concept of the cloudy-to-component process (C-to-C process, see Gassmann, 1997) is especially appropriate for innovation processes in transnational companies. Remember that existing innovation processes have been fine-tuned for collocated innovation. Due to the increased internationalization of R&D and knowledge creation, it has become more difficult and rewarding at the same time to optimize global product development and integrate distributed competencies (Gassmann & Zedtwitz, 1999a).

Our C-to-C process does not imply that projects are carried out without reviews or milestones. Such projects tend to be managed both ineffectively and inefficiently. The solution lies in placing the appropriate focus on what is to be achieved in the two phases. Too many projects are slowed down or canceled because faulty designs have to be corrected late in a project, and too many projects have not achieved their full potential because project managers have pushed for cost efficiency and short-term solutions too early. In transnational innovation projects, there is less slack to compensate for these management errors. At the same time, they offer great potential for 'doing it right the first time'. This separation into two phases must be well planned beforehand and must be

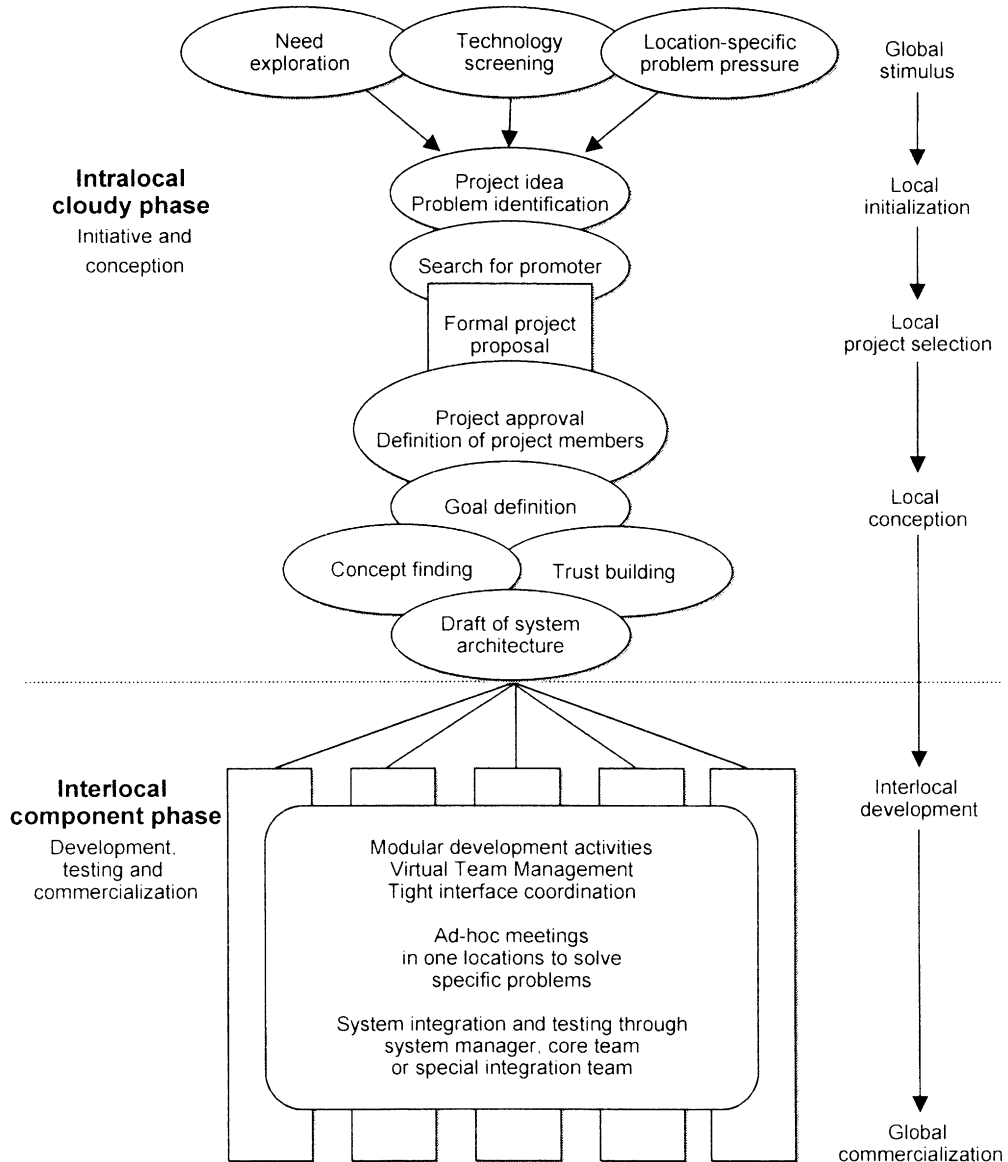

Figure 1. The separation of the R&D process into two phases allows a focus on effectiveness and efficiency in the appropriate stages.

communicated to, and accepted by, all involved parties. The ‘cloudy’ phase is thus reserved for wild, inventive creativity, and every idea is given a chance. Only when the project proposal is finally approved does the cost-intensive component phase set in with structured engineering methods (Fig. 1).

Inputs to the Cloudy Phase

The first phase—the ‘cloudy’ phase—is the domain of creative idea generation, research and advanced devel-

opment. Freedom of thought and an open playing field for engineers should be ensured. During the cloudy phase the principal product features are conceived, the main system characteristics defined, and the project is initiated. This early phase is based on market and technology research, as well as on internal problem pressures.

Market exploration in this phase is based on traditional market research tools such as panel research, focus group interviews, sales and distribution

questionnaires, scenario techniques, lead market analysis, etc. More recent techniques include cooperative forms of R&D such as 'lead users' and 'anthropological expeditions', both of which help to tap into implicit user knowledge (see Leonard-Barton, 1995). Technology screening and assessment also take a variety of forms. Technology listening posts, leading-edge innovation centers, technology intelligence and technology forecasts, expert interviews, patent database research, and reverse engineering of competitor products are typical techniques and sources used here. Exploration of markets and technologies has to be conducted on a global scale, as the sources of technical knowledge are less and less limited to a few regions of innovation and markets are becoming increasingly international in nature.

Needs exploration and technology screening are the two primary sources of good project ideas. Ideally, project ideas result from a balance between market pull and technology push. Dominance of technology-focused engineers would lead to over-engineered products that would not be accepted by the customer. Conversely, short-term profit considerations of sales and marketing people with no technological vision would reduce the long-term innovation capacity of the company (striking the right balance is one of the fundamental problems of innovation management). In the early cloudy phase of a project, it is essential to allow creative input to come from all possible directions.

As well as being influenced by technology and market determinants, the generation of project ideas can be highly affected by location-specific problems and pressures such as low capacity utilization, financial difficulties and fashion trends. Low capacity utilization in a particular site (e.g. due to relocation of manufacturing to another site) will urge local management to search for new businesses. Units with negative financial results and low cash flows are under more pressure to change than units with profitable products. We also found above average creativity and a propensity to initiate projects in R&D units that were in danger of being rationalized due to global efficiency enhancement measures. If management does not succeed in communicating a clear framework and a common vision, the imminent crisis is worsened by the growing paralysis of the work force. For instance, the significant departure of qualified personnel at DASA (a German aerospace company) in 1995 was related to the long uncertainty about goals as well as changes in the leadership of MTU (a German jet engine and power plant company and close business partner of DASA). Unlike ABB, which experienced a 'creative crisis' in its GT-24/26 radical innovation project (see e.g. Imwinkelried, 1995; Zedtwitz & Gassmann, 2002), and IBM, which experienced such a crisis in its VSE (virtual storage extended) development project (see e.g. Gassmann, 1997), MTU was characterized by paralysis

that resulted in a reduction of idea generation and innovation.

Fashion trends often seduce managers into enlarging their product spectrum with the latest and most refined products in the market. Many R&D projects are thus initiated not because of a clear market need or technological potential but rather to improve the image or reputation of a particular business unit. Besides company-external market pull (e.g. request for a new product) and technology push (e.g. exploitation of a technological capability), a major driver of new project ideas is therefore a company-internal problem push (e.g. justification of previous market investments and product commitments). The two external drivers prevail in a global environment, whereas the internal driver is local.

Examples of the C-to-C Process in Industry

The innovation process in the chemical and pharmaceutical industries is two stage and models very much like our C-to-C process. BASF underscores the distinction between cloudy and component phases by speaking of 'R&D activities' in the early R&D stages and of 'R&D projects' in later stages. For Bayer, milestones and project review meetings only start once the preclinical phase has been reached, when the project is started formally (Fig. 2).

General Motors calls this early phase of innovation the 'bubble-up process'. This process is driven by an interdisciplinary team, representing advanced development, strategic purchasing and advanced marketing. Most of the activities focus on strategy development and exploration of markets, brands and technologies. At Schindler, the owner of the cloudy phase is a unit called the Technology Management Area whose technological experts, representatives of innovation marketing and lead users jointly develop so-called concept elevators. These functional prototypes show technical feasibility and market acceptance; they also define the principal product architecture and technology to be used. The individual components will later be developed and fully documented by the development center.

The distinction between cloudy and component phases is therefore not an academic one, but a very real one. Companies succeeding at transnational innovation manage each phase differently and optimize the deployment and utilization of specific organizational and management techniques.

Intralocal Versus Interlocal Execution in the C-to-C Phases

There is substantial research indicating that innovation is spurred by geographical proximity between R&D and other R&D units, suppliers and customers (e.g. Allen, 1971; Hippel, 1988; Tushman, 1979). As Tushman (1979) noted, the patterns and intensity of

Figure 2. Bayer: The first milestones start at preclinical development.

communication differ remarkably between early creative R&D and later-stage development work.

R&D in the early cloudy phase is a contact sport. Many tools based on modern communication technology and advances in virtual engineering may allow people to collaborate more productively at a distance, but the trip to the coffee corner or across the hallway to a trusted colleague is still the most reliable and effective way to review and revise a new idea. Moreover, the internal sociopolitical game of finding and convincing an idea champion as well as building a core team is based on frequent and face-to-face encounters. The early cloudy phase is therefore heavily intralocal.

However, the stimuli for new ideas and projects—customer needs, technology potentials and performance pressures—can have very global origins. Scientists maneuver in an international scientific community in which the locus of the individual is irrelevant. Gatekeepers are active listeners and transferors of outside ideas to the internal R&D organization (Allen & Cohen, 1969). The potential of outside transparency is of course curtailed by the effects of the not-invented-here syndrome (see e.g. Katz & Allen, 1982), which still governs many contemporary R&D organizations.

Once the product or system architecture has been (locally) conceived, and most of the interdependencies between different parts of the final product have been defined and described, the actual R&D work can be separated and assigned to specialized and better prepared R&D units. Some research may still have to

be carried out with respect to the underlying properties and improvements of individual system components, but these should not affect the system as a whole. Coordination and communication about the system is now the task of the overall project management team, which controls and directs the innovation effort through interface coordination, travel and regular project reviews. The integration of local customers in the innovation process, and the restricted availability of critical engineering and testing resources, require the dispersion of project activities, making the component phase part of interlocal innovation (Gassmann & Zedtwitz, 1999b).

Building Blocks for Improving the ‘Cloudy’ Phase in Transnational Innovation

Intensive Idea Flow and Workflow Systems

Although creativity flourishes over shorter distances, recent advances in collaborative workflow systems (see e.g. Carmel, 1999) allow the idea generation for a single project to take place on a global scale. This was demonstrated by ABB’s workflow system PIPE (Project Idea, Planning & Execution), a Lotus Notes-based workflow system designed to transmit and distribute ideas, problems, commentaries and solutions by means of modern information and communication technologies. The generator of an idea also selected the group of persons who could access his contributions. His initial idea, along with his evaluation of commercial

potential and supplementary comments, was then refined and complemented with the ideas and suggestions of other PIPE participants.

If an idea received enough support, a formal project was proposed, for which detailed information about objectives, risk, possible problems and available resources was required. Upon approval of the project proposal, the program manager transferred this information into the PIPE Planning Application. The project idea was then integrated into the overall project plan. A project manager was assigned and a decision was taken on what the participating sites would contribute. Local group managers proposed local project schedules defining sub-goals, costs and means of funding. The program manager, local corporate research managers and business unit representatives then evaluated the consolidated project plan, contributing their priorities by e-mail.

PIPE also supported project execution. Simple and formalized project reports concerning costs, schedules and results served as easy-to-distribute project information. A report archive logged the project history, thus facilitating exchange of experiences across several projects.

Interestingly, after some years of experience with PIPE, ABB decided to restrict the freedom of idea generation and commenting with this workflow system. This decision was motivated by the frequent uncertainties over ownership of shared ideas and inventions. As long as reward and compensation systems are tied to the extent of measurable technological contribution, trust and confidence remain significant determinants of effective transnational idea generation (see De Meyer & Mizushima, 1989).

Good Ideas Require Good Promotion

Although stimulated by global determinants, identifying a problem usually starts with a single person or a collocated group of people. Looking for support for their ideas, they try to convince influential people in their organization about the significance of their insights (see e.g. Hauschildt, 2003; Roberts, 1968; Witte, 1973). The influence of these idea champions is based on their hierarchical position (power promoters), their knowledge (functional promoters) or their communication abilities (process promoters).

With the omnipresence of e-mail and global communication networks, one may be tempted to look for appropriate promoters regardless of their location. Experience shows, though, that personal relations are tremendously important in winning over decision-makers to new ideas. These personal relations are difficult to establish just for the purpose of championing a project idea, particularly at international distances. Decision-makers are influenced by project opponents, who bring in technological and economical arguments against a new project idea. Internal political arguments play an important role, since opponents fear

that new projects may mean a reduction in resources for their own activities.

The better the idea generator is able to communicate his intentions and visions, the more likely he is to succeed in finding top-management support. In order to find a power promoter, a project idea must be fresh and presented very soon after conception. Commercialization potential and project vision are often more important than technical decision criteria. For as long as it remains difficult to inspire people just by means of e-mail and shared workflow systems and convince them to support an idea, the quest for promoters will remain a matter of face-to-face contact.

Bottleneck Product Profitability Calculation

If a project idea finds enough support and passes preliminary evaluations, a formal project proposal demonstrating technical realization and commercialization potentials is made. Product profitability calculations are widely used as they are robust, but they are not always appropriate for project evaluation. For instance, if a market has not yet developed a dominant design of product architecture, project evaluation can lead to unrealistic market forecasts (Fig. 3).

The profitability calculation is based on forecasted market returns discounted to net present value. Before the emergence of a dominant design (e.g. mobile communication), a market is characterized by intense market dynamics, making sales forecasts highly unreliable. Numerical values with many decimal places provide an illusion of only hypocritical exactness. Future project proposals should be complemented with qualitative data and evaluated in light of technological vision.

More recently, some companies have started experimenting with real-option analysis to evaluate R&D projects (see e.g. the special issue of the *R&D Management Journal*, 31 (2), 2001, on real-options in R&D). For R&D projects that allow multi-period investment decisions, real-option analysis is better than the popular net present value approach. NPV undervalues potential projects by as much as several hundred% because it ignores the value of flexibility. Real options include the flexibility to expand, contract, extend or defer R&D projects in response to unforeseen events during the innovation phase. Managers often overrule NPV results by accepting projects with low or negative NPV for 'strategic reasons'. In essence, they are using their intuition to account for the flexibility of a project's real options (see Copeland, 2001). Real-options reasoning offers a way to capture the value of project portfolios, research programs, technological and innovation competence, and technology and product vision.

Project Approval: Rational Criteria Versus Politics

After what the idea promoters consider sufficient conceptualization and refinement, the project proposal

Important: Evaluation of risk:

- Market risk (volume, price)
- Project risk (product, time-to-market)
- Technical risk (product, functionality)
- No consideration of **sunk costs** when deciding about project termination
- Output- and cycle-time **measurements** during the pre-project phase are inherently inaccurate. Only in routine processes during later-stage process phases do measurements start to make sense (e.g., dynamic cycle-time, first-pass-yield, on-time-delivery).

Figure 3. Product profitability and return-on-investment are inappropriate when the market is dynamic and unpredictable.

Source: Boutellier et al. (2000, p. 176).

is presented to a steering committee. This committee is not necessarily located in the same R&D unit where the project will eventually be carried out. For instance, the 'Investment Review Board' of the IBM S/390 system architecture has been meeting in New York to decide about major project activities in the IBM Germany site at Böblingen. Transnational R&D projects require particularly large budgets, which must be approved by the highest authorities of business areas. Project selection always takes place at the location of the decision-maker.

Project approval also includes a decision about key project members and participating locations. It is at this stage that it is determined whether an R&D project will be carried out transnationally or in only one place. In our experience, this decision is rarely based on a structured top-down evaluation, during which project requirements would be systematically combined with competencies, know-how bases, and available capacities of potential R&D units. As the IBM VSE development example demonstrated, project participation was determined in a political agreement finding

process (Fig. 4). Often enough, political considerations outweigh rational criteria.

Profit-center thinking usually gains the upper hand, despite the fact that resource and competency-based decisions would be economically more reasonable from a corporate perspective. Each R&D site strives for full capacity utilization, and projects funded by headquarters or central R&D unit are particularly attractive. Examples of such centrally funded strategic projects are 'Top Projects' at Bosch, 'Golden Badge Special Projects' at Sharp, 'Core R&D' and 'Strategic Business Projects' at Hitachi, and 'Core Projects' at Siemens and NEC.

System Architecture as a Critical Success Factor

Concept finding and definition, which determine the architecture of the system to be developed, partly coincide with the initial goal finding process. Especially during the subsequent interlocal component development phase, an accepted system architecture is one of the critical success factors of the entire project. Interfaces between modules and components must be

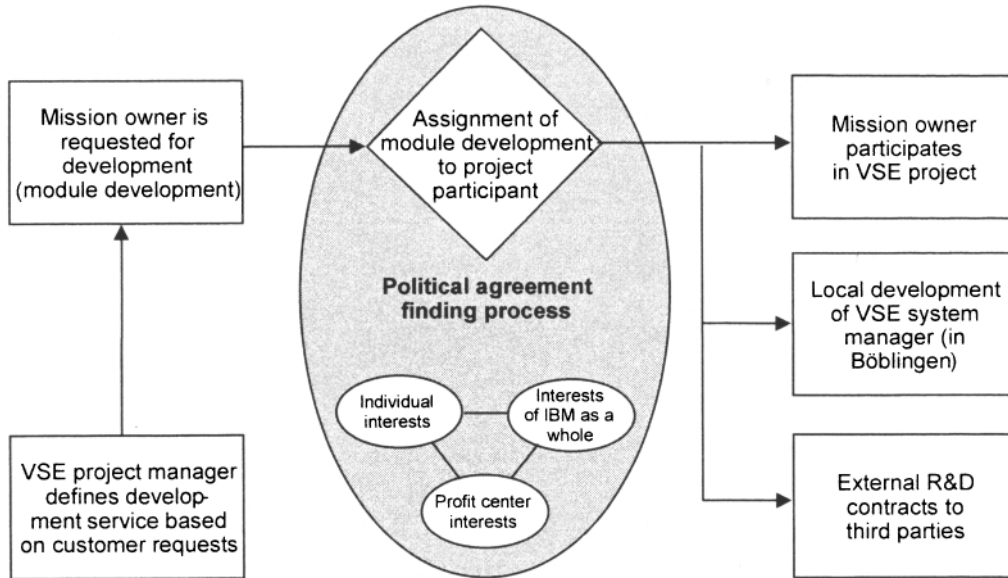

Figure 4. Rational criteria and balancing of interest determine who will eventually participate in a project.

Source: Boutellier et al. (2000, p. 177).

clearly defined. Changes in one module may not affect other modules. The stability achieved through such a system architecture reduces the number of design changes in later stages and consequently the intensity of interaction between decentralized teams (see e.g. Morelli, Eppinger & Gulati, 1995). This stability also makes standardized reporting possible within the same project.

The system architecture defines not only the success of the current product but also the success of future products and perhaps an entire product line. Only if interfaces have been designed clearly and with a wide range of applications in sight can this architecture serve as the basis of a product platform in future modular product development. A reduction in variant complexity (which is an essential part of cost reduction programs in all industries) is supported by a clear conception and designed stability in system architectures during the development phase.

System Management to Speed Up the Component Phase in Transnational Innovation

Goal Conflicts in Teams Jeopardize Project Success

The assignment of teams and locations to the R&D project is the linking step between the cloudy and component phases of innovation. Although much of the knowledge and goals of the cloudy phase may have been tacit and not necessarily well articulated, distributed teams will only be able to work with explicit and easily transferable information.

Although a system concept may have been defined and approved, these local teams may differ significantly in their interpretation and realization of the overall objective. In transnational innovation, the process of goal alignment is highly complex, since differing ideas about goals are not easily resolved because of geographical distances and cultural differences. Goal conflicts may occur between R&D (technologically advanced products), production (manufacturable products), marketing (customer-oriented products) and logistics (storable and transportable products).

In addition to these classical goal conflicts, regional perspectives may complicate the situation. Representatives of product business areas favor global standardization, whereas regional managers request country-specific product variants. Each location tries to justify the importance of its respective product variant with forecasts about how much this variant would contribute to overall product turnover.

Furthermore, every location strives for development and manufacturing share, partly to utilize as much of its R&D and production capacity as possible, and partly to develop new competencies in interesting technology areas. The various expectations of participating interest groups lead to minimal consent in the goal definition, and the participants eventually agree only to a rudimentary core concept (also known as 'concept peeling'). The overall project management team must possess excellent moderation and negotiation skills to align and focus all teams on the optimal

integrated solution, and to motivate and inspire the various participants for a commonly shared goal.

Know-How Redundancy and the Need for Generalists

The stability of a system architecture is made possible through the input of all members of the core team in consultation with invited experts. Much of the underlying knowledge is tacit or implicit, i.e. it resides in the heads of key project members and is not easily accessible or transferable (see e.g. Nonaka et al., 2003). During the project conception, socialization processes are therefore highly important to exchange crucial but otherwise unattainable knowledge. Constructing a common knowledge base goes in parallel with establishing redundant knowledge within project teams to improve project-internal communication.

It is possible to support both a generalist and a specialist focus. The turbine manufacturer MTU Munich introduced ABC teams and thus separated individuals who preferred to avoid working in teams from team-enthusiastic project members. The A-team is organized in the management level and defines the strategic framework for project teams (program decisions and reviews of critical milestones). B-teams carry out much of the component and parts development, while C-teams consist of highly qualified specialists (e.g. for rotor blade materials). C-team members set functional guidelines and are consulted by B-teams when specific problems occur.

Defining technical interfaces is also characterized by a socio-psychological effect. Each team manager tries to enforce high tolerance levels in the interfaces of his module, since this increases the likelihood of successful development of his module. This behavior triggers a cascading effect of tolerance-determined loss of operational range for components and products. High tolerances imply higher costs at lower effectiveness. The overall project manager thus has to ensure that safety thinking and risk aversion do not lead to excessively high tolerances.

Structured Engineering in the Component Phase

The project manager must be a competent system architect himself to implement the highly modular approach to the project successfully. He groups the functional elements of the system into components, defines clear interface standards and protocols, and assigns development tasks to specialist teams. When the system is being divided into individual work tasks, particularly high-risk tasks should not be distributed among a large number of distinct modules but are better concentrated in one component. This critical module is then tackled by a highly qualified R&D unit, preferably with superior management capacity. Risk concentration is not easy to achieve, since risk distribution is an integral part of portfolio thinking and team managers will attempt to shift risk to other locations.

Most of the development, prototyping, testing and eventually commercialization of the product takes place in the component phase. These activities are more detailed, structured and less interdependent than activities in the cloudy phase. Whereas the emphasis in the cloudy phase is on goal-adequate concept generation, the focus in the component phase shifts to efficient concept realization. Since the cost-intensive component phase consumes most of the project resources, it requires resource- and time-conscious project management. Capacity planning and multi-project management become important.

In order to ensure access to critical resources during the component phase, it is necessary for the project manager to report to a steering committee at the highest level, e.g. the executive board or directly below. Typical members of this committee are directors of business areas, R&D, marketing, manufacturing and regional areas. Such a heavyweight steering committee increases the likelihood of successful commercialization of the project outcome.

At ABB, the strategically important 'Common Technology' projects were managed directly by the business area director for power transmission. Only when the project had got off to a good start and was well established would this director hand the project management over to a lower-ranked manager. Since the steering committee was not capable of controlling the entire project because it lacked the required specialist knowledge, component-specific sub-committees were formed to evaluate the project activities. Typically, expert knowledge serves as a foundation for sound decisions in steering committees as well as in project management.

Conclusions: Success Factors for Managing Transnational Innovation Processes

Modern transnational innovation has come a long way from the unmanaged, almost haphazard, exploitation of research in the early decades of the 20th century. There are no illusions about the (un-)predictability of sequential logic in linear R&D models.

By dividing the innovation process into two phases, R&D processes can be adequately designed and managed in each transnational innovation phase. This separation improves process transparency considerably and reduces the cost-intensive development phase significantly. Although the characteristics of the two phases are different, too few companies approach them with distinctive management methods. The creative cloudy phase requires soft management methods, ensuring freedom, flexibility and inventiveness of scientists and engineers. In this phase, tacit knowledge is transformed into explicit knowledge and communicated to other members of the team. In order to keep up intrinsic motivation, it is important to create team spirit, a common project culture and a shared under-

standing of project goals and the underlying system architecture.

In the component phase of the project, the focus shifts to efficient implementation of these goals. Costs and milestones are used to determine the progress of the project. Compared with the cloudy phase, new coordination and control mechanisms are used to complete the project successfully. The component phase then leads into another, often globally executed, market introduction.

These R&D project phases allow a different degree of integration of international contributors to and participants in the innovation process. It is important to find the right form of organization for each phase and project. Critical success factors must be considered well in advance to ensure that upcoming problems are taken care of as they occur.

The interlocal component phase can be executed more successfully if enough emphasis has been placed on an effective creative cloudy phase, since it is here that the basis for the subsequent cost-intensive development stages is defined. Only in the component phase should the focus of innovation shift from effectiveness to measurable efficiency.

Idea generation in the early phase should be supported by modern computer technologies and software products. New tools and software packages are introduced regularly, and it is the responsibility of good innovation managers to back up the idea-finding stages of their engineers with the latest support tools. 'Computers' and 'creativity' are not a contradiction.

Good ideas must be communicated, quickly evaluated and promoted. Potential promoters must be enlisted for new ideas early in the R&D project.

In order for a project to pass from the cloudy phase to the component phase, traditional product profitability calculations must be complemented by alternative assessment models and qualitative criteria such as competence establishment and product visions.

Political power struggles should not be allowed to affect operative project work. A strong steering committee clears the way for project managers.

The actual innovators in an innovation project are rarely team-eschewing specialists, although their input is critical for project success. Separating project members into different teams (ABC-teams) can neutralize this conflict.

During the component phase, highly structured engineering is required. Measurement criteria such as on-time-delivery or first-pass-yields used in manufacturing could be helpful.

An Analysis of Research and Innovative Activities of Universities in the United States

Yukio Miyata

Department of Economics, Osaka Prefecture University, Japan

Abstract: University-Industry collaboration in the United States has been revitalized in the last two decades, but research at universities is still primarily federally funded basic research—a pattern established after World War II. While universities actively obtaining patents, they cannot finance their research budget through licensing revenues alone. This chapter argues that high quality of research has to be supported by the federal government, and that the fruits of university research on regional economy takes a long time to be realized.

Keywords: Innovation; Innovative activities; Research; University-industry collaboration; United States; Technological change.

Introduction

Universities have been involved in promoting scientific knowledge (seeking the truth) and educating people. This chapter analyzes research and innovative activities of universities in the United States, focusing on the university-industry collaboration in research. According to Schumpeter (1934, p. 66), innovations are: (1) an introduction of new products (or products with improved quality); (2) new method of production; (3) new markets and distributing channels; (4) new sources of supply of inputs; and (5) new organizations of an industry. Although the role of business faculty of universities in helping to create new markets, new distribution channels, or new organizations should not be denied, this chapter focuses on how science and engineering knowledge, as well as personnel of universities contributes to creating new products and processes.

As innovations do not stop with application or acquisition of patents but include a necessary commercialization process, private businesses are the agents of innovation. Universities, however, which supply research personnel and scientific/technological knowledge, are an important component of the national innovation system. Understanding the way in which U.S. universities and industry relate is an important step in promoting innovation. This collaboration is now the envy of the world, and an analysis of its actual practice has important policy implications.

The collaboration between university and industry occurs in many forms: contracted research from industry to universities, cooperative research between university and industry personnel, licensing of university-owned patents to industry, informal information exchange between university and industry personnel, consultation by university personnel, and establishing start-up firms by faculty members or graduates of universities in order to commercialize their research results. In this chapter, all of these activities are referred to as ‘university-industry collaboration’.

The chapter is organized as follows. The next section provides theoretical background of university-industry collaboration. Then in the next section, after briefly reviewing the history of U.S. university research, the current status of university-industry collaboration is analyzed. The section after that discusses potential problems in university-industry collaboration, followed by a section of conclusions and policy implications.

Theoretical Background

According to Kline & Rosenberg (1986), innovations are traditionally considered to be based on a ‘linear model’ in which basic research, applied research, development, production, and marketing occurs in succession (see Fig. 1). The fruits of basic research are the fundamental understanding of nature, and are expressed in the form of academic publication. People who read these publications develop theories into

Figure 1. Linear model.

Source: Drawn by the author from Kline & Rosenberg (1986).

commercial products; therefore, the benefits of basic research often cannot be collected by sponsors, normally being utilized by others who do not pay the cost of research. Because of this ‘spillover effect’, private businesses are not willing to invest in basic research, so that, under the market mechanism, basic research would have less investment than that at the socially optimal level. Thus, governments provide universities with funds to conduct basic research. According to the linear model, as long as governments support basic research at universities, firms that find potential commercial benefits in the basic research results will continue on with applied research, development, and manufacturing, thus coming up with the innovations.

However, this simple smooth process of innovation, stated by the linear model, has been criticized as ‘unrealistic’ or ‘too optimistic’, and replaced by the ‘chain-linked model’. According to the chain-linked

model by Klein & Rosenberg (1986), innovations result from the process which consists of the recognition of potential markets, invention and analytical design, detailed design and testing, redesign and production, and distribution, sales, and marketing (see Fig. 2). However, more importantly, among these stages, there are feedback loops. According to this model, it is rare that newly generated knowledge from research leads to innovations. Innovations often utilize and rely on existing knowledge. Scientific and technological knowledge is related to each stage of Fig. 2. Whenever problems occur, one consults with existing scientific and technological knowledge. However, if this existing scientific and technological knowledge cannot solve the problem, new research will be initiated. The universities’ role is to fill the pool of scientific and technological knowledge so that firms can utilize it whenever they need.

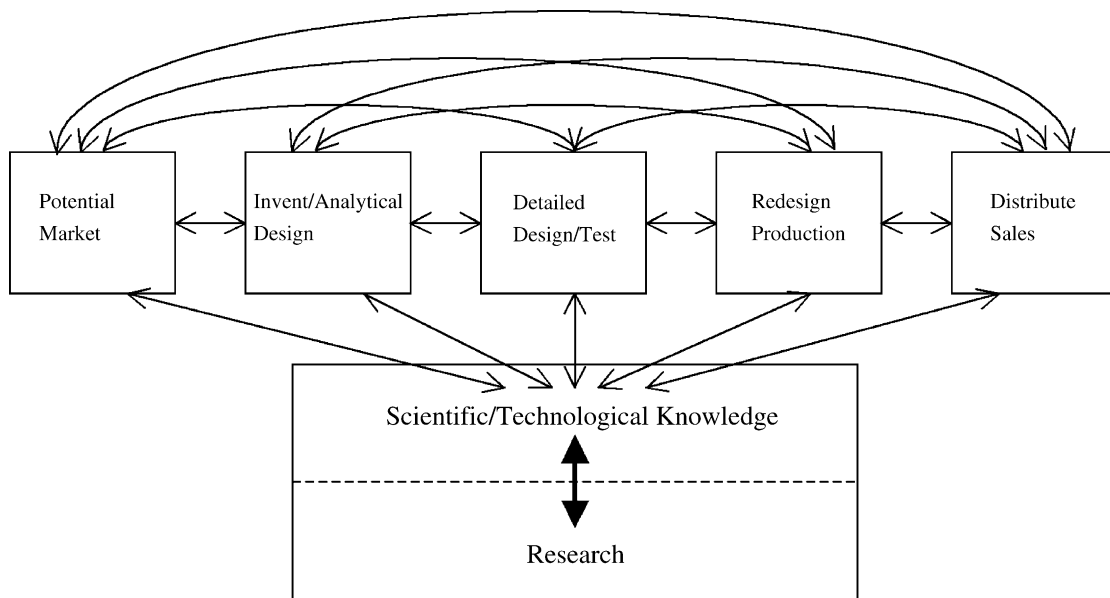

Figure 2. Chain-linked model.

Source: Drawn by the author from Kline & Rosenberg (1986).

University-industry collaboration can be understood as an application of the chain-linked model. Firms have recognized that it is too optimistic to expect investing in basic research at a central laboratory automatically leading to innovations. They must shift their research emphasis to short-term applied research and rely on universities to do basic research. Moreover, connecting scientific and technological knowledge of universities to industry needs is now important on the national level. In the 1950s and 1960s, U.S. firms technologically were far ahead of foreign competitors. When universities supplied scientific and technological knowledge through academic publication, only U.S. firms could utilize such information. However, today's foreign firms can utilize academic research results as soon as they are published in academic journals. So, it is important to build a more direct bridge between universities and industry in the U.S. for exploiting the excellent research capability of U.S. universities, which is shown by the fact that they dominate in the number of Nobel laureates and attract students from all over the world.

However, the university-industry collaboration may not generate the expected benefits for the following reasons. First, university research personnel are good at basic research but may be poor at considering marketability. Thus, firms should not expect universities to generate research results that are ready for manufacturing. Instead of completely contracting out research to universities, firms should keep in touch with university research personnel so that a feedback loop is built and a synergetic effect is generated.¹ In addition, it is not proper for firms to cut in-house research budgets by relying on universities for basic research. Even though basic research has the spillover problem mentioned above, firms should invest in basic research for accumulating scientific and technological knowledge on their own. Otherwise they will not be able to understand recent research trends, making it difficult for them to discover new research topics and partners from university research personnel. Moreover, patents are far from innovations. Technological expertise of licensees is necessary to transform licensed technology into commercial products, and technological expertise is accumulated through in-house research (Rosenberg, 1990).

Second, university research personnel may avoid firms' requests. While several universities clearly consider the contribution of faculty to regional industries through cooperative research, licensing, or consulting as 'criteria for promotion', however, promotion of faculty depends on the quantity and quality of academic research papers. Accepting money from

industry is beneficial for their research purpose, but university research personnel are neither employees nor sub-contractors of sponsoring firms. To prevent shirking, firms should again keep in touch with research progress at universities.

Third, from a social perspective, the university-industry collaboration can be criticized as an exploitation of university research capabilities that should be available to the general public. The government has been supporting university research. When a firm utilizing university research results is able to commercialize it through new products, consumers have to pay twice (tax to support university research and the price of the product). Also, research personnel should conduct research for public interest, such as assessments of pollution damage or risks of new technology, which sometimes conflicts with industrial interests.

Fourth, university-industry collaboration may deteriorate the research capabilities of universities. During university-industry collaboration, firms often ask university research personnel to withhold announcement of research progress or research results even to colleagues at the university. University research has been developed with the free exchange of information. If one knows what other research personnel are doing, they can exchange critical opinions with each other in early stages of their research, making corrections quickly and avoiding duplication of research efforts (Cohen et al., 1998). The secrecy hinders information exchange among research personnel in the academic community and is detrimental to the quality of research conducted by universities. In addition, because graduate education is often based on research experience, deteriorating research quality leads to a decline in its quality, and is costly to industry in the long-term.

Analysis of University-Industry Collaboration

Universities in the U.S. began as private institutes established by churches, followed by state universities. The expansion of state universities was owed to the Morrill Act of 1862, which allowed states to raise funds for their state universities by selling federal lands. The federal government and Congress played a role in this act, but besides that, the federal role in university research was minimal until World War II. According to Table 1, federal assistance for university research was limited to agriculture through agricultural experiment stations. State governments were bigger sponsors of university research than the federal government. Money from industry accounted for 12%, which is greater than the current level (mentioned later). Moreover, money the universities themselves used to fund research came from the gifts or donation from wealthy businesspeople. Hence, the relationship between industry and universities was strong before World War II and

¹ Completely contracting out basic research to universities is a strategy based on the linear model rather than the chain-linked model.

universities often contributed to the development of regional industry (Rosenberg & Nelson, 1994).

During World War II, many university research personnel worked on military related research projects including 'The Manhattan Project'. The role of university research was highly recognized by the federal government: the advancement of scientific knowledge generated by university research was expected to solve economic, social, and national security problems the nation faced. Furthermore, 'The Sputnik Shock' of 1957, which led to the National Defense Education Act of 1958, increased federal basic research money to universities. Figure 3 indicates that R&D money that universities used, increased rapidly in the 1960s, so did federal research money to universities. Also as Fig. 4 indicates, the federal government has been the largest sponsor of university research, accounting for more than 60% of university research spending, while the share of industry or local governments has been less than 10%.

Table 2 indicates which federal agency supports university research. The National Institutes of Health (NIH) has been the largest federal sponsor of university research. The National Science Foundation (NSF), whose function is to support university research, is competing with the Department of Defense (DoD) for second place for federal sponsorship. The NSF is far from a centralized agency that administers university research. U.S. policy supporting university research can be characterized as decentralized, where each agency supports 'directed basic research' so that research results would contribute to the needs of that agency.

As shown later in detail, federal research money to universities is heavily directed toward basic research. Although, compared with industry, universities play a minor role in performing research and development, their share as a performer of basic research increased to above 50% during the 1960s and has since remained at a high level (see Fig. 5). If we include the government-

owned laboratories, which are contracted out to universities to operate, the percentage reaches about 60%.²

U.S. universities continued to remain in contact with industry but the relationship between universities and industry weakened in the 1960s due to an increase in federal funding. Research personnel at universities were interested in basic research. However, at the end of 1970s, federal funding stagnated and universities turned to industry once again as an important financial source. Industry also began seeing universities as a source of scientific and technological expertise. Firms no longer rely on 'the linear model' and reduced basic research at their central laboratories. As firms started utilizing outside information sources, they became interested in cooperative R&D with other firms as well as collaboration with universities. Moreover, in the fields of biotechnology and computer software, university research results were expected to directly result in commercial products.³ University personnel started establishing start-up firms to commercialize their own research results, which was necessary for emerging high-tech industries. The interests of industry and university, therefore, coincided. In addition, policy-makers expressed concerns that, although U.S. universities were excellent in research, they did not help U.S. firms boost their competitiveness. Congress passed the Patent and Trademark Amendments of 1980 (Bayh-Dole Act), which allowed universities to own patents resulting from federal research money and to license them to firms. Then, the relationship between industry and universities was strengthened in the 1980s once again.

However, even after 1980, as Fig. 4 shows, the major source of university research money remained the federal government. Because it is difficult to see the trend, Fig. 6 focuses on the ratio of research money from industry to universities, to the amount of research

² Shapley & Roy (1985) points out that U.S. university research, including second-tier universities, had been heavily inclined towards basic research and neglected engineering, causing a decline in competitiveness of U.S. manufacturing. However, Rosenberg & Nelson (1994) states that Shapley and Roy overstated the lack of applied research in the U.S. university research. For example, in life science, the funding for medical research has been greater than for biological research. Although, in some cases, university research personnel have conducted research to satisfy their intellectual curiosity, in many others, they have had only vague ideas of the potential application of their research results.

³ The emergence of biotechnology does not mean the revival of the linear model. While biotechnology seems to directly result from laboratory research, a great amount of clinical testing is necessary. Also, because firms conduct in-house research secretly, if one only looks at commercialized results, they are seemingly breakthrough innovations. However, in actuality, in-house research is incremental, and feedback loops among marketing, invention, designing, and manufacturing exist (McKelvy, 2000, p. 273).

Figure 4. Sources of university research.

Source: USNSF (2000).

money that universities use. The ratio declined in the 1960s and recovered in the 1980s but was still smaller than 10%. However, research money from industry is often used in university-industry-government cooperative research projects, so industry money is estimated to affect 20%–25% of university research (Behrens & Gray, 2001). The ratio of research money from industry to universities to the research money that industry spends is shown in Fig. 7. It also recovered in the 1980s but still only to about 1.3%. The relationship between university and industry has been strengthened, but the magnitude is still not so strong. Biotechnology has a stronger tie between industry and university. In 1994, research money from industry to universities is 1.5

billion dollars, which accounted for 11.7% of life science research funds that universities obtained from external sources such as federal government or non-profit organizations, and for 13.5% of life science research funded by food-tobacco and pharmaceutical industries (Blumenthal et al., 1996; USNSF 2000). However, even in biotechnology, research money from industry does not dominate the research budget at either, the university, or industry level.

The source of research funding is not so different between private and public universities as Table 3 shows. Private universities rely more on money from the federal government than public universities do, but money from university and non-federal government

sources account for a higher percentage for public universities than for private ones. However, the reliance on money from industry is the same between public universities and private universities. The percentage increased from 1977 to 1987, but it did not change between 1987 and 1997.

Table 4 shows the ratio of basic research, applied research, and development in university research. Even since university-industry collaboration was revitalized in the 1980s, two-thirds of university research funds have been used for conducting basic research. Development accounts for less than 10%. University personnel who are actually involved in collaboration with industry admit that their research has been moved

away from basic research toward applied research and development (Cohen et al., 1994). However, this is not true of all university research.

A possible reason for the stable ratio of research direction at universities is that research money from industry to universities is still relatively small compared with the total university research budget. Moreover, it is interesting to point out that, as Table 5 indicates, basic research accounts for 60% of all research money from industry to universities. It would seem that industry does not think much of the universities' abilities to conduct development projects in which industry has expertise. Industry wants access to university basic research that it cannot adequately

afford because of the spillover effect. Figure 8 indicates the ratio of basic research funding from industry to universities to basic research funding that industry spends on. The ratio is higher than that regarding total R&D expenditure shown in Fig. 7, but it is still less than 20%. As a result, industry does not completely rely on universities to conduct basic research through university-industry collaboration.

Another reason for the large share of basic research at universities even after university-industry collaboration was revitalized in the 1980s is that development work is conducted off-campus through start-up firms which were established by faculty members or graduates to exploit their research results. So, on-campus research remains basic research (Cohen et al., 1998).

Table 6 shows the directions of research money from the federal government to universities. Federal research money actually consists of money from several departments and agencies such as the National Institutes of Health, National Science Foundation, Department of Defense, and National Aeronautics and Space Administration. The share of basic research remains the largest.

Table 7 shows that the composition of non-federal (mainly state) government money had been oriented toward basic research in the 1960s, but since the early 1970s, the percentage of basic research declined. It should be noted that, today, research money from state governments to universities is similarly proportioned for basic research, applied research, and development as research money from industry is. While both state governments and industry like to utilize the basic research strengths of universities, they also like to avoid any spillover from their basic research. State governments do not want the fruits of research funded with their money to diffuse beyond state borders. The federal government does not care much about spillover,

though they recently begin worrying about spillover of federally funded research results to countries who are good at commercializing research results published by the research personnel of U.S. universities.

Research funding allocation to each university is basically decided through a peer review in which prominent scientists can receive research funding based on their ability, excluding political consideration or ‘pork barrel politics’. As a result, top ranked universities that have many able researchers, tend to obtain research money from the federal government and non-profit organizations. Universities that do not receive adequate research money from those sources are more willing to accept money from industry.

Figure 9 plots the ratio of research money from industry to universities to total university research budget (INDRAT) against the total university research budget, indicating no clear trend. If a regression analysis of FY 1997 is done for 61 universities between INDRAT and total university research budget, the coefficient is not statistically significant even at two-sided 10%.

$$\text{INDRAT} = 0.059 + 0.724 \text{ Total Research Budget}$$

$$(t = 1.27, R^2 = 0.027)$$

If the regression analysis is done between INDRAT and research money from the federal government to university, the relationship becomes weaker.

$$\text{INDRAT} = 0.067 + 0.491 \text{ Research Money from Federal Government}$$

$$(t = 0.58, R^2 = 0.006)$$

Highly ranked universities receive a large amount of research money from the federal government, so the reliance on money from industry becomes weaker.

In addition, Fig. 10 shows that the number of patents issued to universities has increased since particularly the mid-1980s, several years after the Bayh-Dole Act of 1980 allowed universities to own patents resulting from federal research funding. Although the direction in university research did not move toward development so much, the surge in patents implies that university research personnel became more willing to apply for patents.⁴ Another reason is that patents resulting from basic research, such as in biotechnology, have been increasing. Since 1981, three life-science/drug-related patent classes have been top-3 patents granted to universities. The share of them was 18.81% in 1981 but increased to 25.33% in 1991, then reached 40.97% in 1998 (USPTO 2000).

In biotechnology, cooperative research between university and industry is productive for generating patents. According to Blumenthal et al. (1996), amongst the 'Fortune 500' pharmaceutical firms, the number of patents issued per \$10 million research spending is 1.7 for cooperative research with university, and 1.2 for 'elsewhere'.⁵ For firms that are not in the 'Fortune 500', the number of issued patents per \$10 million research spending is 6.7 for cooperative research with university and 3.5 for 'elsewhere'.

Mansfield (1998) investigates the percentage of innovations that could not have been produced without academic research and those which were significantly supplemented by academic research. The survey considered the contribution of academic research conducted between 1986–1994, to innovations generated in 1994. Mansfield previously did a similar survey investigating the contribution of academic research conducted between 1975–1985, to innovations generated in 1985, the results are listed together in Table 8. The survey covered 77 major firms that do not include any start-up (spin-off) firms of universities. Drug/Medical products and Instruments (including medical devices) have high scores, but the figures are 30% at most. In other industries, figures are not so high. The contribution of academic based innovations to total sales or to cost reduction was not so large. Moreover, the last row of Table 8 indicates that it takes a long time (6–7 years) to commercialize academic research results, while the time-span became a bit shorter in the 1990s compared with the 1980s. Large firms tend to keep a proper distance from university research.

⁴ For universities such as Stanford University or University of California-Berkeley that have been active in collaborating with industry, the biotechnology revolution of the 1970s increased their patenting activities prior to the Bayh-Dole Act. However, for many other universities, the enactment of Bayh-Dole Act in 1980 was an important opportunity (Mowery, Nelson, Sampat & Ziedonis, 1999).

⁵ Research carried out 'elsewhere' is mainly in-house R&D but also includes cooperative R&D with other firms or with national laboratories.

While both are research intensive industries, compared with pharmaceuticals, in the semiconductor industry, industrial research has been ahead of university research. Universities' role had been limited to research personnel and entrepreneurs. The semiconductor industry organized Semiconductor Research Corporation (SRC) in 1982, which pooled research money from firms and supported research at universities. Since then, SRC has been effective in educating graduate students for industrial opportunities and in providing a desirable scientific knowledge base for industrial practice, although drastic innovations remain to be created at industrial research laboratories (See Gutmann, this handbook).

According to AUTM (1998), in FY 1997, there are 58 universities, which have at least 10 licenses, and total number of license agreements is 2,098. Among them, 10.1% went to start-up firms that were established under license from universities, 49.3% to non-start-up small firms (less than 500 employees), and 40.6% to large firms. When the Bayh-Dole Act was enacted in 1980, exclusive licenses from universities to large firms would be invalid after eight years of licensing or five years of successful commercialization, whichever comes first, so that large firms would not dominant license acquisitions. Since the dominance of large firms did not happen and the restrictions significantly prevented large pharmaceutical firms from commercializing university research results, the restriction was lifted in 1984. Even today, licenses actually go to small firms. Because the number of small firms are many, it may be natural for small firms to account for a greater share of the licensees by universities, though a large individual firm may be able to purchase many licenses from universities.

Inter-organizational technology transfer is difficult unless the recipient has technological expertise. The fact that there are many small firm licensees implies that these small firms have expertise to utilize university research. AUTM (1999) points out that more than 90% of licenses to start-up firms are exclusive, while about half of all licenses to non-start-up small firms or large firms are exclusive. Large firms tend to keep a proper distance from universities, emphasizing informal information exchange between university and industry research personnel. In contrast, start-up firms want a more direct connection to university research (Etzkowitz, 1999).

