# Dedication

---

I dedicate this book to my husband, Mark Hunacek, with gratitude both for his support throughout this project and for our wonderful life together.

# Acknowledgments

---

I would like to thank Executive Editor Bob Stern of Taylor & Francis Group, who envisioned this project and whose enthusiasm and support has helped carry it to completion. I also want to thank Yolanda Croasdale, Suzanne Lassandro, Jim McGovern, Jessica Vakili and Mimi Williams, for their expert guidance of this book through the production process.

I would like to thank the many authors whose work appears in this volume for the contributions of their time and expertise to this project, and for their patience with the revisions necessary to produce a unified whole from many parts.

Without the help of the associate editors, Richard Brualdi, Anne Greenbaum, and Roy Mathias, this book would not have been possible. They gave freely of their time, expertise, friendship, and moral support, and I cannot thank them enough.

I thank Iowa State University for providing a collegial and supportive environment in which to work, not only during the preparation of this book, but for more than 25 years.

**Leslie Hogben**

# The Editor

---

**Leslie Hogben, Ph.D.**, is a professor of mathematics at Iowa State University. She received her B.A. from Swarthmore College in 1974 and her Ph.D. in 1978 from Yale University under the direction of Nathan Jacobson. Although originally working in nonassociative algebra, she changed her focus to linear algebra in the mid-1990s.

Dr. Hogben is a frequent organizer of meetings, workshops, and special sessions in combinatorial linear algebra, including the workshop, “Spectra of Families of Matrices Described by Graphs, Digraphs, and Sign Patterns,” hosted by American Institute of Mathematics in 2006 and the Topics in Linear Algebra Conference hosted by Iowa State University in 2002. She is the Assistant Secretary/Treasurer of the International Linear Algebra Society.

An active researcher herself, Dr. Hogben particularly enjoys introducing graduate and undergraduate students to mathematical research. She has three current or former doctoral students and nine master’s students, and has worked with many additional graduate students in the Iowa State University Combinatorial Matrix Theory Research Group, which she founded. Dr. Hogben is the co-director of the NSF-sponsored REU “Mathematics and Computing Research Experiences for Undergraduates at Iowa State University” and has served as a research mentor to ten undergraduates.

<b>Preliminaries</b> .....	<b>P-1</b>
----------------------------	------------

## **Part I Linear Algebra**

---

### **Basic Linear Algebra**

<b>1</b> Vectors, Matrices and Systems of Linear Equations <i>Jane Day</i> .....	<b>1-1</b>
<b>2</b> Linear Independence, Span, and Bases <i>Mark Mills</i> .....	<b>2-1</b>
<b>3</b> Linear Transformations <i>Francesco Barioli</i> .....	<b>3-1</b>
<b>4</b> Determinants and Eigenvalues <i>Luz M. DeAlba</i> .....	<b>4-1</b>
<b>5</b> Inner Product Spaces, Orthogonal Projection, Least Squares and Singular Value Decomposition <i>Lixing Han and Michael Neumann</i> .....	<b>5-1</b>

### **Matrices with Special Properties**

<b>6</b> Canonical Forms <i>Leslie Hogben</i> .....	<b>6-1</b>
<b>7</b> Unitary Similarity, Normal Matrices and Spectral Theory <i>Helene Shapiro</i> .....	<b>7-1</b>
<b>8</b> Hermitian and Positive Definite Matrices <i>Wayne Barrett</i> .....	<b>8-1</b>
<b>9</b> Nonnegative and Stochastic Matrices <i>Uriel G. Rothblum</i> .....	<b>9-1</b>

10	Partitioned Matrices <i>Robert Reams</i> .....	10-1
----	---	------

**Advanced Linear Algebra**

11	Functions of Matrices <i>Nicholas J. Higham</i> .....	11-1
12	Quadratic, Bilinear and Sesquilinear Forms <i>Raphael Loewy</i> .....	12-1
13	Multilinear Algebra <i>J. A. Dias da Silva and Armando Machado</i> .....	13-1
14	Matrix Equalities and Inequalities <i>Michael Tsatsomeros</i> .....	14-1
15	Matrix Perturbation Theory <i>Ren-Cang Li</i> .....	15-1
16	Pseudospectra <i>Mark Embree</i> .....	16-1
17	Singular Values and Singular Value Inequalities <i>Roy Mathias</i> .....	17-1
18	Numerical Range <i>Chi-Kwong Li</i> .....	18-1
19	Matrix Stability and Inertia <i>Daniel Hershkowitz</i> .....	19-1