Tables 9 and 10 give the results of a survey conducted by Lee (2000) that asked university personnel and industry personnel respectively to rank the actual benefits of cooperative research from 1 (lowest) to 5 (highest) in scale. The survey shown in Table 9 covers 422 faculty members of 40 universities randomly chosen from the top 100 in terms of their total research budgets. University personnel were likely to answer that, through cooperative research with industry, they obtained money and ideas for their own research. The

enhancement of business opportunities was not highly ranked. Lee (2000) also points out that university personnel tend to obtain what they wanted. Even though lowly ranked, university personnel who sought to expand their business opportunities through cooperative research with industry achieved such goals.

The survey shown in Table 10 covers 140 firms of AUTM (Association of University Technology Managers)⁶ members including start-up firms as well as large firms. Industry personnel highly ranked ‘access to new research’ and ‘develop new product/process.’ Solving short-term problems such as ‘technical problems’ or ‘quality improvement’ was not highly ranked. The survey also indicates that, compared with cooperative research between universities and large firms, the one between universities and start-up firms tend to focus on business opportunities and does not contribute much to the enhancement of research and education capabilities of university. The distance between universities and large firms is greater than that between universities and small ones.

Table 11 indicates the correlation among the number of invention disclosures, the number of patent applications, the number of licensing agreements, and the amount of license revenues based on each university’s data of FY1999 (AUTM 2000). The relationship between invention disclosures and patent applications is strong, but the amount of license revenue is not related to any other variable. It is very uncertain which invention will result in huge license revenue. USGAO (1998) states that a small number of highly successful patents or ‘blockbuster’ patents, which are often in the field of medical/life science, account for a large portion of the license revenue of a university. And those blockbuster patents often resulted from federally funded research. Table 12 indicates how much license

revenue of the elite universities come from the results of federally funded research results. In some universities, the percentage is above 90. It is unlikely that cooperative research between industry and university will lead to a blockbuster patent from scratch. A university’s research quality has been built on money provided by the federal government for a long time, and nowadays, industry utilizes the research capabilities of universities by supporting only 10% of the research budget of the universities.

License revenue is not only uncertain but also inadequate to support university research. Table 13 compares license revenue and research spending by universities in FY1997. The ratio of license revenue to total university research budget is very small. Most of the universities have a value of less than 5%. The ratio of license revenue to research money from industry to university is also small. Only seven universities have values of 100% and the majority of universities have values of less than 25%. The license revenue accounts for a tiny portion of the total research budget. It is difficult for universities to finance their research budget with license revenue.

However, license revenue represents only small portion (usually 2%–5%) of sales of new products resulted from licensed technology. According to ATUM (2000) which assumes that 83% of the license income is associated with product sales, the royalty rate is 2% of product sales, and \$151,000 is necessary to support an employee, in FY 1999, licensed technology generated \$35.8 billion of sales and 237,100 jobs. Moreover when a firm receives a license, it increases investment to commercialize that technology. Licenses from universities induced \$5.1 billion investment, supporting 33,800 jobs. As a result, the total impact of universities on North American economy is \$40.9 billion and 270,900 jobs. This is a tiny compared with Gross Domestic Product of the U.S. (\$9000 billion in 1999), but greater than the amount of research spending by universities (\$26 billion in 1998). While

universities cannot earn license revenues to finance their research spending, the impact of their innovations is greater than the research spending, implying the justification of government support for university research.

Table 14 shows the inputs and outputs of research of the elite universities with a high quality of research. As mentioned before, the elite universities receive a large amount of research money from industry, but money from the federal government is much larger, so money from industry is proportionally smaller in total of a research budget. The University of Michigan has not generated a blockbuster patent yet, so its license revenue is small compared with the other three universities. Table 14 also indicates that even elite research universities that generate many patents and licenses and earn license revenue cannot finance their research budget from it alone. Their high quality research has to be federally financed.

In the same way as university-industry collaboration was revitalized in the late 1970s, the university's role in

promoting regional development has been recently re-emphasized. Stanford University and the adjacent Stanford Research Park have successfully attracted many high-tech firms, and have become a nucleus of development for the greater Silicon Valley area. Also, the state of North Carolina has created a research park called Research Triangle Park, through three prominent universities in the state; University of North Carolina, Duke University, and North Carolina State University. These two cases are the envy of the world as well as other state governments.

What is the relationship between university research and innovation in a region? Despite being somewhat dated, the database created in 1982 by the U.S. Small Business Administration (SBA) is excellent because it identifies the actual location of where those innovations occurred, rather than the location of headquarters of innovators. As well as Feldman (1994) and Audretsch & Feldman (1996) who used this database to support spillover effects of university research on regional innovations, Varga (1998) has conducted a

Table 14. Inputs and outputs of major university research (FY 1997).

regression analysis on state and metropolitan area levels. In both cases, the number of innovations depends on the university research budget, the research budget of other firms, and the distance between the firm and the university. As the distance increases, the impact of research spending from other organizations declines. The rate of decline is faster in the case of spillover from other firms' research than that from university research. University research is more characteristic of the public good (spillover effect) than corporate research does. However, the distance between innovator and university is still important.

Furthermore, Varga has calculated how much a university's research budget has to increase in order to generate one more innovation of a region, which he called Marginal University Research Expenditure, MURE. And he categorizes regions into four groups according to calculated MURE values. In the lowest MURE group, which is the most innovative, in order to increase the number of innovations by one, a university's research budget must increase by 5%. In the second group, the university's research budget must increase by 33%. In the third group, the university's research budget must be three-fold. In the fourth group, the university's research budget must be 50 times the current level, which is impossible to implement. Regions where university research has already led to innovations can increase the number of innovations easily by increasing university research budget. However, for regions in which university research has not successfully resulted in innovations, it is very difficult, if not impossible, to increase the number of innovations by increasing university research budget. Thus, a newly built research park is not always successful.

Although the SBA database, on which the above research works were based, is excellent in identifying the actual location of innovations, it is old and was created before the onset of the Internet. The Internet makes complex information exchange possible. The extent to which the Internet will be able to substitute for face-to-face interaction in the future will affect the importance of concentrating research facilities adjacent to universities and thus the policy in building research parks. Further empirical research is necessary in this field.

AUTM (1998) states that while, in FY1997, 333 firms were established under licenses from universities, 83% of them were located in the same state as the licensor universities. It is true that research universities generate and diffuse the scientific/technological knowledge necessary for innovations, and supply and attract entrepreneurs. However, it seems these research parks are only successful in the long term. Stanford Research Park and North Carolina Research Triangle took more than twenty years to successfully develop. Patient support is necessary. Moreover, when these two were developed in the 1960s, competitors were rare. Since the 1980s, many local governments have been inter-

ested in developing research parks as part of their high-tech industrial policy, so competition is rigorous and offers no guarantee that every research park will be successful.

Another important point is that, even if a research park is successful in attracting research facilities, it does not necessarily lead to an increase in employment in the manufacturing industry. State governments do not build research parks near universities for the prestige—they do so to increase employment. Research results of a research park are, however, not necessarily manufactured in the region. Lugar & Goldstein (1991) compares research park regions against adjacent regions that have a similar size population without them. Of 45 research parks, 19 have generated less employment than the adjacent regions. Moreover, they have found that the success factors of research parks for regional economic development are: having time-honored tradition, having good research universities, and being located in regions of 0.5 to 1 million people which offers both a pool of labor forces and a market for manufactured products.

Potential Problems of University-Industry Collaboration

As mentioned previously, university-industry collaboration has potential negative aspects. Money from industry may induce university research personnel to distort research results, called a 'financial conflicts-of-interest' problem. The problem is that the public does not trust research results of university personnel who have financial ties with industry, even though they do not actually forge research results. When university research personnel spend too much time in cooperation with industry, other tasks of the university such as education and research for public interest are neglected, called a 'conflicts-of-commitment' problem. A sponsoring firm might ask university research personnel to postpone the announcement or publication of research results until the firm obtains patents or becomes ready for commercialization, called a 'secrecy' problem. These problems existed before and were discussed when the Bayh-Dole Act was enacted in 1980.⁷ The atmosphere in 1980 was, however, that 'you cannot make an omelet without breaking eggs'

⁷ It is often difficult to distinguish these three problems. For example, the secrecy problem is a neglect of duty to contribute to public interest on the part of university research personnel, so it is also the conflicts-of-commitment problem. Also, it can be viewed as a distortion of behavior by financial interests with the sponsoring firm, making it somewhat like the financial conflicts-of-interest problem. Furthermore, how much university professors should be allowed to use their students for collaboration with firms has both aspects of financial conflicts-of-interest and conflicts-of-commitment problems. Therefore, sometimes all these problems are called simply as 'conflicts-of-interest' without being categorized further.

(one should tolerate some negative aspects in order to exploit the benefit of university-industry collaboration) (White, 2000, p. 96).

An example of a negative aspect of university-industry collaboration was cited by Blumenstyk (1998), referring to that, in 1996, an article pointed out the danger of appetite suppressants. In the same edition of the journal, two other academic physicians made a commentary that minimized the study's conclusions. What was not announced to the public was that these two physicians were paid consultants to companies that made or distributed similar drugs. This is a typical financial conflicts of interest problem. Among 789 life science articles published in 1992, 33.8% of them had at least one chief author who had financial interests with firms whose activities were related to the field of the published research. Financial interests include the research personnel owning stock in a firm, working as a consultant or a director for it, or receiving research money from it (Krinsky et al., 1996). It is difficult to identify whether or not these financial interests actually cause university research personnel to alter research results in favor of the sponsor, but it is important not to make the public suspicious of any such activity.

In 1995, NIH and NSF requested universities that were receiving funds from them to establish a (financial) conflict-of-interest policy. Today, many universities have their own such policy. According to Cho et al. (2000) who surveyed 89 universities of the top 100 NIH fund recipients, it is uncommon (only 19%) for a university to specify prohibited activities. Many universities simply require research personnel to report financial interests as the first step to mitigate a financial conflicts-of-interest problem. Selection of licensees and cooperative research partners should be conducted fairly so that firms which do not have any financial relationship with research personnel would not be disadvantaged. Hence, research personnel who have financial interests with firms should not be a member of any committee that decides licensees or research partners.

In the conflicts-of-commitment problem, university personnel have been allowed to work as a consultant once a week. Although consulting is often a paid job, it is regarded as a community service or diffusion of knowledge, which is the university faculty's duty in addition to research and education. Because inter-organizational technology transfer is difficult, a university researcher often works as a consultant of a licensee firm to provide technical advice for the commercialization of licensed technology. The elite universities tend to set a maximum number of days for off-campus work, which is usually equivalent level to the traditional 'once a week' rate.

About the secrecy problem, Cohen et al. (1994) has conducted a survey regarding restrictions on communication which are placed on the faculty members who participate in industry-university cooperative research.

The survey covered 479 UIRCs (University Industry Research Centers) in which several firms participated in cooperative research programs with several departments of one university and which received financial support from both the federal and local governments. The state government is particularly interested in supporting UIRC so that it would be developed into a nucleus of research park. UIRCs have an aspect of public policy and the UIRC staff state that the purpose is to gain scientific/technological knowledge rather than to improve existing products or to create new jobs/business, but restrictions are found to be rather tight. The survey indicates that 56.6% of UIRCs have some restrictions. 21.3% of UIRCs set restrictions on communications with faculty members of the same university if they do not participate in the same cooperative research project. 28.6% of them set restrictions against the faculty members at other universities, 39.9% of them set restrictions against companies that are members of UIRCs but do not participate in the same project, and 41.5% of them set restrictions against general public.

Blumenthal et al. (1997) has surveyed 3,394 life science faculty members of the top 50 universities of NIH recipients. Among 2,167 responses, 19.8% of them answered that they had postponed publication more than six months. As NIH states that a delay of 60 days is reasonable for sponsoring firms to prepare patent application, six months is rather long. However, the delay of publication is due not only to the sponsoring firms' request but also to the intentions of the research personnel. When a researcher publishes a paper, other researchers may follow the research and publish more and better papers. A researcher wants to withhold publication until many papers are ready to be published. However, in the survey, 27.2% of researchers who participate in cooperative research with industry have experienced publication delays of more than six months, but the percentage is 11.1% for researchers who do not participate in cooperative research with industry. Hence, collaboration with industry may cause publication delays. On the other hand, in the aforementioned survey about conflicts-of-interest policy by Cho et al. (2000), only 12% of the universities set a time limit for how long a publication can be delayed.

Problems of conflicts of interest, conflicts of commitment, and secrecy have been occasionally reported. There is no time-serious data to check whether problems have recently become worse or not. Moreover, it is inconclusive whether or not the negative aspects of university-industry collaboration outweigh the benefits. However, as Table 12 indicates, universities earn a significant portion of license revenue from federally funded research. There are several policymakers who express concerns that federally funded research is being utilized for specific firms which only pay for the last stage in the completion of

research, rather than for the general public interest (Campbell, 1998). The elite research universities of high research quality have a strong negotiating position with sponsoring firms because these universities obtain adequate federal research money and need not rely on money from firms. Moreover, firms definitely want access to the research capabilities of these universities. However, second-tier universities may easily accept firms' demands to attract research money from industry. Firms can threaten even the elite universities by contracting with others that are more responsive to their needs. It may be time for the entire university community to set up rules on the freedom of publication (Nelsen, 1999).

Another problem, which is often called 'institutional conflicts of interest' or 'conflicts of mission,' is that universities have become very interested in earning license revenue. Recently, universities are increasingly taking a too restrictive approach to licensing and putting too high a value on their intellectual property contributions. Firms seek second-tier universities and foreign universities for collaboration when they think that elite universities are tough to deal with (Government-University-Industry Research Roundtable, 1998). Firms complain that university TLO (Technology Licensing Organization) is too oriented toward legal staff, and should have more staff with engineering and marketing backgrounds (Siegel, Waldman & Link, 1999). Moreover, in 1999, NIH issued the guidelines regarding research tools such as cell lines, animal models, reagents, clones, or database, which resulted from NIH funding. NIH thinks that these research tools should not be treated as intellectual property right but shared by the entire research community.

Finally, if government promotes university-industry collaboration, the existence of foreign firms and foreign students would be a problem. If foreign firms can participate in university-industry collaboration, federally funded research results would help them compete against U.S. firms. The Bayh-Dole Act requires that when firms commercialize a product made with the exclusively licensed technology from universities, it should be 'substantially' manufactured in the United States.

USGAO (1992) has found that in 1991, among 197 patents resulting from funding of NIH or NSF, only 18 patents are licensed to foreign firms and 11 patents are licensed to foreign subsidiaries in the U.S. The Bayh-Dole Act does not prohibit licensing to foreign firms, but it does require that manufacturing occurs in the U.S. However, universities do not follow where domestic licensees actually manufacture the product made with the licensed technology (USGAO, 1998).

While a similar concern was discussed to a lesser extent when the Bayh-Dole Act was enacted, access by foreign firms to U.S. universities research was hotly debated by Congress in the late 1980s when economic nationalism peaked. In particular, MIT was criticized.

About half of the members of the MIT Liaison Program, which will be discussed in detail later, were foreign firms, and MIT had a Liaison Office in Tokyo. However, in 1990, 15% of MIT research funds were supported by industry, with 20% of those funds coming from foreign firms; therefore, only 3% of all research money was from foreign firms. 86% of the licenses went to U.S. firms, and 77% of the firms for which faculty worked as consultants were U.S. firms. Among the 215 chairs endowed by firms, only 30 were supported by foreign firms. While some media and politicians expressed concern that elite universities such as MIT helped foreign competitors, the actual involvement of foreign firms was minor.⁸ It was an appropriate policy decision not to impose any restriction on university-industry collaboration in terms of their nationality (U.S. Congressional Hearing, 1993).

Another concern is the existence of foreign students. As university research was increasingly oriented toward industry needs, foreign students may understand what kind of frontier research U.S. firms are interested in. And, when foreign students go home after obtaining a Ph.D. and work for firms in their home country, they compete against U.S. firms.

Figure 11 shows that the percentage of U.S. citizen recipients of science and engineering doctoral degrees⁹ was declining between 1986 and 1994, while the a little increase was observed in the late 1990s. The percentage would be increasing if it included foreign-born permanent residents; however, a significant portion of doctoral degrees are offered to foreign students. The scientific/engineering manpower has to rely on foreign nationals or foreign-born residents. Foreign students could not participate in several research projects funded by the Department of Defense due to national security concerns. There was an opinion that a similar restriction might be necessary for economic competitiveness reasons. In fact, as Korea and Taiwan developed their own high-tech industries, students from those countries increasingly tended to return to their home countries. But students from India and China supplemented this decline in the 1990s.¹⁰

Throughout the 1990s, the percentage of foreign (including permanent residents) doctoral degree recipients in science and engineering fields who plan to stay in the U.S. has been increasing, to above 70% in 1999. The percentage of those who could actually find jobs

⁸ U.S. firms can have an informal relationship with university research personnel, so they do not have to be members of the Liaison Program. As a result, foreign membership must be high.

⁹ Science includes social and behavioral psychology sciences, in which the shares of U.S. citizens and permanent residents are relatively high.

¹⁰ However, Chinese government recently tries to bring back Chinese research personnel by offering financial incentives.

Figure 11. The ratio of U.S. citizens to S&E Ph.D.

and stay in the U.S. has also been increasing, as high as 50% in 1999 (USNSF 2002, Chap. 2). Foreign scientists and engineers have already become important labor force in the high-tech industries and universities. Between 1995 and 1998, 29% of the start-up firms in Silicon Valley were established by Indian or Chinese people. As they keep a relationship with their home country, foreign start-up firms tend to be good at exporting (U.S. Congress Committee Report, 1999). Moreover, even if foreign students from the elite universities such as MIT and Stanford return home after graduation, they are likely to become business/political/academic leaders there, and are expected to contribute to enhanced relations with the U.S. and favor of long-term U.S. interest (U.S. Congressional Hearing, 1993). Because foreign graduate students actually conduct a significant portion of research, excluding them may deteriorate the quality of research carried out at U.S. universities (Burtless & Noll, 1998). It was the correct decision for policymakers not to impose any restrictions on enrollment of foreign students at U.S. universities.

Conclusions and Policy Implications

U.S. universities contributed to regional economies in the second half of 19th century and the early 20th century. However, since World War II, particularly after the Sputnik Shock of 1957, the federal government has been strongly supporting basic research conducted by universities. In the late 1970s, university-industry collaboration was revitalized, thanks to the Bayh-Dole Act, the biotechnology revolution, the financial needs of universities, and a revised of R&D strategy within industry based the linear model.

However, even since the 1980s, university research has still emphasized basic research funded by the federal government. The elite universities obtain a large amount of research money from the federal government as well as industry, so their reliance on industry is small. The elite universities generate both academic research results and research results close to commercialization. However, license revenue results from a few 'blockbuster' patents, often in the field of medical/life science. There is a major mechanism in university-industry collaboration in the U.S.: federal government generously supports medical/life research at universities and its research results are easily protected by patents, resulting in licenses to firms some of which generate huge license revenue for universities. However, license revenue is small compared to the research budget of universities. It is difficult for universities to maintain a high quality of research by earning money themselves. Universities cannot become 'for-profit research organizations', and taxpayer support is still critical for maintaining university research. Because federal government money is still important for university research, how to draw the line between two of the following opinions should be

further discussed: 'university research results should be openly available to the public' and 'industry should be allowed to promote the commercialization of research results that eventually benefit consumers'.

Research universities actually generate innovation by diffusing knowledge and supplying entrepreneurs. Governments of states try to build research parks that concentrate research facilities around universities, hoping to create their own 'Stanford Research Park' or 'North Carolina Research Triangle Park.' However, these two research parks took more than twenty years to become successful, and for research parks to succeed there must exist a high quality research university nurtured by long-term federal research funds. It is not easy for local governments to quickly improve the quality of research done by universities. Moreover, even if a research park successfully attracts research facilities, it is uncertain if they will significantly contribute to an increase in high wage manufacturing employment of the region.

The contribution of universities to industry should not be limited to visible results such as inventions, patents, or licenses. As Cohen et al. (1998) points out, informal linkage such as communication between research personnel is important for industry to transfer university expertise to firms. In this aspect, the role of ILP (Industrial Liaison Program) is important. Firms that become members of the ILP are introduced to proper research personnel at the university to obtain advice. TLO (Technology Licensing Organization) is an organization that licenses patented technology resulted from university research. By promoting the flow of informal information, ILP covers the primitive stage of university-industry collaboration and TLO covers the mature stage of collaboration. In the regions or nations in which university-industry collaboration is not yet so active and where universities do not have many patents to license, ILP rather than TLO should be established first.

An important point is to provide research personnel at universities with incentives for informal cooperation with industry. Visible results, such as the number of publications or patents, can be easily used to evaluate university research personnel, but assistance to regional industry through informal communication is not. The effort a university faculty member spends answering questions from industrial personnel should also be evaluated since it is important for industrial innovations, even if it does not necessarily lead to patents.

Besides contributing to industrial innovations in formal (patents, inventions, licensing, or activity of TLO) and informal ways (advising, communication, or activity of ILP), education remains an important role for universities. Basic research educates research personnel. Middle class engineers are also generated by university education. In addition, universities generate mathematics and science teachers for elementary

and secondary educational institutions. Of course, graduate education has been effectively developed through a mixture of education and research, so good research universities are often strong in generating research personnel, academic research results, and inventions. However, universities can contribute to generating engineers and schoolteachers even if their research is not top-ranked. Local governments should not insist on universities generating innovations, but provide them with financial resources for research and scholarships. Good engineers and scientists have tacit knowledge by which they learn new things not written in books. Therefore, if a region has this kind of human resources, firms can realize a high rate of return on their R&D or manufacturing investment.

In conclusion, there are several ways in which universities contribute to innovations and regional development: they generate inventions, patents, licenses, informal communication with regional firms, spin-off firms, and human resources including scientists, engineers and schoolteachers. One university does not have to attempt all of these functions. The entire university system of a nation or a region should cover them so that the division of labor among their universities is desirable. Needless to say, all of these tasks take a long time to achieve. It is not proper for policymakers to expect quick results with an increase in funding to university research. Funding university research is not the way to solve cyclical recessions. In addition, firms and universities should not expect easy returns from collaboration, remembering the following statement by Doctor Lewis Branscomb, whose brilliant career spans government (National Bureau of Standards, now National Institute of Standards and Technology), private sector (IBM), and academia (Harvard University):

If the universities value the partnership as a means of exposing faculty and students to leading-edge technical issues that are driving innovations of benefits to society, and are not basing their expectations primarily on revenues from patents, a stable, productive relationship may endure. If the firms see universities as sources of new ideas and as windows on the world of science, informing their own technical strategies, rather than viewing students as a low-cost, productive source of near term problem-solving for the firm, they too will be rewarded (U.S. Congress Committee Report 1998, p. 22).

Incubating and Networking Technology Commercialization Centers among Emerging, Developing, and Mature Technopoleis¹ Worldwide

David V. Gibson and Pedro Conceição

IC² (Innovation, Creativity, Capital) Institute, The University of Texas at Austin, USA

Abstract: The ability and desire to access knowledge and to be able to learn and put knowledge to work is central to regional economic development and for globalization to be a force for drawing the world together. This chapter presents the logic, conceptual framework, and key elements for leveraging codified knowledge and tacit know-how through Internet and web-based networks and face-to-face communication and training programs. The objective is to accelerate regional economic development and shared prosperity through globally linked and leveraged Technology Commercialization Centers (TCCs) and to enhance the competitiveness and accelerate the growth of select regionally-based SMEs.

Keywords: Incubation; Innovation; Commercialization; Entrepreneurship; Knowledge creation, diffusion, and adoption; Networking.

Introduction

Technology continues to shrink the world. There is no choice other than to participate in the global community. Science and technology is too precious a resource to be restricted from drawing the world together. That is what the 21st century is all about. (Dr. George Kozmetsky, Chairman of the Board, IC² Institute, The University of Texas at Austin)

This chapter is focused in the belief that technology can be a force for drawing the world together and that the ability to learn, and put knowledge to work is central to regional economic development. Building on these two beliefs the authors present the logic, conceptual framework, and elements of a strategy to leverage codified knowledge and tacit know-how through Internet and web-based networks and face-to-

face training programs—and thereby accelerate technology-based economic development through globally linked and leveraged Technology Commercialization Centers (TCCs) that will facilitate the growth of select regionally-based small and medium sized enterprises (SMEs).

The suggested plan brings together business entrepreneurs, academia, and regional government in targeted emerging, developing, and mature technology regions or Technopoleis worldwide. Each TCC will be viewed as an ‘experiential learning laboratory’ where lessons learned will be used in world-class research, education, and training programs. The activities described in this chapter are designed to function as an integrated program which, over time, will contribute to and leverage local and global initiatives for knowledge transfer, accumulation, use, and diffusion to accelerate sustained economic growth and shared prosperity worldwide.

The ongoing ‘communications revolution’ is making the tasks of globally linking public/private collaboration and knowledge acquisition, transfer, and adoption at least feasible. Indeed, there are two important

¹ Technopoleis (Greek for technology and city state) are regions of accelerated wealth and job creation through knowledge/technology creation and use. Innovation is the adoption of ‘new’ knowledge—knowledge that is perceived as new by the user.

advantages for today's SMEs that were not available to entrepreneurs in the mid- and late-1900s:

- (1) The distance canceling power of Internet and web-based communication; and consequently.
- (2) The possibility of global access to talent, technology, capital, and know-how by leveraging and partnering through modern information and communication technologies (ICT).

This 'death of distance' as Frances Cairncross (1997) puts it, reduces the inherent economies of knowledge clusters and opens up the field to new entrants. These developments appear especially promising for the developing world, potentially enabling them to economically tap into informational and technical sources hitherto available only in mature technopoles. The proposal to accelerate the development of globally linked TCCs is based on the realities that:

- (1) few regions in the developing world can hope to match, at least in the short-term, the physical and smart infrastructure of established technopoles such as Silicon Valley, California and Austin, Texas, where there is an overwhelming agglomeration of technology, talent, capital, and know-how; and
- (2) regional, national, and global computer-based networks in the knowledge age allow for, if not encourage, the development of non-geographic bound or virtual technopoles.

A key question for the 21st century, therefore, is how necessary and sufficient is the regional development of 'smart' infrastructure in all its aspects (i.e. talent, technology, capital, and know-how) or physical infrastructure (i.e. science parks, incubators, and high-tech corridors) in the emerging internet-based economy where the movement of knowledge is increasingly through ICT? And it may be asked, which sectors or components of this infrastructure must be physically co-located or digitally networked at different stages of firms becoming globally competitive?

As a starting point we focus on the importance of fostering entrepreneurship at the grassroots level. To do this we target small and mid-sized technology-based enterprises (SMEs) that might be considered relatively successful at the local level but are in need of assistance (e.g. talent, technology, capital, and know-how) to achieve accelerated growth and global market penetration. At the moment that these virtual networks are created around the SME, it becomes a Learning & Innovation Pole (LIP).

A LIP is operationalized at the most basic level as an SME that is linked to other SMEs in an Internet and web-supported global network and also has access to a range of support activities such as training programs, workshops, and mentoring activities. Rather than relying on a well-defined geographic area to provide all of the networks and services required for success in

knowledge-based economic efforts, LIPs rely on regional and global cooperative and collaborative networks and training programs to provide service and assistance on a real-time, as-needed basis. LIPs will be able to shift and grow to take advantage of emerging opportunities and market needs.

While physical proximity is becoming less and less important to regionally-based economic development because of the pervasiveness of advanced ICT, successfully fostering the growth and global competitiveness of select SMEs in targeted regions will take more than computer-based networks and web connections. There needs to be a sense of community and relationship building. There needs to be local visionaries, champions, and implementers. And to sustain the regional and global partnerships and alliances there needs to be a meaningful flow of know-how and resources and win-win partnerships among all members of the network.

Conceptual Background

Traditionally, wealth creation in developed and developing nations, has emphasized physical assets. The capital stock of a nation was thought to be a measure of national prosperity, and the attraction of foreign direct investment became a prime strategy of less developed regions. As the world moves into the 21st century, however, the emphasis is on knowledge transfer, accumulation, adoption, and diffusion as being critical to economic development. As the World Bank noted in its 1998 *World Development Report*:

It appears that well-developed capabilities to learn—the abilities to put knowledge to work—are responsible for rapid catch-up . . . The basic elements (to develop these learning abilities) appear to be skilled people, knowledge institutions, knowledge networks, and information and communications infrastructure.

This section provides a summary of the theory of knowledge transfer, accumulation, and use to create a better understanding of the process through which knowledge and learning can be leveraged for regional economic development. Knowledge transfer, adoption, accumulation, and diffusion are key to sustainable economic prosperity in the emerging global economy of the 21st century. As stated by Abramovitz & David in a 1996 OECD report, "The expansion of the knowledge base . . . (has) progressed to the stage of fundamentally altering the form and structure of economic growth." Rapid advances in information and communication technologies and declining costs of producing, processing and diffusing knowledge are transforming social and economic activities worldwide (The World Bank, 1998).

While the current knowledge revolution is resulting in many positive outcomes, there is concern that it is accelerating the polarization of the 'haves' and 'have nots'. Scientific and technical advances have increased

the economic welfare, health, education, and general living standards of only a relatively small fraction of humankind to unmatched levels. The unevenness of such development among, and within, both developing and developed regions has increased significantly. Two hundred and fifty years ago, for example, the difference in income per capita between the richest and poorest countries in the world was 5 to 1. Today, the difference is approaching 400 to 1 (Landes, 1998). The underlying reasons for these inequalities are complex and, according to most analyses, are to be found in the outcomes of the social and economic revolutions that pre-date the current knowledge revolution. While the industrial revolution lowered the costs of manufacturing and distribution, over time this economic and social revolution also tended to divide the world into industrialized and non-industrialized nations and fostered bi-modal societies of wealthy and poor.

The current knowledge revolution is critically different from the past industrial revolution. It is based upon a shift of wealth creating assets from physical things to intangible resources based on knowledge (Stevens, 1996). Knowledge-based economic regions tend to be located near leading universities and research centers in the most advanced regions of the world (Quandt, 1998; Smilor, Gibson & Kozmetsky, 1986). Lucas (1988) argues that people with high levels of human capital tend to migrate to locations where there is an abundance of other people with high levels of human capital. Indeed, the importance of the physical proximity of talent, technology, capital, and know-how or 'smart infrastructure' has been argued to be crucial to fostering regional wealth and job creation (Audretsch & Feldman, 1996; Audretsch & Stephan, 1996; Gibson, Smilor & Kozmetsky, 1991; Rogers & Larsen, 1982).

Despite the strong arguments for the importance of physical proximity or agglomeration of 'smart infrastructure', advances in telecommunications and information technologies are transforming our perceptions of geography (Cairncross, 1998). Advances in ICT are key to explaining the shift from the industrial age—coal, steel, and material items—to a global knowledge-based age—information, human capital, and ideas. While it is still difficult to realize what William Mitchell (1995) calls 'cities of bits'—where the majority of the world's people are connected through telephones, televisions, faxes, and computers to a world-wide web—key influencers in business, academia, and government are increasingly realizing opportunities to use the special characteristics of knowledge and ICT to foster regional development through cooperation, collaboration and competition.

A better understanding of the process through which knowledge and learning can contribute to economic development in developing as well as developed regions is urgently required. In this regard, it is important to define knowledge and to realize how it

differs from physical things (Dosi, 1996). Here we follow the analysis of Conceição et al. (1998), who build on Nelson & Romer's (1996) differentiation between ideas and skills, or software and wetware.

- Software ('ideas'): Knowledge that can be codified and stored outside the human brain, for example in books, CDs, records, and computer files. Software (as defined here) is referred to as the 'structural capital' of private and public organizations and includes intellectual property that is codified (Edvinson & Malone, 1997). When employees leave their place of work the software remains.
- Wetware ('skills'): Knowledge that cannot be dissociated from individuals, is stored in each individual's brain, and includes convictions, abilities, talent, and know-how. Wetware is referred to as the 'human capital' of private and public organizations and is the know-how or intangible resources that provide key added-value for enterprise development and accelerated growth (Edvinson & Malone, 1997). When employees leave their place of work the wetware leaves with them.

These two kinds of knowledge differ: (1) in the way they are produced, diffused, and used; and (2) in the level of codification. While ideas correspond to knowledge that can be articulated (in words, symbols, or other means of expression), skills correspond to knowledge that cannot be formalized or codified. This apparently simple difference has very important consequences in terms of the way knowledge is produced, diffused and used.

The classification of knowledge in this manner is very significant in the context of this paper which aims to use Internet and web-based links to accelerate growth and job creation. The transmission of software, or codified knowledge, is not much affected by geographic distance, especially in this age of high-bandwidth and near-zero transmission cost (Swann & Prevezer, 1998). However, the transmission of wetware, or tacit knowledge, cannot be easily accomplished without face-to-face contact (*ibid.*).

Not only does this indicate the importance of including face-to-face contact in the proposed LIP Program, it also indicates the types of industries that will most benefit from an Internet and web-based network. That is, from a technology transfer point of view, leading edge technologies that are highly dependent on wetware skills are unlikely to benefit from only the access that LIP networks provide. But, more standard technologies that are further along their life-cycle and therefore require more codified knowledge would benefit greatly from the financing and marketing links provided through the LIP network. This is because new technologies spur the development of skills required to use them. However, as these technologies become more sophisticated, the required skill levels tend to decrease and the ability to codify the

required knowledge increases. As a result, selection of SMEs in the targeted regions will not necessarily focus on advanced technology (e.g. new materials, semi-conductors, biotechnology), but will emphasize the use of appropriate ICT and business processes in the regionally based enterprises. It is clear that modest technology and innovative management processes can produce substantial wealth and job creation for a region (Conceição, Heitor & Oliveira, 1998).² The business and networking focus of the Learning & Innovation Poles (LIPs) therefore, will be based on the assessment of the technology and infrastructure strengths, weaknesses, opportunities, and threats (SWOT) of each selected region.

Today, the really substantial gains in wealth are to be found in the use and diffusion of knowledge. However, without skills, ideas may be irrelevant. Similarly without ideas, there may be no need for new and better skills. In short, it is important to stress that the accumulation of knowledge leads to the creation of wealth only if the knowledge is effectively transferred, adopted, and diffused.³

In the proposed LIP/TCC Program, personal networks and partnering programs (e.g. education and training, conferences, etc.) linked via ICT will be used to facilitate the collaboration of regionally-based

² For example, in Austin, Texas a Fortune 500 company, DELL Computers was started out of a university dorm room in 1982 by one entrepreneurial student at the University of Texas at Austin. The idea was to build customer designed computers using off-the-shelf technology and direct marketing, initially over the phone and increasingly over the Internet. Based on this modest start-up, over 7,000 people are employed in the Austin area with additional manufacturing and sales operations in Asia, Europe, and Latin America.

³ History is full of examples where the producers of an innovative technology—by not using and diffusing it—were surpassed by others who did. Two examples serve as illustrations: One at the grand scale of the history of civilization; The other at the much smaller scale of contemporary corporate warfare. China developed what was, after the invention of writing, one of the most important ideas for the progress of humankind—the movable type printing press. This technology dramatically increased the possibilities of codifying knowledge. However, Imperial China restricted the use and diffusion of this technology to the affairs of the Emperor and his court. As a result it was Europe that benefited most from this invention by promoting its widespread use and diffusion (Landes, 1998). A more contemporary example is provided by Xerox PARC, a state-of-the-art R&D facility located in Sunnyvale, California. In the 1970s, housing some of the world's most brilliant researchers, PARC discovered many of the fundamental computer and software concepts and technologies that have become the basis of today's computer industry. Apple Computer, at the time a Silicon Valley start-up, used PARC developed knowledge and technologies in its innovative and successful Macintosh computer generating considerable wealth and jobs. In the 1980s it was Seattle-based Microsoft that benefited from the software technologies developed years earlier at PARC.

Learning & Innovation Poles as members of a global learning and innovation network. This global learning and innovation network will facilitate the transfer and use of existing knowledge and the creation of new knowledge for regional economic development. To foster equitable knowledge transfer, accumulation, diffusion and use of both *software* and *wetware*, this project holds to three principles of operation.

Principle No. 1: When establishing Learning & Innovation Poles, we must deal with social as well as physical constructs that link participating people and institutions in networks of knowledge production, sharing, adoption, and diffusion that lead to self-reinforcing learning cycles (Fig. 1).

In competitive marketplace economies, business or financial global networks often do not operate to the benefit of less developed regions, indeed such networks often contribute to unequal development. A key question is whether such networks, linking the 'haves' with the 'have nots', go beyond awareness to the actual development of capabilities for knowledge accumulation and application in the less developed sites.

Principle No. 2: To foster networks in which the interaction leads to increased learning capability in all network nodes, but in which the rate of learning is higher in the less developed nodes (Fig. 2).

This project also strives to encourage and facilitate local ownership of activities and results. To be truly sustainable, the processes of innovation must occur within, and be 'owned' by the champions in each node. Therefore, it is critical that regional champions or businessmen/women feel that they 'own' LIPs. This idea leads to **Principle No. 3**, which is to foster the regional 'ownership' of the activities and the results or return-on-investment of the network. A sense of ownership can be fostered by shared decision-making structures in which the ultimate choice and responsibilities lie with local participants rather than external facilitators.

Technology Commercialization Centers

The objective is to foster the global linking of regional champions and enterprises in view of the realities and challenges of the international marketplace. The networks that we propose building via the LIP/TCC project are centered on identifying select SMEs and regional champions for long-term partnerships. These networks will be sustained by being task focused for short-term success as well as for longer-term vision. Figure 3 depicts how LIPs know-how networks will assist targeted companies in targeted regions to cross the knowledge transfer and application gap to market applications, leading to firm diversification and expansion and new firm formation.

Technology Commercialization Centers through Learning & Innovation Pole Networks will strive to

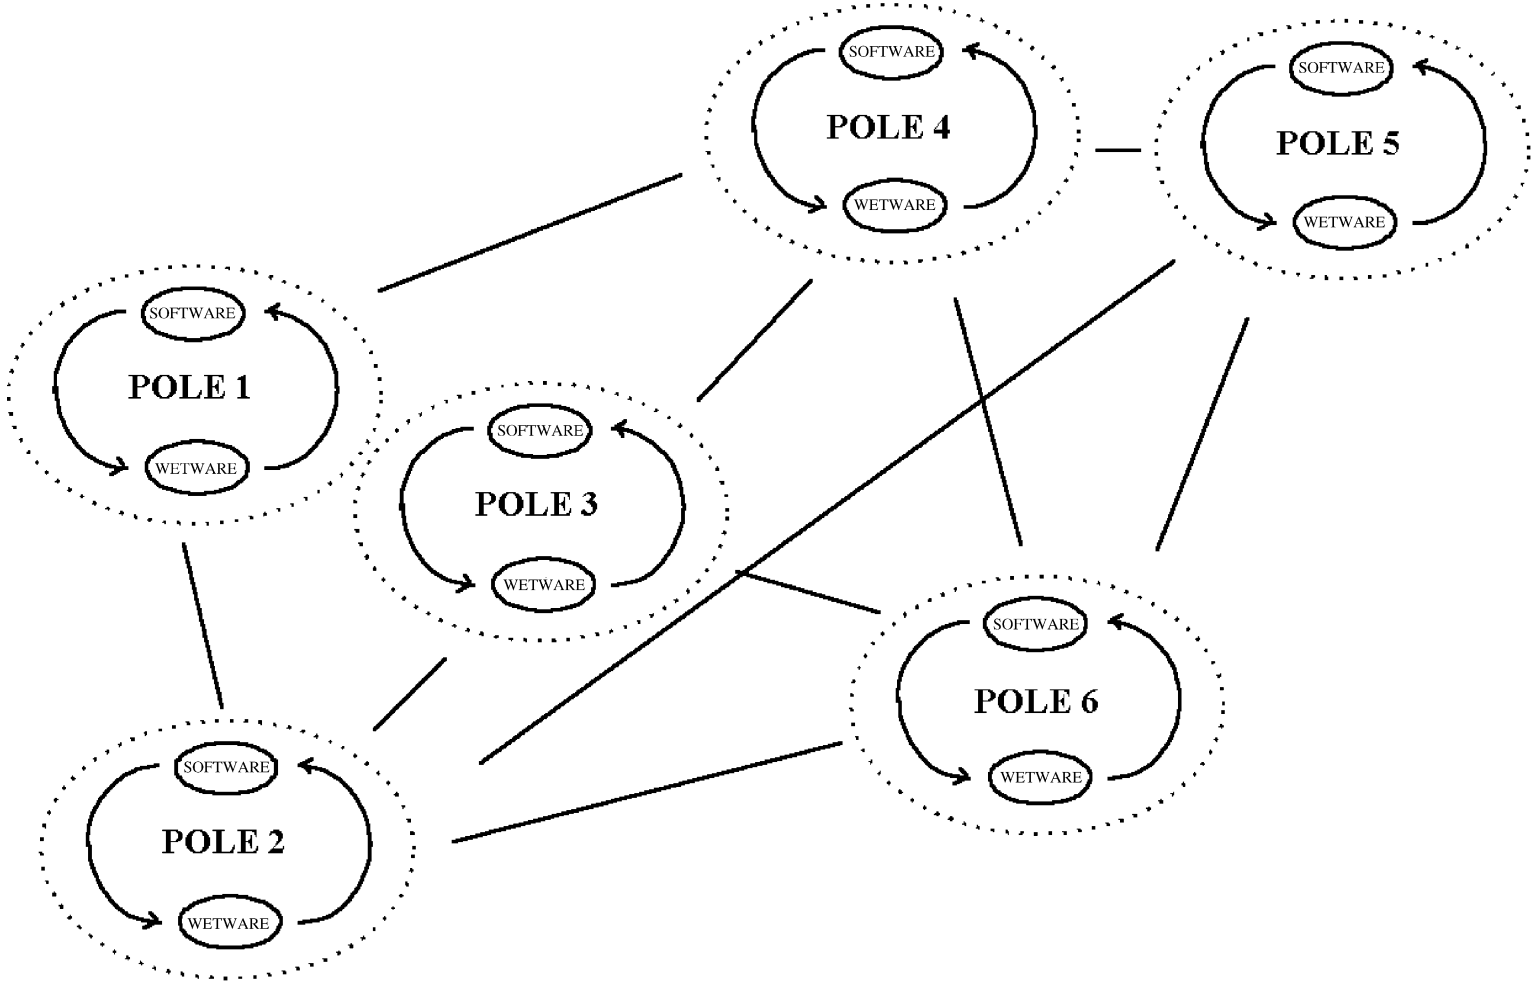

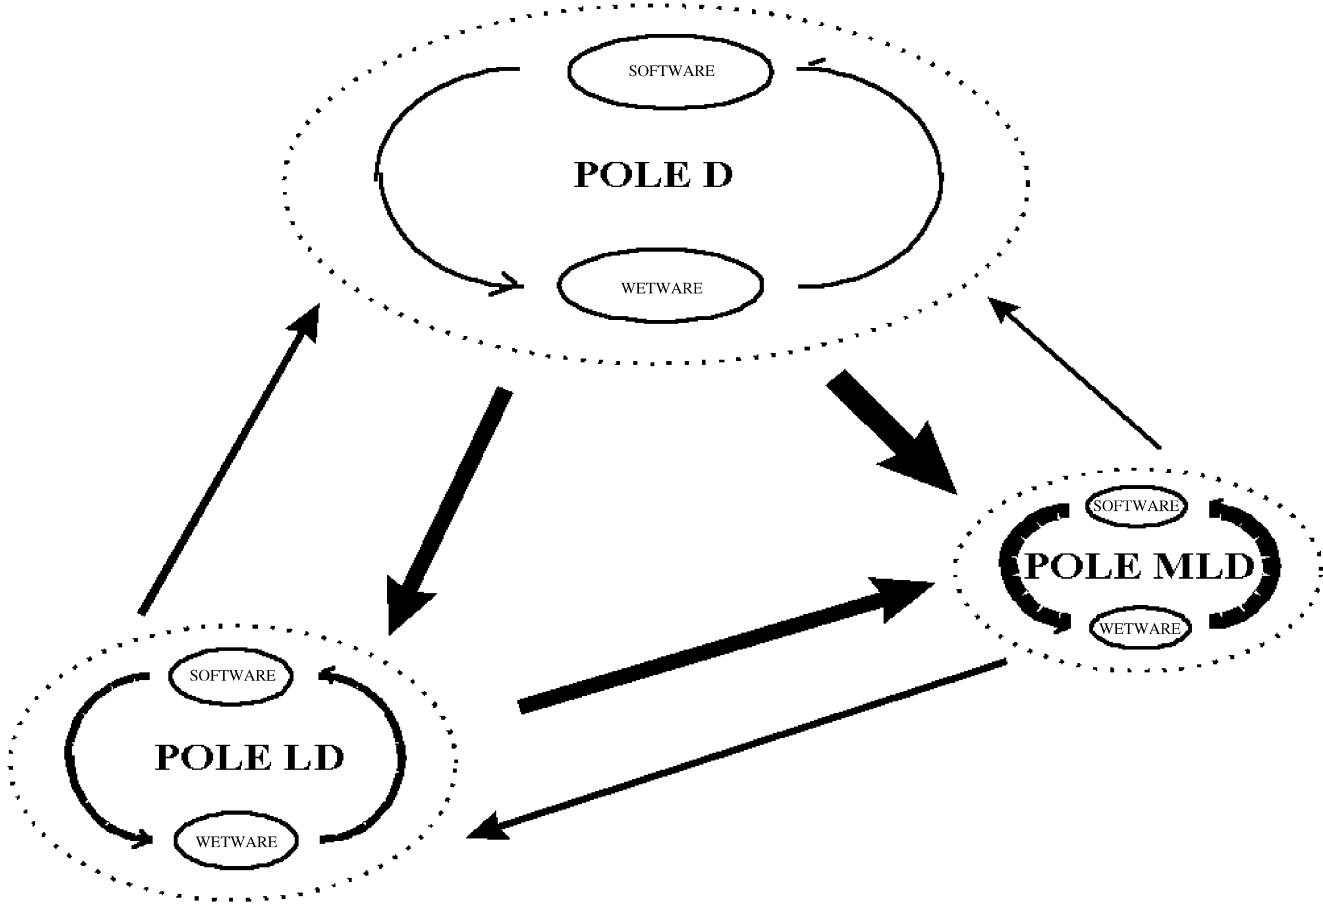

Figure 1. Learning and innovation poles as networks among regions.

D = Developed Pole
LD = Less Developed Pole
MLD = Much Less Developed Pole
Arrow density implies the richness of knowledge transfer and application

Figure 2. A learning network based on proportional reciprocity.

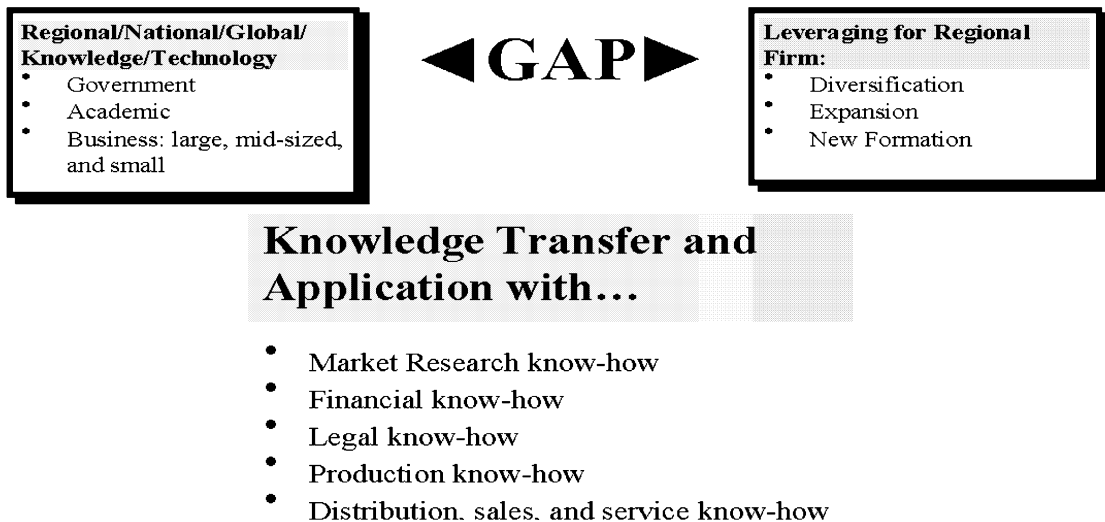

Figure 3. Crossing the knowledge transfer and application gap with know-how.

shorten product development cycles by broadening entrepreneurs’ global know-how in such areas as market research, finance, advertising, quality issues, management, sales, and service (see Figs 4 and 5).

Common challenges to having targeted SMEs think and act globally are:

- (1) success in home markets and a home-country bias
- (2) limited personnel
- (3) limited resources
- (4) limited time
- (5) limited tolerance for extra problems and challenges of going global (e.g. the fear of losing control of one’s intellectual property)
- (6) ignorance of critical success factors in foreign markets
- (7) legal, trade, and governmental constraints

These challenges need to be balanced against the benefits of a SME being part of the LIP/TCC Program. Such benefits include:

- (1) access to needed and often critical knowledge
- (2) global market access and niche market opportunities
- (3) access to needed talent, technology, capital, and know-how
- (4) minimizing mistakes and misspent resources
- (5) maximizing speed to the market and the commercial potential of a venture
- (6) Being aware of ‘your’ firm’s global strengths, weaknesses, opportunities, and threats

The objective of the LIP/TCC program is to foster the global linking of regional champions and enterprises with venture financing, managerial and marketing know-how, and supporting services.

Partnerships with local champions (e.g. business leaders, professors, and students from local universities/colleges, and influencers from the local chambers of commerce) will be formed. Existing institutional data will be used, as much as possible, to conduct a benchmark/scorecard of each targeted

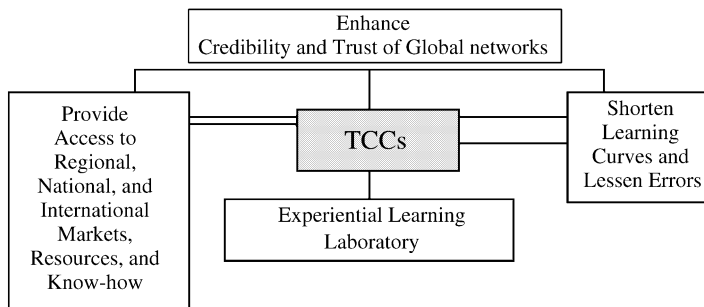

Figure 4. Technology commercialization centers as learning and innovation poles to foster venture success and accelerated growth.

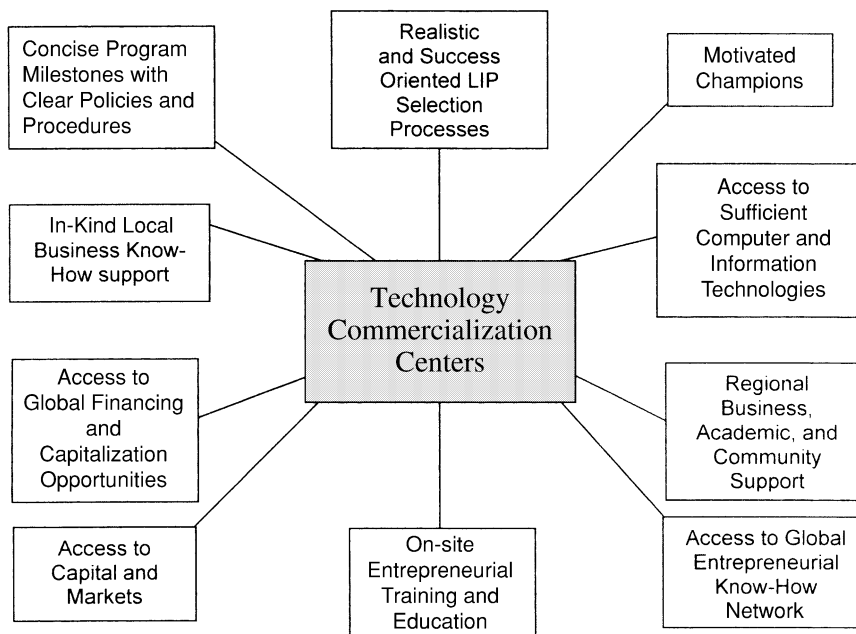

Figure 5. Ten success factors for Learning and Innovation Pole (LIP) development.

region. This benchmark's focus will be to identify and leverage existing capabilities:

- (1) for nurture Technology Commercialization Centers in each target region
- (2) to network these poles nationally and globally through the use of ICT and personal networks

Regional assessments will focus on:

- R&D and technical expertise related to current and future businesses activities in the region—the talent and technology base for growth of existing and new firms and industries
- core strengths and assets, competitive advantages in terms of regional, national, and global markets
- assessment of existing regional innovation systems
- scorecard (employment, founding date, spin-offs, growth, etc.) of existing small, mid-sized, and large firms in the region
- assessment of emerging clusters of activity, location of multi-nationals, branch plants, and headquarters
- interviews and survey of key regional leaders (academic, business, and government) to facilitate regional understanding by the researchers and regional support and ownership by key local champions

A number of data collection activities are recommended to provide local advisory boards and stakeholders the information necessary for them to make informed decision regarding the challenges in

facilitating technology-based economic development in selected LIPs. These aspects may include, but are not restricted to:

- specific and measurable objectives for the regional SME
- formation of business partnerships
- location and size of specific components of the regional SME
- technological profile; market and competitive orientation of the SME
- options for expansion
- financing needs and sources
- time schedule
- networks strengths and needs
- supply of services and consulting
- structure of LIP oversight

Building Networks

ICT personal networks and partnering programs will link TCCs into important resources for sustaining each LIP. Internet and other ICT links (e.g. video) will be established between each of the TCC sites with an emphasis on fostering collaboration among the LIPs. The proposed networks will attempt to identify regional champions for long-term partnerships. These networks will be sustained by being task focused for short-term success as well as longer-term vision.

While there is an appreciation for the national, institutional, and organizational contexts of each TCC, the focus is on the individual level of analysis and action (Fig. 6). The initial objective is to have the

Figure 6. Focus on individual level of analysis and action.

selected TCCs benefit from the codified knowledge and tacit know-how of the LIP network and training activities that focus on access to talent, technology, capital, know-how, and market access. The LIP network will strive to shorten product development cycles and time-to-market by broadening local firms' global knowledge in such areas as finance, market research, advertising, quality control, sales, and after-sales support and service.

The LIP networks will focus on six functional objectives:

- (1) *Networking for Markets*: The identification of markets and successful execution of marketing strategies is a determining factor in the success and sustainability of small and medium technology-based firms.
- (2) *Networking for Capital*: Access to adequate financing is one of the most critical factors for the success of technology-based firms. Broad public/private/NGO partnerships could be established to offer integrated access to services such as financial planning, support for obtaining grants, and opportunities for access to venture, development, and seed capital.
- (3) *Networking for Inter-Firm Linkages*: A networked approach is ideal for maximizing the impact of programs and projects, such as partnerships, alliances, and linkages to outside suppliers. Most clusters in developing countries tend to rely heavily on the local supplier base, which may become insufficient for their rapidly growing needs. Careful coordination is required to ensure that the local suppliers are able to match increases in demand so that jobs may be retained and created and that other substitute supply streams can be brought online as required.
- (4) *Networking For Technological Support*: Electronic networks are extremely useful tools to diffuse the benefits of technological support, providing services such as technology assessment and forecasting, technology gateway (assistance on technological choices and on marketing assessment of innovative projects), and access to outside technical information. These services could also be concentrated in a few centers provided by public

agencies, private consultants and business associations.

- (5) *Networking to Expand Access to Technology Transfer Opportunities*: The use of electronic networks for technology transfer is already being established in several places to stimulate investment in S&T, R&D, technology transfer, development of commercial potential of R&D, spin-offs. Networks are necessary tools to facilitate access to technology transfer opportunities worldwide.
- (6) *Networking for Talent and Know-How*: SMEs often do not have and cannot afford the entire range of technical and business talents and know-how required for success in local and global markets. The process of identifying and hiring such talent and know-how on a short-term as-needed basis is also difficult for smaller enterprises. Networks of talent and know-how would be a great asset that would allow SMEs access to the experts at affordable rates and opportune moments.

While established SME firms will be the initial focus of the LIP Program, there is a critical need to develop the infrastructure and resources of the region to promote accelerated development of knowledge based firms from the bottom-up as a longer term strategy. The basic need is to improve the process of knowledge transfer, acquisition, absorption, and diffusion. The issues involved include education, physical infrastructure construction, and improved policy environments. For example, if knowledge acquisition—whether imported from abroad or created at home—is to lead to economic development, it must be absorbed and applied. This requires universal basic education as well as opportunities for lifelong learning (World Bank, 1998). Also, the extent and economy of modern ICT greatly expand the potential for both the acquisition and the absorption of knowledge, but this can only happen after a basic level of telecommunications infrastructure is acquired.

The following are potential areas for action (Quandt, 1998):

- *Creating and Strengthening Local Technopolis Management Structures*: The first step is the creation of an organizational and functional structure for the

local cluster, preferably leveraging existing groups and associations. This would involve both private and public sector participants. The establishment of linkages between technopolis managers will enable a better understanding of stakeholder needs and markets and will improve organization methods. The creation of a permanent, dedicated business and technology information network would make communications more continuous and interactive, rather than sporadic exchanges that normally occur only at periodic meetings.

- *Determining Educational Needs and Offering Training:* Based on regional descriptive profiles and targeted interviews with local stakeholders, education requirements for the LIPs and targeted companies can be ascertained. Courses could then be offered through local workshops as well as via the Internet to help improve the skills of local trainers. For example, the IC² Institute is currently working with several global partners to offer long-distance educational programs—degree and certificate—focusing on technology commercialization and forming virtual teams of ‘students’ to evaluate the commercial potential of innovative technologies (www.IC2.org).
- *Fostering Personnel Exchanges:* Visits of key personnel among regions in the network would greatly facilitate knowledge, technology and know-how transfer. For example, one of IC² Institute’s global partners, the Instituto Superior Técnico has established an IMPACT Program for leading Portuguese entrepreneurs to build markets in the United States. Exchanges of students, faculty, and entrepreneurs facilitate these processes.
- *Building Local Skills and Training IT Specialists:* A skilled workforce is one of the most important localization factors for technology-based companies, and a major constraint to the development of technopoleis in many less developed regions. This characteristic is essentially place-based, yet virtual technologies may boost the development of human resources in more remote locations through training centers, distance education, career planning, virtual job markets, and also support business development through the establishment of virtual entrepreneur schools providing all kinds of training—technical, managerial, marketing, etc.
- *Optimizing and Sharing Facilities:* For each region, the required facilities for a viable technopolis could be kept to a minimum, provided they are integrated into a shared system. The operational support infrastructure could be optimized and many facilities could be shared over the network, including prototype centers, pilot plants, online libraries, test laboratories, and online conferencing facilities.

Technology Commercialization Centers will focus on select entrepreneurs and business enterprises in tar-

geted regions. These sites will be studied over time to provide data and case examples for research as well as for job and skills training. It is important to involve a range of regions with a variety of characteristics, challenges, and opportunities for wealth and job creation. Metrics for success will be regionally-focused and will be identified and followed over time. In general these metrics will include:

Targeted to Specific SMEs

- Global technology and business assessment
- Market assessment: regional and global, existing and emerging
- Intellectual property rights and protection
- Capital access
- Increased profit
- Accelerated growth
- Access to new technology and business processes
- Shorter time to market
- Management and employee development

Government Oriented

- Job creation
- Space utilization
- Capital creation
- Incremental revenues (i.e. taxes, services, etc.)
- Development of regional ‘smart infrastructure’
- Increased global awareness and competitiveness

Academic Oriented

- Training of faculty and students
- New curriculum development
- Successful placement of students
- Experiential, on-the-job learning
- Enhanced favorable relations with community
- Research and publications
- Revenue generation (i.e. royalty, license fees, etc.)

Conclusions

Establishing a network of LIPs composed of meaningful and sustainable Technology Commercialization Centers depends upon the effective use of ICT—as well as regional and global partnerships and partnering programs that facilitate the diffusion and adoption of tacit knowledge. While the role of business, academic, and government sectors in building regionally-based technology centers (i.e. technopoleis) has been observed and experimented with for over 20 years, it remains unclear what are the key resources and conditions for accelerating the growth of virtual technopoleis and how these criteria might change depending on geographic location. The LIP Program presented here seeks to provide the experimental laboratory to address the following questions:

- (a) How does one best accelerate entrepreneurial wealth and job creation in SMEs through Internet and web-based access to talent, technology, capital, know-how, and markets?

- (b) What 'smart' infrastructure must be physically present at SME locations and what can be virtually linked regionally, nationally, and globally and how does this change over firm growth and maturation?
- (c) What are the critical components of regionally-based technopolis development in the emerging Internet and web-based knowledge economy of the 21st century?
- (d) Can a developing region 'leap-frog' the 20–40 years it has traditionally taken to build technopolis without first building world-class research facilities and state-of-the-art science parks, and the agglomeration of 'smart' infrastructure (i.e. finance, legal, marketing, manufacturing, sales and distribution, global expertise, etc.)?

Science Parks: A Triumph of Hype over Experience?

John Phillimore¹ and Richard Joseph²

¹ *Institute for Sustainability and Technology Policy, Murdoch University, Australia*

² *Murdoch Business School, Murdoch University, Australia*

Abstract: This chapter argues that there is a disjuncture between the critical assessment of the academic literature about most science parks and their growing number worldwide. After briefly detailing the spread of science parks, the chapter explores their nomenclature as part of a broader categorization of the type of parks found today. Several rationales for parks are examined. The skepticism commonly expressed about science parks in the literature is analyzed and contrasted with their continued popularity. The chapter concludes with an assessment of possible new directions for science parks.

Keywords: Innovation; Science parks; Industrial parks; Business incubators; Research park.

Introduction

Depending on the definition used (an issue discussed below), there are now more than 400 science parks spread throughout the world. Fifty years ago, there were just two—the Stanford Research Park next to Stanford University in California and the Research Triangle Park in North Carolina. According to the International Association of Science Parks (IASP), every Park has an average of 3,900 employees, indicating total employment of around 1.5 million employees worldwide (IASP, 2000, p. 4).

Moreover, the number of parks continues to grow. The two major international associations, the European-based IASP and the U.S.-based Association of University Research Parks, each have around 230 members (with little overlap). The IASP has witnessed a doubling of member parks in less than a decade. The first parks appeared in the USA, with the U.K. and France following suit in the 1960s and 1970s. Australia and Canada experienced their main science park growth from the mid-1980s, with continental Europe getting on board in the 1990s. China and other countries in the Asia Pacific have now become the major growth area for science parks, although their size (average employees of almost 10,000 compared to just over 2,000 in Europe and North America) indicates that Asian science parks may be combining elements of more traditional industry parks with science parks proper.

Yet despite this apparently inexorable growth, there has always been a disjuncture between the promise and the reality of the science park model. The great majority of academic evaluations of science parks have invariably failed to show any particularly significant or distinctive benefits arising from science parks in terms of technology transfer between universities and industry, technology and economic development more generally, or local or regional urban renewal in particular.

The purpose of this chapter is to explore in more detail the apparent conflict between the critical assessment of most academic literature about the (lack of) achievements of most science parks and their continued popularity. The chapter begins by outlining the nomenclature of science parks and related concepts (technopoles, technology parks, research parks, etc) as part of a broader categorization of the type of parks commonly found today. Several rationales for parks are then examined in 'Definitions': technology development; regional development; the encouragement of 'synergies' (in particular technology transfer from universities to industry); real estate development; political prestige. The skepticism commonly expressed about science parks in the academic literature on innovation is then analyzed and contrasted with the continued popularity of the concept in 'Rationales for Science Parks'. The chapter concludes with an assessment of possible new directions for science parks.

Definitions

Our focus in this section is to present a nomenclature of science parks and related concepts as a framework for understanding the broad range of developments in these areas that we see today. Specific developments need not conform to a specific category and indeed 'hybrid' developments are more common. What unifies many developments is their underlying rationale. However, we will leave this discussion of rationale for the next section. What we aim for in this section is categorization with an emphasis on functional description as opposed to rationale. This section paraphrases work we have done in looking at definitional issues (Joseph, 1986, 1994; Macdonald & Joseph, 2001; Phillimore, 1999).

The concept of a science park is something that cannot be captured by a static definition. It is inherently dynamic and centered around geography, changing location patterns of industry and technological change. We will first provide a brief historical context and follow this with definitions of the spectrum of categories in use today: small business incubators; technology business incubators; science and technology parks; and business parks and high quality industrial estates.

Historical Context

The growth of residential and industrial districts was once centered around ports, waterways and railways. The development of these districts during the first half of the twentieth century has encouraged alternative forms of location patterns for industry. For example, with the growth of air transport, location near an airport became important. As patterns of industrial location changed, developments in industrial parks followed. Hence, it is now popular to cite such factors as proximity to an airport or university, together with good infrastructure (e.g. telecommunications), as important attributes of a modern industrial park.

The world's first planned industrial park was launched in Manchester (U.K.) in 1896, but it was not until after World War II in the USA that industrial parks gained widespread popularity. Operational characteristics have predominated in the design of these parks (viz. comprehensive planning, zoning, entry control of tenants, development strategy, profitability, etc.). In short, "whatever the name, the presumption is that the industrial park is a project which has been planned and developed as an optimal environment for industrial occupants" (Barr, 1983).

Since the 1970s, there has been growing integration of commercial functions with the industrial activities traditionally associated with industrial parks. One factor driving this integration is technological change—new firms and existing firms introducing new technology are demanding new environments and services (Joseph, 1989a). For example, 'new' industrial activities, such as research and information handling,

require conditions similar to those in a residential environment. Commercial property developers have attempted to reflect these changes in the way industrial parks are marketed and planned. National, regional and state governments, together with universities and research institutions, have also taken a greater interest in the shaping of industrial parks, however defined (Congress of the United States, 1984).

Industrial parks are now functionally diverse in order to meet the needs of new companies and changing industries, changing technologies and a range of policy demands from governments. Because this functional diversity has manifested itself in a variety of activities, definitional problems have arisen (Macdonald, 1987; OECD, 1987). Confusion is compounded by the fact that there are national differences in the use of terms. In some countries, the term 'S&T park' has come to encapsulate all forms of government support for new firms and technology development.

While there are historical reasons explaining the diversification of functions, it is possible to define a range of activities arising from the general industrial park concept. All of them reflect diverging aspects of the central problem of meshing a changing industrial and technological environment to the notion of industry location and increased government involvement in innovation. Despite the fact that terms differ between nations and even regions, categorization is possible and can assist policy development. We have categorized the main terms as:

- small business incubators;
- technology business incubators;
- science and technology parks;
- business parks and high quality industrial estates.

Small Business Incubators and Technology Business Incubators

The terms 'small business incubator', 'enterprise center', 'business technology center', 'technology business incubator' and 'innovation center' are often used interchangeably. As a result, problems have arisen in distinguishing between incubators that support new firms in general and the more specialized incubators that deal with technology-related problems associated with the start-up of technology-oriented new firms. For instance, 'innovation center' is often used when the incubators are close to, or on, a university campus. Incubators may be located on an S&T park and it is presumed that the new start-up firms will have technology development as a core part of their business plan. In general, small business incubators have a number of characteristics:

- they are a method of increasing the efficiency of enterprise development by grouping a number of businesses in one facility under the guidance of an experienced business person;

- the facility provides low-cost, expandable space, frequently in an old building with minimum standards;
- they must have access to a business-consulting network providing low-cost services, such as product development, marketing, finance and services; and
- they provide a forum in which the people in the various businesses can assist each other (Australian Department of Industry, Technology & Commerce, 1989a).

While the characteristics of small business incubators are appropriate to all sorts of new businesses, we suggest that for incubators which are specifically accommodating companies where technology development is a central component of the business plan, the term 'technology business incubator' be used. In practice, however, depending upon local circumstances, small business incubators may also be able to accommodate some technology-based companies. With these qualifications in mind, we suggest the following definitions as a guide for policy.

Small business incubators are converted or purpose-built industrial buildings which offer accommodation and a supportive, growth-oriented environment for newly-formed companies.

Technology business incubators (TBIs) are converted or purpose-built industrial buildings which offer accommodation and a supportive, growth oriented environment for newly-formed companies which have technology development as a core component of their business plan.

Some of the services a TBI can provide, in addition to those provided by a small business incubator, are:

- programs for improving the scientific and engineering training of entrepreneurs;
- an information network incorporating skilled workers and advisers from local universities, schools and business;
- technical and management training;
- evaluation, consulting and referral services;
- an information gathering and dissemination service (e.g. guest speakers and site visits);
- specialist advice on financing technology development; and
- patenting and commercialization advice (Congress of the United States, 1984).

Science and Technology Parks

While small business incubators and TBIs focus on new enterprise development, S&T parks aim to establish concentrations of firms or industries in a particular area. S&T parks are also associated with technology transfer objectives. The terms 'research park', 'science park' and 'technology park' are frequently used interchangeably and distinctions easily become

blurred. The term 'research park' may reflect the original concept behind science parks.

A 'research park' implies the following:

- a high quality, low density physical environment in a park-like setting;
- interaction between academics, researchers and commercial organizations and entrepreneurs; and
- an environment for research and product development, with conventional production and office activities excluded.

A 'science park' can be defined as a property-based initiative which:

- has formal operational links with one or more universities, research centers, or other institutions of higher education;
- is designed to encourage the formation and growth of knowledge-based industries and other organizations normally resident on site; and
- has a management function which is actively engaged in the transfer of technology and business skills to tenant organizations (Australian Department of Industry, Technology & Commerce, 1989b, p. 7).

A 'technology park' can be defined broadly as a collection of high technology industrial companies concerned with both research and manufacturing, located in attractive, well-landscaped surroundings, and situated within a reasonable catchment area of a scientific university or a major research institute (Australian Department of Industry, Technology & Commerce, 1989b, p. 17).

Key differences between the above definitions rest on: (i) what activities are permitted in the park (e.g. research only or some light manufacturing); (ii) the strength of the link with the university (e.g. close operational links or just in the vicinity); and (iii) the extent to which interaction with the university is promoted or expected to occur (e.g. active technology transfer programs in place). In short, a definition of S&T park must reflect a spectrum of activities (Joseph, 1992).

We suggest that a S&T park can be defined as a property-based initiative which:

- has a high quality, low density physical environment in a park-like setting;
- is located within a reasonable distance of a university or research institute; and
- emphasizes activities which encourage the formation and growth of a range of research, new technology or knowledge-based enterprises.

S&T parks may or may not have a TBI associated with them. It is usually the case, however, that for larger developments, a TBI is located on the park, be it a research park, science park or S&T park.

Business Parks and High Quality Industrial Estates

While S&T parks highlight a technology transfer role, there is a class of development which has little direct focus on technology transfer, but which sometimes makes claims in that direction. This class of development—business parks and high quality industrial estates—is defined below (Joseph, 1986):

Business parks provide a high quality prestigious environment, suitable for a wide range of activities, including manufacturing, assembly, sales and other office-based activities. These parks do not require close proximity to academic institutions.

High quality industrial estates are property-based developments which can legitimately claim some features attractive to certain forms of modern light industry. Often a ‘high-tech’ center is planned for a later stage of development of the industrial estate.

The potential for science parks to evolve into business parks and industrial estates and to lose their research and technology focus is discussed further in the next section.

Rationales for Science Parks

Massey et al. (1992, p. 21) list three main classes of science park objectives: economic development, local benefits, and transfer of technology. Castells & Hall (1994, p. 224) amend these slightly in listing three motivations for the establishment of technopoles (their generic term for science and technology parks): reindustrialization, regional development, and the creation of synergies.

The first two of these objectives are fairly straightforward, and could alternatively be described as technology development and urban or regional renewal respectively. The third aim is less clear. At its narrowest, it could be seen simply as the promotion of technology transfer from universities to companies. However, Castells & Hall describe it in more detail as ‘the generation of new and valuable information through human intervention’ to the extent that an ‘innovative milieu’, which generates constant innovation, is created and sustained (Castells & Hall, 1994, p. 224).

In the U.K., with the onset of urban decline in many cities in the 1980s, the second of these three motivations was predominant. Local authorities and universities established science parks as a form of urban redevelopment. In other countries, decentralization of economic and technological activities was an important aim. In both Japan and Korea, for example, the national government’s ambition to shift activities away from Tokyo and Seoul respectively was a strong factor in determining the direction (and subsequent location) of science park developments in those countries. This involved a policy that required particular government research agencies to move from the

capital and become core tenants in regional science parks (Castells & Hall, 1994; Shin, 2001).

In Australia by contrast, the first motivation was more prominent, with technology park development in the 1980s being an integral aspect of government (high) technology policy in many States. This was partly due to the relative absence of the urban problems facing Britain, but also because of the greater role undertaken by State governments in developing technology parks in Australia. These governments had a responsibility for, and interest in, industry development.

In all countries, however, technology transfer has been an avowed aim of science park development—in particular, the encouragement of knowledge transfer from universities and government research institutions to the commercial sector. However, Castells & Hall’s more comprehensive notion of knowledge and information networking was, until relatively recently at least, less evident. The language and rationale behind most parks tended instead to reflect a uni-directional flow of research emanating from universities and being commercialized by park-based companies. Measuring the extent of technology transfer from university and research centers to park-based companies has formed the core of most academic assessments of science park performance—and of most of the criticism of this performance.

A further rationale for the establishment of science parks has been their real estate potential. As property-based ventures, the real estate component of science parks is ever-present, especially in privately owned and managed parks where generating income through rent and property sales is crucial to the park’s (and the manager’s) commercial future. This may necessitate a relaxation of ‘selection’ criteria for park tenants (i.e. allowing tenants without a commitment to R&D or an interest in accessing nearby universities or research centers) (Westhead, 1997, p. 57). Indeed, it has been argued that science parks can too easily become glorified business parks, attracting firms for reasons of prestige and image rather than any substantive benefits in terms of linkages with university research (Shearmur & Doloreux, 2000, p. 1067). Westhead (1997, p. 57) considers that ‘property-based initiatives which link with a local HEI (higher education institution) for solely promotional reasons do the Science Park movement a disservice’, and that science park associations should be stricter in applying conditions to those parks wishing to use the ‘science park’ label. But such moves will clash with pressures to improve the commercial success of science parks.

Image and prestige are not only of concern to companies considering locating on a science park. They are also very important to park owners and sponsors, especially governments, who are keen to demonstrate their commitment to modern technology development through showcase developments such as

science parks. From this perspective, science parks can be seen as a 'place marketing' tool, promoting the virtues of a certain location in competition with other localities trying to entice inward investment to the park. The competition may be intra- or inter-metropolitan, and may or may not result in a net increase in investment for the state or country in which the science park is located. As a consequence, it has been argued that 'the popularity of science parks may be more fruitfully analyzed from this local political perspective than from a more aggregate perspective' (Shearmur & Doloreux, 2000, p. 1079).

In assessing the effectiveness of science parks and the extent to which they are meeting their objectives, it is important to keep in mind these various possible rationales behind their establishment.

Assessments

The question of making an assessment of science parks is not easy. There are various complicating factors. First, in 'Definitions', we saw that a multitude of definitions exist and as a result it is difficult to identify exactly what sort of development is being assessed, especially since 'hybrid' activities exist on many parks (eg. a TBI is frequently associated with a science park). Second, in 'Rationales for Science Parks', we observed that the rationale for parks varies and teasing out these strands is not easy either. Third, there is politics. Many park developments have received substantial support from the state or are solely public initiatives and form part of public policy support for industry or technology development. As a result, while it may be possible to subject privately funded ventures to purely commercial criteria, those with public investment usually have broader long-term policy objectives and this makes assessment based on commercial criteria alone difficult.

Furthermore, compounding this theme is the policy analysis process itself (Joseph, 1994). Since the objectives of parks are often changing, pinning down a clear cut link between identifying an objective and the successful attainment of that objective often evades policy analysts, especially if vested interests are involved. Finally, trenchant academic criticism of science parks (particularly in the U.K. over the past 10 years), has questioned whether science parks work (Grayson, 1993). It is primarily to this last point that we will direct our attention in this section.

How accurate is it to say that hype has triumphed over experience? Asking the question 'has hype triumphed over experience' is slightly different to asking the question 'do science parks work?' There are numerous studies of the latter. Many are reviewed in Grayson (1993), and there are more recent assessments of parks in Sweden (Lofsten & Lindelof, 2001), Canada (Shearmur & Doloreux, 2000), Korea (Shin, 2001), Greece (Bakouras et al., 2002) and Australia (Phillimore, 1999). None of these studies is definitive

in being able to resolve this latter question. Proponents and opponents of science parks often take rather entrenched positions.

The aim of this section is to examine why such entrenched positions have evolved and the underlying reasons for this situation. We will explore this theme below by analyzing different positions taken in the debate by proponents, the U.K. Science Parks Association (UKSPA), and opponents, Massey, Wield and Quintas (1992), who wrote a very critical book entitled *High Tech Fantasies*. Grayson (1993) reports on these two positions.

Grayson's (1993, p. 104) review of the science park literature addresses the question 'do science parks work?'

The answer to this question may seem self evident given the rapid growth of science parks developments in both the U.K. and overseas, and the low failure rate of the companies which locate on them . . . However, there are doubts: about whether the science park is a necessary vehicle for the development of small high tech companies, whether the concept of technology transfer it embodies is a fruitful one, whether it can succeed as a focus for local or regional regeneration, and (on a broader level) whether the concept of high tech, small firm-led growth itself is reasonable.

The doubts about science parks noted in the above quotation relate to criticisms by Massey et al. (1992) and others (e.g. Macdonald, 1987) that British science parks fail to meet the criteria laid down by the UKSPA definition. As noted in 'Definitions', this definition covers the following areas:

- a science park has formal links with a university or other higher educational or research institution;
- a science park is designed to encourage the formation and growth of knowledge-based and other organizations normally resident on site; and
- a science park has a management function which is actively engaged in the transfer of technology and business skills to the organizations on site.

On all counts, Massey et al. (1992) argue that British science parks fall short.

Grayson (1993, pp. 119–133) summarizes the UKSPA's response to this criticism below.

UKSPA argues that, far from being based on an outdated linear notion of innovation, the science park plays a more important role in the more complex interactive model by providing the conditions for feedback between academics and the market, and by contributing to technology diffusion throughout industry as a whole. It claims that much of the critical academic analysis is based on misunderstandings derived in part from the unrealis-

tic claims made by some science park proponents, but also from a misinterpretation of the evidence.

In addition to the above claims, the UKSPA strongly suggests that since so many countries have chosen the science park route, if its potential was so limited these countries would have hardly adopted these policies:

... the science park concept has been employed by economies and societies as diverse as France, Germany, Spain, the former Soviet Union, Taiwan, Japan and Korea; successful economies are spending huge resources—much more than Britain—on this kind of systematic conversion of science into technology and that is difficult to see how, otherwise, new industries are going to be born (Grayson, 1993, p. 123).

The above interchange from the U.K. debate allows us to generalize as to why hype and experience are not easy bedfellows in evaluating science parks. There are three reasons why hype might be able to triumph over experience, and these could be applicable in any country.

First, there is no clear-cut agreement between proponents and opponents of science parks about the model of innovation that applies. This is an area where there will perhaps never be agreement but the phrase used by the UKSPA—‘systematic conversion of science into technology’—indicates that they have a vested interest in protecting a linear way of looking at the innovation process as opposed to other ways. Yet, in the same breath, the UKSPA, is comfortable in claiming that science parks are about ‘more complex interactive models’. Here we see the phenomenon of ‘the shifting goal posts’ in policy analysis. That is, policy objectives are subtly changed so that definitive analysis based on agreed criteria become difficult. Critics have difficulty in making a criticism stick since science park proponents are able to redefine their objectives all too readily. This is particularly acute for science parks since they are long-term ventures, with success periods measured by decades, not just a few years. Little wonder, then, that there is deep-seated disagreement.

Second, the UKSPA blames academics for misunderstanding the role of science parks and partly attributes this to ‘unrealistic claims made by some science park proponents’. This point glosses over and simplifies a very significant attribute of science parks—they have often been portrayed as symbolic of high technology development policy and as such, politicians have a vested interest in seeing them succeed. In our view, it is not so simple as interpreting this as a few enthusiastic land and property developers having over-stepped the mark. Rather, some science parks have become ‘flagships’ for political agendas, either at the national, state or regional level. From this aspect, it is very easy to see that science parks will be

defended at all costs. Two defences that the UKSPA use are the ‘correct’ interpretation of ‘reliable’ statistics and the time factor over which science parks are expected to deliver benefits:

The U.K. Science Park Association has for several years collected statistical information on the national science park movement and this provides a broad basis for the assessment of progress ... Nevertheless, behind the statistics lie factors which must be frankly recognized and taken into account when the numbers are interpreted. It is unrealistic to expect that science parks in themselves and in the short to medium term will have a major effect on the national level of employment or economic activity (Grayson, 1993, p. 120).

Once again, ‘shifting goal posts’ can act as a vehicle for allowing hype to triumph over experience. However, what qualifies as ‘experience’ is contestable since there is no agreed view on what statistics are allowed as authentic. Moreover, once political reputations and public money are involved, it is very difficult for specific science parks to be labeled as an outright failure. For example, commercial failure could be disguised by changing the entry criteria for the park. Policy failure could be disguised by obfuscating the grounds for policy analysis.

Finally, the third area where hype may triumph over experience relates to the UKSPA’s view that since so many countries have chosen the science park route, if its potential was so limited these countries would have hardly adopted these policies. This too is an interesting observation in that it suggests that the copying of the science park model from one country to another implies that the model itself is successful. We claim that this argument is flawed since science parks themselves were conceived with a logic of trying to emulate Silicon Valley (Joseph, 1989b; Macdonald, 1983). The Silicon Valley model is a narrative about how the Californian high technology mecca, Silicon Valley, came about. The narrative, which has no doubt influenced and been the part justification of many policies for high technology (including science parks), includes some or all of the following features: a faith in entrepreneurialism; a vital role for venture capital; a critical role played by research universities; a healthy supply of highly qualified researchers; and benefits for firms co-locating (agglomeration economies). Apart from the process of modeling itself having its own complications (Joseph, 1997), Macdonald (1998, pp. 160–188) points out that the science park route of trying to copy or model the Silicon Valley phenomenon is flawed in a number of ways:

- policy makers who have modeled Silicon Valley have consistently misunderstood the crucial role that information plays in Silicon Valley itself;

- the Silicon Valley model provides for a misinterpretation of the sort of information that is important to high technology; and
- the Silicon Valley model has given rise to a view that the Stanford Industrial Park, established by Stanford University, somehow caused the growth of Silicon Valley, which it has not.

More recently, Cook & Joseph (2001) have added state and cultural factors to the above in criticizing the Silicon Valley model, demonstrating just how difficult it is to transfer policy ideas such as science parks into a different cultural context (eg. southeast Asia).

What then are our conclusions about the triumph of hype over experience? Macdonald summarizes our view above:

Policy portrayed high technology as something magical: apply public money with the right incantation and wondrous things would happen. When they failed to happen, there was no incentive for policy makers to explain what had gone wrong. The good performer hides his embarrassment and quickly moves on to the next trick. The audience will never be told why the high-technology miracle never happened. But behind the scene, there is the opportunity for policy makers and their political masters to learn from what went wrong (Macdonald, 1998, p. 183).

However, it would be irresponsible of us to dismiss science parks out of hand. They form a permanent and significant element of the technology policy landscape and they are continually being copied and established in many countries. They obviously fill a need, especially if tenants are willing to locate in them. However, such a need has more to do with property development than technology, industry or regional development policy.

This section has attempted to address why hype may have triumphed over experience and we have demonstrated that for some very strong reasons, criticisms of science park hype are likely to be ignored by their proponents. What this means in practice is that science parks will have a role but that role will need to be reassessed in the light of fundamental criticisms of their rationale and the continuing experience of their contribution to policy objectives. Because hype may triumph over experience (or logic for that matter), there is the risk that the science park phenomenon will prove to be a pale imitation of the sort of benefits that many countries are now seeking from high technology development policy. There is an opportunity to learn and this must be grasped. It is not even a case of replacing a 'good policy measure' with a 'better policy'. Rather, science parks are an opportunity to learn and there are many obstacles preventing that lesson from being learnt. It is to this that we turn our attention in the next section.

Conclusion

Science parks have been in existence now for over fifty years, have been a regular and conscious tool of government technology and regional development policies for at least twenty years in the USA, U.K., Canada, Australia and parts of Europe, and are growing rapidly in number in Asia and parts of Latin America. The high hopes held by many government, academic and business proponents of science parks have called forth a worldwide science park 'movement'. Other observers, however, consider them to be 'high tech fantasies' based more on hype than substance and a relative waste of public money compared to how those funds might otherwise have been spent to achieve the same goals.

As the discussion in this chapter shows, the jury is still out on whether science parks can best be seen as the last hurrah of old-style, place-based industrial development, or as the harbinger of new-style, information and network-based technology development in the information economy.

While these opposing views are effectively irreconcilable, it is still possible for both sides to learn from the various assessments that have been made of science parks. For whatever one's views on science parks, the fact remains: they exist. And so the question also remains: where now for science parks?

In our view, the way forward comprises several possible elements:

- enlisting more pro-active and supportive science park management aimed at encouraging more frequent and more dense linkages (both formal and informal) between park companies, universities and research institutes (Westhead, 1997, p. 59);
- using the existing and expanding international science park network as a source of 'value added' for park tenants in the form of information provision, marketing expertise and contacts, technical support and business links (Phillimore, 1999, p. 679);
- encouraging science parks to integrate more closely with their civic, urban and regional environments so that they actively use their spatial characteristics to promote interaction and networking possibilities, rather than cutting themselves off from their surrounding innovative milieu through maintaining an 'elitist' image. Some parks in Australia, for example, are now evolving into technology precincts with the explicit aim of linking more closely to the wider community (Phillimore, 1999, p. 679);
- creating new science parks with a more specific focus, such as particular technologies (e.g. biotechnology) or environmental objectives. This enables more distinctive park developments to emerge and should make it easier to encourage closer links between park tenants themselves as well as between the tenants and relevant university and government researchers; and

- Moving beyond a linear view of innovation towards a network view which emphasizes ‘the creation, acquisition and handling of information’ as a core function of science parks (Joseph, 1994, p. 54).

While these initiatives should assist science parks in their quest for relevance and performance, no-one should consider that they are likely to answer the question contained in the title of this chapter. That is as much a political as it is an economic question, the answer to which is unlikely to be settled in the near future.

Challenges in Innovation Management

John Bessant

School of Management, Cranfield University, U.K.

Abstract: Innovation represents the core renewal process in any organization. Unless a business is prepared to work continuously at renewing what it offers and how it creates and delivers that offering, there is a good chance that it won't survive in today's turbulent environment . . . So managing innovation becomes one of the key strategic tasks facing organizations of all shapes, sizes and sectors. This chapter reviews the question of managing innovation and particularly looks at some of the key challenges, which must be addressed.

Keywords: Innovation; Innovation management; Organization; Business; Innovation culture; Learning.

Introduction

Innovation represents the core renewal process in any organization. And unless a business is prepared to work continuously at renewing what it offers and how it creates and delivers that offering, there is a good chance that it won't survive in today's turbulent environment. It's a sobering thought that only one firm out of the Dow Jones 100 index actually made it through from the beginning to the end of the 20th century—even the biggest enterprises have no guarantee of survival and the mortality rate for smaller firms is very high (de Geus, 1996). Nor is this only a problem for individual firms; as Utterback's study indicates, whole industries can be undermined and disappear as a result of radical innovation which rewrites the technical and economic rules of the game (Utterback, 1994). Two worrying conclusions emerge from his work; first, that most innovations which destroy the existing order originate from newcomers and outsiders to a particular industry, and second, that few of the original players survive such transformations.

So the question is not one of whether or not to innovate but rather of *how* to do so successfully. Managing innovation becomes one of the key strategic tasks facing organizations of all shapes, sizes and sectors. This chapter reviews the question of managing innovation and particularly looks at some of the key challenges which must be dealt with.

What Has to be Managed?

One of the difficulties in managing innovation is that it is something of a 'Humpty-Dumpty' word. In 'Alice in

Wonderland' this character used words to mean 'whatever I want them to mean'—and in similar fashion people talking about innovation often use the term in widely different ways! The word originally comes from the Latin *innovare* meaning 'to make something new', but it helps to think of it in terms not only of 'invention'—creating something new—but also of its development and take up in practice. A useful definition is that offered by Freeman; ' . . . the technical, design, manufacturing, management and commercial activities involved in the marketing of a new (or improved) product or the first commercial use of a new (or improved) process or equipment' (Freeman, 1982). Rothwell reminds us that it is not always about radical change; '*. . . innovation does not necessarily imply the commercialization of only a major advance in the technological state-of-the-art . . . But it includes also the utilization of even small-scale changes in technological know-how . . .*' (Rothwell, 1992). Perhaps the most succinct definition is offered by the Innovation Unit of the U.K. Department of Trade and Industry who see it simply as 'the successful exploitation of new ideas'.

Getting this process right once is possible through luck—the skill comes in being able to repeat the trick. Whether the organisation is concerned with bricks, bread, banking or baby care, the underlying challenge is still the same. How to obtain a competitive edge through innovation—and through this, survive and grow? (This is as much a challenge for non-profit organizations—in police work, in health care, in education the competition is still there, and the role of

innovation still one of getting a better edge to dealing with problems of crime, illness or illiteracy).

Essentially organizations have to manage four different phases in the process of turning ideas into successful reality (Tidd, Bessant et al., 2001). They have to:

- scan and search their environments (internal and external) to pick up and process signals about potential innovation;
- strategically select from this set of potential triggers for innovation those things which the organization will commit resources to doing;
- having chosen an option, organizations need to resource it—providing (either by creating through R&D or acquiring through technology transfer) the resources to exploit it;
- finally organizations have to implement the innovation, growing it from an idea through various stages of development to final launch—as a new product or service in the external market place or a new process or method within the organization.

One other phase is relevant, albeit optional. Organizations need to reflect upon the previous phases and review experience of success and failure—in order to learn about how manage the process better, and to capture relevant knowledge from the experience.

Although this process is generic, there are countless variations in how organizations actually carry it out. But innovation management is about learning to find the most appropriate solution to the problem of consistently managing this process, and doing so in the ways best suited to the particular circumstances in which the organization finds itself.

The trouble is that the innovation puzzle which organizations are trying to solve is constantly changing and mutating. This chapter looks at some of the current challenges which are involved in trying to manage innovation, but we should recognize that there is no ‘one best way’ to do this. There will always be a need to develop new approaches to meet new and emerging challenges.

Challenge 1: Why Change?

Innovation matters. In an uncertain world the only certainty is that simply sitting still carries with it a high risk. History teaches us that innovation is not a luxury item on the strategic agenda but a survival imperative—unless organizations are prepared to change what they offer and how they create and deliver that offering they may simply not be around in the long term (Braun & Macdonald, 1980; de Geus, 1996; Tushman & Anderson, 1987).

Innovation is what agile firms do—they constantly re-invent themselves in terms of their solutions to the puzzle posed by the threats and opportunities in their environment. This may mean adoption of new technology, or generation of their own. It may involve

reconfiguring products, processes or markets. But in each case it involves learning and unlearning, and it requires strategic direction to focus this process (Tidd, Bessant et al., 2001).

Firms often follow a ‘resource-based’ strategy of accumulating technological assets—essentially the building of technological competence. But evidence suggests that simply accumulating a large knowledge base may not be sufficient—as the cases of well-established firms like IBM, GM, Kodak and others demonstrate. The firms which demonstrate sustained competitive advantage exhibit ‘*timely responsiveness and rapid product innovation, coupled with the management capability to effectively co-ordinate and redeploy internal and external competencies*’ (Teece & Pisano, 1994).

Whilst it is easy to pay lip service to this kind of challenge the historical evidence suggests that firms are not good at learning and that seeing—and responding to—the need for continuous innovation is not a widely distributed capability (Christenson, 1997; Hamel, 2000; Womack, Jones et al., 1991).

Challenge 2: What to Change?

Even if firms recognize and accept the need for continuous innovation they may find difficulties in framing an appropriate innovation agenda. With limited resources they may risk putting scarce eggs into too few or the wrong baskets. Innovation can take many forms—from simple, incremental development of what is already there to radical development of totally new options. It can range from changes in what is offered—product or service—through to the ways in which that offering is created and delivered (process innovation). It can reflect the positioning of a particular offering—for example, putting a well-established product into a new market represents a powerful source of innovation. And it can involve rethinking the underlying mental models associated with a particular product or service (Francis, 2001).

The challenge here is for firms to be aware of the extensive space within which innovation possibilities exist and to try and develop a strategic portfolio which covers this territory effectively, balancing risks and resources. Table 1 maps out some options.

Challenge 3: Understanding Innovation

Part of the problem in managing innovation is the way people think about it. Whilst the term is in common usage, the meaning people attach to it—and hence the way in which they behave—can vary widely (Dodgson & Bessant, 1996; Tidd, Bessant et al., 2001). For example, there is often considerable confusion between ‘invention’ and ‘innovation’. The former is essentially about the moment of creative insight which first opens up a new possibility—the discovery of a new compound, the observation of a new phenomenon, the recognition of an unmet market need. But whilst this is

Table 1. The innovation agenda.

	Do what we do better— improvement innovation	Do different— radical innovation
Product or service offering	Improved versions of existing products, Mk2, and later releases, etc.	Radical new product or service concepts
Process for creating and delivering that offering	Improvements to established processes—lean approaches to driving out waste, quality improvements, etc.	Radical alternative routes to achieving the process goal—for example, float glass as an alternative way of making flat glass to traditional grinding and polishing
Positioning in market context	Repositioning or relaunching established products or services in different context—e.g. opening up new market niches	Radical re-framing of what is being offered—for example, many utility businesses are now being seen as commodities which can be traded in dealing rooms—as opposed to service businesses. Christensen's work on disk drives, mini-mills and other industries highlights the potential for reframing to create new markets.
'Paradigm' - underlying mental models	New business models	New ways of conceptualizing the problems—for example, mass production vs. craft production

essential to start the process off, invention is not enough. Taking that brilliant idea through, on an often painful journey to become something which is widely used involves many more steps and a lot of resources and problem-solving on the way. As Edison is reputed to have said, "it's 1% inspiration, 99% perspiration!"

History is littered with forgotten names which bear testament to the danger of confusing the two. Spengler invented the vacuum sweeper but Hoover brought it through to commercial reality. Howe developed the first sewing machine but Singer is the name we associate with the product because he took it from invention to widespread acceptance (Bryson, 1994).

The problem isn't just a confusion of invention and innovation. Other limits to our mental models include the view that innovation is all about science and technology creating new opportunities—what is sometimes called the 'technology push' model (Coombs, Saviotti et al., 1985; Rothwell, 1992). It has elements of truth about it but on its own it is a weak basis for managing innovation—plenty of great technological possibilities fail to find markets and never make it as innovations. Similarly, the view that 'necessity is the Mother of invention' may sound persuasive—but a totally marketing led approach to innovation may miss some important tricks. The emergence of the Walkman family of products within Sony took place despite strong marketing input to suggest there was no demand for this kind of product (Nayak & Ketteringham, 1986).

Table 2 lists some common misperceptions and partial views of innovation. The challenge to managing the process well is to ensure a broader and integrated

view to underpin the structures and procedures which firms put in place to make it happen.

Challenge 4: Building an Innovation Culture

In effect, innovation poses a constantly mutating puzzle, or set of puzzles. Firms cannot afford not to play the game but the rules are anything but clear. There is not the comfort of a single 'right' answer because the question keeps changing. And even if one firm does come up with a solution which works for them it does not follow that everyone else adopting it will meet with the same degree of success. Copying may simply make the problem worse.

So what can an organization do? Research suggests that the task of managing innovation is about creating firm specific routines—repeated, reinforced patterns of behavior—which define its particular approach to the problem (Cohen, Burkhart et al., 1996; Nelson & Winter, 1982; Pavitt, 2002; Tidd, Bessant et al., 2001). 'Routine' in this sense does not mean robotic but it does mean an established pattern—'the way we do things around here'—which represents the approach a particular organization takes to dealing with the innovation challenge.

Routines of this kind are not mindless patterns; as Giddens points out '*... the routinized character of most social activity is something that has to be 'worked at' continually by those who sustain it in their day-to-day conduct ...*' (Giddens, 1984). It is rather the case that they have become internalized to the point of being unconscious or autonomous. They become part of 'the way we do things round here'—in other words, part of the dominant culture of the organization.

Table 2. Common problems associated with partial views of innovation (Tidd, Bessant et al., 2001).

If innovation is only seen as the result can be
Strong R&D capability	Technology which fails to meet user needs and may not be accepted
The province of specialists in white coats in the R&D laboratory	Lack of involvement of others, and a lack of key knowledge and experience input from other perspectives
Meeting customer needs	Lack of technical progression, leading to inability to gain competitive edge
Technology advances	Producing products which the market does not want or designing processes which do not meet the needs of the user and which are opposed
The province only of large firms	Weak small firms with too high a dependence on large customers
Only about 'breakthrough' changes	Neglect of the potential of incremental innovation. Also an inability to secure and reinforce the gains from radical change because the incremental performance ratchet is not working well
Only associated with key individuals	Failure to utilize the creativity of the remainder of employees, and to secure their inputs and perspectives to improve innovation
Only internally generated	The 'not invented here' effect where good ideas from outside are resisted or rejected (Katz & Allen 1982)
Only externally generated	Innovation becomes simply a matter of filling a shopping list of needs from outside and there is little internal learning or development of technological competence

Innovation routines are increasingly recognized as contributing to competitive advantage and one important feature is that such routines cannot be simply copied from one context to another; they have to be learned and practiced over a sustained period of time. (Pavitt, 2000) Thus, for example, the Toyota Production System with its high levels of participation took over 40 years to evolve and become embedded in the culture. (Monden, 1983) Whilst it is easy for Toyota executives to demonstrate this to others, it is not easy to replicate it; the Ford and General Motors needed to go through their own learning processes and come up with their own firm-specific versions of the idea. (Adler, 1992; Wickens, 1987).

Routines can begin by the chance recognition of something that worked or as the result of trying a new and different approach. But if they work repeatedly, they gradually get established and eventually formalized into structures and procedures—until finally they are part of the organization's personality. A useful analogy can be made with learning to drive a car; in the early stages the problem is one of unfamiliarity with the whole experience. Learning is concentrated on trying to understand and master the individual low level skills associated with things like steering, the clutch, the brakes, the accelerator and so on. Gradually facility with these is developed but then the challenge comes of linking the individual behaviors together in complex sequences—for example, changing gear or making a hill start. Eventually, and after extensive trial and error and practice the point is reached where you

qualify for a driving licence—but this only indicates an expression of basic competence; the real challenges of becoming a good driver, able to cope with different cars, weather conditions, road types, etc. still lie ahead. Much, much later, after years of practice in different vehicles and under different conditions, the point is reached where the conscious effort required is minimal and driving can take place simultaneous with listening to the radio, talking to other passengers or even daydreaming!

Some examples of routines—behavior patterns—which are needed for innovation are given in Table 3.

Challenge 5: Continuous Learning

The innovation agenda—as we have seen—is constantly shifting and firms need to develop routines to deal with the key challenges, which emerge from their environment. There is plenty of scope for learning and adapting of these routines—not everything has to be engineered from scratch. The distinction is between blind copying and adopting and developing a good practice, which someone else uses.

So, for example, in the area of new product development there is now an accepted 'good practice' model of how an organization can create and deliver a stream of new products and services (Cooper, 1993, 2000, 2003; Smith & Reinertsen, 1991; Wheelwright & Clark, 1992). (It is important to stress the repeatability here—anyone can get lucky once but only those organizations, which have in place relevant routines, are in a position to repeat the trick. 'The way we do

Table 3. Key routines needed for basic innovation capability (based on Tidd, Bessant et al., 2001).

Basic capability	Contributing capabilities
Recognizing	Searching the environment for technical and economic clues to trigger the process of change
Aligning	Ensuring a good fit between the overall business strategy and the proposed change—not innovating because it's fashionable or as a knee-jerk response to a competitor
Acquiring	Recognizing the limitations of the company's own technology base and being able to connect to external sources of knowledge, information, equipment, etc. Transferring technology from various outside sources and connecting it to the relevant internal points in the organization
Generating	Having the ability to create some aspects of technology in-house—through R&D, internal engineering groups, etc.
Choosing	Exploring and selecting the most suitable response to the environmental triggers which fit the strategy and the internal resource base/ external technology network
Executing	Managing development projects for new products or processes from initial idea through to final launch. Monitoring and controlling such projects
Implementing	Managing the introduction of change—technical and otherwise—in the organization to ensure acceptance and effective use of innovation
Learning	Having the ability to evaluate and reflect upon the innovation process and identify lessons for improvement in the management routines
Developing the organization	Putting those new routines in place—in structures, processes, underlying behaviors, etc.

Table 4. Key features of emerging 'good practice' model in NPD (Bessant & Francis, 1997).

Theme	Key characteristics
Systematic process for progressing new products	Stage-gate model (Cooper, 1994) Close monitoring and evaluation at each stage (Bruce & Bessant, 2001)
Early involvement of all relevant functions	Bringing key perspectives into the process early enough to influence design and prepare for downstream problems (Wheelwright & Clark, 1992) Early detection of problems leads to less rework
Overlapping/parallel working	Concurrent or simultaneous engineering to aid faster development whilst retaining cross-functional involvement (Bowen, Clark et al., 1994)
Appropriate project management structures	Choice of structure—e.g. matrix/line/project/heavyweight project management—to suit conditions and task (Bruce & Cooper, 1997)
Cross-functional team working	Involvement of different perspectives, use of team-building approaches to ensure effective team working and develop capabilities in flexible problem-solving (Francis & Young, 1988; Shillito, 1994)
Advanced support tools	Use of tools—such as CAD, rapid prototyping, computer-supported cooperative work aids—to assist with quality and speed of development
Learning and continuous improvement	Carrying forward lessons learned—via post-project audits, etc. (Rush, Brady et al., 1997) Development of continuous improvement culture (Caffyn, 1998)

Table 5. Examples of company routines for successful innovation (based on 'How 3M keeps the new products coming'. R. Mitchell in Henry & Walker, 1990).

Company	Routines
3M	<ul style="list-style-type: none"> • keep divisions small so that each division manager knows the names of all staff. When divisions get too big, split them up • tolerate failure and encourage experimentation and risk-taking. Divisions must derive 25% of sales from products introduced during the past five years • motivate the champions—when someone comes up with a new product idea, he/she can recruit an 'action team' to develop it. Salaries and promotion are directly tied to the product's progress; if successful the champion ends up running his/her own division • stay close to the customer, through regular interaction between research, marketing and customers • encourage experiment—staff can spend up to 15% of their time on ideas of their own to try and prove they are workable. For those needing seed money an internal venture fund—Genesis—awards grants of up to \$50,000 for development
Hewlett-Packard	<ul style="list-style-type: none"> • researchers are encouraged to spend up to 10% of time on their own pet projects, and have 24 hour access to laboratories and equipment • keeps divisions small to focus team efforts
Merck	<ul style="list-style-type: none"> • gives researchers time and resources to pursue high-risk, high payoff products
Johnson and Johnson	<ul style="list-style-type: none"> • freedom to fail is a key value • extensive use of autonomous small operating units for development
General Electric	<ul style="list-style-type: none"> • jointly develops products with customers—for example, developed the first thermoplastic body panels for cars through joint work with BMW
Rubbermaid	<ul style="list-style-type: none"> • 30% of sales must come from products developed in the last five years
Dow Corning	<ul style="list-style-type: none"> • forms research partnerships with customers

things round here' has to include structures and procedures to make this happen.) These basics of the 'good practice' model are given in Table 4.

But making the model work in a particular organization requires taking these ideas and shaping them to suit a particular and highly firm-specific context. Table 5 shows how some firms have evolved their own variants on these routines to help with the problem of product innovation.

The Moving Frontier

The trouble with innovation, as we have already seen, is that it is not a static problem to which we might try and find a particular solution, which fits. Instead, it is a mutating and shifting set of puzzles—and firms have to try and find their own particular ways of solving them and continuing to be able to do so as the puzzles shift and change. The routines identified in Table 3 are a good starting point but firms will need to adopt, adapt and create new routines as the puzzle shifts. In the next section we look at some areas and challenges, which represent the frontier of innovation management around which there are few proven routines and much room for experiment and learning.

Challenge 6: High Involvement Innovation

Traditionally innovation has been the province of the specialist who often works apart from the mainstream of the organization's operations—for example, in R&D

or IT functions. The roots of this division of labour can be traced back at least to the late 19th century and the emergent mass production models based on 'scientific management' (Boer & Berger et al., 1999; Schroeder & Robinson, 1991). Here emphasis was placed on a belief in 'one best way'—in the way work was organized, the products and services offered, etc.—and any interference with the designs produced by innovation specialists was seen as disruptive. Such separation of 'head' and 'hand' became institutionalized in the functional and hierarchical modes of organization, which became the dominant blueprint for much of the 20th century (Best, 1990; Kaplinsky, 1994).

The limitations of such an exclusive model of innovation quickly become clear. Innovation is fundamentally about creative problem-solving and as environments become more turbulent and uncertain, so the requirement for this capability increases. With uncertain markets, rapidly changing technological threats and opportunities, increasing regulatory pressures, shifting customer and competitive requirements, and a host of other variables to deal with the likelihood of getting the 'right' innovative response is low. Organizations need to increase their innovative capacity, and one powerful mechanism for doing so is to extend participation in the process to a much wider population.

This simple point has been recognized in a number of different fields, all of which converge around the view that higher levels of participation in innovation

represents a competitive advantage (Caulkin, 2001; Huselid, 1995; Pfeffer & Veiga, 1999). For example, in the field of quality management it has become clear that major advantages accrue from better and more consistent quality in products and services (Brown, Bessant et al., 2000; Garvin, 1988). But the underlying recipe for achieving 'total quality' is an old one, originally articulated in the early part of the 20th century and making extensive play on the contribution which participation in the process of finding and solving quality problems could make (Deming, 1986; Juran, 1951).

Similarly, the concept of 'lean manufacturing' emerged from detailed studies of assembly plants in the car industry and has since diffused widely around the world and across business sectors. Central to this alternative model was an emphasis on team working and participation in innovation—for example, the average number of suggestions offered by workers in Japanese 'lean' plants was approximately 1 per week; in contrast the European average was around half a suggestion, per worker, per year! (Womack, Jones et al., 1991).

Studies of high performance organizations, especially those, which achieve significant productivity improvements through their workforces, place considerable emphasis on involvement in innovation (Bessant, 2003, forthcoming; Guest, Michie et al., 2000; Pfeffer, 1998). Characteristic of such cases is a blurring of the lines of responsibility for the innovation process, moving away from specialists and towards higher levels of participation by others in incremental innovation as a complement to specialist activity (DTI, 1997; Pfeffer & Veiga, 1999).

Much discussion has focused on the concept of 'learning organizations', seeing knowledge as the basis for competition in the 21st century (Garvin, 1993; Senge, 1990; Pedler & Boydell et al., 1991). Mobilizing and managing knowledge becomes a primary task and many of the recipes offered for achieving this depend upon mobilizing a much higher level of participation in innovative problem-solving and on building such routines into the fabric of organizational life (Leonard-Barton, 1995; Nonaka, 1991).

There is nothing new nor difficult in this concept; indeed, it would be hard to disagree with the premises that we need as much creative problem-solving as possible and that everyone has the basic wherewithal to do it. It is also a theme which recurs in the literature on innovation; many studies report on the importance of involvement and participation in sustained incremental improvement (Figueroa, 2001; Hollander, 1965; Tremblay, 1994). Such high involvement innovation lies at the heart of the 'learning curve' theory which has had such a strong impact on strategic thinking; learning curves only work when there is the commitment and enabling structure for participative problem-solving (Garvin, 1993).

The difficulty comes not in the concept but its implementation. Mobilizing high levels of participation in the innovation process is unfamiliar and, for many organizations, relatively untested and apparently risky. The challenge is thus one of building routines—establishing and reinforcing behavior patterns. Table 6 lists some examples of the kinds of routines which are needed to begin to build high involvement innovation. This information is drawn from an extensive European research program looking at the development of high levels of participation in continuous improvement (CI) innovation (Bessant, Caffyn et al., 2001).

Whilst the generic routines can be specified in terms of particular new behaviors which must be learned and reinforced—for example, systematic problem solving through some form of learning cycle or monitoring and measuring to drive improvement—the particular ways in which different organizations actually achieve this will vary widely. Thus routines for CI are essentially firm-specific; this is one reason why simply imitating what was done successfully within Japanese firms has proved to be such a poor recipe for many Western firms. There is no short cut in the process; CI behaviors have to be learned, reinforced and built upon to develop capability.

Challenge 7: Dealing with Discontinuity

Much innovation can be seen as a 'steady state' activity. Of course it is about change, but it takes place within a framework which is relatively consistent. Most change happens as incremental developments of what is already there—'doing what we do better'. For example, theories of innovation dynamics suggest that when a new product concept emerges there is an initial period of uncertainty during which there is considerable experiment around different configurations (Laurila, 1998; Tushman & Anderson, 1987; Utterback, 1994). But then a 'dominant design' or 'technological trajectory' becomes established and the emphasis shifts to incremental improvements and variations on this basic theme. The same can be said of process innovation—the introduction of a radically new process is followed by a long period of refinement and improvement, stretching and developing the performance of that process, driving out waste, eliminating bugs, etc.

This pattern of innovation is sometimes called 'punctuated equilibrium', borrowing a term from the field of evolutionary biology which explores how species emerge and develop. Its implication is that the way in which we organize for innovation will be around keeping up a steady stream of incremental developments within an envelope established by the original product or process concept (Tushman & Anderson, 1987). Such work might persist for decades—for example, the electric light bulb with which we are all familiar has been around since the late 19th century when work by Swann & Edison created the

Table 6. Key routines in developing high involvement in continuous improvement (CI) innovation (Based on Bessant, Caffyn et al., 2001).

Ability	Constituent behaviors
‘Understanding CI’—the ability to articulate the basic values of CI	<ul style="list-style-type: none"> • people at all levels demonstrate a shared belief in the value of small steps and that everyone can contribute, by themselves being actively involved in making and recognizing incremental improvements • when something goes wrong the natural reaction of people at all levels is to look for reasons why etc. rather than to blame individual(s)
‘Getting the CI habit’—the ability to generate sustained involvement in CI	<ul style="list-style-type: none"> • people make use of some formal problem-finding and solving cycle • people use appropriate tools and techniques to support CI • people use measurement to shape the improvement process • people (as individuals and/or groups) initiate and carry through CI activities—they participate in the process • closing the loop—ideas are responded to in a clearly defined and timely fashion—either implemented or otherwise dealt with
‘Focusing CI’—the ability to link CI activities to the strategic goals of the company	<ul style="list-style-type: none"> • individuals and groups use the organization’s strategic goals and objectives to focus and prioritize improvements • everyone understands (i.e. is able to explain) what the company’s or department’s strategy, goals and objectives are • individuals and groups (e.g. departments, CI teams) assess their proposed changes (before embarking on initial investigation and before implementing a solution) against departmental or company objectives to ensure they are consistent with them • individuals and groups monitor/measure the results of their improvement activity and the impact it has on strategic or departmental objectives • CI activities are an integral part of the individual or groups work, not a parallel activity
‘Leading CI’—the ability to lead, direct and support the creation and sustaining of CI behaviors	<ul style="list-style-type: none"> • managers support the CI process through allocation of time, money, space and other resources • managers recognize in formal (but not necessarily financial) ways the contribution of employees to CI • managers lead by example, becoming actively involved in design and implementation of CI • managers support experiment by not punishing mistakes but by encouraging learning from them
‘Aligning CI’—the ability to create consistency between CI values and behavior and the organizational context (structures, procedures, etc.)	<ul style="list-style-type: none"> • ongoing assessment ensures that the organization’s structure and infrastructure and the CI system consistently support and reinforce each other • the individual/group responsible for designing the CI system design it to fit within the current structure and infrastructure • individuals with responsibility for particular company processes/systems hold ongoing reviews to assess whether these processes/systems and the CI system remain compatible • people with responsibility for the CI system ensure that when a major organizational change is planned its potential impact on the CI system is assessed and adjustments are made as necessary.
‘Shared problem-solving’—the ability to move CI activity across organizational boundaries	<ul style="list-style-type: none"> • people co-operate across internal divisions (e.g. cross-functional groups) in CI as well as working in their own areas • people understand and share an holistic view (process understanding and ownership) • people are oriented towards internal and external customers in their CI activity • specific CI projects with outside agencies—customers, suppliers, etc.—are taking place • relevant CI activities involve representatives from different organizational levels

Table 6. Continued.

Ability	Constituent behaviors
‘Continuous improvement of continuous improvement’—the ability to strategically manage the development of CI	<ul style="list-style-type: none"> • the CI system is continually monitored and developed; a designated individual or group monitors the CI system and measures the incidence (i.e. frequency and location) of CI activity and the results of CI activity • there is a cyclical planning process whereby the CI system is regularly reviewed and, if necessary, amended (single-loop learning) • there is periodic review of the CI system in relation to the organization as a whole which may lead to a major regeneration (double-loop learning) • senior management make available sufficient resources (time, money, personnel) to support the ongoing development of the CI system
‘The learning organization’—generating the ability to enable learning to take place and be captured at all levels	<ul style="list-style-type: none"> • people learn from their experiences, both positive and negative • individuals seek out opportunities for learning/personal development (e.g. actively experiment, set their own learning objectives) • individuals and groups at all levels share (make available) their learning from all work experiences • the organization articulates and consolidates (captures and shares) the learning of individuals and groups • managers accept and, where necessary, act on all the learning that takes place • people and teams ensure that their learning is captured by making use of the mechanisms provided for doing so • designated individual(s) use organizational mechanisms to deploy the learning that is captured across the organization

dominant design for the incandescent filament bulb. Whilst there has been extensive incremental innovation within that envelope—for example, in new materials, in more efficient manufacturing processes, in new markets for light bulbs, etc.—the basic pattern for over a century has been one of incremental development within the broad framework established in the 1880s. (For more on this particular innovation see the chapters by Weisberg and by Sternberg and colleagues in this book (Sternberg & Pretz et al., 2003; Weisberg, 2003)).

But there are points at which the rules change. It may well be as a result of scientific progress creating new possibilities, or it may be a result of dramatic shifts in the demand side for innovation—for example, radical restructuring of markets through deregulation or the opening up of trade barriers. At such points the old rules may no longer apply—for example, the technical knowledge associated with a particular product or process may become redundant as it is replaced by a new one. (The shift from valve electronics in the period up to 1947 to the era of solid state and integrated circuits, which was ushered in by the invention of the transistor, is a good example of this (Braun & Macdonald, 1980).) (The chapter by Ronald Guttman in this volume also provides a detailed discussion of this theme (Guttman, 2003).)

This kind of transition poses very big management challenges. Historical evidence suggests strongly that when such discontinuous changes take place the old

incumbents do not usually do well and it is at this point that new entrants become key players. (See, for example, the case of the ice industry (Utterback, 1994; Weightman, 2002), the automobile industry (Altschuler, Roos et al., 1984), the cement industry (Tushman & Anderson, 1987), and the mini-mill case in steel-processing (Christenson, 1997). In part this is because of the high level of investment committed to the older generation of technology which established players have but there is also much to suggest that organizational barriers are also a problem. (In this volume Hadjimanolis discusses this ‘barriers’ approach to innovation (Hadjimanolis, 2003)). Established players are not always quick to pick up on the signals about change or to make sense of them, they may react too slowly and in the wrong directions—or they may simply try to deny the importance or magnitude of the change affecting their business (Henderson & Clark, 1990).

There is an inherent conflict underpinning this pattern. The routines which well-managed firms build up to sustain and develop their innovations in product and process within a particular ‘envelope’ are not the same as those they will need to create innovations outside that space. Radical, ‘out of the box’ thinking and the high-risk project management approaches which accompany completely new directions in innovation do not sit well within existing and relatively highly structured frameworks. For this reason many firms set up ‘skunk works’ or other mechanisms to

create more and different space within which people can work (Christenson, 1997; Leifer & McDermott et al., 2000). It is also here that the role of innovation champions and promoters becomes significant—a point addressed in detail elsewhere in this volume in the chapter by Hauschildt (Hauschildt, 2003).

The challenge here is to develop what some writers have called ‘the ambidextrous organization’ (Tushman & O’Reilly, 1996). That is, to manage under one roof to operate routines for ‘doing what we do better’ innovation (within the envelope) and simultaneously to allow space for another set of routines for ‘doing differently’—moving beyond the envelope into new and uncharted territory. The risk, if they cannot develop these two sets of routines, is that people will migrate out of the organization to set up their own operation (Tushman & O’Reilly, 1996). The chapter by Katz, (this volume), deals with this issue in some detail (Katz, 2003).

Challenge 8: Managing Connections

Characteristic of the routines developed and shared around ‘good practice’ in innovation management is the focus on the individual firm (Ettlie, 1999; Tidd, Bessant et al., 2001; Van de Ven & Angle et al., 1989). Whilst there are gaps in this model it is, as we have seen, possible to build up a useful model on which to build and develop innovation management capability. But increasingly the challenge to business organizations is to operate not in ‘splendid isolation’ but in relationships with others. Whether this takes place in the context of supply chains or as part of a network of small firms sharing resources, or in a network of firms sharing knowledge resources to develop a new product or service, the emphasis is shifting towards managing the inter-firm dynamics of innovation. And this calls for a whole new set of routines.

Such inter-organizational networking is becoming an issue of considerable interest amongst researchers, policy-makers and practitioners (Best, 2001; Gereffi, 1995; Porter, 1990; Nadvi & Schmitz, 1994). (The chapter by Swan (this volume) takes up this theme in detail (Swan, 2003)). In part this reflects the perception of advantages of networking over traditional transactional models of organization, in which there is often a trade-off between modes of interaction (Williamson, 1975) and in part it acknowledges the impact of technological and market changes which have blurred the boundaries between enterprises and opened up the arena in which new forms might emerge. ‘Virtual enterprises’, ‘boundary-less organizations’ and ‘networked companies’ are typical examples of the thinking and experimentation which is going on to try and establish different approaches to the problem of inter-organizational relationships (De Meyer, 1992; Dell, 1999; Harland, 1995; Magretta, 1998; Meade, Liles et al., 1997).

There are numerous examples of inter-firm activity where it is clear that some forms of emergent ‘good practice’ can be seen to operate. For example, in the area of buyer/supplier relationships there is growing recognition that the traditional arms-length bargaining type of relationships may not always be appropriate (Carlisle & Parker, 1989). In particular as firms need to work more closely in strategic areas and where their interdependence increases (as, for example, with just-in-time delivery systems), so there is a need to build more cooperative forms of relationship. The prescriptions for such cooperative relationships are relatively easy to write—the difficulty is in implementing them successfully. Effectively new routines are needed to deal with issues like trust, risk, gain-sharing, etc. (Lamming, 1993).

Similarly, there has been much discussion about the merits of technological collaboration, especially in the context of complex product systems development (Dodgson, 1993; Hobday, 1994; Marceau, 1994). Innovation networks of this kind offer significant advantages in terms of assembling different knowledge sets and reducing the time and costs of development—but are again often difficult to implement (Oliver & Blakeborough, 1998; Tidd, Bessant et al., 2001).

Studies of ‘collective efficiency’ have explored the phenomenon of clustering in a number of different contexts (Humphrey & Schmitz, 1996; Nadvi & Schmitz, 1994; Piore & Sabel, 1982). From this work, it is clear that the model is widespread—not just confined to parts of Italy, Spain and Germany but diffused around the world—and under certain conditions, extremely effective. For example, one town (Sialkot) in Pakistan plays a dominant role in the world market for specialist surgical instruments made of stainless steel. From a core group of 300 small firms, supported by 1,500 even smaller suppliers, 90% of production (1996) was exported and took a 20% share of the world market, second only to Germany (Schmitz, 1998). In another case the Sinos valley in Brazil contains around 500 small firm manufacturers of specialist high quality leather shoes. Between 1970 and 1990 their share of the world market rose from 0.3% to 12.5% and they now export some 70% of total production (Nadvi, 1997). Both of these examples show gains resulting from close interdependence in a cooperative network.

In all of these cases it appears that networks form for particular purposes but then offer the possibility of additional activity based on the core cooperative framework. So, for example, the clusters of middle Italy may have originally formed as an economic response, providing a way of resolving the basic difficulties of resource access for small firms (Nadvi & Schmitz, 1994; Piccaluga, 1996). But having established a core framework, which allowed for resource sharing and collective efficiency, these networks began to grow, adding a dimension of technological learning

Table 7. Core processes in inter-organizational networking.

Process	Underlying questions
Network creation	How the membership of the network is defined and maintained
Decision-making	How (where, when, who, etc.) decisions get taken
Conflict resolution	How (and if) conflicts are resolved
Information processing	How information flows and is managed
Knowledge capture	How knowledge is articulated and captured to be available for the whole network
Motivation/commitment	How members are motivated to join/ remain in the network—e.g. through active facilitation, shared concerns for development, etc.
Risk/benefit sharing	How the risks and benefits are shared
Integration	How relationships are built and maintained between individual representatives in the network

to them. The case of CITER—the Centro Informazione Tessile di Emilia Romagna in Italy is a good example here (Cooke & Morgan, 1991; Murray, 1993). The predominantly small-scale of firm operations in the fashion textile sector meant that none could afford the design technology or undertake research into process development in areas like dyeing. A cooperative research centre—CITER—was established and funded by members of the *consorzio* and chartered with work on technological problems related to the direct needs of the members. Over time, this has evolved into a world-class research institute but its roots are still in the local network of textile firms. It has become a powerful mechanism for innovation and technology transfer and has helped to upgrade the overall knowledge base of this sector (Rush, Hobday et al., 1996).

In essence, what we are seeing is a process of learning and experimentation around routines for inter-firm working. Whilst these are not yet clearly established it is possible to see a pattern in which the whole—the network—can perform at a level which is greater than the sum of its parts. It appears that firms need to explore and develop routines in at least eight critical areas which are shown in Table 7.

Arguably, inter-organizational networks will be more or less effective in the ways in which they handle these processes. For example, a network with no clear routines for resolving conflicts is likely to be less effective than one, which has a clear and accepted set of norms—a ‘network culture’—which can handle the inevitable conflicts, which emerge.

Building and operating networks can be facilitated by a variety of enabling inputs—for example, the use of advanced information and communications technologies may have a marked impact on the effectiveness with which information processing takes place. In a number of cases independent facilitation appears to have a strong influence on many of the behavioral dimensions. For example, the U.K. Society of Motor Manufacturers and Traders established a shared learning network called the ‘Industry Forum’ in order to

help develop performance improvement amongst small and medium-sized component makers. This program makes use of a number of trained engineers who work with firms individually and collectively, facilitating learning and development (DTI, 2000). Similar programs have now been rolled out with government support to eight other sectors including chemicals, ceramics and aerospace (DTI, 2000; DTI/CBI, 2000). Similar work is going on in the food industry in Australia and in the automobile and furniture sectors in South Africa (AFFA, 2000; Barnes & Bessant et al., 2001). Developing learning networks of this kind can be carried out around a number of groupings including regional, sectoral, supply chains and those organized around a key innovation theme or topic (Bessant & Francis, 1999; Bessant & Kaplinsky et al., 2003 forthcoming; Bessant & Tsekouras, 2001; Dent, 2001).

Conclusions

We have explored some—but by no means all—of the challenges confronting firms in their quest to manage innovation successfully. In dealing with these challenges the key management task lies in creating and reinforcing patterns of behavior—building ‘the way we do things around here’—through identifying and establishing innovation *routines*. Some routines are a basic prerequisite—if the organization has no mechanisms for picking up signals about the need for change in its environment it may not survive for long. Equally, if its mechanisms for managing innovation as a process are based on models of invention being the key activity, then it will be a powerhouse for new ideas but probably an unsuccessful business.

But beyond the basic routines, which firms need to learn and maintain, there are others which become increasingly important to graft on. Once the firm has mastered the basic ‘skills’ of innovation, it needs to look at how well it can involve the full range of its staff, how well it can manage to operate in networks

rather than on its own, how well it can handle continuous and discontinuous changes, etc.

This makes the management task not simply one of building and sustaining routines for innovation but also—and most importantly—one of creating the underlying learning routines, which enable the organization to do so.

Managing Technological Innovation in Business Organizations

Ralph Katz

College of Business, Northeastern University and Sloan School of Management, MIT, USA

Abstract: Organizations in today's hypercompetitive world face the paradoxical challenges of 'dualism', that is, functioning efficiently today while innovating effectively for tomorrow. Corporations, no matter how they are structured, must manage both sets of concerns simultaneously. They must build those seemingly contradictory structures, competencies, and cultures that foster not only more efficient and reliable processes but also the more risky explorations needed to recreate the future. This chapter describes the patterns of innovation that typically take place within an industry and how such patterns affect an organization's ability to manage its streams of innovative projects along technological cycles.

Keywords: Innovation; Innovation management; Technological innovation; Technology cycles; S-curve; Dominant design.

Introduction

Innovation is often broadly defined as the introduction of something new while Luecke (2002) defines technical innovation as the embodiment, combination, or synthesis of knowledge into new products, processes, or services. More recently, Drucker has argued that innovation is change that creates a new dimension of performance (Hesselbein & Johnston, 2002). Regardless of the particular definitions used, a plethora of research studies has convincingly demonstrated over the past decades a very consistent, albeit somewhat disturbing, pattern of results with respect to the management of innovation (see Adizes, 1999; Christensen & Bower, 1996; Cooper & Smith, 1992; Grove, 1996) for some recent examples). In almost every industry studied, a set of leading firms when faced with a period of discontinuous change, fails to maintain its industry's market leadership in the new technological era. Tushman & O'Reilly (1997) nicely emphasize this point in their research when they describe how Demming, probably the individual most responsible for jump-starting the quality revolution in today's products, would highlight this recurring theme in his lectures by showing a very long list of diverse industries in which the most admired firms rapidly lost

their coveted market positions.¹ It is indeed ironic that so many of the most dramatically successful organizations become so prone to failure (Miller, 1994).

This pathological trend, described by many as the *tyranny of success* (Christensen, 1997), in which winners often become losers—in which firms lose their innovative edge—is not only an American phenomenon, but a worldwide dilemma, exemplified by the recent struggles of firms such as Xerox in the U.S., Michelin in France, Philips in Holland, Siemens in Germany, EMI in England, and Nissan in Japan (see Charan & Tichy, 2000; Collins, 2001; Tushman & O'Reilly, 1997). The Xerox brand, for example, has penetrated the American vernacular so strongly that it has the distinction of being used both as a noun and as a verb though the company is probably now hoping that to be 'Xeroxed' won't eventually take on a different meaning. The histories of these and so many other outstanding companies demonstrate this time and time again. It seems that the very factors that lead to a firm's success can also play a significant role in its demise (Henderson & Clark, 1990). The leadership, vision,

¹ Industries such as watches, automobiles, cameras, stereo equipment, radial tires, hand tools, machine tools, optical equipment, airlines, color televisions, etc.

strategic focus, valued competencies, structures, policies, rewards, and corporate culture that were all so critical in building the company's growth and competitive advantage during one period can become its Achilles heel as technological and market conditions change over time. In the mid-1990s, an outside team of experts worked for more than three years with senior management on a worldwide cycle time reduction initiative at Motorola Corporation, arguably one of the world's most admired organizations at that time (Willyard & McClees, 1987). In just about every workshop program they conducted across the different businesses, the consultants strongly reminded all of those managing and developing new products and services of this alarming demise of previously successful companies by referring to a notable 1963 public presentation made by Thomas J. Watson, Jr., IBM's Chairman and CEO. According to Watson:

Successful organizations face considerable difficulty in maintaining their strength and might. Of the 25 largest companies in 1900, only two have remained in that select company. The rest have failed, been merged out of existence, or simply fallen in size. Figures like these help to remind us that corporations are expendable and that success—at best—is an impermanent achievement which can always slip out of hand (Loomis, 1993).

Dualism and Conflicting Organizational Pressures

It is important to recognize, however, that this pattern of success followed by failure—of innovation followed by inertia and complacency—is not deterministic. It does not have to happen! Success need not be paralyzing. To overcome this tendency, especially in today's rapidly changing world, organizations more than ever before are faced with the apparent conflicting challenges of *dualism*, that is, functioning efficiently today while innovating effectively for the future. Not only must business organizations be concerned with the financial success and market penetration of their current mix of products and services, but they must also focus on their long-term capabilities to develop and incorporate what will emerge as the most customer-valued technical advancements into future offerings in a very quick, timely, and responsive manner. Corporations today, no matter how they are structured and organized, must find ways to internalize and manage both sets of concerns simultaneously. In essence, they must build internally those contradictory and inconsistent structures, competencies, and cultures that not only foster more efficient and reliable processes but that will also encourage the kinds of experiments and explorations needed to re-create the future even though such innovative activities are all too often seen by those running the organization as a threat to its current priorities, practices, and basis of success (Collins, 2001; Foster & Kaplan, 2001). Fortunately,

there is more recent evidence, as reported in the research studies conducted by Tushman & O'Reilly (1997), of a few successful firms, such as GE Medical System, Alcoa, and Ciba Vision, that have managed to do this very thing—to continue to capture the benefits of their existing business advantages even as they build their organizational capabilities for long term strategic renewal. They are somehow able to transform themselves through proactive innovation and strategic change, moving from today's strength to tomorrow's strength by setting the pace of innovation in their businesses.

While it is easy to say that organizations should internalize both sets of concerns in order to transform themselves into the future, it is a very difficult thing to do. The reality is that there is usually much disagreement within a company operating in a very pressured and competitive marketplace as to how to carry out this dualism (Roberts, 1990). Amidst the demands of everyday requirements, decision-makers representing different parts of the organization rarely agree on the relative merits of allocating resources and management attention among the range of competing projects and technical activities; that is, those that directly benefit the organization's more salient and immediate needs versus those that might possibly be of import sometime in the future.

Witness for example the experiences of Procter and Gamble (P&G) over the past five or more years. In the beginning, the analysts claimed that P&G was doing a very good job at managing its existing businesses but unfortunately was not growing the company fast enough through the commercialization of new product categories (Berner, 2001). Over the last couple of years, P&G impressively introduced a number of very successful new products (swiffer, whitestrips, thermacare, and febreze—just to name a few) that are collectively bringing in considerably more than a billion dollars in added revenue per year. The analysts, however, now claim that while P&G has managed to introduce some very exciting new products; in doing so, it took its eye off the existing brands and lost important market share to very aggressive competitors (Brooker, 2002). It is not particularly surprising that these same analysts now want P&G to de-emphasize its new venture strategies and investments in order to concentrate on protecting and strengthening its bedrock major brands. The pendulum just seems to keep on swinging.

While much has been written about how important it is to invest in future innovative activities—'to innovate or die'—as management guru Tom Peters so picturesquely portrays it (Peters, 1997), there is no single coherent set of well-defined management principles on how to structure, staff, and lead organizations to accommodate effectively these two sets of conflicting challenges (See John Bessant's *Challenges in Innovation Management* chapter in this volume). Classical

management theories are primarily concerned with the efficient utilization, production, and distribution of today's goods and services (Katz, 1997). Principles such as high task specialization and division of labor; the equality of authority and responsibility; and the unities of command and direction (implying that employees should have one and *only* one boss and that information should *only* flow through the formal chain of command) are all concentrating on problems of structuring work and information flows in routine, efficient ways to reduce uncertainty and facilitate control and predictability through formal lines of authority and job standardization (Mintzberg, 1992). What is needed, therefore, are some comparable models or theories to help explain how to organize both incremental and disruptive innovative activities² within a functioning organization such that creative, developmental efforts not only take place but are also used to keep the organization competitive and up-to-date within its industry over generations of technological change.

While empirically tested frameworks and theories for achieving dualism may be sparse, there is no shortage of advice (Micklethwait & Wooldridge, 1998). In one of the more recent prominent books on the subject, for example, Hamel (2000) proposes the following ten rules for reinventing one's corporation:

- (1) *Set Unreasonable Expectations*: Organizations must establish bold, nonconformist strategies to avoid the typical bland, unexciting goals that most organizations use especially if they hope to avoid behaving and thinking like managers of mature businesses or like mature managers trying to lead mature businesses. Only nonlinear innovation, according to Hamel, will drive long-term success, or as Collins & Porras (1997) describe it—organizations that are 'built to last' have *BHAGs* (i.e. Big Hairy Audacious Goals).
- (2) *Stretch Your Business Definition*: Companies need to define themselves by what they know (their core competencies) and what they own (their strategic assets) rather than by what they do. Senior managers must look continuously for opportunities outside of the business they manage, redefining their markets and challenging their assumptions in ways that allow them to challenge conventional wisdom and outgrow their competitors. One company with which I worked, for example, required all of its business units to periodically redefine their markets in larger contexts. As a consequence, the associated market

² Many other terms have been used to denote this continuum of activities, including continuous versus discontinuous; pacing versus radical; competence-enhancing versus competence-destroying; and sustaining versus disruptive innovation (see Foster & Kaplan, 2001, for the most recent publication in this area).

shares would be smaller but the opportunities for both extension and growth would now be more salient and enticing. General Electric's CEO, Jack Welch, adopted this approach whenever his division managers 'gamed' his demands that their businesses be 'number 1 or 2' by narrowing the definition of their markets. Welch made them redefine their markets globally so that they had no more than 10% and had to grow (Welch & Byrne, 2001).

- (3) *Create a Cause, Not a Business*: Revolutionary activity must have a transcendent purpose or there will be a lack of courage to commit and persist. Employees within the organization have to feel that they are contributing to something that will make a genuine difference in the lives of their customers or in society.
- (4) *Listen to New Voices*: If a company truly wants to remain at the forefront of its business, it must refrain from listening only to the old guard that is more likely to preserve its old routines and comfort levels. Instead, management must give disproportionate attention to three often under-represented constituencies; namely, those with a youthful perspective, those working at the organization's periphery, and newcomers who bring with them fresh ideas and less preconceived notions.
- (5) *Design an Open Market for Ideas*: What is required to keep an organization innovative is not the vision per se but the way the vision is implemented through at least three interwoven markets: a market for ideas, a market for capital, and a market for talent. Employees within the organization must believe that their pursuit of new frame-breaking ideas are the welcomed means by which the organization hopes to sustain its success and they must be able to give their new possibilities 'air time' without rigid bureaucratic constraints and interference.
- (6) *Offer an Open Market for Capital*: Rather than designing control and budgeting processes that weed out all but the most comfortable and risk averse ideas, the organization needs to think more like a venture capitalist and permit investments in experiments and unproven markets. Individuals or teams experimenting with small investments and unconventional ideas should not have to pass the same screens and hurdles that exist within the large established business. The goal is to make sure there are enough discretionary resources for winners to emerge—not to make sure there are no losers.
- (7) *Open Up the Market for Talent*: Organizations should create an internal auction for talent across the different businesses and opportunities. The organization's professional and leadership talent cannot feel that they are locked inside moribund,

mature businesses. Instead, they must have the chance to try out something new, to experiment with an idea, or to proceed with their imaginations. With more fluid boundaries inside the organization, people can search out and follow through on the most promising new ventures and ideas by voting with their feet.

- (8) *Lower the Risks of Experimentation*: Neither caution nor brash risk taking is likely to help an organization maintain its innovative vitality. Successful revolutionaries, according to Hamel, are both prudent and bold, careful and quick. They prefer fast, low-cost experimentation, and learning from customers to gambling with vast sums of money in uncertain environments. And just like experienced venture capitalists, the organization needs to invest in a portfolio rather than in any single project.
- (9) *Make Like a Cell—Divide and Divide*: Using cell division as a metaphor, Hamel claims that innovation dies and growth slows when companies stop dividing and differentiating. Division and differentiation free the leadership, the professional talent, and the capital from the constraints and myopic evaluations of any single large business model. And just as important, it keeps the business units small, focused, and more responsive to their customers.
- (10) *Pay Your Innovators Well—Really Well*: To maintain entrepreneurial enthusiasm, companies need to reward those individuals taking the risks in ways that really demonstrate that they can have a piece of the action. The upside has to look sufficiently attractive for them to stick around—to create something out of nothing. Innovators should have more than a stake in the company, they should have a stake in their ideas. If you treat people like owners, they will behave like owners.

Implicit in all of this well-intentioned exhortation, as well as in so many other similar examples of advice (Handy, 2002; Sutton, 2001) is the need to learn how to build parallel structures and activities that would not only permit the two opposing forces of today and tomorrow to coexist but would also balance them in some integrative and meaningful way. Within a technological environment, the operating organization can best be described as an ‘*output-oriented*’ or ‘*downstream*’ set of forces directed towards the technical support of problems within the business’s current products and services in addition to getting new products out of development and into the marketplace through manufacturing and/or distribution (Katz & Allen, 1997). For the most part, these kinds of pressures are controlled through formal job assignments to business and project managers who are then held accountable for the successful completion of product outputs within established schedules and

budget constraints, that is, for making their quarterly forecasts.

At the same time, there must be an ‘*upstream*’ set of forces that are less concerned with the specific architectures, functionalities, and characteristics of today’s products and services but are more concerned with all of the possible core technologies that could underlie the industry or business environment sometime in the future (Allen, 1986). They are essentially responsible for the technical health and vitality of the corporation, keeping the company up-to-speed in what could become the dominant and most valued technical solutions within the industry. And as previously discussed, these two sets of forces, downstream and upstream, are constantly competing with one another for recognition and resources which can either be harmful or beneficial depending on how the organization’s leadership resolves the conflicts and mediates the priority differences.

If the product-output or downstream set of forces becomes dominant, then there is the likelihood that sacrifices in using the latest technical advancements may be made in order to meet more immediate schedules, market demands, and financial projections. Strong arguments are successfully put forth that strip the organization of its exploratory and learning research activities. Longer-term, forward-looking technological investigations and projects are de-emphasized in order to meet shorter-term goals, thereby mortgaging future technical expertise. Under these conditions, important technological changes in the marketplace are either dismissed as faddish or niche applications or go undetected for too long a period. To illustrate, Walter Robb, the general manager of GE’s medical business at the time EMI was just starting to commercialize CT scanners, readily admits that GE medical was so focused on running, improving, and protecting its existing X-ray business that it could only see CT scanners as nothing more than a minor niche market application that would never seriously affect GE’s medical business. The dilemma in these instances of course is that the next generation of new product developments either disappears or begins to exceed the organization’s in-house technological capability. Only two of the leading producers of vacuum tubes in 1955, for example, were able to make the leap to transistors by 1975; similarly, almost none of the major 35 mm camera producers were the pioneer marketers of digital photography (see Anderson & Tushman, 1991; Foster, 1986; Iansiti, 2000; Tripsas, 2001 for additional examples and discussion).

At the other extreme, if the research or upstream technology component of the business is allowed to dominate development work within R&D, then the danger is that products may include not only more sophisticated and more costly technologies but also perhaps less proven, more risky, and less marketable technologies (Pate-Cornell & Dillon, 2001; Scigliano,

2002). This desire to be technologically aggressive—to develop and use the most attractive, most advanced, most clever, state-of-the-art technology—must be countered by forces that are more sensitive to the operational environment and the infrastructure and patterns of use. Customers hate to be forced to adapt to new technologies unless they feel some pressing need or see some real added value. Technology is not an autonomous system that determines its own priorities and sets its own standards of performance and benchmarks. To the contrary, market, social, and economic considerations, as so poignantly pointed out by Steele (1989), eventually determine priorities as well as the dimensions and levels of performance and price necessary for successful applications and customer purchases. Unwanted technology has little value and technical performance that is better than what customers want nearly always incurs a cost penalty and is rarely viable. Such effects are vividly portrayed by the painful experiences of all three satellite consortia—Motorola's, Qualcomm's, and Microsoft's—as each consortia group still tries to penetrate the cellular and wireless tele-markets with their respective Iridium, Globalstar, and Telstar systems (Crockett, 2001; Morgan et al., 2001). To put it simply, few customers will pay for a racing car when what they really want is a family sedan.

A Model of Innovation Dynamics in Industry

In a previous but still seminal piece of research, Abernathy & Utterback (1978) put forth a model to capture some interesting dynamics of innovation within an industry (see Utterback, 1994, for the most thorough discussion of these issues and their implications). The model, as shown in Fig. 1, suggests that the rates of major innovations for both products and processes within a given industry often follow fairly predictable patterns over time; and perhaps more importantly, that product and process innovation interact with each other. In essence, they share an important tradeoff relationship.

The rate of product innovation across competing organizations in an industry or product class, as shown in Fig. 1, is very high during the industry's early formative years of growth. It is during this period of time, labeled the *fluid* phase by Abernathy & Utterback (1978) in their model, that a great deal of experimentation with product design and technological functionality takes place among competitors entering the industry. During this embryonic stage, no single firm has a 'lock' on the market. It seems that once a pioneering product has demonstrated the feasibility of an innovative concept, rival products gradually appear. As long as barriers to entry are not too high, these new competitors are inspired to enter this new emerging market with their own product variations of design choices and features. No one's product is completely perfected and no organization has as yet mastered the

Figure 1. The dynamics of innovation (Reprinted by permission of Harvard Business School Press. From *Mastering the Dynamics of Innovation* by James Utterback, Boston, MA 1994, p. xvii).

manufacturing process or monopolized all of the means of distribution and sales. Furthermore, customers do not as yet have a firm conception of what an ideal product design would look like nor enough experience from which to indicate what they would want or even what they would be willing to pay for in terms of features, functions, and attributes in this new product class. In a sense, the market and the industry are in a *fluid* stage of development with all of the involved participants learning as they move along together.

One of the more illustrative examples offered by Abernathy & Utterback (1978) phase lies in the early years of the automobile industry in which a bewildering variety of *horseless carriages* were designed and sold to the public. Not only were internal combustion machines being commercialized as the power source at this time but a whole host of other electric and steam-driven cars were emerging from the workshops of dozens of other producers as viable competitive alternatives. Each manufacturer hoped to capture the allegiance of the public with its own novel new design and driver amenities. Electric or battery powered cars, in fact, were produced and sold to customers from the earliest years of the industry and were discontinued primarily because Henry Ford eschewed the battery option (influenced in part on advice he received from Thomas Edison) and selected the internal combustion engine as the basis of his Model T design. In addition to relatively poor acceleration and the inconvenience of finding outlets for re-charging, batteries became an unpopular choice simply because they were much too heavy for the mostly unpaved muddy roads that existed at that time.

According to the model, in many product class situations, this period of fluidity usually gives way to a *transitional* phase in which the rate of major innovations in the product's design decreases substantially but

the rate of major innovations within the process begins to increase. It is within this period that the wide variety of different designs within the product class begins to disappear mainly because some aspects of a design standard have emerged. Most commonly, certain elements within the overall design have proven themselves in the marketplace as most desirable for satisfying the customers' needs or because certain design standards have been established either by formal agreements among major producers or by legal and regulatory constraints. As the basic form of the product becomes more predictable and consistent, the industry begins to concentrate more on improvements in the way the product is produced and how costs in the overall production and operation can be reduced.

In discussing their automobile example, Abernathy & Utterback (1978) describe how early imaginative designs of the auto age (three, four, and five-wheel auto designs, for example) gave way to a set of fairly standardized designs among the many competitors. As a result of this convergence, the features and basic form of the automobile achieved a reasonable degree of uniformity. In a sense, customers had developed a pretty clear understanding about what cars should look like and how they should be driven. The automobile companies developed a set of technologies and the driving public developed a set of expectations that mutually adjusted to one another over time to essentially define the basic format of the automobile. At the same time, however, substantial progress was being made in the overall ability of the firms to manufacture large quantities of cars at lower costs. By 1909, the rate of product design innovation had diminished so much that an article in the prestigious journal of *Scientific American* proudly proclaimed:

That the automobile has practically reached the limits of its development is suggested by the fact that during the past year no improvements of a radical nature have been introduced (*Scientific American*, 1909, p. 145).

Undoubtedly, it was this kind of standardization and general stability in the overall design that probably allowed Henry Ford to devote the numerous years it took to establish successfully his assembly line manufacturing process for the Model T.

If the market for the product class continues to grow, the industry gradually passes into what Abernathy & Utterback (1978) call the *specific* phase as shown in Fig. 1. The researchers deliberately chose the term '*specific*' to emphasize the notion that during this period, the business unit strives to manufacture very specific assembled products at the highest possible rates of efficiency. During this progression, the products themselves become increasingly well-defined with product similarities greatly outpacing product differences. Customers, moreover, have grown considerably

more comfortable and experienced with the product mix; and consequently, they have become more demanding and price sensitive. With this increase in familiarity, customers are now more capable of assessing what they need and value and what they are willing to pay. What typically results from all this movement is the gradual commoditization of the marketplace in which the value ratio of perceived functional quality to price (i.e. the business unit's cost) essentially becomes the basis of competition. Furthermore, the interrelationships between product and process are so intertwined that changes in either one of them require corresponding changes in the other. Even small changes can therefore be difficult and expensive.

Dominant Designs

The critical supposition underlying this gradual shift from a *fluid* phase to the *transitional* and *specific* phases is the emergence of a dominant design within the industry. Retrospective studies of innovation within a product class typically reveal that at some point in time there emerges a general acceptance of how the principal components comprising the product's overall architecture interface with one another (e.g. Anderson & Tushman, 1990; Meyer & Lehnerd, 1997; Utterback, 1994). A dominant design does not necessarily incorporate the best technologies nor is it necessarily the most optimal. It is established and defined experientially by the marketplace when a particular design architecture becomes the one most preferred by the overwhelming majority of the product's purchasers. Ford's Model T; the Douglas DC-3 aircraft; Boeing's 700-series; the QWERTY keyboard; IBM's 360 mainframes and PCs; JVC's VHS format; the Sony Walkman; WINTEL-based PC's; Powerpoint, Word, and Excel software programs; and CDMA or GSM-type cell phones, for example, all accounted for upwards of at least 70% to 80% of their respective markets at the height of their popularity (Cusumano & Yoffie, 1998; Teece & Pisano, 1994).

What the emergence of a dominant design does seem to lead to, however, is a shift in concentration of an industry's innovative resources and energies away from coming up with significant design alternatives to focusing on process improvements in what has become the ensconced product architecture. To put it bluntly, it would be a very risky bet for any organization to make a significant and irretrievable capital investment in a manufacturing process dedicated to a specific architectural configuration while there is still major flux among competing designs within the industry. In creating a convergent set of engineering conventions and design choices, a dominant design also provides equipment and component suppliers within the industry a clearer and more well-defined product and technological context within which their engineers can work to improve their pieces of the overall manufacturing system (Fine, 1999; Reinertsen, 1997).

Once a dominant design emerges, the basis of competition within the marketplace changes substantially. The industry changes from one characterized by many firms with many unique designs to one that will eventually contain many fewer firms competing with very similar product designs (Valery, 1999). A dominant design, therefore, is not a particular product or machine but a set of engineering standards and options representing an accepted pattern of design choices within the product's scope. Customers today, for example, rarely have to ask how to start, drive, or steer their cars; use their lights, windshield wipers and brakes; check their tires; or fill their gas tanks. When children's battery-operated toys are purchased, customers expect to use either the AA or AAA-standard size batteries that can be purchased in just about every retail outlet—the initial A and B-size batteries having fallen by the wayside in most of today's product designs.³

More recently, scholars have begun studying the survival rate of organizations in industries as a function of their entry with respect to the dominant design. Research by Suarez & Utterback (1995) and by Christensen et al. (1998), for example, revealed that firms attempting to enter and compete in industries after dominant designs had become established faced much lower chances of success and survival. According to these scholars, the existence of a dominant design significantly restricts the engineers' freedom to differentiate their products through innovative design. As a result, there are fewer opportunities for small or entering firms to find beachheads in markets operating in a post-dominant design era. Their data on company survival further suggests that there might be a bounded 'window of opportunity' for entry in fast-moving industries. In their industry samples, not only did the firms that entered after the dominant design had emerged have much lower probabilities of survival but the firms that entered too early also had reduced chances of survival. Perhaps many of these early firms had exerted efforts that built proprietary or specialized technological and design capabilities—which in the high turbulence of the fluid phase may have been appropriate and therefore successful—but which are now no longer sought by markets enveloped by a dominant architecture in which other factors and capabilities are more relevant and highly valued (Agarwal & Bayus, 2002).

The emergence of a dominant design is a watershed event in that it delimits the *fluid* phase⁴ in which a rich

mixture of design experimentation and competition had been taking place within the product class. It is important to understand that a dominant design is not predetermined. Nor does it come about through some rational, optimal, or natural selection process. Instead, it emerges over time through the interplay of technological possibilities and market choices that are influenced and pushed by the many individual and allied competitors, regulators, suppliers, and sales channels, all of whom have their own technological, political, social, and economic agendas.

Exogenous Factors Influencing the Dominant Design

Complementary Assets

By understanding the many factors that can influence the establishment and persistence of a dominant design within a given industry, managers can try to enhance the long-term success of their products by making sure they are actively involved in this process rather than dismissing, resisting, or functioning apart from it (Tripsis, 2001; Utterback, 1994). In one of the more notable articles on how companies capture value from technological innovation, Teece (1987) describes just how powerful complementary assets can be in shaping the dominant design that eventually wins in the marketplace. Complementary assets are those assets necessary to translate an innovation into commercial success. Innovative products usually embody the technical knowledge about how to do something better than the existing state of the art. However, to generate attractive financial returns and profits, this technical know-how must be linked with other capabilities or assets in order for them to be sold, used, and serviced in the market. These assets span a wide variety of non-technical properties, including brand name and company image, supply chain logistics, distribution and sales channels, customer service and support, specialized manufacturing capabilities, deep financial pockets, peripheral products, switching costs, political, regulatory, and customer knowledge, critical real estate or institutional associations, and control over raw materials or key components (Lynn & Reilly, 2002; Rosenbloom & Christensen, 1994).

The more a firm possesses control over these kinds of complementary assets, the more advantage it has over its competitors in establishing its product as the dominant design. While numerous PCs were available in the market long before IBM introduced its first personal computer in 1981, the IBM PC quickly became the dominant design, primarily because of its exceptional brand name, service reputation, and the emergence of so much other peripheral and applications software (Scott, 2001). In controlling access to homes through their established infrastructures, the 'baby bell' companies had an enormous advantage over new DSL and other telecom start-up competitors most

³ According to Tony Mazzola, a technical marketing manager at Eveready, the A battery is still used in some power tools and camcorders and the B battery is used for bicycles in Europe. Also, there are still AAAA, F, J, and N-size batteries but the E and G-size have become obsolete (Hartlove, 1998).

⁴ In their descriptive model of these innovation patterns, Tushman & O'Reilly (1997) call this fluid period an 'era of ferment' to denote the intense agitation that transpires among alternative designs and features within the product class.

of whom, to their dismay, realized much too late just how precarious a situation they were in even though they may have had attractive cost-performance capabilities and governmental support as a result of industry deregulation (Rosenbush & Elstrom, 2001). Not surprisingly, established telephone and cable companies, accustomed to operating as near monopolies, were not particularly eager to open their systems and infrastructure to rivals bent on offering similar services. The Verizons and Time Warners of the world threw up numerous legal and technological roadblocks to the upstart service providers (Trudel, 2002).

In sharp contrast, Christensen (2001) recently concluded from his historical investigations of disruptive technologies that one of the reasons the new entrepreneurial transistor-type companies were able to successfully displace the leading vacuum tube producers was that they were, in fact, able to bypass the critical distribution channels that had been controlled, or at least heavily influenced, by the premier vacuum tube companies. The new transistor firms did not have to rely solely on the legion of existing appliance store outlets that had grown all too comfortable with the opportunistic profits they were deriving from the servicing and replacement of vacuum tube components and products. They were, instead, able to sell their 'revolutionary' transistorized products through the many large department store chains that were also rapidly growing at that time throughout the country.

External Regulations and Standards

Government requirements and regulations can also play a significant role in defining a dominant design especially when they impose a particular standard within an industry (Bagley, 1995). The FCC's (Federal Communications Commission) approval of RCA's television broadcast standard, for example, provided RCA a tremendous advantage not only in establishing its receivers as the dominant design within the industry but also in favoring its black and white TV strategy over the color TV strategies that were being developed and lobbied by very worthy competitors at that time.⁵ Many governments around the world, either individually or collectively, try to determine standards for emerging technologies within their industries to facili-

tate easier and quicker product developments and to encourage increased compatibility among system components within the infrastructure of use (Caves, 1996).

The standards that a government establishes for package labeling, high definition television, telecommunications, automobile safety, or even for the content definitions of certain foods, such as ice cream, orange juice, or peanut butter, can either favor or undermine the interests and strategies of particular competitors within an industry. Governmental requirements and regulations can also be used to enhance the attractiveness of domestic producers over foreign competitors. By knowing that the U.S. government was going to require synthetic detergent producers to eliminate phosphates in order to reduce environmental pollution, Whirlpool Corporation realized that suppliers would have to augment their synthetic detergents in the future with more potent chemical additives to compensate for the banned phosphates (Knud-Hansen, 1994). The company also understood that over time these more forceful chemical compounds would probably be substantially more corrosive to many of the washing machine's internal parts, including the inside pumps and drums. As a result, Whirlpool gained a distinct advantage in the industry when it quickly developed new washing machine appliance models that could be marketed to withstand the reformulated, albeit more corrosive, detergents. Whirlpool's products were offered with a complete three-year warranty on its newly designed machines. Most of its major competitors, in comparison, found themselves backpedaling when they had to lower their equivalent warranties to only a couple of months. Obviously, such companies subsequently rushed to recover with stronger model designs that could resist the caustic characteristics of the new detergents' chemical compositions. An alternative scenario could easily unfold in 2007 when the Federal Government, in order to promote greater water conservation, has purportedly mandated that all washing machines sold in the U.S. will be 'front' rather than 'top loaders' (Van Mullekom, 2002). Front load machines are exactly the kind of design that has been made and used extensively for many years throughout all of Europe while American manufacturers have concentrated predominantly on top load designs.

Organizational Strategies

The business strategy pursued by a firm relative to its competitors can also significantly influence the design that becomes dominant. The extent to which a company enters into alliances, agreements, and partnerships with other companies within its industry can substantially effect its ability to impose a dominant design. One very notable example of this in recent times is the success of JVC's VHS system over Sony's Betamax system in the VCR (Video Cassette Recorder) industry. By establishing formidable alliances first in

⁵ RCA's political and VHF technical strategies, masterminded by the renowned David Sarnoff for the direct benefit of its NBC network, were pitted directly against the UHF color strategy of CBS, led by the relatively young unknown Peter Goldmark, who was hired for the expressed purpose of getting CBS into television and 'the urge to beat RCA and its ruler, David Sarnoff'. When the FCC unexpectedly affirmed the monochrome standards of RCA on March 18, 1947, CBS scrambled to buy, at what became a quickly inflated price, the VHF licenses it had previously abandoned. Interestingly enough, the U.S. Government is now seriously reconsidering UHF as the possible standard for its broadband (Fisher & Fisher, 1997).

Japan, then in Europe and finally the United States, JVC was able to overcome Sony's initial market success even though it is generally acknowledged that Sony's Betamax was better technologically (Cusumano et al., 1992). To its regret, Sony deliberately chose to go it alone, relying for the most part on its own strong brand name, reputation, and movie recordings. Sony avoided the kind of technical alliances and market partnerships that would ultimately make JVC's VHS-product so much more attractive and successful than Betamax. Microsoft and Intel pursued similar relationships when they embarked on a strategy to make their 'WINTEL' machine and its associated application programs more dominant than many alternative products (Gawer & Cusumano, 2002). At the time, many of these competitive products were seen as technically superior and most had already been successfully commercialized, including Lotus's 1-2-3 spreadsheet, Wordperfect's word processor, Harvard's graphics package, the Unix and OS/2 operating systems, or the Macintosh PC (Cusumano & Selby, 1995).

It is also quite common for companies planning to develop products in an emerging industry to send qualified participants to industrial meetings and/or professional conferences that have been convened explicitly to reach agreements on specific technical and interface standards for the common interest of all, including product developers, suppliers, and users. A great many of the technical protocols and specifications underpinning today's Internet architecture, for example, come from such organized meetings and resultant agreements. The World Wide Web, for example, is currently coordinated through a global consortia of hundreds of companies organized and led by MIT's Laboratory of Computer Science, even though Tim Berners-Lee developed the World Wide Web while he was working in Europe at CERN, the world's largest particle physics center.⁶

However, companies often disagree about the comparative strengths and weaknesses of particular technical approaches or solutions. As a result, those with similar views often band together to form coalitions that will both use and promote their technical preferences within their product class (See Gawer & Cusumano, 2002; Roberts & Liu, 2002 for some recent frameworks and examples). Alternative technical camps can subsequently evolve into rival company consortia. Direct competition within the industry

becomes centered around these different but entrenched innovative design choices. In replacing cables with wireless technology, for example, many companies have decided to design their new innovative products around the blue tooth wireless set of specifications originally developed by Ericsson (Ferguson, 2000). Contrastingly, many other companies, including Hewlett Packard, Philips, Samsung, and Sharp, have chosen to base their wireless products on the newest IEEE 802.15.3 set of professional standards (Reinhardt, 2002). The marketplace has yet to decide which if any of these will emerge as the dominant design.⁷

For a business unit to be successful over time with its innovative products, it needs to know much more than whether the innovation creates value for the targeted customers. The firm also needs to consider at least two other important factors. First, it needs to know whether it can 'appropriate' the technology, that is, to what extent can it control the know-how within the innovation and prevent others from copying, using, or developing their own versions of it (von Hippel, 1998). And secondly, the firm needs to know whether it has or can secure the necessary complementary assets to commercialize the innovation in a timely and effective manner within the marketplace (Leifer et al., 2001).

It is critical for senior management teams to realize that their businesses should be building their strategies based on the combined answers to these two important questions. As shown in Fig. 2, economists discovered long ago that profitability within an industry can be significantly affected by the interplay of answers to these two questions (Porter, 1990; Teece, 1987). In general, the more a company can protect its intellectual knowledge and capability from competitors, whether it be through patents, license agreements, technical secrecy, or some other means, the more likely the company can derive profits from its product innovations as long as the complementary assets are freely available. However, if the complementary assets (e.g. distribution channels, raw materials, specialized machinery or key components) are tightly controlled, then there is likely to be 'tugs of war' or alliances between the 'keepers' of the technology and the 'keepers' of the complementary assets. For example, although Procter and Gamble and Kimberly Clark might dominate the U.S. development and production

⁶ Neil Calder, who was the Director of Public Relations at CERN, sadly tells of the day that Tim Berners-Lee walked into his office wearing jeans and a T-shirt to tell him of his progress and latest developments. After listening in complete bafflement, Calder thanked Tim for coming and to 'keep in touch'. It was only much later that Calder realized that Berners-Lee had just described to him the creation of the World Wide Web. 'It was the biggest opportunity I let slip by', says Calder (2002) who is now Director of Communications of the Stanford Linear Accelerator Center.

⁷ It is by no means clear which wireless standard will emerge as the winner or even if a single winner will emerge. The professional IEEE 802.11 specifications have split into four separate 802.15 standards project groups with differing views on low-complexity and low-power consumption solutions. The older 802.11a standard, for example, has a throughput of 54 Mbits/s while 802.11b has a throughput of only 11 Mbits/s. Additional company coalitions have formed to develop products based on other possible wireless standards including the standards known as WI-FI and IPv6. Clearly, wireless products are firmly in the *fluid* stage of Abernathy & Utterback's (1978) model.

Complementary Assets

		Freely Available	Tightly Controlled
Intellectual Property	Freely Available	Profitability Is Difficult in a Commodity Business	Holders of Complementary Assets Are Profitable
	Tightly Controlled	Owners of Intellectual Property Are Profitable	Profitability Based on Power Alliances

Figure 2. Profitability winners.

of new disposable diaper products technologically, the companies have to work within the constraints and pressures that Walmart imposes on them if they want to sell their products to consumers through Walmart’s vast array of store outlets, i.e. its powerful complementary assets (Olsen, 2001). If the intellectual property, however, cannot be appropriated, that is, the technical knowledge and capability are widely available to all competitors, then profits are likely to be made by those firms that control the complementary assets. If both complementary assets and the intellectual property are freely available, then it will be hard for any of the major businesses operating in such an industry to secure and maintain high profitability.

Corresponding Changes Across the Product/Process Model

Organizational Changes

As a business unit forms around an initial new product category and becomes highly successful over time, it goes through the same transformation that any entrepreneurial enterprise experiences as it grows in size and scope (Morgan et al., 2001; Roberts, 1990). During the pioneering period of the new product industry, i.e. the *fluid* stage, the processes used to produce the new products are relatively crude and inefficient (Abernathy & Utterback, 1978). As the rates of product and process innovation inversely shift, however, the organization has worked to take more and more costs and inefficiencies out of its processes, making production increasingly specialized, rigid, and capital intensive. Through the early 1920s, major auto-makers could assemble a car in four to five hours but it still required three to eight weeks to paint.⁸ With ever increasing

capital improvements and innovations in the painting process, especially Dupont’s development of Duco lacquer, the painting time had been cut by 1930 from more than 25 separate operations requiring many weeks to a more continuous spraying process applied over a few days. Painting had become another unskilled task and the strong, independent painters’ union collapsed (Funderburg, 2002).

In recounting the rich example of incandescent lighting, Utterback (1994) points out that Edison’s initial lighting products were made by a laborious process involving no specialized tools, machines, or craft laborers. At the time, getting the product to work was far more exciting and important to the innovators than creating an efficient volume production process. However, as companies built capacity to meet the growing market demand for incandescent lighting more cost effectively than their competitors, vast improvements in the process were gradually developed and introduced by both manufacturers and suppliers, including the use of specialized glass-blowing equipment and molds in addition to high-capacity vacuum pumps (Graham & Shuldiner, 2001). As a result of all these process improvements, especially the development of successive generations of glass-blowing machines, the number of manufacturing steps, according to Utterback (1994), fell dramatically from 200 steps in 1880 to 30 steps in 1920. The manufacturing process had evolved over this period into an almost fully automated continuous process. Amazingly enough, the glass-blowing Ribbon Machine which was introduced in 1926 is essentially the same device that is used today, and it still remains the most cost effective way to produce light bulb blanks (Graham & Shuldiner, 2001).

As organizations make these kinds of shifts, that is, from focusing on exploratory product designs to concentrating on larger-scale operational efficiencies and the production of more standardized offerings, many other important parallel changes also take place

⁸ Part of Ford’s rationale for offering the Model T in ‘any color as long as it was black’ was that black absorbed more heat than lighter colors and therefore dried significantly faster. It also lasted considerably longer as black varnish was most resistant to ultraviolet sunlight (Funderburg, 2002).

within the industry (Gawer & Cusumano, 2002; Roberts & Liu, 2002; Tushman & O'Reilly, 1997; Utterback, 1994). Not only do changes in products and processes occur in the previously described inverse systematic pattern, but organizational controls, structures, and requirements also change to adjust to this pattern. In the *fluid* period of high market and technical uncertainties, for example, business leaders are more willing to take the risks required for the commercialization of radical new ideas and innovations. Individuals and cross-functional areas are able to function interdependently, almost seamlessly, in order to enhance their chances of success (Golder & Tellis, 1997; Klepper, 1996). Formal structures and task assignments are flatter, more permeable, and more flexible—emphasizing rapid response, development, and adjustment to new information and unexpected events. The company is *organic* in that it is more concerned with the processing of information and the effective utilization of knowledge than the more rigid *mechanistic* following of formal rules, bureaucratic procedures, and hierarchical positions (Mintzberg, 1992).

As the industry and its product class evolve, the informal networks, information exchanges, and fast-paced entrepreneurial spirit that at one time had seemed so natural and valued within the organic-type firms slowly give way to those leaders increasingly skilled at and experienced in the coordination and control of large, established businesses (Roberts, 1990). As operations expand, the focus of problem-solving discussions, goals, and rewards shifts away from those concerned with the introduction of new, radical innovations to those who are capable of meeting the more pronounced and complex market, production, and financial pressures facing the organization (Miller, 1990; Tushman & O'Reilly, 1997). Such demands, moreover, become progressively more immediate and interconnected as the products become more standardized, the business more successful, and the environment more predictable—all of which combine to make it even more difficult and costly to incorporate disruptive kinds of innovations. Rather than embracing potentially disruptive innovations and changes—encouraging and sponsoring explorations and new ways of doing new things—the organization seeks to reduce costs and maximize the efficiencies in its on-going tasks and routines through more elaborate rules, procedures, and formal structures (Katz & Allen, 1997).

The real dilemma in all of this is that major changes in the environment get responded to in old ways. The organization myopically assumes that the basis by which it has been successful in the past will be the same basis by which it will be successful in the future. As the technical and market environments become increasingly stable, the growth of the enterprise relies to a greater extent on stretching its existing products

and processes (Tushman & O'Reilly, 1997; Valery, 1999). The organization encourages and praises its managers and leaders for achieving consistent, steady results that predictably build on past investments and sustainable improvements. More often than not, ideas that threaten to disturb the comfortable stability of existing behavioral patterns and competencies will be seriously discouraged, both consciously and unconsciously. Contrastingly, ideas that build on the historical nature of the business's success, including its products, markets, and technical know-how, are more likely to be positively received and encouraged (Katz & Allen, 1989). A large body of research shows that when comfortable, well-run organizations are threatened, they tend to increase their commitments to their status quo—to the practices and problem-solving methodologies that made them successful in the past; not necessarily to what's needed or possible for the future (e.g. Jellinek & Schoonhoven, 1990; Hamel & Prahalad, 1994; Miller, 1990; Weick, 2000). They tend to cultivate the networks and information sources that affirm their thinking and commitments rather than diligently search for information and/or alternatives that might disagree with their inveterate patterns. Without outside intervention, they become increasingly homogeneous and inward-looking, demanding increased loyalty and conformity. They hire and attract individuals who '*fit in*' rather than those who might think and behave in significantly new and different ways (Hambrick & D'Aveni, 1988; Katz, 1982).

Industry Changes

During an industry's *fluid* stage, there is usually sufficient flux in both the technology and the marketplace that large numbers of competitors are able to enter the industry with their own product variations. In their detailed studies of the cement and minicomputer industries, for example, Tushman & Anderson (1986) show just how fragmented industries can be in this stage as each industry had more than a hundred separate firms introducing new products during the early formative years of the product's initial *fluid* cycle. Utterback (1994) draws the same conclusion when he quotes Klein's (1977) assessment of the auto industry's competitive landscape. According to Klein (1977), there were so many initial competitors jockeying for market share leadership positions in the early 1900s that it would have been impossible to predict the top ten '*winner*s' over the next 15 or so years. Even today, we tend to forget that many of the initially successful PC competitors included firms that were at one time very well known but which have now disappeared, firms such as Sinclair, Osborne, and Commodore Computer.

After the emergence of a dominant design, the industry moves towards a more commodity-type product space with many fewer surviving competitors. One would expect rapid market feedback and consumer

value to be based more on features and functionality than on cost per se during the industry's *fluid* period (Utterback, 1994). As markets become more stable with fewer dominant players, however, the basis of competition also shifts. Market feedback tends to be slower and direct contact with customers tends to decrease, although there are increases in the availability of industry information and statistical analyses (Tellis & Golder, 2001). While incremental changes in products may stimulate market share gains during the *transitional* and *specific* stages of the product-process lifecycle, they can usually be copied quickly and introduced by competitors, thereby resulting over time in much greater parity among the price, performance, features, and service characteristics of competitors' comparable products (Christensen, 1997; Tushman & O'Reilly, 1997). At the same time, however, there is much greater emphasis within the industry on process innovation. Each organization tries to make the kinds of changes and improvements that benefit its particular manufacturing process, changes that are not easily copied or transferable between rival production lines that have been uniquely modified and fine-tuned. In short, price and quality become relatively stronger elements within the overall competitive equation (Fine, 1999; Hamner & Champy, 1993).

As the longevity of a particular dominant design persists within the industry, the basis of competition resides more in making refinements in product features, reliabilities, packaging, and cost. In this kind of environment, the number of competing firms declines and a more stable set of efficient producers emerges. Those companies with greater engineering and technical skills in process innovation and process integration have the advantage during this period. Those that do not will be unable to compete, and ultimately, will either fail, ally together, or be absorbed by a stronger firm (Roberts & Liu, 2002). It is perhaps for these reasons that Mueller & Tilton (1969); Tushman et al. (1986); Tyre & Orlikowski (1993); Utterback (1994); and many others contend that large corporations seldom provide their people with real opportunities or incentives to introduce developments of radical impact during this stage. As a result, changes tend to be introduced either by veteran firms or new entrants that do not have established stakes in a particular product market segment. Radical innovations and changes are usually introduced by disruptive players in small niche market segments (see Christensen, 1997) for as technological progress slows down and process innovation increases, barriers to entry in the large established markets become more formidable. As process integration proceeds, firms with large market shares, strong distribution networks, dedicated suppliers, and/or protective patent positions are also the organizations that benefit the most from product extensions and incremental improvements (Utterback, 1994). It should not be particularly surprising, therefore, that in their study

of photolithography, Henderson & Clark (1990) discovered that every new emerging dominant design in process innovation in their study's sample was introduced by a different firm than the one whose design it displaced. Radical, disruptive innovations that start in small market segments are too easily viewed as distractions by the more dominant firms trying to satisfy the cost and quality demands of their large customer base. These same innovations, however, are more easily seen as opportunities by both smaller firms and new entrants.

Innovation Streams and Ambidextrous Organizations

Because industry forces and corresponding organizational priorities operate so differently between product and process innovation phases, Tushman & O'Reilly (1997) argue that a business unit must redirect its leadership attention away from a particular stage of innovation and move towards managing a series of contrasting innovations if it is to survive through recurring cycles of product-process innovations. An organization has to function in all three phases simultaneously, producing streams of innovation over time that allow it to succeed over multiple cycles of technological products. Innovation streams emphasize the importance of maintaining control over core product subsystems and proactively shaping dominant designs while also generating incremental innovations, profiting from architectural innovation introductions that reconfigure existing technologies, and most importantly, by initiating its own radical product substitutes.

To demonstrate this stream of innovations capability, Tushman & O'Reilly (1997) refer to the enviable success of the Sony Walkman. Having selected the WM-20 platform for its Walkman, Sony proceeded to generate more than 30 incremental versions within the WM-20 family. More importantly, it commercialized four successive product families over a 10-year period that encompassed more than 160 incremental versions across the four families. This continuous stream of both generating incremental innovation while also introducing technological discontinuities (e.g. flat motor and miniature battery at the subsystem level) enabled Sony to control industry standards and outperform all competitors within this product class.

The obvious lesson, according to the two authors, is that organizations can sustain their competitive advantage by operating in multiple modes of innovation simultaneously. In organizing for streams of innovation, managers build on maturing technologies that also provide the base from which new technologies can emerge. These managers emphasize discipline and control for achieving short-term efficiencies while also taking the risks of experimenting with and learning from the '*practice products*' of the future. Organizations that operate in these multiple modes are called 'ambidextrous organizations' by Tushman & O'Reilly

(1997). Such firms host multiple, internally inconsistent patterns of structures, architectures, competencies, and cultures—one pattern for managing the business with efficiency, consistency, and reliability and a distinctly different pattern for challenging the business with new experimentation and thinking.

Each of these innovation patterns requires distinctly different kinds of organizational configurations.⁹ For incremental, sustained, and competence-enhancing types of changes and innovations, the business can be managed with more centralized and formalized roles, responsibilities, procedures, structures, and efficient-minded culture. Strong financial, supply chain, sales, and marketing capabilities coupled with more experienced senior leadership teams are also beneficial. In sharp contrast, the part of the organization focusing on more novel, discontinuous innovations that have to be introduced in a more fluid-type stage requires a wholly different kind of configuration—a kind of entrepreneurial, skunk-works, or start-up spirit and mentality. Such organizational entities are relatively small with more informal, decentralized, and fluid sets of roles, responsibilities, networks, and work processes. The employees themselves are usually less seasoned and disciplined—they are, however, eager to ‘push the state of the art’ and to test ‘conventional wisdoms’ (Tushman & O’Reilly, 1997).

What all too often becomes very problematic is that the more mature, efficient, and profitable business sees its entrepreneurial unit counterpart as inefficient and out of control—a ‘renegade, maverick’ group that violates established norms and traditions. The contradictions inherent in these two contrasting organizational configurations can easily lead to powerful clashes between the traditional, more mature organizational unit that’s trying to run the established business vs. the part that’s trying to recreate the future. If ambidextrous organizations are to be given a real chance to succeed, the management teams need to keep the larger, more powerful business unit from trampling and grabbing the resources of the entrepreneurial entity. While the company can protect the entrepreneurial unit by keeping the two configurations physically, structurally, and culturally apart, the company also has to decipher how it wants to integrate the strategies, accomplishments, and markets of the two differentiated units. Once the entrepreneurial unit has been separated, it becomes all too convenient for the firm to either sell or kill the smaller activity. One well-known European electronics organization, for example, sadly discovered from its own retrospective investigation that the vast majority of its numerous internal skunk-works for new products in the 1990s were

eventually commercialized by competitors. Even more worrisome was the finding that none of the skunk-work products commercialized by the firm *itself* became successful businesses. Clearly, the need to differentiate is critically important to foster both the incremental and radical types of innovation; but at the same time, the organization has to figure out how it is going to eventually integrate the so-called ‘upstart’ unit into the larger organization so that the potential of the ambidextrous organization is not lost. The ability of senior executives and their teams to integrate effectively across highly differentiated organizational configurations and innovative activities remains the true challenge of today’s successful enterprise.

Towards a Constructivist Approach of Technological Innovation Management

Vincent Boly, Laure Morel and Jean Renaud

Laboratoire de Recherche en Génie des Systèmes Industriels, France

Abstract: This chapter describes a constructivist approach to the understanding of technological innovation management within French SME's. Firstly, it presents findings from technological innovation surveys in French SME's and analyzes the emerging trends (e.g. the non-existence of a single ideal new product development process, a high degree of variability of technological evolution, and the importance of cognitive aspects). Secondly it describes a constructivist approach and its key aspects (e.g. development of a value-oriented strategy; a systemic vision of innovation management through its three levels: strategy, piloting, and sparking), as well as limitations of current practices in different kind of French SME's.

Keywords: Innovation; SME's; Constructivism; Strategy; Piloting; Sparking; Value; Knowledge.

Introduction

Companies having less than 500 employees represent around 90% of the total number of French enterprises. As a result, their impact on the country's global economic performance is highly significant. Our attention is directed toward innovation, in SME's (Small and Medium Enterprises). One can define innovation as:

- the steps processing an idea into a new product or service, launched on the market and creating new value;
- the development process of a new industrial activity within an existing company or in the context of a company launching project (Garcia et al., 2002);
- a cognitive approach within an industrial system, characterized by a paradigm change (out of the box thinking, rules breaking). It begins with creation tasks and ended with standardization (Swan et al., this volume);
- the technological reaction of an adaptative industrial system facing an internal signal or an external evolution (this includes changes in the boarder between the company and its environment in order to invest opportunity spaces).

Note that a technology is considered as a sum of scientific knowledge and connected know-how (knowledge aiming at the industrialization of the first one).

In its last survey, the SESSI, Statistic Service of the French Ministry of Industry (SESSI, 1999), states that the percentage of innovative SMEs is improving. Accordingly, investment devoted to R&D is rising (Table 1): the number of small companies developing a formal research activity has doubled during the last 15 years. Nevertheless, research remains mainly the domain of international industrial groups (60.9% of them carry out formal research).

Table 1. Percentage of companies having a formal research program in 1996.

Number of employees	% in all French companies
20 to 49	3.7
50 to 99	9.3
100 to 249	20.7
Small Entr.	7.6
250 to 499	38.1
Total SME	9.2
Big companies	60.9
Total*	11.0

Table 2. *Entreprises with technological innovation in French industry between 1994 and 1996 (% of the total number of companies).*

	20 to 49 employees	50 to 99 employees	100 to 249 employees	250 to 499 employees	SME
Innovation in products or process	33.3	43.8	53.4	66.3	40.0
Innovation in products (including new products on a market)	26.6	37.3	46.3	59.5	33.3
Innovation in process	15.8	19.8	29.6	36.4	19.7
Entreprises having on-going projects in 1997	23.1	30.9	39.0	50.5	28.4
Total innovative companies (including on-going projects)	26.7	37.1	46.4	61.3	33.4
	38.4	48.9	58.1	70.6	45.0

Source: SESSI, 1999.

This analysis of the 'formal research' criteria contains several limitations and other surveys suggest a greater number of innovative SMEs (Table 2). Among these limitations one can note: some SME's do not consider as researchers part time technology developers, and on the other hand some company managers integrate any collaboration with academic structures (training period of students for example) as research activities. Moreover many French SME's have 'informal research': experiments and design activities realized off the official working time.

This difference between innovative companies and those having a formal research activity can be explained by the high degree of variability in the innovation process (Boly et al., 2000). Increased attention is directed by SME's top management toward the creation of a continuous adjustment between products and production practices, and their external technological environment. As a result, research activities do not systematically represent the first step of the innovation process. New customer requirements, quality problem solving, supplier propositions and internal ideas also induce technological evolution. Moreover, few small companies are involved in a formal innovation process. Finally, innovation often emerges from action and not from study organized by top management.

It should be noted that in new company creation, the percentage of business working in innovative fields is still improving: 5% in 1999 and 6.5% in 2000 (DIGITIP, 2001). This represents about 11,000 new innovative enterprises in 2000.

As in many other parts of the world, the strategies of French SMEs depend heavily upon the related industrial sector (3.6% more employees in innovative companies compared to 1999). Innovation investments remain weak in sectors requiring high capitalization, or high promotion costs. These include: energy and raw materials production.

In fact, most surveys on radical innovation highlight a U trend between the size of the enterprises and their performance (Bernard, 1994). Many small companies valorizing high technological and/or specialized know-how are involved in innovation as well as major

companies investing in research.

In short, the number of French SMEs trying to strengthen their competitive advantage through innovation is increasing. Funds mobilized to support innovative projects tripled in 2000 compared to 1999: this includes stock offerings as well as venture capital (Ministère de l'Economie, 2001).

As far as SMEs are characterized by weak resources, high reactivity and their degree of information integration, their innovation piloting approaches constitute an interesting research area.

This section emphasizes some of the phenomena observed in innovative French SMES and the resulting new innovation piloting concepts.

Technological Innovation: Emerging Concepts

Observation of Some Basic Phenomena in French SMEs

In order to get a better understanding of the innovation process within SMEs, our team generally adopts an anthropological type approach: data gathering includes observation, listening, conversations, questions and answers and internal document reading. This approach suits our special interest in reporting qualitative and quantitative data. As a matter of fact, decision and action in the field of innovation stem not only from logical thought and a scientific approach, but also from intuition or non linear thinking (Buckler et al., 1996). Our clinical methodology implies that the researchers both participate in (strategy definition, technical design and project reviews) and study organizational change with the aim of contributing both to the advancement of knowledge and to practical questions that organizations may have. Via this involvement, it is possible to gain access to a wealth of data which is denied to other approaches (Karlsson et al., 1997).

At the end of the inquiry stage (direct observation and analysis of documents), information is gathered through clinical data tables (Fig. 1).

Information analysis is based on two systemic models: 'the result flowsheet' and the 'activity Gantt chart'. In each firm, and at the end of each experimental period, individual and collective productions

Internal and external customers of Mr/Mrs X	Results: what did Mr/Mrs X give to them	Related activities: what does Mr/Mrs X do	Resources used by Mr/Mrs X	Internal and external suppliers of Mr/Mrs X

Figure 1. Clinical data tables: description of individual or collective involvement in the NPDP.

were gathered into a series of results (Fig. 2). Thus modelling consists of the immaterial (information, advice, ...) and material (prototype, plan, ...) result sequence. This model is consistent with the focus on studying the dynamic evolution of innovative projects. It is indeed meaningful to describe decision making and to understand project management practices and mental perceptions.

First, information about individual or collective activities from clinical data tables is assembled into a ‘Gantt chart of the activities’: a diagram indicating the following activities carried out by people involved in each innovation task (Fig. 3). Activities are chronologically ordered and additional items included: who was in charge of the activity, who was concerned by this activity. This model is meaningful to determine actual responsibilities. It captures a broad spectrum of responsibility sharing: technical studies, validation of other activities and final decision-making.

Further analysis of the two models includes common activity sequence identification within the tasks of panel firms. These standard activities determine general project management practices. Second, comparison between the thirteen ‘result flowsheets’ is used at three different stages: initial idea, industrial report

(documents include technical, commercial and financial statements) and final innovative activity launched.

What Kind of Concepts are Emerging?

The Non Existence of a Single Ideal New Product Development Process

Two main observations are in conflict with the idea of a meta-innovation process. First, the variable position of certain activities and results within a global New Product Development Process (NPDP). Second, the different ways to undertake certain given tasks. As a consequence, it is not possible to assemble the 13 flowsheets into one model.

In the technical field as well as in that of trade, strategy and finance, the variable position of results and activities is confirmed. For example, prototype creation is generally planned after initial drawings and technical surveys. But, in some cases (Firm G, M), even before validating the start of the project, technical feasibility tests are carried out.

Moreover, some technical steps are managed in very variable ways. For example, routing definition sometimes represents a single task. But in some cases (Firm B, C, D), routing is analyzed as forecast routing before the final product plan design, and is defined as final

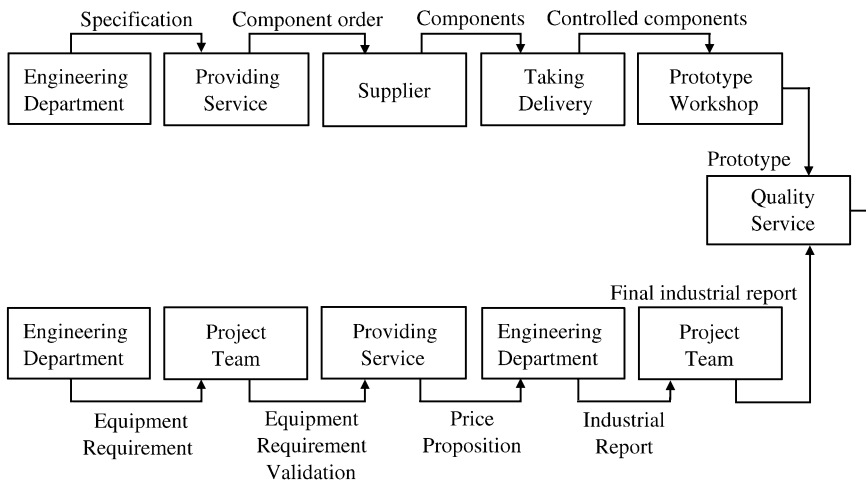

Figure 2. Modelling of NPDP through the ‘result flowsheet’.

<i>ACTIVITY</i>	<i>Project Leader</i>	<i>Top Management</i>	<i>Engineering</i>	<i>Production</i>	<i>Sales Force</i>	<i>Quality</i>

routing in a later step. Engineers argue that forecast routing allows anticipation with regard to the correlation between the new product requirements and the current production equipment.

Market analysis attests to the same variability. A ‘result flowsheet’ study indicates that some firms begin market analysis after prototype production (Firm D, G, I). However, companies undertake customer surveys before development (Firm B, E, F, H). Moreover, separate studies of different target markets are undertaken throughout NPDP in Firm A.

Diversity also exists in the field of partnership. Top management sometimes tends to contract with partners before plan drawing, while others wait until technical tests have been carried out on the product. In fact, partnership as a result of an external offer could occur at any moment.

It should be noted that certain activities and result transfers are lacking even when comparing all NPDPs. Market analysis, contact with potential partners and legal studies are not systematically undertaken during successful projects. For example, some firms investigate direct market confrontation and experienced retroaction (Firm M).

As a result, the project manager’s capacity to select and order these activities influences success rates. Lists of activities, or intermediary results are at the manager’s disposal in order to define the appropriate innovation process. Then, key factors for success

include: a correct NPDP and its on going improvement. Fundamentally, innovation induces more adaptation approaches than attempts at optimization.

The High Degree of Variability in Technological Evolution

Authors such as Song et al. (1996), state that the way an idea is processed into an innovative activity depends heavily upon factors including: strategy (i.e. whether top management investigates partnerships or non targeted markets (i.e. single principal or large size market) and production process (i.e. single know-how or combinations of technologies). NPDP results from these internal decisions but also from external events (Ducharme et al., 1995) and is made up of highly variable ordered standard activities. Hence, purposely or in reaction to external constraints, personnel involved in the project do or do not undertake certain activities. Consequently, competitive advantages emerge from activity position modification within NPDP. One particular aspect is described by Swan et al. (this volume): the role of networks and the way they are managed, vary across the innovation process.

Our outcomes highlight that NPDP is not the only source of instability. Within our panel, we observe that various strategies were applied by top management during the projects. Although the same people participated throughout the project, initial ideas always differed from the final activities launched (we had only

one exception: Firm D). The improvement of technological knowledge via R&D or feasibility studies may partly explain this evolution. However other factors influence not only the product but also the global targeted industrial structure, such as contact with suppliers of funds, sales opportunities during development stages or new norms. Innovation emerges from a phenomenon of confrontation.

Variability may also be considered through the impact of some of the technical decision taken during the project. For example, the innovative ergonomic manholes produced by Firm K, were based on design decisions requiring little evolution in production know-how whereas success induced important changes in the field of organization. However, some innovations are only made possible by adding new abilities (at the design, development or production launching stages).

Within some enterprises and at the same time, different organizational structures are developed to manage innovative projects: multifunctional project teams, single functional departments or individual missions (Griffin, 1997). And yet, the concepts of innovation and project are not strictly correlated. Informal structures may lead to innovation. We had the example of a company that innovated by applying the proposition of a student at the end of a training period.

Basically, innovation relies, in part, on this variability. Indeed, people facing a context of instability have to be reactive and creative. These are two basic abilities promoting innovation.

The Process of Technology Transformation and its Impact on Success

The success of a new product depends on its characteristics, on external variables (such as customer acceptability or political events) but also on its development process. The McKinsey survey on the financial margin brought by innovative projects offers some thoughts regarding the impact of the technology transformation process. Delayed launching, real production costs higher than the objective and (but with a slighter impact) under-estimated research costs constitute major obstacles when aiming at maximum value. This outcome suggests that:

- the use of project management tools (including planning and cost control) (Firm B, C, D, L, K);
- human resource management (including time and individual assignment to the project), (Firm A, H, C, J, M);
- information processing approaches (such as objective cost design) (Firm J, C);

influence the success of an innovation.

One other dimension of the impact of the innovation process on the success of the product is the partnership strategy. Mitchell et al. (1996) states that codesigned products have a better survival rate: 57% for innova-

tions managed by two or more companies together against 39% for products developed by a single enterprise. The existence of confrontation or negotiation steps between the partners within the innovation process has an impact. In our panel, we observed that project duration was reduced in the case of partnership. Handling the agenda seems easier when two or more top managers are involved.

Other considerations rely on the sociological dimension of the innovation process. While participating in development tasks, people try to forecast their own place in the future activity. Hopes, desires and fears influence these representations. As a result, at the individual level, decisions are not only based on objective reasoning approaches. Interrelation management and individual variables may change decisions about the product, its production organization and, as a result, the corresponding global activity.

The Necessary Integration of Complexity, Risk and Uncertainty

Pascale (1999) considers innovative companies as complex adaptive systems. As long as innovation is 'technological activity in a constant state of flux' an anthroposocial dimension is to be taken into account. As a consequence, describing and understanding innovation phenomena relies on the concept of evolution and its complex related principles.

The multivariable structure of the innovation process (Iansiti et al., 1997) and the multiplicity of links between these variables, represents the first phenomenological aspect of complexity (Benghozi et al., 2001). Any evolution in the production process for example, may have an impact on other processes such as distribution, maintenance and quality control (Firm B, G). Moreover, all industrial activities require financial resources and innovation often implies a modification of investment allocation principles. Even the relations between the industrial system and its environment move to a new temporary balance: innovation success may depend on new supplier selection or other responsibility sharing with traditional suppliers (Firm J). The environment itself changes following the development of the innovative projects of the company. Firm G had to adapt to European norms in the field of acoustics for its new activity, whereas, there were legal constraints relating to mechanics for its previous product.

In summary, multivariable aspects and analyzing *in situ* observation in French companies, we can state that innovation influences (Boly et al., 2000):

- the results, being the common outcome of several internal processes (an efficient prototype is the result of quality and design processes);
- the transverse activities (forecasting the new product cost is an activity concerning people in charge of design, finance and production);

- the resources to be shared between different processes (including investment);
- the cross impact between process performance: stock control and production performance for example.

Complexity also arises from the contradiction in the objectives of the company departments. Innovation aims at improving *value* in the company. But global value evolution is not the simple sum of local value improvements. Transforming value improvement strategy into local objectives remains difficult: safety and productivity, ecological impact and yield, quality and financial results. As far as innovation creates local disturbances (evolution of quality control procedures, logistic evolution, responsibility modifications in the purchasing department in the case of Firm C) another coherence level has to be defined to further innovation, taking into account that the responsibility area of an individual is no longer adapted. Moreover, the impact of design decisions between global and local levels has to be managed.

The concept of discontinuance also leads to complexity. Considering innovation as a radical phenomenon upsetting the equilibrium between an industrial system and its environment, we observed an improvement in the susceptibility of the company to changes. As a consequence, innovation modifies the necessary reactions of the company to external disturbances. Extra costs and negotiations with the customer are the consequences of a temporary production delay (Firm E of our panel). But, not setting the agenda to produce the final prototype of a new product to be presented to the annual trade fair may cause definitive project failure. Complexity arises from these evolutions in daily manager behavior necessitated by innovation.

Uncertainty is the second basic notion to integrate while aiming at a better understanding of innovation. In many cases, negative outcomes from feasibility studies are not consistent with the following success of an innovation. Thus, Firm J believed there would be an improvement in the global market for road verge cutting machines following the introduction of its innovation. They established a profitable business plan although first analysis of the traditional sales volume was negative. In fact, success is often based on antinomial decisions. Moreover, any member of a team involved in the innovation process faces hazards (events they foresee but without knowing their final form: currency levels for example) and uncertain (unforeseeable) events (bankruptcy of a major customer for example). As a result, top management gains useful insight by defining a possible risk level: what is the maximum gap between the final result described by the project team and the real future one. A risk reduction policy may represent a limitation to innovation.

More precisely, links between innovation and uncertainty can be detailed as follows:

- considering innovation as a decision process, we can state that uncertainty relies on the quality of the main resource of this process: information. For example, precision in the customer needs description remains fundamental. As time to market reduces, that quality and volume of information available may be critical;
- uncertainty is positively correlated to the novelty degree (Beaudoin, 1984): people in companies are inexperienced with the new know how linked with innovation. As a consequence, their understanding and control of new technical aspects are not optimum;
- complexity is associated with uncertainty. Thus, the exhaustive prediction of the impact of an innovation on the previous industrial system or its environment, is generally impossible for the human brain. Due to this limitation, problems remain unstudied at the end of a project;
- uncertainty depends on the strategy: uncertainty is often greater when aiming to be first at launching a new product than when deciding to be a follower. Moreover, innovation decisions imply an evolution in the global strategy of the firm;
- uncertainty emerges from the constructivist approach in innovation management. New information modifies the initial representation of the project and as a consequence the 'future product' is characterized by on going evolution. Moreover the project team itself may change;
- innovation considered as breaking the rules in the company (technical concepts, production process, organizational structures, and so on) is source of uncertainty as long as people lack references;
- uncertainty emerges as innovation requires top managers ability to identify opportunities within their environment. Innovation success then partly depends on unstable variables like curiosity, perspicacity, intuition and culture;
- uncertainty is related to the company's size. In particular, financial resources may be critical in the case of small businesses to achieve complete feasibility studies and experimental tasks;
- basically, each technology is highly adapted to the particular characteristic of the industrial system. Uncertainty arises from the abilities of people to adjust general knowledge to their specific context (machine, organization, or behavior);
- the sociological dimension of innovation is also a source of uncertainty: relations between people involved in the project, the emergence of 'champions' as project leaders, individual strategy influences the outcomes of the innovation process;
- is there a chaotic phenomenon in project management? Does the repetitive use of some methodological tools lead to results that are clearly different from expectations (many functional analyses may lead to a lack of formalization)? In this case,

uncertainty would arise from the systematization of management practices.

In summary, innovation requires a complex approach to problems. It is not approximation thinking nor disorder management (The Minnesota Studies, 2000). Integrating complexity deals with creating methodologies and developing reasoning modes, in order to analyse links between variables, to articulate different concepts and to organize the reflection between local and global approaches.

Local Performance Optimization Versus Creation of New Value

Because of the increasing complexity of industrial practices, the general evolution of economic demand and the non linearity of innovation processes, the notion of local performance evolves toward a more global notion of value. Indeed, firms require the development of new abilities to be able to cope with complex problems in all their dimensions, and to initiate and direct new development actions. To transform the constraints into opportunities of development represents one of these abilities.

Optimization of industrial unit processes (such as production monitoring, product/process design and project monitoring) is a major concern in companies focusing on performance control and an intangible objective. As a consequence, finding solutions to the problems by adopting a short-term emergency mentality remains the priority. The result is often a technical solution with a better financial return. But, only visible indicators are considered (facts or objects) such as product quality or better productivity.

Obviously this type of management presents limitations. Indeed, this logic does not take into account individual and collective behavior whereas proposing innovative solutions requires the mobilization and implication of all people involved. Furthermore, this management, based on a sequential approach to each operational problem avoids any feedback effects. So,

diagnosis seems completely disconnected from action and can lead to aberrations (for example, within our panel, some firms driving an environmental approach, were completely disrupted by the fact that indicators could give contradictory results depending on the point of view chosen: quality or environment).

As a result, innovation managers gain useful insight by developing an integrated and simultaneous approach to the technological, human and organizational dimensions (as a whole). This, so called 'logic of value creation', guarantees both the improvement of the technological system as well as the integration of individual behavior. It should be noted that value is an evolving concept according to specific criteria (see 2.2).

Value development rests mainly on the principle of integration, highlighting the dimension or dimensions, which may be used as a lever when attempting to solve a global problem. Each action or decision has to be made or taken considering its impact on the technical variables of the project, the organization of the company, the individual behaviors and the present reasoning modes of the employees.

As a consequence, innovation appears as a new principle of action based on novelty, transforming a set of constraints into an opportunity of new value development and taking into account both local optimization (development of tools and methodologies) and global development (study of the links and interactions existing between the dimensions described in Fig. 4). Finally, this challenge also relies on the firms' abilities to create a synergy between the social environment, technology and organizational processes to effectively contribute to the satisfaction of its customers.

The Importance of Cognitive Aspects

The complex aspect of innovation ends in the creation of a new status for knowledge and thus action.

First, innovation suggests a confrontation of individual representations. The purpose of managers is to

Figure 4. Control of the performance to the creation of the value.

build gradually a *common vision* (Longenecker et al., 2000), confronting words, signs, models and trying to connect them to the other. Various domains of science may be investigated. This favors the creation of emergent structures and new ways of development thanks to an effective transfer from one domain to another. This process is especially convenient to the 'radical' or 'break' innovation because it questions the traditional reasoning and action modes of company at a given time. Innovation arises from a confrontation between individuals or from organizations, which have strategies and thus different models of action ('variety of points of view' (Morin, 1977)). Companies thus invent new solutions by improving existing answers.

Second, in numerous cases, observation of our panel attests that the emergence of a new technology is bound to the emergence of a *new way of thinking*: this can be induced by networking conditions (Swan et al., this volume). Simplicity and surprising aptness of change of analysis of a problem, or a situation often create success. Weld the manhole onto the tool generally used to remove it: here is the innovation of Firm K. Analyzing the covering of nuts with different layers of compounds as a succession of hydrophilic and hydrophobic coverings before the formulation step: here is the beginning of a new sweet formulation (Firm M). Through the image of the 'frog paradox', Debaig et al. (1999) shows numerous cases where this break in representations drives innovation.

As a consequence, innovation may be considered as a cognitive process, during which individuals show themselves creative and capable of developing several approaches to the same situation. Thus, innovation would be a mechanism of *building new representations of the 'reality' or the object*. A sawing machine became a technological engine and the driver a pilot (Firm J)! The major obstacle consists in going beyond the first reflex: 'to make reality possible'. On the contrary, theory of complexity states that from possible to reality, something else exists, which we can call innovation or progress (Lemoigne, 1994). Innovation consists also in a process of *modification of the ways of reasoning*. For example, certain hypotheses at the origin of innovative knowledge arise from the use of deductive reasoning modes instead of analogical ones.

In other words, creation of new knowledge partly relies on the variation in problem approaches:

- in certain cases, it will be necessary to think globally in order to act locally;
- in other cases, it will be necessary to leave local contexts to act globally (changing representations, reasoning modes and corporate culture).

Finally, innovation is also a knowledge creation process thanks to *action*. In certain cases, only using experience allows new concepts to be discovered: Firm F found a brand new product concept of educational equipment by listening to people criticizing one of its

playground prototypes. The process of innovation joins in a dialectic between the certainties of experience and the uncertainties of novelty (Divry, 1998; March, 1991) illustrating the tension between the exploitation of the knowledge already acquired and the exploitation of new ways. In other words, the process of innovation activates a process of learning, which in return feeds innovation. It is similar to a process of creation, even re-creation of knowledge having several modes: socialization, outsourcing, combination, internalization (Nonaka, 1995). Vinck, 1999, states that the construction of a collective service is consubstantial in the construction of objects: innovation appears then through the process of realization of knowledge through action.

As a conclusion, innovation is the outcome of a collective intelligence, based on a mobilization of formal and validated knowledge. It requires an ability to experiment. Innovation thus appears from the interaction between various cognitive territories and a representation shared through action and consists in a stream evolving by construction.

2. Toward a Constructivist Approach to Technological Innovation Piloting

2.1. Assets and Limitations of Project Management Practices

In this section, focusing on the confrontation between innovation management (all the activities promoting innovation within a company) and project management (methods and tools supposed to be adapted to any project), we will refer to the AFITEP recommendations. Founded in 1984, this French industrial association formalizes methodological tools and abilities acquisition processes in the fields of planning, estimation and cost control. Most of its recommendations has been taken into account in the definition of norms by the French Bureau of Certification AFNOR: the X50-400 norm on terminology, the X50-105 and ISO 10006 norms on concepts and the X50-107 norm on the certification method. Historically, the main application fields of AFITEP notions in France were civil and process engineering.

To describe the assets and limitations of project management practices in France when projects are characterized by a high innovativeness level, four factors are considered:

- the objectives and goals;
- the approaches;
- the tools;
- the competences.

Objectives of Project and Innovation Management

Project management is not recent as it was applied within cathedral building during the 12th century. This

know-how was the result of a long learning process called 'compagnonnage': a system of training apprentices. The first formalized methods, including PERT, appeared during the 19th century.

Today project management goals can be clearly summed up: to optimize financial results while transforming customer demand into a measurable object (a bridge or a building for example). Through projects characterized by a beginning and an end, companies try to achieve a triple objective: to control costs and set the agenda while improving performance.

Whereas project management focuses on profit, innovation highlights the concept of *value*. This is the consequence of international competition but also of methodological constraints. As a matter of fact, in the case of projects without innovative aspects, planned or referential budgets are generally defined during the early stages. Moreover, contracts with the customer guarantee any occasional over cost (O'Connell, 1999). On the other hand, as ideas and concepts move (some times radically) throughout the innovation process, notions such as risk instead of guarantee, and global impact measurement instead of expense control represent major top management concerns. Innovation is linked with multidimensional goals and as a result with multidimensional evaluation including variables such as: finance, competitiveness, notoriety, novelty and knowledge acquisition.

Approaches

Project management is highly influenced by the concept of a dominant operational logic focusing on a hierarchical succession of phases (Heerkens, 2000). Among others, approaches consist of: needs analysis, feasibility study, development, construction and closing (Bonner, 2002). Cost estimation is developed within study steps while cost control is carried out within realization phases. The end of a phase is specified by a marker and backwards tasks are avoided as much as possible.

On the other hand, innovation managers gain useful insight by using (Bück, 1999):

- a divergent process (enlarging the solution research area) in alternation with a convergent process (selecting more valuable solutions);
- iterative approaches: succession and repetition of steps including regular calling into question of outcomes;
- phases put in parallel.

Moreover, innovation is consistent with experimental approaches. Testing represents a major know-how improvement process. People involved in innovation face new problems, new scientific subjects. But, studies are not the only way to get the new required expertise. Some important information emerges only from a confrontation with actual production or selling tests.

Tools

Literature attests to the existence of many methodological tools in the field of project management. They allow profitability evaluation, market quantification, investment comparison and financial risk and resource planning. Nevertheless, in numerous innovation success cases, project management tools (information processing) lead to decisions different from those taken by top management. Entrepreneurs, when questioning the outcomes of formal analysis, applied the successful strategy: in France market studies were negative before the launching of the 'Espace Car', the future leader in the multipurpose vehicle market. Therefore, project management tools contain evident limitations within contexts characterized by newness. Among others, two explanations can be proposed:

- the reliability of information is often weak in the case of innovation (acceptability degree for example). Consequently, project management tools considered as data processing methods produce unreliable outcomes;
- project management tools describe static situations while innovation is a dynamic process. The launching of an innovative product modifies the characteristics of the environment of the company: for example the market size may be greater thanks to a new image of the product through innovation. The volume of chocolate eaten with coffee in France doubled as Firm M (see Appendix 1) proposed its innovation. Thus, managers lack references within their analysis: positive or negative correlation between the launching and the variables describing the environment being almost impossible to forecast.

This is particularly important when considering risk evaluation tools. Risk analysis approaches (Monte Carlo method for example), suggest that the best solution is linked with the weakest degree of risk. But, examples given previously show that this risk reduction policy presents strong limitations.

Competences

Project managers have a special interest in some basic abilities such as rigor, communication competences and technical skills (Tidd, 2000). Innovation highlights some complementary abilities. Creativity remains fundamental as innovation emerges from projects (Boylston, 2000). Curiosity is an asset to invest in approaches such as technological forecasting or benchmarking. Moreover all individual skills facilitating the cognitive phenomena are important.

In conclusion, project management methods and tools attest of strong limitations in the case of innovative projects. In the following section we will detail some of the characteristics of innovation piloting.

2.2. Key Aspects of the Emerging Piloting Approach

Adopting a Constructivist Approach

As described in the previous section, to enter into a process of innovation requires abandoning dynamics of reproducing facts in favor of the dynamic of creating value (Hamel, 2000). The consequences are a renewal and improvement of the ways of thinking, exchanging and working together. This evolution highlights the following needs:

- to intensify the way in which a given system is studied so that a global view may be arrived at;
- to seek a methodology to understand systems rather than to analyse or explain them.

Constructivist approaches tend to be consistent with these fundamental needs. The epistemologies developed by Simon (1974), Morin (1980) and more recently Lemoigne (1995) deal with individual modes of constructing mental approaches to reality, with the models created to read the world thereby rendering it more intelligible. As a consequence they encounter the problem of complexity and hence that of innovation processes.

Constructivist approaches are not based on the definition of strict objectives or provisional strategies or on the management of the subsequent tasks to achieve these goals. However, they enhance the description of a global development direction: what are the technologies the company tries to control, does it focus on services, what is its position in the sector, what are the priorities in terms of value acquisition? As individual or collective strategies integrate this general orientation, projects will emerge. Through constructivism, increased attention is directed to drawing up original solutions, collective acceptability, and a development process co-constructed by all the individuals involved. In Firm J, for example, one major task consisted in discussions within the company about this question: how to become a supplier of people piloting high technology equipment from a previous situation as a producer of cutting machines to be driven? From this, different projects arose aiming at the evolution of the product, the company image and its logistics organization. Few individual obstacles to changes could be observed as the future (rather than a diagnosis of previous performance) led the evolution. Coordination between different projects was facilitated thanks to the socialization element inherent in the development direction.

Constructivism lends importance to the process of knowledge production more than the discovery of stable knowledge. It admits both the constructed and constructive character of any competence created by man. One example is the case of Nippon Roche Company (Nonaka et al., this volume). Its 'Super Skill Transfer' consists in transferring to every medical representatives of the company some tacit knowledge

developed by high-performing representatives. Constructivism is therefore an epistemology of invention production by doing. It seeks to invent, build, design and create projective knowledge and could be considered as a representation of phenomena creating meaning, designing the intelligible with reference to a project (Lemoigne, 1994).

Constructivists state that piloting innovation consists in achieving a project building management based on this idea: the future is not written, it has to be constructed through the interactions between individuals and groups of people. It aims at coherence when thinking global and acting local.

In practice, managers' attention is directed toward:

- the definition and diffusion of the global direction for the development of the company;
- the knowledge emergence or acquisition mode: how teams collect and process information, what are the reference models of people (what are the basic individual mental representations, do people develop several reasoning modes when faced with problems, are there common representations of the future within the team?), how individuals transmit new knowledge to the other members of the group, how to improve collective experience by analysing on going activities;
- the actions changing the borders in management practices: multidisciplinary teams, internal mobility, outsourcing design activities;
- the creation and stimulation of networks: co-designing, partnership;

Development of a Value-Oriented Strategy

In France, several disciplines (economy, management, and engineering sciences) investigate the notion of value.

Our purpose is not to establish a complete overview of the notion of value. We shall quote only some fundamental elements. Economists measure value according to two references: the utility and the physical quantity. Two things are then considered: the costs of obtaining the necessary quantities of the product and the price that the consumer is ready to pay to acquire it.

Later, by taking into account the tastes and needs of consumers, the notion of 'value in use' appeared: value is bound to the reported needs/satisfied needs. The value of a product is specific to the company, its environment and the type of user: a cutting machine that works with a jet of water does not have the same value for a sawmill operator as for a micromechanics manufacturer.

Value is also personalized and characteristic of the industrial system in the same way as the technology. It is represented by different variables: financial margins, skills, technical objects . . . But also individual aspirations: the product also translates the motivations and

the moral values of the individuals who are associated with its production. If the tasks relative to the production of a 'high tech' object motivate the staff, this object will have more value for them even if it generates less profit than a classical product.

In France, the value notion is generally defined as:

- financial: a profit created to allow the survival and/or the development of the company;
- strategic: an advantage over existing competitors or new competitors (an idea defended by Microsoft);
- intellectual: knowledge or new know-how which represents a possibility of future development: sale of licenses, potential reduction of costs (the value owned by Toyota in the 1990s with the development of the 'Just in Time' concept). We can also refer here to Nippon Roche experience (Nonaka et al., this volume);
- commercial: measured in market share;
- functional: the product supplies a supplementary service which is significant for the users (for example, the first multipurpose vehicle of the French car manufacturer, Renault);
- bound to the degree of newness: for the customers, the product appears innovative;
- bound to notoriety: value is attached to image as with Coca-cola or Nike;
- hedonist: it is the pleasure and motivation of people who work. Indeed, the craftsman/woman looks at his/her creation with pride;

The value of a product is therefore the result of these eight constituents. Thus, one can consider it as a spatial extension of the notion of performance. Value gives performance a pluridimensional character. It is objective, subjective and evolutionary over time.

If there is a real value, there is also a beneficial effect for the customer or the user, for the producer and for the various partners (suppliers, financial). The notion of value is thus relative to the receiver. It is evolutionary and conditioned by the context, which surrounds it.

In practice, innovation or new value creation thus supposes (Sarlemindj, 1988):

- the capacity to integrate different dimensions based on an 'organizing principle' called: the vision. This allows the understanding of the phenomena by synthesis or by simple analysis;
- the opening of possibilities which is translated by a greater number of configurations;
- access to a global vision;
- meaning to be given to individual and collective actions;
- increased openness and flexibility.

In fact, we note a development of value oriented strategies and a switch from a risk reduction objective to an opportunities capturing approach.

A Management Through Three Levers: Strategy, Piloting, and Sparking

All our observations lead to the question 'is there an integrative process for steering innovation?' This integrative process would be based on the following notions:

- a continuous value development dynamic relies on the integration of various physical processes (design, quality) through a steering process (tools, reasoning, organization) that is oriented towards the development of new values;
- changing the way of considering a situation or an object favors the emergence of new concepts (for example the TRIZ method);
- considering disturbances, uncertainty and paradoxical situations as opportunities constitutes a way to spark innovation;
- innovation is linked to the concept of the learning organization (Nembhard, 2000).

Using a systemic model designed by Lemoigne (1995), suggests the following description of the process of piloting innovation:

- the functional pole represents the production of the process: in the case of innovation, the steering process leads to the design of a new industrial activity and its launching. To sum up, we propose the *confirmed strategy* as a result;
- the ontological pole describes the very nature of the process: in the case of innovation, the steering process is made up of reasoning activities and actions. Intellectual operations and human actions make innovation happen. That is the *sparkling* pole;
- the genetic pole is represented by basic evolution mechanisms: in the case of innovation, the steering process is controlled through project management. More precisely, this integrates methodological tools, organization, indicators and all aspects of evaluation. This constitutes the *piloting* tasks.

This *strategy/sparking/piloting* model seems helpful for a better understanding of the global constructivist supervision of innovation.

In fact, the systemic approach suggests a two level model (Fig. 5). Each of the three poles can be defined as a *strategy/sparking/piloting* submode.

Considering the *strategy* pole, for example, the following elements may be described:

- *the sparking of strategy*: all tasks stimulating or being a resource to strategy design. This includes: technological forecasting, benchmarking;
- *the piloting of strategy*: all variables structuring the definition of the development strategy (Gavidarayan et al., 2001). This includes: the use of grids (Meyer grids for example) or structured approaches (Porters Value chain for example);

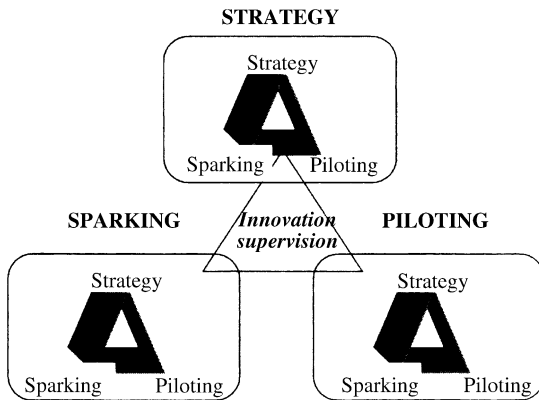

Figure 5. A nine pole systemic representation of the global supervision of innovation.

- *the strategy of strategy*: the very fundamental decisions concerning the global evolution of the company. Among others: the basic techniques the company invests in, know how to buy.

This model is useful to determine the possible impact of decisions or actions on innovation. It captures a broad spectrum of tasks: technical studies, organizational changes, management practices. It is also consistent with a value improvement objective and/or a new value nature strategy. Thus, managers can analyze the construction and the influence of their decisions and actions on projects. As a result, this model facilitates the constructivist management of innovation. It ensures a certain level of consciousness about the global evolution of value variables throughout the project. It also enables researchers to observe and define the position of any innovation phenomenon thanks to the nine poles.

Taking the example of technological forecasting into account, efficiency depends on:

- *the sparking of strategy*: is the information gathered really at the origin of new project ideas and of successful strategic decisions?
- *the piloting of strategy*: is technological forecasting a way to organize strategic design by structuring information and inducing an agenda?
- *the piloting of sparking*: as a consequence of collecting external information, do people involved in innovation develop their reasoning modes, enrich their mental representations, become more open to change and more creative?

Our team is carrying out on-going research in France to validate this model and to precisely define its strengths and limitations.

Conclusion

The ways in which specialists are considering innovation are numerous and very diversified. And yet is this

not the direct consequence of the intrinsic nature of the innovation process?

Of course, one can argue that research in this field is recent, but a consensus seems to be emerging concerning technological innovation. Technical innovation can be considered as:

- complex;
- uncertain;
- a process of technical, cognitive and social transformations;
- formal or not.

Innovation can be considered through various references scales: structures (production or services organizations), teams or individuals. One can also consider all the company's activities or just the innovative projects. Furthermore, the way of acting is a key factor in a process of innovation. We saw that in many cases, new concepts emerge from action, resulting from individual or collective experience.

Finally, an ideal innovation process does not exist. Each technological transformation is characteristic of the project, the finality of the firm, its environment, and the period studied. When one compares the evolution of two projects in an industrial system, one can notice strong differences in most cases. One of the reasons is that the piloting of innovation results from 'engineering', that is to say a capacity to adapt basic knowledge in order to lead a project (for example, the development of an innovative project and/or an innovative industrial system). This leads to the development of new competences and so to new jobs in order to respond to this new way of acting.

The constructivist approach to innovation management shows that the success of an innovative project is based on an organization and piloting methodologies, adapted well through out. Furthermore, one of the key factors of success is located on the team project quality. In this way, a new element emerges: the 'integrating agent', whose role is to help people to develop new ways of acting, the opening up toward a culture of relationships and diversity. This highlights the need for new competences, such as:

- To be able to imagine the possible in the impossible;
- To be able to concretize the 'thing' by passing from 'real' to 'possible' (i.e. the idea), and to return from 'possible' to 'real' (i.e. the action).

Perhaps this is more a question of leading individuals toward the discovery of new possibilities, making them aware that there is always another way of posing a question or a problem and thereby, considering the constraints involved in a different light. This is a real new turn of spirit which may be developed in order to promote a new kind of manager: 'business entrepreneurs', capable of:

- anticipation;
- curiosity;
- facing risk;
- managing uncertainty and the irrational.

Appendix 1: Panel of Firms

Figm	Activity
FIRM A	Industrial activity is based on an invented process transforming wood waste into insulation. FIRM A manages an experimental production unit and a subsidiary involved in technology trading. Both activities represent twenty employees and an international technology user network working under license.
FIRM B	SME working in the electronics sector. Their new product is a beverage vending machine. FIRM B invests in trading and vending machine stock operating whereas machine production is totally undertaken by external partners.
FIRM C	In the mechanical sector, FIRM C is the largest of our panel : 250 employees, producing turbo-compressors for international automotive customers.
FIRM D	Top management is committed to the launching of the large and innovative product family of the 21st century. The 200 employees of FIRM D manufacture towing trailer trucks.
FIRM E	Here, the business is design, assembly, selling and maintenance of workshop doors. Customers are manufacturing companies as well as supermarkets and hospitals. FIRM E numbers 35 people.
FIRM F	In the wood sector, this firm of 10 persons produces outdoor community playgrounds. The originality of its catalogue is its major competitive advantage.
FIRM G	FIRM G and FIRM E have the same shareholders. Firm G (25 people) produces and installs professional partitions. Top management has targeted an innovative product range.
FIRM H	Firm H (20 employees) is in the furniture sector. Their new product reflects radical innovation in the sports equipment sector.
FIRM I	The 150 employees of FIRM I manufacture agricultural machine components. FIRM I is involved in a continuous innovation strategy (new surface treatment process, new materials, . . .)
FIRM J	Firm J has 80 employees and a national agency network. The central structure is in charge of the design and assembly of road verge cutting machines while agencies sell and maintain these machines.
FIRM K	Firm K (50 people) innovates by integrating the concepts of ergonomics and biomechanics in the design of its products: manholes.
FIRM L	Firm L produces cheese and is involved in the renewal of its product range (45 people).
FIRM M	The confectionary market is changing. The traditional products of Firm L are being replaced by products based on chocolate eaten daily with coffee.

Promoters and Champions in Innovations: Development of a Research Paradigm

Jürgen Hauschildt

Institute for Research in Innovation Management, University of Kiel, Germany

Abstract: The success of innovations is to a great extent dependent upon the activities and the abilities of individuals who enthusiastically support the new product or process. In the Anglo-Saxon world these persons are called ‘champions’, in Europe the term ‘promoters’ (in the Latin version) is in use. This chapter presents 30 years of research in this field on both sides of the Atlantic. To date, we know for sure that a specific division of labor between three types of promoters is the most effective and efficient constellation. First, innovations need a technical expert who acts as ‘promotor by expertise’. Second, innovations need top management’s sponsorship by a ‘power promotor’. Third, innovations need boundary spanning skills of a ‘process promotor’. The ‘troika’-model itself is influenced by the size and the diversification of the company and by the complexity and newness of the innovation.

Keywords: Innovation; Champions; Promoters; ‘Troika’ model.

Phases of Development

Phase 1: The Discovery of the Champion

Josef Schumpeter can be credited with being the first to draw attention towards the *entrepreneur* in innovation processes, in a book published in 1912 (Theory of Economic Development, Leipzig). The entrepreneur creates new combinations, on a discontinuous basis, in totally new forms, in an act of creative destruction. He brings forth new products, introduces new production methods, opens up new markets, conquers new sources of supply or reorganizes (Schumpeter, 1931, p. 100). The ‘dynamic entrepreneur’ was thus characterized and described. Apparently, this was sufficient to incorporate him into economic models. To understand him as a real person or even to analyze him in further detail seemed superfluous.

That changed when Schon (1963) introduced a new term for this creative individual: the ‘*champion*’. The term which has dominated discussion to date was thereby established for the Anglo-Saxon countries. In contrast, in the German-speaking countries this term was not accepted because of a slightly negative connotation.

About ten years later, this precedent phase came to an end, when almost simultaneously in three different

parts of the world, mutually independent studies focused on individuals in innovations in empirical investigations. They confirmed that committed and enthusiastic persons play a decisive role in promoting innovations:

- in *Germany*¹ in 1973, Witte (1973) investigated the first procurement of computers. In his survey he proved that the existence of ‘promoters’—as he termed the champions—led to significantly higher levels of innovation and of activity than found for processes in which such individuals were absent (‘COLUMBUS’ Project);
- in the *USA* in 1974, Chakrabarti (1974) discovered that product champions could be found chiefly in successful cases in the further development of NASA innovations (‘NASA Study’);
- in *England* in 1974, Rothwell (1974) and his team, conducting research into innovations in chemical processes and scientific instruments, found that the human factor was a key determinant for the success of innovation (SAPPHO Project).

¹ For the development of German empirical research on promoters in the last 25 years see Hauschildt & Gemünden (1998).

The breakthrough was thus achieved: the importance of the human factor was established beyond doubt. Many research projects, particularly by Howell & Higgins (1990), have confirmed over and over again that identifying the champions or promotors in innovation processes is not a great problem. They normally stand out clearly because of their original contributions and/or because they make quite deliberate use of their power to push the innovation process. Consequently, it is easy to identify the active individuals in the innovation processes. *Champions are no longer merely literary figures, but empirically observable individuals who can be described using suitable quantification conventions and who are clearly successful.*

Phase 2: Confusion

The three seminal studies were not the only ones, but they were the ones which dealt most clearly with the human side of innovation. Other studies published in the early 1970s by Rogers & Shoemaker (1971), Langrish et al. (1972), Globe et al. (1973), and Havelock (1973) should be mentioned. As a rule, these studies identify more than one outstanding individual simultaneously present in innovation processes. The single champion, however, is the exception. Different terms were thought up to distinguish these committed individuals from another. The initial consequence was a confusing *variety of terms* in the literature (Chakrabarti & Hauschildt, 1989), often colored by the language used in normal practice. The following is a small selection:

Inventor, initiator, stimulator, legitimizer, decision-maker, executor, catalyst, solution giver, process helper, resource linker, technical innovator, product champion, business innovator, chief executive, technology promotor, power promotor.

This plethora of terms for those who actively promote innovation processes has even increased since then. More terms can also be found in publications being addressed to practitioners:

Political coordinator, information coordinator, resource coordinator, market coordinator, management champion, decider, planner, user, doer, expert, person affected, process promotor, relationship promotor.

Roberts & Fusfeld (1981) did not just describe this variety of terms, they also had them caricatured in a particularly impressive manner.

But what was the outcome?

On the *negative side*, complaints included confusion, lack of clarity, redundancy of terms and encouragement of different schools of thought. Researchers are not exempt from the ambition to establish 'their' terms and to provide evidence that the distinctions they have

selected are particularly useful either for further research or even for direct application.

On the *positive side*, variety became apparent. The fact that a different number of individuals with different functions would be found in different innovation processes was established as a certainty. As a result, the question of the cause and effect of these differences could be raised.

Phase 3: Order

Alok Chakrabarti & Jürgen Hauschildt stood amazed in front of this bewildering variety. They saw it as their first task to establish order so that further research could follow a systematic concept. This concept had to take into account the two functions of an organization: first, to efficiently regulate the *work* to be done, second, to effectively regulate the *power* relationships between the incumbents. We took the terms for those engaged in innovation processes to express certain *activities* performed by them during the process, or certain *power bases* from which they derived their influence on these innovation processes. This produced the following twofold distinction by contributions and power bases (see Table 1).

Phase 4: Explanation of Success

(1) The first studies on the champions in the Anglo-Saxon countries differed from the German promotor studies in one very significant point: in the publications of Rothwell et al. (1974) and Chakrabarti (1974), the *paired comparison approach* was used. The intention was to identify the characteristics which distinguished successful cases from unsuccessful ones. This approach was undoubtedly focused, drawing on the basis of everyday experience and academic topologies, but was not driven by concise theory and did not test a theory in the strict sense.

This is the most prominent difference from the German research conducted under Witte (1977, 47 ff.). He first of all developed a *theoretical concept*, which explains why the presence of promotors improves the success of the innovation process. Witte worked with the hypothetical construct of *barriers*: resistance to the innovation is due to the barrier of *ignorance* and due to the barrier of *unwillingness*. Promotors commit enthusiastically to the innovation and help to overcome these barriers. Witte's promotor model contains three core theorems:

- (1) each type of resistance has to be overcome by a specific type of energy. The barrier of unwillingness is overcome by *hierarchical potential*, the barrier of ignorance is overcome by the use of *specific knowledge in a certain technical field* (correspondency theorem);
- (2) these types of energy are provided by different people. The *power promotor* ('Machtpromotor') contributes resources and hierarchical potential and the *technology promotor* ('Fachpromotor')

Table 1. Roles in innovation management.

Activities and roles in innovation management	
Activities	Roles in innovation management
1. Initiation of innovative process	Initiator, catalyst, stimulator
2. Development of a solution	Solution finder, solution giver, idea generator, information source
3. Process management	Process helper, connector, resource linker, idea facilitator, orchestrator
4. Decision making	Decision maker, legitimizer
5. Implementation	Realizer, executor

Source: Hauschildt & Chakrabarti (1988, p. 383)

Power bases and roles in innovation management

Power bases	Roles in innovation management
1. Knowledge specialty	Technology promotor, technical innovator, technologist, inventor
2. Hierarchical potential	Power promotor, chief executive, executive champion
3. Control of resources	Business innovator, investor, entrepreneur, sponsor
4. Organizational know-how and communication potential	Process promotor, product champion, project champion
5. Network know-how and potential for interaction	Relationship promotor

Source: Chakrabarti & Hauschildt (1989, pp. 165–166); Gemünden & Walter (1995, 973 ff.)

contributes specific technical knowledge to the innovation process (theorem of division of labor); (3) the innovation process is successful when the power promotor and technology promotor form a *coalition* and are *well coordinated*, i.e. when they really co-operate (theorem of team-interaction).

The promotor model is thus based on the specific use of *power bases*. In addition, however, close cooperation between the promotors is also important. Witte chose the term ‘tandem structure’ (or ‘dyad’) for this, in the sense of two horses harnessed to a carriage in tandem.

Using a sample of 233 initial acquisitions (by purchase or lease) of computers, the empirical test showed that not only were much more innovative solutions found, but that the work also proceeded much faster and with greater diligence in those cases where such a tandem structure was present (Witte, 1973).

(2) It is undoubtedly true to say that one significant contribution made by promotors lies in overcoming resistance to an innovation. However, this assumption is also a target of criticism of Witte’s concept: the promotors do more than just cope with conflicts. This is particularly true when the opposition, overall, has a loyal attitude, as the findings of Markham et al. (1991) prove. The original promotor model was in essence, a conflict-handling model. However, this view distracts from the informative and creative aspects of innovations. After all, innovations are particularly characterized by the fact that information is newly generated and/or a combination of them. Furthermore,

innovations are processes of problem definition, goal formation, generation and identification of new combinations. When Witte’s model was developed, these *cognitive tasks* were given less consideration than the *conflict-handling functions* of the promotors. The cognitive tasks could probably supply a different theoretical base for the interaction among the promotors.

The research by Ancona & Caldwell (1992) went into this *interaction of cognitive and conflict-handling activities by the champions* in more detail. The Ancona/Caldwell study determines four characteristic areas of activity by factor analysis.

- ‘Ambassadorial activities’: Formation of goals and blocking of opposition, above all conflict-handling activities.
- ‘Task coordinator activities’: Coordination, negotiation and interface management, also basically conflict handling.
- ‘Scouting activities’: Obtaining information, building expertise, seeking solutions, clearly cognitive activities.
- ‘Guard activities’: Prevention of an undesirable leak of ideas and information, activities which are not covered by our concept.

This seems to us to provide sufficient evidence of the cognitive contributions of the promotors. The comprehensive model explaining the human influence on the innovation process must definitely combine cognitive and conflict-handling activities.

Phase 5: Systematic Differentiation of the Division of Labor in Contingency Models

(1) The variety of the incumbents which emerged in the wake of the Witte, Rothwell & Chakrabarti studies raised two questions:

- ‘What effect does such variety have?’
- ‘What determines it?’

The traditional *contingency view* of organizational theory could thus also be applied to innovation management.

The next question was:

- How do external circumstances affect the number of promotors and, the way in which they approach the division of labor?

(2) Witte’s (1973, 1977) findings had already indicated that the division of labor between the technology promotor and the power promotor was clearly a phenomenon of *firm size*. Rothwell (1974) and his research team proved that the *industry* is a determinant of division of labor. The *degree of innovativeness* and the *degree of diffusion* of the innovative products or processes also influence the division of labor. With the increasing diffusion of the innovation in an economy, the importance of the technology promotor declines. Maidique (1980) arrived at similar results.

If we put these findings together, we find *two influences superimposed* which are important for the division of labor in innovation management: *system complexity* and *problem complexity*. The resulting *overall complexity* has to be compared with the capability of the active individuals. If there is a considerable discrepancy between the complexity of the innovation and personal innovative capability, the two center model of division of labor has to be modified. This assumption was confirmed by Lechler (1997) in his survey of 448 projects.

Maidique (1980) dealt with the type of instance where more extensive division of labor becomes an inevitable result of *high system complexity*. In the simplest case, in a small, entrepreneurial company, a *two-center constellation* of technology promotor and power promotor is found. According to Maidique, a *three-center constellation* is typical in medium-sized companies with a functional structure which are still limited to one product line. A *four-center constellation* is to be found in very large, diversified companies.

(3) The many and varied completed research projects which have been analyzed by Hauschildt & Chakrabarti (1988) contained many references to three-center constellations. To find an explanation, we applied the complexity concept, based our work on Witte’s concept and identified a third species of promotor: the *process promotor*. Process promotors are needed when innovations affect a very large number of individuals

personally, in relatively large institutions, and trigger conflicts. Like other promotors, process promotors rely on specific power bases: *on system know-how*, *organizational and planning power*, and *on interactive skills*. They, too, overcome characteristic forms of resistance: those of an established organization whose aim is to execute routine procedures as efficiently as possible and which rejects innovations as a disruption of its smooth running. Process promotors do not have the formal authority of the power promotor or the expertise of the technology promotor. They rely on leadership qualities and influencing tactics, and like the other two promotors they are characterized by the fact that they take risk and are prepared to sink or swim with the innovation. The study of Howell & Higgins (1990) demonstrated this side of the process champion in particular. This was confirmed for the German-speaking countries: the successful ‘interactive project managers’ are particularly characterized by a high level of interactive skills, cooperative leadership, above-average problem-solving capabilities and constructive creativity (Medcof, Hauschildt & Keim, 2000).

Building on Witte’s concept of the ‘tandem structure’ we call the team of three the ‘*troika*’ of *power*, *process* and *technology promotor*. In a study of 133 innovation projects in the mechanical engineering industry, we found that this troika structure achieves better technical results, but above all, better economic results, than any other structure (Hauschildt & Kirchmann 2001). These findings correspond with the investigation of Lechler (1997).

In a case research study of ten major innovations, Folkerts (2001) presents new perspectives of the promotor model. Using a role concept, she interprets the promotors as clusters of functions and not necessarily as individuals. She finds the three clusters, i.e. the types of promotors, that are present in each stage of the innovation process. But their roles can be fulfilled by different persons with changing contributions.

Figure 1 summarizes the conflict handling and cognitive activities in the division of labor between the promotors in the troika structure.

(4) Finally, Gemünden & Walter (1998) indicate a further modification of the troika concept: they point out that more and more innovations require *cooperation with external partners* in the value-chain, i.e. with customers or suppliers. There are barriers in this cooperation, too. Just as promotors are needed to eliminate in-house barriers, they are also called upon to overcome extramural barriers of interaction. The barrier concept is developed similarly to Witte’s theoretical approach. In place of the process promotor, who overcomes in-house barriers only, Gemünden & Walter’s concept includes the ‘*relationship promotor*’. In a study of 94 technology transfer projects, they proved that processes are more successful if a person is present who deliberately establishes and maintains relationships with the partners.

In summary, research initially proved that an active, committed champion was the most important factor for success in the management of innovations. However, at the same time a variety of other persons were observed who were also striving to make the innovation successful. These individuals could be distinguished by their contributions and their power bases. The successful impact of these individuals is due to their skills in dealing with conflicts constructively and handling information creatively. Finally, we know that the extent and type of the division of labor among these individuals is determined by the complexity of the innovation problem to be solved and by the complexity of the organization concerned. Accordingly, the troika structure consisting of power promotor, process promotor and technology promotor in particular, is the most successful structure for the management of typical innovation projects within a company. It is possible that the increase in extramural innovation activity will shift the role of the process promotor more towards that of a relationship promotor.

Possible Routes for Future Research

As we ask: “How is the research process likely to move forward?”, we are entering the realms of science fiction. One can see four routes in future, three of which are theoretical, addressing the problem of *explanation*. The fourth route is directed at the

application of the promotor or champion concept in practice. Let us first of all go down the theoretical routes:

Route 1: Further Details on the Promotor Model

Any serious academic will have no great difficulty in spontaneously reeling off a list of questions which the current body of research cannot answer, or cannot answer satisfactorily. It follows logically that a whole generation of academics can be occupied with identifying and proving further details of the promotor model. We see the following as the most pressing questions:

- Which *key events* stimulate individuals to act as promotors of innovations?
- *How do promotors come together?* The fuzzy front end of innovation is normally lost in mystic obscurity. This phase, when the promotors come together, is a stage which can obviously only be described in social and psychological categories.
- And once these promotors do actually encounter one another—how is the *personal fit* determined and secured? A good fit is essential for the subsequent innovation project to come to a successful end with all its difficulties, and to get it completed in the face of all resistance. Such teams need considerable group cohesion in order to withstand all the pressures from outside.

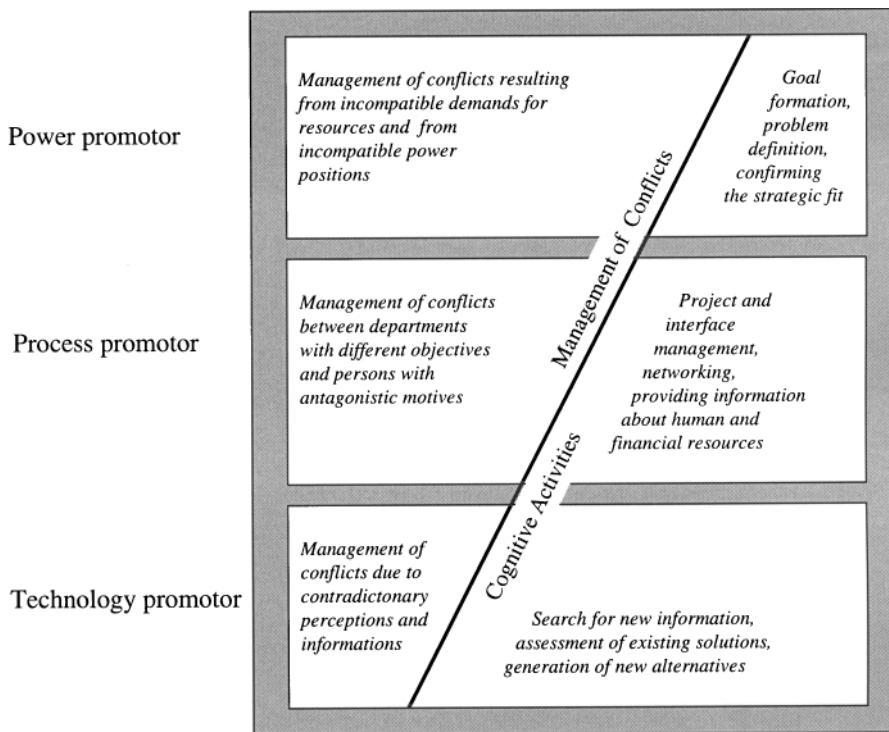

Figure 1. Management of conflicts and of cognitive activities in the troika structure.

- We know very little about the conditions under which promotor structures are *dissolved*. Even if a promising promotor team comes on the scene at the beginning of a process, it is by no means certain that it will see the process through and complete it successfully. On what reefs might the tandem or troika founder?
- The interaction of the promoters and champions is couched in somewhat mysterious terms as ‘*good cooperation*’. What does that mean specifically? We know very little about whether and how the individual promoters have to take a hand during the innovation process. Do they play changing roles? Do they always appear as a team? What contribution is absolutely essential for which key occurrences?
- Does the promotor model apply *regardless of time and space*? Organizations have changed in the last 20 years: they have become more open, more tolerant of conflict, more process-related, more project-orientated, more targeted, more risk-aware, more informative, and more cooperative. New forms of organization have developed. As a result, the types of resistance have changed. Does the promotor model have to be adapted to these organizational developments?

Let us stop here. The trend is obvious: the deeper one delves into the concepts of leadership and management, the more questions about the details and development of the promotor structures will arise.

Route 2: Extension of the Promotor Model

(1) The promotor model is based on the concept of resistance. Only vague theoretical concepts filed under ‘brakers and drivers’ or ‘devil’s advocates’ or ‘loyal opposition’ are currently available to describe the people who embody such resistance. The opposition model by Witte (1973), Chakrabarti & Hauschildt (1988), and Gemünden & Walter (1998) objectivizes the resistance but does not personalize it. It should be asked how *opponent structures* are formed and behave—in accordance with the development of promotor structures. Can an innovative solution with a successful overall outcome be explained through the dialectic of promoters and opponents?

(2) A second corresponding model refers to the firm’s partners in the innovation process. If we accept the premise that more and more innovations will be inter-organizational processes, the question of *corresponding promotor structures* arises: The promotor and champion constellation of a firm could be envisaged in that of the cooperating partners, like a mirror image. The hypothesis would be that the success of the inter-organizational depends upon corresponding promotor structures.

Route 3: Focus on Supporting Instruments

Research to date has been based on the tacit assumption that promoters or champions alone determine the

success of innovations, without additional supporting instruments or backing. That is, of course, not the case. Actually, success does also depend on other means, which are certainly not neglected by research. However, we know little about the reinforcing or attenuating effects with regard to the human constellation:

- Informal *information and communication* is quite certainly a major factor for success in innovation. And it is also definitely true that promoters quite clearly tend towards an informal interactive and communication style. To this extent, the two effects seem to reinforce one another. But what does informal information and communication mean in the age of electronic media? What type of informality is expected and useful? Is formal information obsolete or even disadvantageous?
- Promoters and champions are active ‘temporarily’, for a brief period. They have the end of the innovation process in mind. What awaits them then? On the surface, this concerns the question of *incentives*, of rewards, of penalties, of all types of sanctions that firms hold in reserve for successful or unsuccessful managers. The problem is so acute because promoters and champions generally do not only commit themselves because of extrinsic drivers, but intrinsically. They get involved, they commit, they are not called in or appointed. How does a firm react to such self-appointed activists? How does it deal with failing or unsuccessful innovators?
- What role does the change in *organizational or corporate culture* play in the readiness to participate and the success of promoters and champions in innovation processes? Even if we no longer accept the classical dichotomy of ‘mechanistic’ and ‘organic’ organization culture, Burns & Stalker (1961) nevertheless show that there is a problem: the more mechanistic an organizational culture is, the more important power promoters are. The more organic it is, the more important process and technology promoters are. The forms of organizational change mentioned above tend more to indicate that organic forms are gaining in importance. Will the role of the power promotor become obsolete?

These three routes may initially be significant more from the theoretical point of view—but we have now learned that there is nothing so practical as a good theory which explains and forecasts reality. To this extent, the contrast between theory and practice—or in our interpretation, between explaining and doing—is much less important than claimed so often.

Route 4: Focus on Application

(1) Innovations are projects, but not all projects are innovations. How far can the practically orientated proposals of *project management* be used in innovation processes? The following striking point emerges from

an analysis of the literature on project management and on innovation management:

- The project management literature emphasizes formal organizational tools for project support, such as matrix management, project controlling, network planning, cost control, information management. In contrast, it devotes much less attention to the human aspects of project management.
- The literature on innovation is quite different. Here, considerable skepticism prevails about formal organizational tools, while at the same time the human perspective on the management of innovation processes is emphasized.

The following question thus arises: Can the domains and overlapping areas of project management and innovation management (promotor concept) be more sharply defined?

An analysis of the available research results prompts the following conclusions:

- Quite clearly, the *degree of innovativeness or the complexity of the innovation problem* is of major importance to the human management of the process. Lechler's (1997) research findings show that, in particular, 'strategic' projects of high complexity with a high degree of innovativeness can be progressed successfully by a troika constellation. It is notable that the formal organizational coordination tools of participation, planning, control, information and communication play a minor role. The promotor concept can be recognized very clearly here: the troika of promotors substitutes for formal coordination;
- The *basic notion* by which the innovation is driven is important: if the *innovation is driven by its end* (demand pull), with new technologies being sought to meet known objectives, this is the domain of the project management concept. However, in *means-driven innovation* (technology push), a known technology is available for which a completely new application is being sought. In this case, the innovators must free themselves of the earlier constraining ties and relationships. They are much more dependent on spontaneous ideas and ad hoc creativity. Collaboration with customers or other external partners in the innovation process play a more important role. Means-driven innovation is the domain of the promotor concept;
- A third influence on the application of certain process management models undoubtedly are the *phases of the innovation process*. Innovation processes generally have a relatively long, relatively fuzzy front end phase in which the problem has to be defined and the objectives have to be generated. According to all the findings available, this phase seems to be a domain of the promotor and champion

concept. After completion of this definition phase it is possible to think about transferring the problem into a 'project', i.e. of institutionalizing it, setting a time frame on it, scheduling it, giving it accountability and responsibility, a formal structure for interaction. Empirical findings advise a certain amount of caution here, since the leap from the 'loose' to the more 'tight' phase is not at all clearly mapped out. Nevertheless, it would be wrong to approach innovative projects from the start with the toolkit of project management, developed for routine situations. It would also be wrong to practice the full openness of self-management in the realization phases, which would allow many sections of the process to be repeated.

- (2) A further practical question arises in the light of the frequent observation that champions or promotors occur 'spontaneously' and that their emergence is not amenable to organizational intervention. At first glance, it seems that we have to inquire resignedly whether this is a question which may satisfy our intellectual interest in explanations, but not our practical interest in 'doing'.

It is obvious that the cooperation of promotors or champions cannot be obtained by force. But it can be facilitated. This calls for opportunities or nurturing conditions which improve the chances that these creative spirits will get together. Thus, we are propagating the *idea of 'meeting points'*: a firm should create opportunities for those people who show an enthusiastic interest in a certain technological or market-specific segment to meet, to become acquainted, to evaluate and appreciate one another. We are thus putting in a plea for meeting places, for informal opportunities for communication, for regular, institutionalized, open and non-hierarchical meetings.

Perspectives

Effectivity and effectiveness of innovations are, and will be, dependent upon:

- (1) whether or not the promotors will commit themselves to the innovation;
- (2) how individually the promotors will react to changing opposition;
- (3) how early the promotors will assume their roles and their responsibilities in a conscious division of labor;
- (4) whether or not the promotors have some experiences in the management of innovations—even in other roles;
- (5) whether or not the promotors are willing and able to make themselves familiar with the domains of the other promotors;
- (6) whether or not one of the promotors will accept the additional role of a 'relations promotor' in case of external cooperations;

- (7) whether or not the promotors will be supported by the innovation culture of the firm.

Innovation and Leadership

Jean Philippe Deschamps

International Management Development Institute (IMD), Switzerland

Abstract: This chapter is about innovation leaders, those critical senior executives which top management sees as the linchpins of its innovation process and the ‘evangelists’ of an innovation and entrepreneurship culture. It will start with a well-accepted list of generic leadership imperatives as they relate to the specific challenge of innovation. It will continue by listing the common traits of innovation leaders in terms of personal profile and behavioral attributes, also derived from the author’s research. The chapter will end with a discussion of the beliefs and management philosophy on innovation leadership adopted by some innovative companies and top managers (CEOs and CTOs).

Keywords: Innovation; Leadership; Innovation management; Innovation champions; Innovation attributes; Leader profile.

Innovation leadership? It is passion; it is learning; it is humility in front of mistakes and errors—understanding that they are necessary elements to learn faster than the others—and it is the target setting . . . yes, stretched targets!

Pekka Ala-Pietilä (2001)
President of Nokia

Introduction

Is innovation just one of the common dimensions of business management? Or is it a special domain that requires a different type of leadership, unique attributes or talents? If the former is true, then most, if not all, business leaders should excel at innovation, provided they pay attention to it, of course. This doesn’t seem to fit with practice. Few of the revered leadership icons celebrated by the media for their achievements in shareholder value creation could claim that innovation is their forte. Most would not qualify as innovation leaders. And the opposite also seems to be true: Not all innovation leaders are fully-fledged business leaders. It is, therefore, reasonable to postulate that innovation may require a special leadership profile. If this is true, then we should try to find out how to recognize and develop innovation leaders so we can leverage their talent. This chapter describes some of the main characteristics and attributes of innovation leaders, and also tries to identify what makes them so special.

What do we mean by ‘innovation leaders?’ We are talking here neither about front-line innovators in R&D or marketing, nor about entrepreneurial middle managers. The general profile of these creative, determined individuals is relatively well known because it has attracted the attention of business scholars. Many stories have described how these mavericks have managed, against all odds, to convince their organizations to allow them to pursue their visions and then pushed them through.

Innovation leaders are senior executives—whatever their functions or positions—who spontaneously instigate, sponsor and steer innovation in their organizations. Even in the face of resistance from their top management colleagues, these executive champions always stand up for innovators and challengers of the status quo. Hauschildt (this volume) calls these champions ‘promotors’ and distinguishes between three types: ‘promotors by expertise’, ‘power promotors’ and ‘process promotors’, who need to work as a ‘troika’ to stimulate and support innovation. Whatever their types, true innovation leaders tend to share the same determination, i.e. they are unafraid to risk their credibility with top management in case of failure. Lewis Lehr (1979), the highly charismatic former CEO of 3M, described the behavior of an innovation leader very convincingly when he said: ‘We learned to follow the fellow who follows a dream!’

The ideal place for an innovation leader is, obviously, at the head of the company or one of its

businesses. The archetype of the innovation leader is the CEO of the company he or she has helped create. Famous names spring to mind: Edwin Land at Polaroid, Robert Noyce at Intel, Steve Job at Apple and, more recently, John Chambers at Cisco or Jeff Bezos at Amazon. But it is restrictive to refer to such charismatic entrepreneurs as the *only* innovation leaders worth considering because it tends to make the management of established ‘old-economy’ companies feel excluded, and thus authorized to abstain from promoting that special form of innovation leadership. There are, indeed, innovation leaders in most large, mature organizations, although top management does not always properly acknowledge or recognize them. So, we should extend our definition of innovation leaders to include those critical senior executives who—with or without top management blessing—act as the linchpins of the company’s innovation process, the ‘evangelists’ of an innovation and entrepreneurship culture.

Some of the core characteristics of innovative organizations have been amply described in the management literature (Drucker, 1985; Quinn, 1985; Knox, 2002). Jones & Austin (2002, p. 160) highlight five core characteristics of ‘innovation leaders’ from their research:

- In-depth customer insight;
- Leading-edge technical awareness;
- Inspirational leadership;
- Motivational organizational rewards;
- Sharing knowledge.

But these ‘differentiators of enhanced innovation performance’, as they call them, relate more to the collective management of innovative companies than to specific individuals. There has been no formal attempt, yet, at brushing a comprehensive portrait of ‘innovation leaders’, as defined in this chapter.

For the most part, innovation leadership is discussed either by innovation management researchers in the context of the role of top management in innovation (Bessant, this volume; Katz, this volume; Senge, 1999; Tidd et al., 1997; Van De Ven et al., 2000) or by leadership scholars mainly within the topic of ‘leadership and organizational change’ (Robert, 1991; Schrujjer & Vansina, 1999; Shamir, 1999) involving, for example, such concepts as ‘transformational leadership’ (Bass, 1999) and/or ‘effective leadership’ (Yukl, 1999). However, not all managers are leaders and not all leaders are innovation leaders. Likewise, not every organizational change leads to innovation as well as not every transformational leadership implies innovation leadership. The phenomenon of innovation leadership thus remains terra incognita from a research viewpoint, being partially known primarily from some (auto) biographies of famous innovation leaders (Grove, 1996; Morita, 1987). This chapter is based on a new direction of research, which tries to analyze specifi-

cally the profiles and attributes of innovation leaders, as defined earlier. This portrait will, by necessity, be more impressionistic than realistic and systematic because it will have to fit a great diversity of characters. It will be built through a succession of brush strokes, each one adding a layer to our description of the special form of leadership that fosters innovation.

We will start with a broad-brush description of the key challenges in innovation, and derive from them a few general leadership imperatives for senior corporate officers. We will also define innovation leaders by what they do specifically to make innovation happen. We will then look at the two main phases of innovation, and identify the various leadership styles and profiles needed to steer them. We will complete our portrait of innovation leaders by listing some of their apparently common personal traits and behavioral attributes. We will end with a discussion of the beliefs and practices of some innovative companies that effectively identify, develop, motivate and retain innovation leaders.

The Innovation Leadership Imperatives

To start, it is useful to recall some of the essential aspects of innovation—the ones that most innovation leaders would probably put on the top of their lists—and reflect on the challenge they raise for business leaders. We will focus on six of these innovation imperatives:

- the urge to do new things;
- an obsession to redefine customer value;
- the courage to take risks;
- an ability to manage risk;
- speed in spotting opportunities and project execution;
- a shift in focus and mindset from business optimization to business creation.

Innovation Requires an Insatiable Urge to Try New Things

It is trite to say that innovation is about challenging the status quo and introducing new and, one hopes, better products, processes, services or management approaches. Fundamentally, innovation requires curiosity, experimentation and openness to change. Innovation leaders are therefore likely to be found among managers who constantly challenge the present state of affairs in their companies, and encourage wild ideas about doing things very differently or even doing new things.

The challenge for innovation leaders is to encourage their subordinates to try new things and experiment, despite the fact that such encouragement is usually not the surest way to move up the management hierarchy. The urge to challenge the status quo, in society as in family life, is normally viewed as the privilege of youth. With maturity, we believe, people normally calm down and become considerably more tolerant of the current state of affairs. This belief applies to

companies as well. The desire to change things is an accepted—if not always welcomed—behavioral trait of young managers. To climb the ladder, however, managers are expected to demonstrate maturity and realism. And this often means exhibiting dependability and predictability. Challenging the status quo is encouraged only when the situation is bad enough to call for some fundamental changes. Otherwise, testing the status quo is accepted solely if it does not put the company at risk and if it leads to success. The right to fail is generally limited; not by words, for sure, but in speed of promotion. Despite frequent management denials, many companies still live under the ‘If-it-ain’t-broken-don’t-fix-it’ banner. Therefore, under the pressure for order and stability, innovation leaders must have the courage to foster a climate of experimentation and permanent change in their organizations.

It is not surprising, consequently, to find few mavericks and highly charged innovation champions in most top management circles. The career progression rules in mature companies favor managers who deliver results without making waves, not corporate activists. The creators of ‘managed or organized chaos’, so dear to innovation scholars (Peters, 1987; Quinn, 1985), often meet obstacles on way to the top of their organizations. To stimulate innovation, however, it is incumbent on companies to promote ‘challengers’, not just ‘fixers’.

Innovation Requires an Obsession to Redefine Customer Value

Innovation has to do with adding value, and the way to add value is through leadership, argues Nick Shreiber (2002), CEO of Tetra Pak, an innovative company and world leader in liquid food packaging:

Adding value is a worthwhile goal in any endeavor, and is particularly true in professional life. One can add value in many ways. The most important, perhaps, is through leadership—a very elusive concept! Just like good judgment, good leadership is hard to define, but you know it when you see it! Leadership can inspire an organization to reach goals it had never dreamed of, and will encourage each employee to reach his or her full potential in pursuit of their objectives. Inspired leadership will encourage new ideas through innovation and entrepreneurship, and will provide the resources to implement them.

In hindsight, highly successful innovators have generally established new standards of value in their industries. For a long time, value creation has come primarily from revolutionary, technology-based products or processes. Michelin redefined the notion of value in tires—as expressed in mileage life—with its radial tire technology, and Sony did something similar with its Trinitron TV screens. So did Pilkington with its revolutionary low-cost flat-glass process. What is new,

perhaps, is the fact that value creation is now felt to come also from introducing radically new business models or management methods. It is no longer necessary to have been a great technical innovator to qualify as an innovation leader. It is by radically changing the economics of the PC industry—some would say forever—not the product itself, that Michael Dell (2001) can arguably be called a great innovation leader:

People look at Dell and they see the customer-facing aspects of the direct-business model, the one-to-one relationships. What is not really understood is that behind these relationships lies the entire value chain: invention, development, design, manufacturing, logistics, service, delivery, and sales. The value created for our customers is a function of integrating all those things.

W. Chan Kim & Renée Mauborgne (1997) postulate that redefining value starts with questioning current industry assumptions and imagining a new value curve. They advocate asking four probing questions:

- Which of the factors that our industry takes for granted should be eliminated?
- Which factors should be reduced to well below the industry standard?
- Which factors should be raised well above the industry standard?
- Which factors that the industry has never offered should be created?

Consciously or instinctively, innovation leaders challenge industry assumptions in order to unearth opportunities for a quantum jump in customer value. An obsession for customers often fuels this urge to redefine value. Value creators, typically, have an insatiable curiosity for their customers’ needs, empathy for their conscious or latent frustrations, and an instinct for what they might need or want in the future. As Akio Morita (1987) eloquently stresses in his story of Sony’s legendary *Walkman*TM, this type of curiosity is not synonymous with a thirst for traditional market information. No market research, he posits, would have indicated a need for the *Walkman*TM. Morita (1987) is referring, rather, to the kind of customer intimacy that comes from a deeply ingrained, quasi-instinctive curiosity. Sony’s recent advertising slogan: ‘You dreamt it! Sony made it’, reflects the company’s view of its innovation mission: redefine value constantly by right-guessing the customer’s unarticulated desires, and applying its technological expertise to satisfy them.

The challenge for innovation leaders is to encourage this constant reappraisal of value factors, despite the fact that, at times, such an attitude may prove highly destabilizing. Challenging the current ways of delivering value in your industry is, indeed, very difficult when you are an established player and, a fortiori,

when you are the market leader. Defying the status quo is much more natural for new entrants looking for ways to challenge incumbents. This is why many innovations have originated with outsiders who forced their way into the market with radically new concepts.

The story of easyJet (Kumar & Rogers, 2000), the latest—and highly successful—European no-frills airline, is a good illustration of this rule. Its founder, Stelios Haji-Ioannou, a typical innovation leader, challenged every single prevailing assumption in the traditional airline industry¹ to come up with a revolutionary business model. This gave him unbeatable low costs and allowed him to redefine the notion of value for Europe's budget-conscious air travelers. Haji-Ioannou carved out a fast-growing share of the European budget airline market. Arguably, it would have been very difficult for any European flag carrier to introduce such radical changes internally. The defenders—companies like British Airways or KLM—had no alternative but to create their own budget airlines by emulating easyJet's business model. But, given the constraints these new airlines inherited from their established owners, imitation proved impossible.

Innovation Requires the Courage to Take Risks

One of the most widely recognized drivers of innovation is management's willingness to take risks. It is, nevertheless, hotly debated because the very concept of risk-taking is subject to all kinds of interpretations. In its classical definition, risk-taking for innovation is related to the concept of entrepreneurship, i.e. being ready to bet one's resources on a new, hence untested, business proposition.

The challenge for innovation leaders is to live up to this principle in the day-to-day reality, and make their managers down the ladder comply with it as well (Perel, 2002). Indeed, if many companies advocate risk-taking as one of their core values, how many fail to change their performance review and reward systems to make them congruent with that belief? We seldom hear stories of managers being penalized for not taking risks, as long as they are meeting their budgets. The right to fail comes up in most innovation speeches, but it is not necessarily applied across the board.

Andy Grove (1996), Intel's legendary former CEO, adds two very interesting dimensions to the risk-taking imperative. First, he claims that innovation leaders must have the courage to focus, which means identifying unambiguously either the things they will *not* do, or the things they will stop doing. The decision to

abandon the fabrication of D-RAM memory chips in order to concentrate on microprocessors was, reportedly, one of the toughest decisions Andy Grove (1996) and his management team ever had to take. Yet, it is this kind of foresight and gamble that enabled Intel to mobilize all its R&D resources for manufacturing microprocessors and, ultimately, to build its success. Second, Grove (1996) believes that innovation leaders must have the courage to 'self-cannibalize', i.e. to make their own business obsolescent before others force obsolescence on them. As we all know, it takes courage to kill one's own products before milking them fully, and replace them with higher-performance, but unproven ones. Arguably, it is this policy, coupled with management's belief in the now-famous Moore's law² that enabled Intel to stay on top of its industry for so long. Whereas the willingness to take entrepreneurial risk applies to all managerial echelons, Grove's (1996) observations apply only to the highest level of innovation leaders, say, the CEO, and this is why they are so relevant.

Innovation Also Requires an Ability to Manage Risk

The debate about acceptable levels of risk in an innovation project often pits risk takers (usually the project champions) against risk-containers (typically senior managers). Without risk, argue the former, there will be no innovation. Yes, respond the latter, but without proper risk-management, there will never be any successful or affordable innovation. Innovators often complain that the controlling attitude of their top managers hides a fundamental aversion to risk. And the more conservative proponents of risk-management often suspect risk-takers of being irresponsible. But this debate is fruitless because both arguments are obviously right. Innovation is as much about good risk-containment and management, as it is about risk-taking. This is well known to development engineers, who are increasingly adopting sophisticated approaches to minimizing design risk.

The challenge for innovation leaders is, therefore, to strike the balance between dogged, enterprising risk-taking, and pragmatic, cautious risk-management. The first attitude is necessary for pushing ahead and brushing away objections. In a sense, front-line innovation champions should be so determined and persistent that they can be accused of being both blind and stubborn. Innovation leaders carry the burden of ensuring that all the known risk-factors have been identified at each stage and properly managed. And this needs to be done, one hopes, without discouraging innovators and entrepreneurs.

¹ Point-to-point connections using low-cost airports and without prearranged connection possibilities; direct sales (90% through internet), by-passing travel agents; sales staff paid on commission; no fixed prices for tickets (extensive use of 'yield management methods'); no tickets; one type of aircraft; no business class; no meals; etc., but high punctuality level and unbeatable prices.

² Gordon Moore, one of Intel's founders, predicted in 1965 that the number of transistors inserted on a silicon chip would double every 18 to 24 months. As Intel tried to follow that 'law', it became a kind of self-fulfilling prophecy.

A dilemma arises whenever the CEO or the Business Unit Head is simultaneously both the champion of a particular project *and* the leader, who is supposedly responsible for containing risk. No manager will dare oppose his or her hierarchical head by spotlighting dangerous risk factors on the boss' favorite project. The story of Philips' ill-fated CDi³ illustrates that danger. It was well known in Philips that its CEO, Jan Timmer, had adopted the CDi as his pet project, as he had successfully championed the CD-Audio years earlier. Many in the company argue today that the CDi concept had inherent flaws, and that its proponents blindly underestimated the competing PC-based technology: CD-ROM. But hardly anyone, it seems, dared openly challenge the notoriously tough Jan Timmer. It took Philips a few years and huge losses to abandon the project.

A similar story can probably be told about Robert Shapiro's energetic pursuit of the market for genetically modified organisms (GMOs) at Monsanto. As CEO, Shapiro was consumed by the vision of Monsanto becoming a life-science powerhouse on the strength of its genetic engineering technology. And he was convinced that realizing his vision meant betting the company's future on GMOs and promoting them aggressively worldwide. But experts are likely to point out that after the controversy over the company's commitment to GMOs erupted in the media, Monsanto's top management failed to grasp the power of the arguments of GMO's detractors. It is hard to be a visionary, risk-taking innovation champion while, at the same time, being a cautious risk-analyzer and container. This, nevertheless, is the challenge of innovation leaders.

Innovation Requires Speed in Spotting Opportunities and Project Execution

Silicon Valley innovators and entrepreneurs have known for a long time that the best idea or the best technology does not necessarily win; the winner is the one that is implemented first (Rogers & Larsen, 1984). Whoever comes first learns fastest. Success with new products comes from launching first, then learning fast to correct mistakes, before others have readied their response, and relaunching a superior product as competitors start coming in. That kind of speed requires three unique skills: (1) an attitude characterized by searching continuously for opportunities; (2) a great deal of management decisiveness at all stages in the process; and (3) speed in execution, typically achieved through a pragmatic reliance on external and internal resources, and, of course, highly effective teams (Cooper, this volume).

Innovation leaders instinctively create an environment that values the search for opportunities and the generation of ideas to exploit them. They typically encourage people to flag opportunities very early and make their ideas bubble freely upwards for discussion. The challenge lies in the decision process. On what grounds should the project go ahead? What criteria should be met at each stage? When and on what basis should the plug be pulled? This challenge relates directly to our previous discussion on risk-taking versus risk-containment. As the champions of risk-taking entrepreneurs, innovation leaders are bound to allow their staffs both a fair amount of freedom to experiment and the necessary resources. Yet, as advocates of a cautious approach to managing risk, they must ensure that the funding justifications required from their teams are commensurate with the investment amounts requested. Finding an acceptable balance is a challenge, and so is the necessity to decide fast, whatever the decision. In Silicon Valley, innovators usually get the same advice from venture capitalists: if you are going to fail, at least fail fast and fail better.

Innovation Requires a Shift in Focus and Mindset: From Optimizing Business to Creating Business

Most managers see their career progress first through managing a function, and then—if they are of a high enough calibre—through running a business unit and later, a division. Unless they come from R&D, few are asked to manage large projects as their prime job. Their *raison d'être* and training is managing and optimizing what already exists, not create something new. And if they do happen to innovate, it is as part of their normal business responsibilities. Indeed, business unit heads are generally responsible for new product development in their fields. Nevertheless, even in such cases, innovation is generally pursued to protect and grow the current business, seldom to create new businesses. This is why most companies struggle to exceed the growth rate of their industry. How can Unilever or Nestlé grow in the mature food industry, except by creating entirely new, hence fast-growing product categories? Now that the second-generation mobile phone market is nearing saturation, the same question applies to Nokia and Motorola. Creating new businesses is completely different from tweaking product lines to introduce extensions.

So innovation leaders face a double challenge. The first is to strike the right balance between running the current business and growing new businesses, or as Derek Abell (1993) advocates, between mastering the present and pre-empting the future. The sudden shift in what financial markets demand in the way of share performance—yesterday: growth potential; today: profitability—makes finding the right balance a tough task. Katz (this volume) addresses this dilemma by referring to a series of models to help companies avoid

³ CDi: Compact Disk interactive, a precursor of CD-ROMs and DVDs, introduced by Philips towards the end of the 1980s and abandoned in the early 1990s due to the growing success of CD-ROMs.

the ‘tyranny of success’ and learn to ‘organize both incremental and disruptive innovative activities’. The second challenge for innovation leaders is sensing market opportunities and choosing promising areas to pursue. Here, innovation leaders must have the ability to shape a vision that will guide them towards new business opportunities.

What Innovation Leaders Really Do

If we follow John Kotter’s (1990) research and track what innovation leaders really do, we will note that they excel at six fundamental leadership tasks:

- breeding or attracting and retaining innovators and entrepreneurs;
- formulating a clear innovation vision, and setting innovation priorities;
- charting a roadmap towards their vision, and mobilizing people to implement it;
- accepting the risk of spotting and backing new ideas;
- assembling and nurturing complementary teams of champions; and
- building an innovation process and culture.

The Innovation Leader as a ‘Magnet’ for Innovators

Marvin Bower (1997), McKinsey’s legendary Managing Partner and leadership guru, postulates that ‘... a business should be run by a network of leaders positioned right through the organization’ (Bower, 1997, p. 6). This postulate probably applies more to innovation leaders than to any other types of leaders. Indeed, innovation is never the result of a single person’s efforts, neither at the project level nor at the sponsoring level. As the well-known saying goes, ‘It takes only one “No” coming after nine “Yeses” to kill a project’. Innovation is always in danger if it hangs in the hands of an isolated innovation leader in the top management team, whatever his/her charisma. The first roles of an innovation leader are, therefore, breeding or attracting others to take on leadership roles, propagating innovation values, and supporting concrete projects.

It is relatively easy for innovation leaders to build a team of subordinates who share similar values and behaviors, for two reasons. First, people tend to be attracted by their likes. And second, unless they are authoritarian (which sometimes happens), innovation leaders usually exude a high level of openness and communicate enthusiasm, to say nothing of passion. Working for them is generally exciting.

The situation is more complex at the top management level. Innovation leaders, unless they occupy the top job themselves, may be unable to influence the profile and behavior of their top management colleagues. They can only muster CEO support. If they show growth and results, they can hope to propagate their values through sheer emulation. When they have established a reputed nursery of talent in their organi-

zations, they can also volunteer to transfer some of their best and most motivated staff into other divisions, in the hope of initiating a bottom-up movement of contagion.

The Innovation Leader as a Vision-Builder and Priority Setter

Many people disagree on the very nature of the innovation process. Innovation practitioners, particularly in R&D, often believe in serendipity. They argue that, most of the time, innovation occurs in an unplanned and somewhat erratic fashion, fuelled by randomly generated new ideas and new inventions in search of an application. They claim that the innovation process is often an a posteriori rationalization of a series of trials and errors. It is the result of constructive experimentations by curious and determined individuals who are able to sense a market opportunity behind a serendipitous idea or discovery. The now-famous development of 3M’s *Post-it*TM pad provides a near-perfect illustration of this non-linear, ‘bubble-up’ innovation process. As everyone knows by now, it all started with two determined and inventive engineers trying, on their own initiative, to find applications for a strangely weak glue that had failed all of 3M’s classic sticking tests (Nayak & Ketteringham, 1986).

Innovation leaders, in contrast with some of these front-line innovators, do not want to rely only on serendipity. They cannot accept their role in innovation being limited to a kind of benign *laissez-faire*, i.e. to hiring creative people, giving them the freedom to experiment, and hoping that some innovation will emerge! True innovation leaders tend to be more deterministic. They believe that innovation can also result from management ambition and vision. In addition to the traditional ‘bottom-up’ approach, they strive to create an organized ‘top-down’ process, starting with a broad vision of environmental changes that are creating new market needs, and selecting priority areas for further exploration. The initial vision, albeit often vague at the outset, determines the boundaries of the search area and triggers a focused pursuit of concrete product or service opportunities. Following such a vision-led process, innovation is no longer random. Would-be front-line innovators in marketing or R&D receive a mandate to explore a number of well-defined areas management has identified and prioritized. Their task is to generate the best ideas, concepts and solutions for implementing the vision.

Tetra Pak’s worldwide success in liquid food packaging provides a compelling illustration of such a vision-led process. Ruben Rausing, Tetra Pak’s Swedish founder, did not build his company on a serendipitous discovery. Rather, he was animated by a vision of transforming the antiquated milk distribution system that prevailed in 1950s Europe by adapting it to the mass-retailing supermarkets that were emerging.

For the first time, someone tried to optimize a package by creating value throughout the chain, from producers to users, via transporters and retailers. It was Rausing's vision that a package should save more than it costs that led him to search systematically for rational container shapes and efficient filling systems. That search led him, in turn, to invent the first tetrahedron package, now called *Tetra-Classic*TM, and a few years later, the ubiquitous *Tetra-Brik*TM. And it was this very same vision and ambition to add value to his dairy customers, retailers and consumers that brought him, after a few years, to introduce the first aseptic filling systems and packages. This innovation created an entirely new product category: UHT⁴ milk and juice.

Even if they are not visionaries personally, top managers cannot shirk the task of specifying where they expect to see innovation happen in their company. If they want innovation to support their business strategy and priorities, instead of occurring randomly, they need to point towards specific privileged directions. Where do we need to put our innovation priorities and for what purpose? Which market or segment do we want to rejuvenate? On what aspect of our value chain do we want to concentrate our efforts? To what unmet or ill-met customer needs do we want to give priority?

The Innovation Leader as 'Vision Roadmapper' and Implementation Planner

Visions alone do not change things. If they remain vague dreams or ambitions, without any concrete implementation activity, they do not mobilize people either. Innovation leaders get personally involved in charting a roadmap towards their vision; they direct their implementation teams. The involvement of innovation leaders in implementation will, obviously, vary according to the nature of the challenge and the management level at which they operate.

When they occupy the top job, innovation leaders are usually keen to choose, or at least influence the choice of the leaders of their critical corporate innovation projects. They typically see their role as providing strategic direction, empowering, releasing resources, and ensuring that obstacles to implementation are removed. When Jürgen Schremp, DaimlerChrysler's CEO, formulated the vision of his group becoming one of the first automotive manufacturers to offer fuel-cell powered cars, he clearly left it to others in his management team to plan how to achieve that ambitious objective. Nevertheless, as CEO, he surely played an important role in assigning the mission to trusted aides, and in clearing the way for

extending the scope of the company's technology and business alliances, notably with Ballard Power Systems, the Canadian fuel-cell engineering specialist, and with Ford Motor Company, DaimlerChrysler's strategic partners.

When they sit at the supervisory level, such as the Executive Committee, innovation leaders may actually get much more involved, for example, in supervising innovation teams. Many companies—Tetra Pak is one of them—have adopted the practice of having a member of their top management team personally coach each major corporate innovation project. This involvement brings about two major benefits. First, it provides the team with a high-level supporter and protector. A senior coach can shield a team from the natural tendency of any corporate hierarchy to encroach on its autonomy, and thus reducing its level of empowerment. Second, the senior coach is exposed to the day-to-day reality of the project, and hence shares the team's experience and learning.

Nearer the level of operations, the innovation leader may actually direct the overall project, taking responsibility for charting the project path from vision to implementation. Years ago, when Hiroshi Tanaka, Managing Director of Canon's Office Products Development Center, became the official champion of the company's ambitious 'family copier' project, his challenging mission could be summed up in very few words: develop a very small, service-free personal copier to retail under \$1,000. His first role as innovation leader was to develop a game plan that would meet his CEO's vision. This meant planning the project management organization, the project itself, the way to fence competitors out, and the launch and rollout. As the anointed innovation leader for this undertaking, his task was not only to chart a path for a breakthrough mission, but also to convince his sceptical team that the job was feasible, and ultimately, to lead them to success (Deschamps & Nayak, 1995).

The Innovation Leader as a 'Spotter and Backer' of Good Ideas

As noted earlier, innovation calls for a delicate balance between risk-taking and risk-containment. Innovation leaders are constantly confronted with this difficult challenge since they are usually the ones who are in contact with, and manage front-line innovators. Consequently, they tend to get involved very early in evaluating new product, process, service or business ideas. They decide, alone or as part of a group, which ideas they should bet on, shelve for a while, or diplomatically turn down.

Obviously, it is critical for the innovation leader to take the right decision. A good flair is needed to ensure that interesting opportunities are not passed over, and that business resources are not squandered on useless pursuits. The difficulty comes from the fact that creative ideas cannot be evaluated with the same

⁴ UHT: Ultra High Temperature, a conservation process that maintains most of the qualities of fresh (i.e. pasteurized) milk or juice while allowing it to keep, unopened, for months in ambient conditions (i.e. unrefrigerated).

methods and certainty as other types of management decisions (Mannarelli, 2001). They cannot follow the traditional approach through which most companies analyze investment opportunities, e.g. with a detailed justification analysis leading to a single 'Go/No Go' decision point. They need to go through a process of progressive refinement and risk reduction, with funding in phases and in proportion to the removal of major uncertainty factors. This always involves a high degree of management ambiguity that innovation leaders need to accept and explain to their management colleagues.

To preserve the motivation of their creative staff, and hence maintain a positive innovation climate in the future, innovation leaders must ensure that decisions on new ideas are discussed, taken, justified and communicated through a transparent process. This is why having a single person playing the role of 'judge of ideas' is ill advised, particularly if the judge happens to be the 'idea submitter's' direct supervisor.

Some companies have publicly identified (with contact numbers) a number of influential 'idea sponsors' or 'idea advocates' over their corporate intranets. These special types of innovation leader have multiple roles:

- identify the kernels of opportunities behind the raw idea;
- help the originator of the idea to argue it;
- assist in 'packaging' the idea for a presentation to management;
- defend it against hasty negative judgments in management discussions; and
- coach the initial idea validation phase until the next review point.

Increasingly, innovative companies entrust this important screening and backing of ideas to a collective body, which some call an 'Innovation Council'. Whatever its name, this innovation management mechanism bears the important responsibility of selecting the best opportunities for company or business unit funding. There are many advantages in delegating this important task to a management group, instead of a single manager:

- broader and more formal review of the idea's merits and risks;
- more objective assessment through multiple perspectives;
- more credible justification for decisions (positive or negative);
- a pool of resources for coaching initial projects;
- more visibility and transparency in evaluating and selecting ideas.

But the key advantage is the possibility for top management to bring innovation leaders together—traditional and conservative managers should be kept

out of such a body—to give them a chance to influence the flow of new corporate projects.

The Innovation Leader as 'Assembler and Composer' of High-Performance Teams

The team is at the heart of most, if not all innovations. Few advocates of innovation teams are more vocal than the folks at Ideo, America's leading design studio and innovation culture evangelists (Kelley, 2001). A commonly heard saying at Ideo is "Enlightened (team) trial and errors succeeds over the efforts of the lone genius". To reflect the sense of passion that animates design teams as they work on an innovation project, Ideo calls them 'hot groups'.

As the firm's ultimate innovation leader, Dave Kelley—Ideo's founder and CEO—devotes considerable attention to the process through which teams are assembled and formed. Because he believes that teams perform better when they are made of volunteers, he has instituted a very original approach to forming teams. The company is organized around 'hot studios', a Hollywood-like system for quickly building teams around projects and disciplines (Kelley, 2001). Under this approach, studio heads—Ideo's second-level innovation leaders—do not pick the teams they need. They simply describe the project for which they are responsible and the location they will be using; designers then select the projects they want to work on. . . and their leader. Ideo managers are also keenly aware of the fact that it takes a lot of positive reinforcement to turn a group of inspired individuals into a 'hot team', even if it is made of volunteers. This is why they devote so much time and effort thinking about how to make their managerial and physical environment friendlier for teams.

Traditional companies will object that Ideo is a maverick organization. They are right. But while the management style at Ideo may be unorthodox, when it comes to the attention its leaders bring to composing their teams, it is certainly not an isolated case. The experience of large Japanese technology-based companies shows a similar pattern. In firms like Canon or Toshiba, the highest-ranking innovation leader is usually the Chief Technology Officer (CTO), or Chief Engineer, whatever his title. These senior managers are usually not hierarchically responsible for R&D departments, which often report to divisional or plant management. Nevertheless, they consider it one of their key tasks to advise on the leadership and composition of important new product development teams. Japanese innovation leaders actually make up their own 'hot teams' with the same devotion and care as a barman mixing an exotic cocktail. They look for balance in age, seniority, experience, skills, personality and even mindset. This contrasts sharply with many of their Western counterparts who sometimes assemble teams rather rapidly on the basis of staff availability. So, if great products come from great teams, it is

undoubtedly a key task of the innovation leader to build such teams very carefully.

The Innovation Leader as Builder of an Innovation Process and Culture

At their inception, most companies were innovators. They were born from the vision and ambition of their owners, for sure, but this vision usually focused on a market opportunity and an innovative idea for exploiting it. At their early stage, innovative companies typically benefit from a strong, almost instinctive entrepreneurial culture. Most probably, very few spend much time building and formalizing what we would today call an innovation process, i.e. a systematic and repeatable approach to generating innovations.

Over time, as they grow in size and complexity and as new management replaces the founding team, many of these early innovators lose some of their natural entrepreneurial spirit. In exchange, though not always, they develop more formal methods, procedures and mechanisms for managing their innovation process, which Bessant (this volume) calls ‘routines’. Such processes are certainly helpful and at times indispensable, but they do not completely substitute for culture. World-class innovators such as 3M—the most frequently cited innovation archetype—typically combine culture *and* process. Their innovation culture, which promotes individual freedom, learning and sharing, favours creativity, experimentation, risk-taking and teamwork. Their innovation process adds a market-, technology-operational and economic discipline in the way they finance and manage projects and, ultimately, go to market. Lewis Lehr (1979), former CEO of 3M, expresses well how this combination of culture and process creates a challenge for management:

Innovation can be a disorderly process, but it needs to be carried out in an orderly way. The truly good manager finds the means to manage a disorderly innovative program in an orderly way without inhibiting disorderly effectiveness.

Innovation leaders tend to recognize these two complementary dimensions and work proactively to improve them, inasmuch as their position in the company allows them to do so, of course. Actually, it is often easy to identify innovation leaders in a top management team: they are they ones who volunteer to set up and animate taskforces to work on innovation improvement tasks. Since it is generally easier to build processes than to change cultures, such taskforces often focus on streamlining or speeding up the innovation process. Unless the effort leads to excessively rigid or bureaucratic rules, this emphasis on process generally conveys a positive message throughout the organization—that management cares about innovation and is determined to enhance it. This, by

itself, often helps improve the innovation culture in the company, thus creating a virtuous circle.

Combining Different Styles and Profiles to Lead Innovation

In the past, leadership seemed to come in one flavour. It was an absolute trait of character. You had leadership or you did not. If they had ‘the right stuff’, leaders could take over almost any company and address any challenge. This simple belief in the universal application of leadership is now under question. Different kinds of leadership, we feel intuitively, may be required for different kinds of objectives. The determined leader needed for business restructuring, cost-cutting and profit improvement may not have what it takes for a growth or globalization strategy, and even less for innovation. The common denominator in leadership is the ability to mobilize, motivate and direct a group of people towards a worthwhile goal. But as the nature of the objective changes, different types of leadership, or at least different leadership styles and attitudes, are required. And this also applies within the very domain of innovation.

Innovation Leadership: The Art of Combining Complementary Styles and Profiles

If we define innovation as the process by which an invention is successfully brought to market, there are clearly two complementary facets or broad phases in this process. At its ‘fuzzy front-end’, as it is sometimes called, innovation requires a number of ‘soft’ leadership qualities: strong curiosity, sense of observation, urge for exploration, ability to detect patterns in weak signals, willingness to experiment and learn, openness to new ideas, determination to pursue risky avenues, etc. However, implementing ideas and getting them to market requires a set of very different and ‘harder’ qualities: rigor in analysis, speed in decision making, clarity in objectives, willingness to dedicate resources, ability to manage risk, skills in problem solving, sense of urgency, faculty to coordinate multiple functions, etc.

This duality of requirements is what makes innovation so difficult to lead from A to Z. At its front-end, innovation requires all the qualities related to creativity. At its back-end, it demands a considerable degree of discipline. Daniel Borel (2001), Chairman of the Board of Logitech, the innovative leader in computer pointing devices, defines the needed capability as ‘a mix of emotion and realism’.

What kind of leaders and leadership styles are needed to manage such a complex and multi-faceted process? Can leaders be found with the skills and qualities required to steer both the creative front-end and the disciplined back-end of innovation? Asking these questions to selected leaders of world-class, innovative companies like Logitech, Medtronic, Philips

or Nokia serves as an interesting starting point for further discussion.

Logitech's Borel (2001) highlights this challenge by giving his personal definition of the innovation leader:

Innovation leaders are those unique people who are able to motivate the full set of qualities you need from A to Z to deliver an innovative product. (. . .) They start from the pure innovative aspect and reward creative people, but they do not put too much highlight on them, because you also need the other person who is going to extract every penny out of a design to make it a viable product in the marketplace, so that it is affordable and profitable as well. The real leader is the one who appreciates the passion aspect, the emotion, yet is able to put it in a framework where execution is going to eventually deliver to the customer and end-user a product which is profitable for the company. (. . .) If you look into companies, it is very hard to find someone who is great in execution and at the same time great at the purely creative part of innovation. As a matter of fact the great leader is the one who is able to build a team with people who have a different psyche, and get them to work together and share the same language for the sake of the company.

William George (2001), Chairman of the Board and former CEO of Medtronic, the world's leading medical technology company, uses a sports metaphor to underscore this need for a plurality of innovation talents:

You might think of it like a (football) team. You need somebody who is going to score. You need someone who can defend. You need somebody who is disciplined, someone who can make the brilliant move!

Ad Huijser (2001), Chief Technology Officer and Management Board Member of Philips, the innovative Dutch electronic giant, concurs with this emphasis on team building:

On one hand, innovation leaders quite often express the vision behind which the troops align, but at the same time, they are very much team players because they cannot do it themselves. Innovation is absolutely a team effort, and innovation leaders know how to make and build teams, because you need a number of capabilities at the same time to make it happen. And balancing that team is a capability that you quite often see as the strong point of an innovation leader.

Pekka Ala-Pietilä (2001), Nokia's President, extends the team building scope of the innovation leader beyond the boundaries of his company. In his business—mobile telecommunications—different players for hardware, software, services and content need to

come together and understand how to contribute in the best possible way to expand the market:

We have to make sure that there are companies which can come together and win together. We feel that this is not a 'win-win' world! It is a 'win-win-win-win' world, because there are so many partners.

If innovation is a multi-faceted process requiring a diversity of complementary talents and attitudes, then we need innovation leaders who can draw the best from a diverse team. They need not only to be good team integrators, but they also need to have a deep understanding of what it takes to steer the different phases in the process. The leadership profile needed at the creative front-end is, indeed, quite different from the profile needed to support the disciplined back-end. Since very few senior innovation leaders combine these two sets of qualities, one of their key tasks is to develop other innovation leaders who will focus on and excel either at the front-end or at the back-end of the innovation process.

Leading the Creative Front-End of Innovation

The creative-variety of innovation leaders has a relatively well-known profile because it is the one most often described in the innovation literature. But how do the senior business leaders quoted earlier characterize such innovation leaders? William George (2001) sees in Medtronic's Vice-Chairman and Chief Innovation Officer, the man he dealt with in his previous COO job, an archetype of the creative innovation leader:

He was a Medical Doctor, always open to new ideas. He was always going to try something. He was always willing to put some money aside to fund a new venture that came along, having no idea whether it was going to work or not.

For William George (2001), the main qualities of this purely creative innovation leader are curiosity and tolerance:

He is really intrigued by the technology; he is very hands-on; he very much knows the products. He can take an idea and has a vision that maybe this is a kernel of an idea. It is like a needle in a haystack, but he is always looking for that needle and says, 'How can you make this work?' and not, 'Oh, that'll never work!'. Sometimes, the business leader may say, 'That'll never work! Look at all the flaws in it!' and he will say, 'No! Look, there is potential in there!' It's like taking a diamond in the rough and polishing it up to make it into something. (. . .) There is also, in that very creative innovation leader, a high tolerance for failure. In fact, he/she realizes, as I do, that most of the great breakthroughs come through failure, through an experiment that does not go as you thought it would. The experiments that go

as you think they would, all they do is confirm previous knowledge. The experiment that doesn't go that way leads you to say, 'Oh! What can I learn from that?' and then you apply that to making it better.

Philips Research, claims Ad Huijser (2001), is trying to encourage its creative innovation leaders to strike the right balance between risk-taking and risk management:

A creative environment, for me, is an atmosphere in which creativity can flourish, but at the same time is constrained by budgets, manpower, etc. So, if you want to create new things, you have to stop other things. That stimulates people to do both: to push new ideas, but also to be very critical of their own ideas, not at start, but during the course of the action.

Logitech's Daniel Borel (2001) adds an extra dimension to this portrait of the 'front-end' innovation leader: an openness to go outside and 'borrow' technology from whatever source without any trace of 'not-invented-here' syndrome:

One of the characteristics of the innovation leader is to be open-minded, but I would say open-minded in a way that goes much beyond what we call naturally open-minded, as in accepting any ideas. He/she is able to get out of the box, to look outside the company. (. . .) He/she has this ability to take input from inside, from outside, to take technology here and there, and do the equation that will bring a unique product for the user at the end of the day.

Ad Huijser (2001) concurs with these qualities—curiosity, tolerance for failure and openness to go outside—but adds two nuances. Even at the front-end, innovation leaders need to show a good dose of realism:

Innovation leaders are creative, but in a balanced way. They are not creative everyday with a new idea, because you cannot lead an organization towards innovation if you change the direction everyday. (. . .) Leadership is also about knowing when to 'pull the plug'. Starting is easier than stopping in a research environment. Stopping requires making choices and taking the enormous risk of stopping something of value. Therefore, stopping projects asks for more leadership than starting projects. Real leaders dare to make choices and say 'No', if they don't believe things will have added value for the company.

Leading the Disciplined Back-End of Innovation

Innovation obviously does not stop with the generation of good market-oriented ideas and product or service concepts. Concepts need to be fleshed out and turned

into business propositions and products that can be developed, engineered and produced time- and cost-effectively, then launched into the market. These processes constitute the critical back-end of innovation. Whereas the front-end deals with exploring and inventing, the back-end deals with planning superbly and then—and only then—'running like hell'. Surprisingly, the innovation literature is a lot less loquacious about the leadership traits required for steering these critical back-end activities. Are such leaders only good 'executors'? Is there something specific about leading the implementation of an innovation project? On this point, again, it is interesting to hear what top managers in innovative companies have to say.

The first characteristic of these implementation-oriented innovation leaders, according to William George (2001), is their urge to get new products to market:

It is the disciplined person that is going to ensure you get the new products to market, because he or she knows that it is only when you get to market that the rubber meets the road, so to speak, and creates the innovation that generates the revenues for the next round of innovation. (. . .) He or she would take a little bit less of a product, accept a less perfect product knowing that, well, we can improve it the next time around! This person is driven to get it to market.

The second characteristic, again according to George (2001), is a strong sense of discipline and speed:

In the old culture, a timetable was a goal to be shot for, and not a requirement to be met. So, if you missed it, maybe your products got delayed six months, then twelve months, then eighteen months, and everyone accepted it. (. . .) So we had to change that and that meant putting disciplines in place. (. . .) Scientists resented this at first. They kept saying, 'Are we no longer interested in real creativity and breakthroughs?' And we said, 'Oh, Yes. We are very interested, but you have to follow the discipline too (. . .) and if you can't, you are not going to be punished for it; you just can't get on board this product. The product is going to market. You need to be there'! (. . .) The business- and execution-oriented innovation leader also knows what it takes to go through the regulatory process, the quality insurance process, and the production, i.e. gearing up a production line so you are not producing only a hundred, you are producing a hundred thousand.

Logitech's chairman argues that everyone in his company has to be execution-oriented (Borel, 2001):

Execution is, at the end of the day, what will make a huge difference at the bottom line. In my career, the most productive people I have seen are the ones who, eventually, came from an angle of passion and

emotion, but were able to contain this passion and emotion through experiences that, sometimes, have been extremely expensive. (. . .) Once you have burnt yourself with a huge inventory of the wrong thing, then you learn how to integrate the value of the two sides of the equation.

Passion: The Common Trait of All Innovation Leaders

Leaders generally tend to demonstrate a high level of emotional involvement in the mission they assign themselves. This is particularly true with innovation leaders. Whether they are of the creative type and work at the front-end of innovation, or belong to the disciplined, execution-oriented group, all innovation leaders share one thing in common: a high level of energy and passion. At Medtronic, William George (2001) reckons, all senior managers share that passion:

People who had no passion for the patients, the doctors, the actual process of the company, did not fare very well in the Medtronic culture. The execution-oriented innovation leaders share the same passion as the creative-types, but it is a different way of looking at the world. In a way, they say, ‘What good is your idea if it is in a lab and never helps a patient? I want to drive it and get it to market to help patients, because, you know, these people are out there, dying every day’.

Nokia is so convinced of the need for passion that it actually selects its new entrants, whether they deal with the front-end or the back-end of innovation, on that basis as well. Ala-Pietilä (2001) expresses this conviction unambiguously:

Whatever you do, if you don’t have a passion, then you have lost the biggest source of energy. If you have teams and individuals who don’t have the passion—the passion to change the world, the passion to make things better, the passion to always strive for better results and always excel—then you will end up with mediocre results.

Developing and Retaining a Cadre of Innovation Leaders

The general debate about the origin of leadership—whether it is an inborn talent or an acquired skill—has not spared the domain of innovation. Not surprisingly, the answer to the question is the same for leadership *in general* and leadership *for innovation*. There seems to be a consensus that both result from a combination of natural aptitudes that are developed and enhanced through specific leadership development experiences. It is worth considering these two facets in some more detail: the appointment of people with the right skills and attitudes, and the personal development path that turns them into experienced innovation leaders. It is also worth asking, to round out this discussion, what

motivates, and hence helps retain innovation leaders in the company.

Identifying Innovation Leaders

Few companies seem to have developed an explicit, formal process for screening new hires on the basis of their specific potential for innovation leadership. But most classical processes for selecting candidates, be it for R&D or junior business positions, try, somehow, to detect indicators of innate or potential leadership. These provide a first set of clues on innovation leadership, of course. But other more specific pointers are worth taking into account. Not surprisingly, the various business leaders quoted in this chapter share views on what to look for when interviewing candidates for future innovation positions.

Besides checking for compatibility with their culture—a must, since most innovative companies have a very strong culture—they seem to particularly value, and look in their new hiring candidates for at least six main personality traits:

- A high level of passion, or at least energy for what they do;
- A propensity to take risks (and a track record proving that they have taken risk);
- An ability to see the big picture and think ‘out of the box’;
- An urge to keep learning and to broaden their interests;
- A sense of humility, or at least modesty; and
- A commitment to performance or excellence in whatever they undertake.

The ability to identify potential innovation leaders at entry level, as new hires, is obviously quite valuable. But it becomes much more critical later on, when the new managers make their first important career moves. Actually, the task is not too complicated. Innovation leaders are, indeed, easier to identify in practice than to describe in theory because they usually stand out from the crowd, even in generally innovative companies. It is not necessary to list all their inherent skills and attitudes in order to identify them. It suffices to highlight some of the traits that distinguish them at first glance from other equally competent business leaders. Anyone who has been exposed to innovation leaders will recognize them through their combination of unusual attributes. Not surprisingly, most of these attributes have to do with a high level of emotional intelligence and well-developed ‘right-brain’ capacity, and that is, perhaps, what makes them so special.

The first and often most distinctive trait of innovation leaders is a strong focus on customers and products. Innovation leaders share the same passion, whether they come from the purely creative side of the business—R&D, for example—or from the business

side. But that passion is not disembodied. It is embedded in their products or services. Innovation leaders love their products or services, not for themselves, but for what they do for their customers. And because they instinctively adopt the customer's viewpoint, they are never fully content with their offering. Whereas other business leaders talk daily about strategies, performance, processes and organization, innovation leaders constantly refer to their customers and the products or services they have bought or might want. And when they are part of the top management team, or even sit on the Board of Directors, innovation leaders ensure that discussions on technologies, products and customers get a fair share of all executive meeting agendas.

Those who have known him claim that Akio Morita, Sony's legendary President, was one of those typical 'product-nuts'. History has it that he always came back from trips to his research labs with plenty of miniature electronic 'gizmos' in his pocket to keep there to play with and show his management colleagues. He couldn't help communicating his love for his products, and that love became contagious.

Innovation leaders are also recognizable by their ability to 'fire-up' people at all levels with their enthusiasm. The innovation leaders we tend to notice have enthusiastic followers because they exude a sense of fun, adventure, challenge and self-fulfillment. Their ability to communicate their passion upwards to their bosses—hence to get support for their risky undertakings—is probably just as important, if not more so, than their talent to mobilize the best in their own disciples. This reflects an innate sense of communications, which certain academics would qualify as Aristotelian, since it brings to bear the three classical elements of communications: *logos*, reaching peoples' sense of rationality and logic; *pathos*, touching peoples' emotions; and *ethos*, addressing people's sense of values and beliefs (Eccles et al., 1992). Rosabeth Moss Kanter, of the Harvard Business School, postulates that leaders are characterized by the energy and persistence with which they communicate their aspirations (Blagg & Young, 2001):

Leaders must pick causes they won't abandon easily, remain committed despite setbacks, and communicate their big ideas over and over again in every encounter. (...) Leaders must wake people out of inertia. They must get people excited about something they have never seen before, something that does not yet exist.

This certainly applies to innovation leaders, and it is often what makes them so special in the eyes of their more conservative colleagues, to the point of being sometimes perceived as 'corporate agitators' or 'innovation zealots'.

Innovation leaders often stand out from the crowd through their healthy disrespect for organizational hierarchies, corporate norms and rules. They tend to be non-conformists and are sometimes considered mavericks by their peers. They are so mission-driven or task-oriented that they resent all forms of organizational or bureaucratic encroachment on their freedom and initiatives. This liberty is more easily reached at the top of the pyramid than in the middle, of course, but at any level of management, the urge remains.

Jack Seery (1997), the former head of the Overseas Business Group of Philips Consumer Electronics, is a good example of a high-level 'rule buster'. When asked how he managed to halve TV development lead-times in his overseas business group, he answered:

The product creation process in our company was getting undue attention, without due results. So, I started at the other end. I said, 'I'm not interested in how long it takes. I'm telling you how long we can stand, and it's 12 months by coincidence, and the next time it will probably be shorter. So that's our target! And the only element you have to worry about is the timing. Nothing else. (...) I want it done in 12 months. And I will give you the possibility to see why it has to be 12 months. I'll send you all out in the market place if necessary. No problem. You can have all the exposure you need, but you have to do it'. (...) I wanted our development crew, also, to show what they were worth, because I always had the feeling that because of our organization split, the development crew never realized their real potential. They were frustrated. They were always being hammered for what they didn't do. They could tell you how they could do things much better, but the system didn't permit it. So, I got the system out of their way. The rules that I banned were all the rules that were restricting them. 'Write your own rules', I said, 'but you have to guarantee me the integrity of the product at the end of the day, and you're responsible ... to me.'

Innovation leaders differ from traditional managers in their outward-orientation. They stimulate their staffs to go out and broaden their horizon. Ideo's Dave Kelley is adamant that the people who create the most value for the company are not the ones management sees all the time at their desks. They are the ones who go out in the market place to meet customers, users, competitors and suppliers. So, innovation leaders force people out into the field. Jack Seery shares this philosophy. He loves to tell how he pushed his staff to dive into the market and visit consumer electronic shops when they were traveling overseas, not just meet expatriates in the local Philips office. To give his admonition some teeth, he adopted the habit of reimbursing overseas travel expenses of his staff only upon presentation of a field

report indicating what they had learned from the market.

Innovation leaders often contrast with their colleagues by daring to defend a long-term view of the business. Companies that conduct surveys to measure their internal innovation climate often come to the same conclusion: one of the greatest perceived obstacles to innovation is management's excessive short-term orientation. Many business managers are reluctant to make a commitment to projects or undertakings with a risky profile or a long-term payback. In the eyes of innovative companies like DuPont, this common reluctance justifies continued heavy spending on central research. If business managers hesitate to invest in the long-term renewal of their products, applications and markets, the corporation must show the way. Of course, the corporation must have earmarked resources for such long-term undertakings.

Innovation leaders tend to resent the 'short-termism' of their business colleagues and will typically lobby hard with top management to be allowed to continue exploring new opportunities and keeping some 'risk-money' at hand. Medtronic's Chief Innovation Officer, alluded to earlier in this chapter, was one of those leaders with a longer-term orientation. His rank as Vice-Chairman, his personal prestige and the support he had from his CEO allowed him to operate in this long-horizon mode (George, 2001):

When an organization said, 'Well, we don't really believe in this idea!' he said, 'Fine! I'll just set up a little team over here and spend a million dollars a year, and we will finance this little team and we will let them go work on it. If you don't want to do it, fine'. And then, when it worked, all of a sudden the organization would say, 'I want it back'.

Finally, innovation leaders can be identified by their instinctive desire to keep trying harder. They never pause and are never satisfied. Richard Teerlink (1997), the charismatic CEO of motorbike manufacturer Harley-Davidson, likes to refer to what he calls the three enemies of sustained success: arrogance, complacency and greed. Innovation leaders behave very much as if they shared the same belief. The Nokia culture and values, according to its President (Ala-Pietilä, 2001), address these 'innovation killers' almost frontally:

The key elements or key attitudes derived from our values are 120% target setting, which means that we are not content with 100% target setting, because we already know how to do that. Why bother? So, in everything we do, we try to stretch the target setting to the 120% level, which means that we don't know today how to achieve that goal, but we have confidence in individuals and in teams that they will

come up with the innovative solutions which will then lead to that set target level. That is probably one of the most important and most distinct attitudes: A non-arrogant, non-complacent way of looking at the future.

Tetra Pak's Nick Shreiber (2002) stresses the same point in the leadership values he advocates:

Delivering value also requires drive—giving energy to others, bringing excitement and enthusiasm—and never allowing complacency to set in. Remember the old English saying, 'Even if you are on the right track, you will get run over if you just sit there'.

Michael Dell (2001) sees his personal role as the CEO of a maverick company very much in this way, too:

When I see things that are important, I will push on. And also by nurturing things when they are in the skunk works stage and don't necessarily have the organization's support. I am the agitator for progress and change.

Developing Innovation Leaders

The abundance of leadership programs on offer in business schools all over the world is the best evidence that innate leadership talents can be further developed. This development potential applies to *leadership for innovation* as well. In all cases, it seems, developing leadership talents and good reflexes comes from a combination of practical field experiences, coaching and feedback, and periods of reflection and self-examination. For innovation, nothing seems to replace an early exposure to the uncertainties of new product or business development projects. Innovation leadership cannot be taught; it has to be experienced. Venture capitalists know the lesson well: nothing replaces the painful experience of earlier failures and the learning that goes with them. As the Economist noted recently (Micklethwait, 1997), "In Silicon Valley, bankruptcy is treated like a duelling scar in a Prussian officers' mess". William George (2001) also emphasizes the importance of giving people the right experience:

The best development is achieved by putting people on the right road, saying to them, 'Would you take over a venture? We will put together a little team of ten to twelve people, and let's see how it comes out. Would you take over this project and run it? Start this business from scratch and see if you can create something there?' That is the real test. And then, we would give the young engineers or scientists who joined the company succeeding levels of challenge to see if they could take it on. We would give them a chance, a small budget, a small risk, to see how it comes out. And we would take the creative ones and

give them more and more responsibility, bigger and bigger projects, more and more challenge.

Ad Huijser (2001) concurs with giving scientists and engineers this type of progressive experience-building assignments. But he maintains that research group leaders will not be able to become fully-fledged innovation leaders if they stay in the cozy confines of their research environment. He believes in the learning value of exposing them to the market:

It is my conviction that, even in research, we have to build on those leaders who have business experience. They have to have been, for a certain while, in one of our business units. If not, I do not believe that they can feel the heat of the market and understand the constraints of the business area. Because in research you can say, 'The sky is the limit'. In business it is not. It is not just understanding the business context, but also being able to interface with colleagues in the business.

As suggested earlier, coaching by senior managers is generally felt to be the necessary complement to this type of experiential leadership development. Through coaching, senior managers can help would-be innovation leaders reflect on their experience. As Harvard's Nitin Nohria discovered in his course (Blagg & Young, 2001), you cannot 'teach leadership':

When I teach leadership to MBAs, I don't believe that in thirty class sessions I will immediately make them better leaders. What I hope, however, is that I have taught them the capacity for deeper and more thoughtful reflection on their experiences so that they can learn from them and therefore become better leaders.

Coaching is particularly important for R&D staff when they find themselves at the traditional crossroads of having to choose a career orientation. Do they want to go in the direction of management and take on more and more responsibilities and become innovation leaders? Or do they prefer to go in the direction of pure science and technical work, and stay as innovators? Most CTOs recognize that this choice is highly personal, and because they need both types of talents, they tend to avoid influencing their staff one way or another.

Motivating and Retaining Innovation Leaders

The obvious conclusion from the above discussion is that true innovation leaders—managers with technical knowledge and strong leadership capabilities—are rare and precious birds in any company. So one last question remains: How can a company keep its rare innovation leaders loyal and motivated, and avoid their being poached by aggressive competitors? The chal-

lenge is, of course, particularly acute in environments with a high degree of industry competition and staff volatility, like the Silicon Valley, where people shift employers very easily. One possible answer is that companies can keep their innovation leaders with compensation packages and stock options. Money is, undoubtedly, an important motivator and probably still one of the key drivers in Silicon Valley. But even in the Valley, money alone cannot buy talents and maintain loyalty. People want to work on 'cool projects', and innovation leaders tend to be achievement-oriented. They will stay if they are doing something meaningful, if they are allowed to break new ground, and if the company they work for is successful. Even in the highly competitive field of medical technology, as William George (2001) reminds us, financial incentives are not the prime driver:

I even know engineers who are offended, literally, by financial incentive programs that almost deny them the importance of their work. In many ways they want to feel that they are really doing something important, and the financial follows rather than leads.

Ad Huijser (2001) agrees:

Mobility—going to work where there is nice work—has increased tremendously. People move particularly to the areas or the places where the excitement is. I believe that, certainly in a technical domain, people want to work at the leading edge. They want to be with the winners. So, as a company, you have to stay at the leading edge. If you fall behind, the first thing you will see is that the good people, your best people, will move out. So, we have bonuses, we have stock option plans, etc. But the best motivators for me are two things: One is the challenge of the work, and second, it is the leadership that people want to work for.

Conclusion: The Key Role of Top Management

Despite all their talents and qualities, innovation leaders will always remain vulnerable, even if they are part of senior management. Their more conservative management colleagues will challenge them for the risks they are taking. Some will not lose any opportunity to remind them, for years, of the failed projects the innovation leaders have launched or supported. Again, William George (2001):

Innovation leaders need to feel personally secure, and also supported by the organization, from the top. Otherwise, the organization will grind them out. When it comes to budget time, they will get pushed aside. If their projects don't get along, then their budget will be cut. Because, what happens in

organizations (is this): the short-term tends to overtake the real opportunities, the project budgets, and the new products.

Even within a highly innovative culture like 3M, top managers have to be reminded of their personal responsibility in championing innovation leaders. The company cherishes this concluding quote, expressed in 1944 by one of the 3M historical CEOs (Lehr, 1979):

As our business grows, it becomes increasingly necessary to delegate responsibility and to encourage men and women to exercise their initiative. This requires considerable tolerance. Those men and women, to whom we delegate authority and responsibility, if they are good people, are going to want to do their jobs in their own way. These are characteristics we want, and people should be encouraged as long as their way conforms to our general pattern of operation. Mistakes will be made, but if a person is essentially right, the mistakes he or she makes are not as serious in the long run as the mistakes management will make if it is dictatorial and undertakes to tell those under its authority exactly how they must do their job. Management that is destructively critical when mistakes are made kills initiative, and it's essential that we have many people with initiative if we are to continue to grow.

Innovation and Market Research

Paul Trott

Business School, University of Portsmouth, U.K.

Abstract: Market research results frequently produce negative reactions to discontinuous new products (innovative products) that later become profitable for the innovating company. Famous examples such as the fax machine, the VCR and Dyson's bagless vacuum cleaner are often cited to support this view. Despite this, companies continue to seek the views of consumers on their new product ideas. The debate about the use of market research in the development of new products is long-standing and controversial. Against a backcloth of models of innovation, this chapter examines the extent to which market research is justified and whether companies should sometimes ignore their customers.

Keywords: Innovation; Innovative products; Market research; Marketing; New product development.

Introduction

There is much agreement in the literature that innovation¹ occurs through the interaction of the science base (dominated by universities and industry), technological development (dominated by industry) and the needs of the market (Christensen, 1997; Cooper, 1999; Tidd, Bessant & Pavitt, 2001). Indeed, it is the explanation of the interaction of these activities that forms the basis of models of innovation today. There is, however, much debate and disagreement about precisely what activities influence innovation and, more importantly, the internal processes that affect a company's ability to innovate. Market research results frequently produce negative reactions to discontinuous² new products that later become profitable for the innovating company. Famous examples such as the fax machine, the VCR and Dyson's bagless vacuum cleaner are often cited to

support this view. Despite this, companies continue to seek the views of consumers on their new product ideas. The debate about the use of market research in the development of new products is long-standing and controversial. Against a backcloth of models of innovation, this chapter examines the extent to which market research is justified and whether companies should sometimes ignore their customers. The first section reviews the various models of innovation that have been used to try to delineate the activities that need to be in place if innovation is to succeed. The section concludes by arguing that it is necessary to view innovation as a series of linked activities, which can be best, described as a management process. The next section looks at the role of market research in innovation. For many years this was seen as controversial and has once again been identified in the literature as troublesome, especially when discontinuous new products are considered (Christensen, 1997; Kumar, Scheer & Kotler, 2000; Lukas & Ferrell, 2000). The final section suggests that organizations may be able to improve their new product development process by emphasizing the internal and external linkages within the management of innovation.

Background

Traditional arguments about innovation have centred around two schools of thought. On the one hand the social deterministic school argued that innovations were the result of a combination of external social

¹ Innovation is not a single action but a total process of interrelated sub-processes. It is not just the conception of a new idea, nor the invention of a new device, nor the development of a new market. The process is all these things acting in an integrated fashion' (Myers & Marquis, 1969).

² Discontinuous innovations often launch a new generation of technology; whereas continuous product innovations involve improving existing technology. Discontinuous products are generally used to refer to new products that involve dramatic leaps in terms of customer benefits relative to previous product offerings (Chandy & Tellis, 2000; Meyers & Tucker, 1989).

factors and influences, such as demographic changes, economic influences and cultural changes (Drucker, 1985). The argument was that when the conditions were ‘right’ innovations would occur. Today this view is incorporated and referred to as the *market-based view of innovation*, which argues that market conditions provide the context that facilitates or constrains a firm’s innovative activity (Porter, 1985; Slater & Narver, 1994). However, the individualistic school argued that innovations were the result of unique individual talents and such innovators are born (Drucker, 1985). Intertwined with this view is the important role played by serendipity (Boden, 1991; Cannon, 1940; Kantorovich & Ne’eman, 1989; Roberts, 1989; Simonton, 1979). Today this view is incorporated within the *resource-based view of innovation*, which considers that the volatile nature of society and markets is insufficiently stable for a firm to develop long-term technology and innovation strategies. And that a firm’s own knowledge and capabilities (resources) better enable firms to cultivate its own markets (Cohen & Levinthal, 1990; Grant, 1997; Hamel & Prahalad, 1994).

Many studies of historical cases of innovation have highlighted the importance of the unexpected discovery (Gallouj, 2002; Sundbo, 2002; Tidd, Bessant & Pavitt, 2001). The role of serendipity or luck is offered as an explanation. This view is also reinforced in the popular media. It is, after all, every persons dream that they will accidentally uncover a major new invention leading to fame and fortune. On closer inspection of these historical cases, such serendipity is rare indeed. After all, in order to recognize the significance of an advance one would need to have some prior knowledge in that area (Cohen & Levinthal, 1990; Simonton, 2002). Hence, most discoveries are the result of people who have had a fascination with a particular area of science or technology and it is following extended efforts on their part that advances are made. Discoveries may not be expected, but in the words of Louis Pasteur, ‘chance favors the prepared mind’.

It was U.S. economists after the Second World War who championed the linear model of science and

innovation. Since then, largely because of its simplicity, this model has taken a firm grip on people’s views on how innovation occurs. Indeed, it dominated science and industrial policy for 40 years. It was only in the 1980s that management schools around the world seriously began to challenge the sequential linear process. The recognition that innovation occurs through the interaction of the science base (dominated by universities and industry), technological development (dominated by industry) and the needs of the market was a significant step forward (see Fig. 1). The explanation of the interaction of these activities forms the basis of models of innovation today.

There is, of course, much debate and disagreement about precisely what activities influence innovation and, more importantly, the internal processes that affect a company’s ability to innovate.

Nonetheless there is broad agreement that it is the linkages between these key components that will produce successful innovation. From a European perspective an area that requires particular attention is the linkage between the science base and technological development. The European Union (EU) believes that, compared to the USA, European universities have not established effective links with industry. Whereas in the U.S. universities have been working closely with industry for many years (Miyata, 2003).

Traditionally the innovation process has been viewed as a sequence of separable stages or activities (Gallouj, 2002; Sundbo, 2003). There are two basic variations of this model for product innovation. First, and most crudely, there is the technology driven model (often referred to as ‘technology push’) where it is assumed that scientists make expected and unexpected discoveries, technologists apply them to develop product ideas and engineers and designers turn them into prototypes for testing. It is left to manufacturing to devise ways of producing the products efficiently. Finally, marketing and sales will promote the product to the potential consumer. In this model the market place was a passive recipient for the fruits of R&D. This so-called ‘technology-push’ model dominated industrial policy after the Second World War. While

Figure 1. Conceptual framework of innovation.

this model of innovation can be applied to a few cases, most notably in technology-intensive industries such as the pharmaceutical industry, it is not applicable in many other instances. In particular where the innovation process follows a different route.

It was not until the 1970s, that new studies of actual innovations suggested the role of the market place was influential in the innovation process (von Hippel, 1978). This led to the second linear model, the 'market-pull' model of innovation. The customer 'need-driven' model emphasizes the role of marketing, as an initiator of new ideas as a result of close interactions with customers. These, in turn, are conveyed to R&D for design and engineering and then to manufacturing for production.

Whether innovations are stimulated by technology, customer need, manufacturing and a host of other factors, including competition, misses the point. The models above concentrate on what is driving the downstream efforts rather than on how innovations occur (Galbraith, 1982). Hence, the linear model is only able to offer an explanation of where the initial stimulus for innovation was born. That is, where the trigger for the idea or need was initiated. The simultaneous coupling model suggests that it is the result of the simultaneous coupling of the knowledge within all three functions (i.e. marketing, production and R&D) that will foster innovations (Rothwell & Zigweld, 1985; Sundbo, 2003). Furthermore, the point of commencement for innovation is not known in advance.

The interactive model develops this idea further (see Fig. 2) and links together the technology push and market pull models of innovation (Rothwell & Zigweld, 1985; Sundbo, 2003). It emphasizes that innovations occur as the result of the interaction of the market place, the science base and the organization's capabilities. Like the coupling model there is no explicit starting point. The use of information flows is

used to explain how innovations transpire and that they can arise from a wide variety of points.

While still oversimplified, it is a more comprehensive representation of the innovation process. It can be regarded as a logically sequential, though not necessarily continuous process, that can be divided into a series of functionally distinct but interacting and interdependent stages (Rothwell & Zigweld, 1985). The overall innovation process can be thought of as a complex set of communication paths whereby knowledge is transferred. These paths include internal and external linkages. The innovation process outlined in Fig. 2 represents the organization's capabilities and its linkages with both the market place and the science base. It is argued that organizations that are to manage this process effectively will be successful at innovation.

At the centre of the model are the organizational functions of R&D, engineering and design, manufacturing and marketing and sales. While at first this may appear as a linear model, the flow of communication is not necessarily in a linear fashion. There is provision for feedback. Also, linkages with the science base and the market place occur between all functions not just with R&D or marketing. For example, as often happens, it may be the manufacturing function which initiates a design improvement that leads to the introduction of either a different material or the eventual development by R&D of a new material. Finally, the generation of ideas is shown to be dependent upon inputs from three basic components (as outlined in Fig. 1): organization capabilities; the needs of the market place; the science and technology base (Bessant, 2003; Katz, 2003).

The preceding discussions have revealed that innovation is not a singular event, but a series of activities that are linked in some way to the others. This may be described as a process and involves (Kelly & Kranzberg, 1978):

Figure 2. Interactive model of innovation.

- (1) a response to either a need or an opportunity that is context dependent;
- (2) a creative effort and if successful results in the introduction of novelty;
- (3) the need for further changes.

There have been a plethora of models to help us understand the innovation process (see: Gallouj, 2002; Rothwell, 1992; Trott, 1998). Usually in trying to capture this complex process the simplification has led to misunderstandings. The simple linear model of innovation can be applied only to a few innovations and is more applicable to certain industries than others. As previously stated, the pharmaceutical industry characterizes much of the technology push model or resource-based view. Other industries, however, like fast moving consumer goods (FMCG) industries are better represented by the market pull model or market-based view. For most industries and organizations innovations are the result of a mixture of the two. Managers working within these organizations have the difficult task of trying to manage this complex process.

Market Research

Christensen (1997) investigated why well run companies that were admired by many, failed to stay on top of their industry. His research showed that in the cases of well managed firms such as Digital, IBM, Apple and Xerox, 'good management' was the most powerful reason why they failed to remain market leaders (sic). It was precisely because these firms listened to their customers and provided more and better products of the sort they wanted that they lost their position of leadership. He argues that there are times when it is right not to listen to customers. Recent research by Ovans (1998) supports this claim. He suggests that purchase-intention surveys are not effective predictors of sales of new products. The research revealed that people aren't generally reliable predictors of their own long-term purchasing behavior. The type of question used and whether or not the question is placed in context greatly affects the reliability of such market research. James Dyson has good reason to be suspicious of the role of market research in new product development. Not only did he struggle for many years to get anyone in the U.K. to believe it was worth manufacturing his bagless vacuum cleaner, he faced the same scepticism when he launched in the U.S. (Thrift, 1997).

Many industry analysts and business consultants are now arguing that the devotion to focus groups and market research has gone too far (Chandy & Tellis, 2000; Christensen, 1997; Francis, 1994; Martin, 1995). Indeed, the traditional new product development (NPD) process of market research, segmentation, competitive analysis and forecasting, prior to passing the resultant information to the research and development (R&D) department, leads to commonality and

bland new products. This is largely because the process constrains, rather than, facilitates innovative thinking and creativity. Furthermore, and more alarming, is that these techniques are well known and used by virtually all companies operating in consumer markets. In many of these markets the effect is an over-emphasis on minor product modifications and on competition that tends to focus on price (Veryzer, 2003). Indeed, critics of the market-orientated approach to new product development argue that the traditional marketing activities of branding, advertising, positioning, market research and consumer research act as an expensive obstacle course to product development rather than facilitating the development of new product ideas (Cooper, 2003).

For many large multi-product companies it seems the use of market research is based upon accepted practice in addition to being an insurance policy. Many large companies are not short of new product ideas, the problem lies in deciding in which ones to invest substantial sums of money (Trott, Cordey-Hayes & Seaton, 1995), and then justifying this decision to senior managers. Against this background one can see why market research is so frequently used without hesitation, as decisions can be justified and defended. Small companies in general, and small single product companies in particular, are in a different situation. Very often new product ideas are scarce; hence, such companies frequently support ideas based upon their intuition and personal knowledge of the product. This is clearly the situation with James Dyson's bagless vacuum cleaner (Dyson, 1998).

Morone's (1993) study of successful U.S. product innovations suggests that success was achieved through a combination of discontinuous product innovations³ and incremental improvements. Indeed, Lynn, Morone & Paulson (1997) argue that: in competitive, technology-intensive industries success is achieved with discontinuous product innovations through the creation of entirely new products and businesses, whereas product line extensions and incremental improvements are necessary for maintaining leadership. This, however, is only after leadership has been established through a discontinuous product innovation. This may appear to be at variance with accepted thinking that Japan secured success in the 1980s through copying and improving U.S. and European technology. This argument is difficult to sustain on close examination of the evidence (Lynn et al., 1997; Morone, 1993; Nonaka & Takeuchi, 1995). The most successful Japanese firms

³ Discontinuous innovations often launch a new generation of technology; whereas continuous product innovations involve improving existing technology. Discontinuous products are generally used to refer to new products that involve dramatic leaps in terms of customer benefits relative to previous product offerings (Chandy & Tellis, 2000; Meyers & Tucker, 1989).

have also been leaders in research and development (see: Deshpande, Farley & Webster, 1993; Lyons, 1976; Nonaka, 1991; Nonaka & Kenney, 1991; Nonaka & Takeuchi, 1995). Furthermore, as Cohen & Levinthal have continually argued (1990, 1994) access to technology is dependent on one's understanding of that technology.

Adopting a resource-based view or technology push approach to product innovations can allow a company to target and control premium market segments, establish its technology as the industry standard, build a favorable market reputation, determine the industry's future evolution, and achieve high profits. It can become the centerpiece in a company's strategy for market leadership. It is, however, costly and risky; this is the dilemma facing firms. Such an approach requires a company to develop and commercialize an emerging technology in pursuit of growth and profits. To be successful, a company needs to ensure its technology is at the heart of its competitive strategy. Merck, Microsoft and Dyson have created competitive advantage by offering unique products, lower costs or both by making technology the focal point in their strategies. These companies have understood the role of technology in differentiating their products in the marketplace. They have used their respective technologies to offer a distinct bundle of products, services and price ranges that have appealed to different market segments. Such products revolutionize product categories or define new categories, such as Hewlett-Packard's Laser-jet printers and Apple's (then IBM) personal computer. These products shift market structures, require consumer learning and induce behavior changes, hence, the difficulties for consumers when they are asked to pass judgment.

It seems the dilemma faced by companies when using market research findings is twofold:

- At the policy level: to what extent should companies pursue a strategy of providing more room for technology development of products and less for market research that will *surely* increase the likelihood of failure, but will also increase the chance of a major innovative product.
- At the operational level: to what extent should Product and Brand Managers make decisions based upon market research findings.

Market Research and Discontinuous New Products

In one of the most comprehensive reviews of the literature on product development Brown & Eisenhardt (1995) develop a model of factors affecting the success of product development. This model highlights the distinction between process performance and product effectiveness and the importance of agents, including team members, project leaders, senior management, customers, and suppliers, whose behavior affects these outcomes. The issue of whether customers can hinder

the product development process is not, however, discussed.

It is argued by many from within the market research industry that only extensive market research can help to avoid large scale losses such as those experienced by RCA with its Videodisc, Procter and Gamble with its Pringles and General Motors with its rotary engine (see: Barrett, 1996; Kotler, 1999; Urban & Hauser, 1993). Sceptics may point to the issue of vested interests in the industry, and that it is merely promoting itself. It is, however, widely accepted that most new products fail in the market because consumer needs and wants are not satisfied. Study results show that 80% of newly introduced products fail to establish market presence after two years (Barrett, 1996). Indeed, cases involving international high profile companies are frequently cited to warn of the dangers of failing to utilize market research (e.g. Unilever's Persil Power and R J Reynold's Smokeless cigarette).

Given the inherent risk and complexity, managers have asked for many years whether this could be reduced by market research. Not surprisingly, the marketing literature takes a market driven view, which has extensive market research as its key driver (Booz, Allen & Hamilton, 1982). The benefits of this approach to the new product development process have been widely articulated and are commonly understood (Cooper, 1990; Kotler, 1998). Partly because of its simplicity this view now dominates management thinking beyond the marketing department. Advocates of market research argue that such activities ensure that companies are consumer-orientated. In practice, this means that new products are more successful if they are designed to satisfy a perceived need rather than if they are designed simply to take advantage of a new technology (Ortt & Schoormans, 1993). The approach taken by many companies with regard to market research is that if sufficient research is undertaken the chances of failure are reduced (Barrett, 1996). Indeed, the danger that many companies wish to avoid is the development of products without any consideration of the market. Moreover, once a product has been carried through the early stages of development it is sometimes painful to raise questions about it once money has been spent. The problem then spirals out of control, taking the company with it.

The issue of market research in the development of new products is controversial. The debate will continue for the foreseeable future about whether product innovations are caused by resource-based or market-based factors. The issue is most evident with discontinuous product innovations, where no market exists. First, if potential customers are unable adequately to understand the product, then market research can only provide negative answers (Brown, 1991; Chandy & Tellis, 2000). Second, consumers frequently have difficulty articulating their needs. Hamel and Prahalad (1994) argue that customers lack

foresight; they refer to Akio Morita, Sony's influential leader:

Our plan is to lead the public with new products rather than ask them what kind of products they want. The public does not know what is possible, but we do.

This leads many scientists and technologists to view marketing departments with skepticism. As they have seen their exciting new technology frequently rejected due to market research findings produced by their marketing department. Market research specialists would argue that such problems could be overcome with the use of 'benefits research'. The problem here is that the benefits may not be clearly understood, or even perceived as a benefit by respondents. King (1985) sums up the research dilemma neatly:

Consumer research can tell you what people did and thought at one point in time: it can't tell you directly what they might do in a new set of circumstances.

This is particularly the case if the circumstances relate to an entirely new product that is unknown to the respondent. New information is always interpreted in light of one's prior knowledge and experience. Roger's (1995) studies on the diffusion of innovations as a social process argue that it requires time for societies to learn and experiment with new products. This raises the problem of how to deal with consumers with limited prior knowledge and how to conduct market research on a totally new product or a major product innovation. In their research analyzing successful cases of discontinuous product innovations, Lynn et al. (1997) argue that firms adopt a process of probing and learning. Valuable experience is gained with every step taken and modifications are made to the product and the approach to the market based on that learning. This is not trial and error but careful experimental design and exploration of the market often using the heritage of the organization (Nonaka, 2002). This type of new product development is very different from traditional techniques and methods described in marketing texts (see Kardes, 1998; Kotler, 1999).

Knowing what the customer thinks is still very important, especially when it comes to product modifications or additional attributes. There is, however, a distinction between additional features and the core product benefit or technology (Levitt, 1980). Also, emphasis needs to be placed on the buyer rather than the consumer, for the buyer may be the end user but equally may not, as is the case with industrial markets. Furthermore, for a product to be successful it has to be accepted by a variety of actors such as fellow channel members. In industrial markets the level of information symmetry about the core technology is usually very high indeed (hence the limited use of market research),

but in consumer markets this is not always the case. For example, industrial markets are characterized by:

- Relatively few (information rich) buyers;
- Products are often customized and can involve protracted negotiations regarding specifications;
- And, most importantly, the buyers are usually expert in the technology of the new product (i.e. high information symmetry about the core technology).

A Framework for the Management of Innovation

Industrial innovation⁴ and new product development⁵ today has evolved considerably from their early beginnings. Indeed, as we have seen, innovation is extremely complex and involves the effective management of a variety of different activities within the organization. It is precisely how the process is managed that needs to be examined. A framework is presented in Fig. 3 that helps to illustrate innovation as a management process. This is simply an aid in describing the main factors that need to be considered if innovation is to be successfully managed by organizations. It helps to show that while the interactions of the functions⁶ inside the organization are important, so too are the interactions of the functions with the external environment. Scientists and engineers within the firm will be continually interacting with fellow scientists in universities and other firms about scientific and technological developments (Major & Cordey-Hayes, 2000; Rothwell, 1992). Similarly the marketing function will need to interact with suppliers, distributors, customers and competitors to ensure the day-to-day activities of understanding customer needs and getting products to customers is achieved. Business planners and senior management will likewise communicate with a wide variety of firms and other institutions external to the firm, such as government departments, suppliers, customers, etc. All these information flows contribute to the wealth of knowledge held by the organization (Major & Cordey-Hayes, 2003; Woolgar, Vaux, Gomes, Ezingard & Grieve, 1998). Recognizing this, capturing and utilizing it to develop successful new products is the difficult management process of innovation.

Within any organization there are likely to be many different functions. Depending on the nature of the business, some functions will be more influential than others. For example in fast moving consumer product

⁴ Industrial innovation refers to innovation occurring within competitive industrial markets as opposed to research conducted within academia and government funded agencies.

⁵ New product development is referred to as the introduction of a new or improved product (Booz, Allen & Hamilton, 1981).

⁶ Function here refers to a business function such as marketing, manufacturing or Research and Development (R&D).

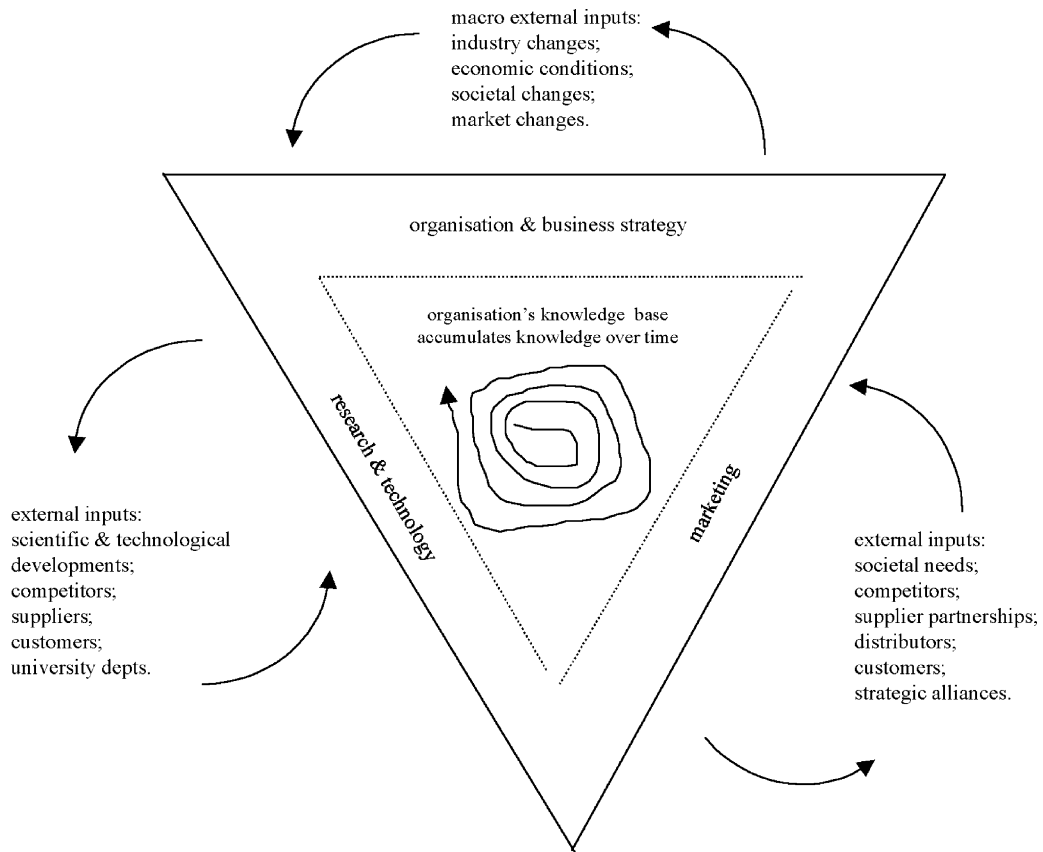

Figure 3. Innovation management framework.

firms Brand Managers are frequently very influential, whereas in technology intensive firms the R&D function is often dominant. The framework shown in Fig. 3 identifies three main functions: marketing, R&D and manufacturing, and business planning. Historical studies of innovations have identified these functions as the most influential in the innovation process (Gallouj, 2002; Sundbo, 2003; Tidd, Bessant & Pavitt, 2001). Whether one lists three or seven functions, misses the point, which is that it is the interaction of these internal functions and the flow of knowledge between them that needs to be facilitated (Nonaka & Takeuchi, 1995; Nonaka, Toyama & Konnon, 2000; Trott, Cordey-Hayes & Seaton, 1995). Similarly, as shown on the framework, effective communication with the external environment also requires encouragement and support (Oliver & Blakeborough, 1998).

The Need to Share and Exchange Knowledge

The framework in Fig. 3 emphasizes the importance placed of interaction (both formal and informal) within the innovation process. Indeed, innovation has been described as an information creation process that arises

out of social interaction (Trott et al., 1995). In effect, the firm provides a structure within which the creative process is located (Nonaka & Kenny, 1991; Nonaka, Sasaki & Ahmed, 2003).

These interactions provide the opportunity for thoughts, potential ideas and views to be shared and exchanged. However, we are often unable to explain what we normally do; we can be competent without being able to offer a theoretical account of our actions (Polyani, 1966). This is referred to as 'tacit knowledge' (Sternberg, Forsythe, Hedlund, Horvath, Wagner, Williams, Snook & Grigorenko, 2000). A great deal of technical skill is 'know-how' and much industrial innovation occurs through on the spot experiments, a kind of action oriented research with ad hoc modifications during step-by-step processes, through which existing repertoires are extended. Such knowledge can only be learned through practice and experience. This view has found significant support from a study of Japanese firms (Nonaka, 1991); where the creation of new knowledge within an organization depends on tapping the tacit and often highly subjective insights, intuitions and hunches of individual employees and

making those insights available for testing and use by the organization as a whole. Hence, this implies that certain knowledge and skills, embodied in the term 'know-how', are not easily understood, moreover are less able to be communicated. This would suggest that to gain access to such knowledge one may have to be practising in this or related areas of knowledge. Cohen and Levinthal (1990) refer to this condition as 'lockout' suggesting that failure to invest in research and technology will limit an organization's ability to capture technological opportunities. 'Once off the technological escalator it's difficult to get back on' Cohen & Levinthal (1990, p. 128).

In addition to informal interactions, the importance of formal interactions is also highlighted. There is a substantial amount of research stressing the need for a 'shared language' within organizations to facilitate internal communication (Allen, 1977; Rothwell, 1991; Tushman, 1978; Woolgar et al., 1998). The arguments are presented along the following lines: if all actors in the organization share the same specialized language, they will be effective in their communication. Hence, there needs to be an overlap of knowledge in order for communication to occur. Such arguments have led to developments in cross-function interfaces, for example between R&D, design, manufacturing and marketing (Nonaka & Takeuchi, 1995; Souder, 1988). Concurrent Engineering is an extension of this; in this particular case a small team consisting of a member from each of the various functional departments manage the design, development, manufacture and marketing of a product.

Such thinking is captured in the framework outlined in Fig. 3. It stresses the importance of interaction and communication within and between functions and with the external environment. This networking structure allows lateral communication, helping managers and their staff unleash creativity. This framework emphasizes the importance of informal and formal networking, across all functions.

This introduces a tension between the need for diversity, on the one hand, in order to generate novel linkages and associations, and the need for commonality on the other, to facilitate effective internal communication. Clearly there will be an organizational trade-off between diversity and commonality of knowledge across individuals (Beveridge, 1957; Martindale, 1995; McCrae, 1987; Shadish, 1989).

Organizational Heritage

Finally the center of the framework is represented as organizational heritage, sometimes referred to as the organizational knowledge base. This does not mean the culture of the organization. It represents a combination of the organization's knowledge base (established and built up over the years of operating) and the organization's architecture that is unique to a firm (Freeman, 1991; Kay, 1993; Teece & Pisano, 1994; Tushman &

Anderson, 1986). This organizational heritage represents for many firms a powerful competitive advantage that enables them to compete with other firms. For 'American Express' it is its customer service and customer relations, developed and built up over decades, that provides the company with a powerful competitive advantage. 'Bayer, BASF and Siemens' organizational heritage is dominated by their continual investment over almost a hundred years in science and technology and the high profile given to science and technology within their businesses. For 'Unilever', its organizational heritage can be said to lie in its brand management skills and know-how developed over many years. These heritages cannot be ignored or dismissed as irrelevant when trying to understand how companies manage their innovative effort.

Conclusions

Very often product innovation is viewed from purely a marketing perspective with little, if any, consideration of the R&D function and the difficulties of managing science and technology. Likewise many manufacturing and technology approaches to product innovation have previously not taken sufficient notice of the needs of the customer. Finally, the organizational heritage of the firm will influence its future decisions regarding the markets in which it will operate. The point here is that firms do not have a completely free choice. What it does in the future will depend to some extent on what it has done in the past.

Market research can provide a valuable contribution to the development of innovative products. The difficulties lie in the selection and implementation of research methods. It may be that market research has become a victim of its own success, that is, business and product managers now expect it to provide solutions to all difficult product management decisions. Practitioners need to view market research as a collection of techniques that can help to inform the decision process. The conceptual framework outlined in this chapter should help Product and Brand Managers to consider when and under what circumstances market research is most effective. The right sort of market research can be invaluable. The problem is that within consumer markets there are technology intensive and technology vacant industries. In many of the technology intensive industries such as telecommunications, computer hardware and software, these firms are able to utilize their industrial market heritage to balance the need for technology and listen to the needs of consumers. In technology vacant consumer markets, such as food and personal care, the danger is that the technology agenda is completely dominated by market research findings. Minor product modifications may keep a product and brand competitive in the short-term, but if long-term growth is sought then more free-thinking and creativity needs to be afforded to the R&D department.

Marketing and the Development of Innovative New Products

Robert W. Veryzer

Rensselaer Polytechnic Institute, Lally School of Management and Technology, USA

Abstract: This chapter examines innovation from the perspective of marketing concerns and challenges. The role of marketing in the development of highly innovative products is discussed as are a number of the relevant key questions and concerns inherent in this type of product development. As part of this discussion, a framework consisting of three dimensions useful in conceptualizing innovation is presented. This is extended to include a number of influencers of product adoption that are important to consider during the design and development process (and also later on with respect to product launch) for innovative products.

Keywords: Innovation; Discontinuous innovation; Marketing; Consumer behavior; Product adoption.

Introduction

Innovation, or the introducing of new and more effective ways of doing things, is critical to the success of new products. As the competition inherent in a global marketplace increases, product (and service) innovation is the driving force for maintaining company viability and better satisfying customer needs. Really new or discontinuous new products play an important role in building competitive advantage and can contribute significantly to a firm's growth and profitability (Ali, 1994; Cooper, 2002; Kleinschmidt & Cooper, 1991; Robertson, 1967). However, while innovation plays a crucial role in the success (or continued success) of most companies, it does not come easily. As Wheelwright & Clark (1992, pp. 28–29) point out: 'Perhaps no activity in business is more heralded for its promise and approached with more justified optimism than new-product and new-process development. The anticipated benefits almost defy description . . . Unfortunately, in most firms the promise is seldom fully realized. Even in many very successful companies, new product development is tinged with significant disappointment and disillusionment, often falling short of both its full potential in general and its specific opportunities on individual projects'. This is true for new product development in general and is especially true for discontinuous new product development.

New product development in the context of high innovation usually involves greater uncertainty than is present for the development of more incremental innovation products. Developing highly innovative product offerings involves considerable risk along with requiring both insight and foresight. The implications of technological advances are often obscured by the high levels of technical and market uncertainty that surround them. Often, it is difficult to know what direction to take for an emerging technology on the path to commercialization as an innovative new product. Appreciating the potential of any disruptive technology for development into a useful product form is a large part of the innovation challenge. Even though innovation at the high end of the spectrum usually entails more 'degrees of freedom' in one sense, it also requires either a great deal of luck or an ability to effectively envision what the market will respond to and embrace in order to produce a successful outcome. The key to this is the ability to link advanced technologies to market opportunities of the future so that the project can be guided through the uncertainties inherent in the development of these types of products. The task of bridging the uncertainty between technological capability and market need is critical for the effectiveness of the development effort if it is to yield a useful and commercially viable new product.

The potential rewards and risks from developing successful new products are high, and many factors can impel organizations to consider new product development activities. Although some companies may survive by trying one product after another in the market until success is achieved, this can be both costly and risky (Urban & Hauser, 1993). Studies of high-tech firms have found that a critical factor for success is an orientation toward marketing (Cooper, 1990, 2002; Gupta, Raj & Wileman, 1985; Kotler, 1999; Souder, 1988; Trott, 2002; Urban & Hauser, 1993).

Although one can look at 'innovation' in many ways, in the context of marketing there are specific aspects that need to be taken into consideration. The role of marketing usually begins with the inception of a product development project. In cases when the project is more than simply technology push, marketing's role may precede the inception phase in the form of explorations of possible customer needs and wants, and usually continues through introducing a new product into the marketplace as well as supporting it with various marketing programs. The heart of marketing concerns and challenges lies in the development of the product itself, for it is here that information (e.g. customer needs, product specifications, market trends, product tests, price points) is most needed if the ultimate product produced is to be one that both benefits consumers (and society at large) and is commercially viable. The key requirement is the alignment of the marketing and market research approaches with the product development task so that they may be used effectively to help develop the product and understand market potentials—in many cases for a market that does not yet exist! Proper alignment is crucial, since without it marketing inputs may seriously undermine innovation efforts.

Marketing's Role in Innovation

Innovation, and especially radical or 'high' innovation, involves fundamental questions that must be answered at some point during the new product development process. Whether these questions are addressed formally by marketing personnel or touched on by people like R&D scientists or engineers, it is inherent to innovation that inputs are needed in order to effectively broach a new commercial frontier (Veryzer, 1998a). Either these questions are considered and examined prior to or as an innovative new product is being formulated, or they will be answered when the product is judged (perhaps harshly) by the marketplace if the product even reaches the introduction stage. Critical questions center around understanding issues such as: what are the potential applications of a technology as a product?, and which application(s) should be pursued first?; what benefits can the proposed product offer to potential customers?; what is a gross estimate of potential market size?; Will the market be large enough to justify moving forward with the project? (Leifer,

McDermott, O'Connor, Peters, Rice & Veryzer, 2000). In addition, in the development of an innovative new product there is always a need to be sensitive to two further issues: (1) the possibility of a product lacking distinctiveness, that is, its being less than unique or the ease with which it may be quickly imitated by competitors; and (2) the possibility of a 'moving target' in terms of matching the product that is actually developed to a set of customers for which it is most beneficial and appropriate (Wheelwright & Clark, 1992). As Wheelwright & Clark (1992, p. 29) point out:

... too often the basic product concept misses a shifting technology or market, resulting in a mismatch. This can be caused by locking into a technology before it is sufficiently stable, targeting a market that changes unexpectedly, or making assumptions that just do not hold. In each of the cases the project gets into trouble because of inadequate consistency of focus throughout its duration and an eventual misalignment with reality. Once the target starts to shift, the problem compounds itself: the project lengthens, and longer projects invariably drift as the target continues to shift.

Despite the need to answer these sorts of questions, there has been some debate among marketing scholars concerning the nature of the relationship between marketing and innovation (e.g. Lukas & Ferrell, 2000; Trott, 2002). One view holds that the effect of a market orientation on product innovation yields 'superior innovation and greater new product success' (Lukas & Ferrell, 2000, p. 239; see also: Cooper, 1990, 2002; Gupta, Raj & Wileman, 1985; Kotler, 1999; Montoya-Weiss & Calantone, 1994; Nonaka, Sasaki & Ahmed, 2002; Ortt & Schoormans, 1993; Souder, 1988; Trott, 2002; Urban & Hauser, 1993). *Market orientation* has been defined as the process of generating and disseminating market intelligence (i.e. a 'deep understanding' of the intended customers and product environment) for the purpose of creating superior buyer value (Kohli & Jaworski, 1990; Narver & Slater, 1990). It encompasses both a focus on customers and competitors along with the synthesis and dissemination of market intelligence to various functional areas within a company that may benefit from such information (Lukas & Ferrell, 2000; Narver & Slater, 1990). There are a number of studies that support the view that a market orientation yields superior innovation as well as greater new product success (e.g. Cooper, 1990, 2002; Deshpande, Farley & Webster, 1993; Kohli & Jaworski, 1990; Kotler, 1999; Montoya-Weiss & Calantone, 1994; Trott, 2002). Some researchers go even further in their view of the degree to which customer information should be incorporated into the development of innovative new products. For example, von Hippel

(1988) suggests that focusing on ‘lead users’—those customers that identify and craft a solution to a problem being experienced in advance of the rest of the market—is the key to innovation. He suggests that “the locus of almost the entire innovation process is centered on the user and offers a model of the user as the primary actor” (von Hippel, 1988, p. 25). Von Hippel (1988) reports that lead users accounted for 100% of the semiconductor and PC board innovations.

At the same time, a number of researchers have argued that a strong market orientation may result in reduced innovation (e.g. Chandy & Tellis, 2000; Christensen, 1997; Cooper, 2002; Hamel & Prahalad, 1994; Kumar, Scheer & Kotler, 2000; Leonard-Barton & Doyle, 1996; Lukas & Ferrell, 2000). The primary concern involves listening too closely to customers who are focused on current as opposed to future needs. Christensen (1997) has argued that the very decision-making and resource-allocation processes that are key to the success of established companies are the same processes that lead firms to reject the disruptive technologies that they should be embracing—and chief among these is ‘listening carefully to customers’ (Christensen, 1997, p. 98). He points out the highly negative impact in the disk drive, steel mini-mill, and numerous other industries of a firm’s focus on current customers to the exclusion of considering longer-term technological innovations that offer no apparent immediate benefit to the loyal customer base (Christensen, 1997). The result is often new products that are marginally innovative. Concern has also been expressed about the impact of focusing too closely on the competition. A number of researchers have suggested that being overly focused on competitors can lead to a greater introduction of imitations or ‘me-too’ products (Chandy & Tellis, 2000; Christensen, 1997; Cooper, 2002; Hayes & Abernathy, 1980; Kumar, Scheer & Kotler, 2000; Lukas & Ferrell, 2000; Trott, 2002; Zahra, Nash & Brickford, 1995).