**Topics in Advanced Linear Algebra**

20	Inverse Eigenvalue Problems <i>Alberto Borobia</i> .....	20-1
21	Totally Positive and Totally Nonnegative Matrices <i>Shaun M. Fallat</i> .....	21-1
22	Linear Preserver Problems <i>Peter Šemrl</i> .....	22-1
23	Matrices over Integral Domains <i>Shmuel Friedland</i> .....	23-1
24	Similarity of Families of Matrices <i>Shmuel Friedland</i> .....	24-1
25	Max-Plus Algebra <i>Marianne Akian, Ravindra Bapat, Stéphane Gaubert</i> .....	25-1

26	Matrices Leaving a Cone Invariant <i>Bit-Shun Tam and Hans Schneider</i> .....	26-1
----	---	------

## Part II Combinatorial Matrix Theory and Graphs

---

### Matrices and Graphs

27	Combinatorial Matrix Theory <i>Richard A. Brualdi</i> .....	27-1
28	Matrices and Graphs <i>Willem H. Haemers</i> .....	28-1
29	Digraphs and Matrices <i>Jeffrey L. Stuart</i> .....	29-1
30	Bipartite Graphs and Matrices <i>Bryan L. Shader</i> .....	30-1

### Topics in Combinatorial Matrix Theory

31	Permanents <i>Ian M. Wanless</i> .....	31-1
32	D-Optimal Designs <i>Michael G. Neubauer and William Watkins</i> .....	32-1
33	Sign Pattern Matrices <i>Frank J. Hall and Zhongshan Li</i> .....	33-1
34	Multiplicity Lists for the Eigenvalues of Symmetric Matrices with a Given Graph <i>Charles R. Johnson, António Leal Duarte, and Carlos M. Saiago</i> .....	34-1
35	Matrix Completion Problems <i>Leslie Hogben and Amy Wangsness</i> .....	35-1
36	Algebraic Connectivity <i>Steve Kirkland</i> .....	36-1

## Part III Numerical Methods

---

### Numerical Methods for Linear Systems

37	Vector and Matrix Norms, Error Analysis, Efficiency and Stability <i>Ralph Byers and Biswa Nath Datta</i> .....	37-1
38	Matrix Factorizations, and Direct Solution of Linear Systems <i>Christopher Beattie</i> .....	38-1

39	Least Squares Solution of Linear Systems <i>Per Christian Hansen and Hans Bruun Nielsen</i> .....	39-1
40	Sparse Matrix Methods <i>Esmond G. Ng</i> .....	40-1
41	Iterative Solution Methods for Linear Systems <i>Anne Greenbaum</i> .....	41-1

## Numerical Methods for Eigenvalues

42	Symmetric Matrix Eigenvalue Techniques <i>Ivan Slapničar</i> .....	42-1
43	Unsymmetric Matrix Eigenvalue Techniques <i>David S. Watkins</i> .....	43-1
44	The Implicitly Restarted Arnoldi Method <i>D. C. Sorensen</i> .....	44-1
45	Computation of the Singular Value Decomposition <i>Alan Kaylor Cline and Inderjit S. Dhillon</i> .....	45-1
46	Computing Eigenvalues and Singular Values to High Relative Accuracy <i>Zlatko Drmač</i> .....	46-1

## Computational Linear Algebra

47	Fast Matrix Multiplication <i>Dario A. Bini</i> .....	47-1
48	Structured Matrix Computations <i>Michael Ng</i> .....	48-1
49	Large-Scale Matrix Computations <i>Roland W. Freund</i> .....	49-1

## Part IV Applications

---

### Applications to Optimization

50	Linear Programming <i>Leonid N. Vaserstein</i> .....	50-1
51	Semidefinite Programming <i>Henry Wolkowicz</i> .....	51-1

**Applications to Probability and Statistics**

52 Random Vectors and Linear Statistical Models  
*Simo Puntanen and George P. H. Styan* ..... 52-1

53 Multivariate Statistical Analysis  
*Simo Puntanen, George A. F. Seber, and George P. H. Styan* ..... 53-1

54 Markov Chains  
*Beatrice Meini* ..... 54-1

**Applications to Analysis**

55 Differential Equations and Stability  
*Volker Mehrmann and Tatjana Stykel* ..... 55-1

56 Dynamical Systems and Linear Algebra  
*Fritz Colonius and Wolfgang Kliemann* ..... 56-1

57 Control Theory  
*Peter Benner* ..... 57-1

58 Fourier Analysis  
*Kenneth Howell* ..... 58-1

**Applications to Physical and Biological Sciences**

59 Linear Algebra and Mathematical Physics  
*Lorenzo Sadun* ..... 59-1

60 Linear Algebra in Biomolecular Modeling  
*Zhijun Wu* ..... 60-1

**Applications to Computer Science**

61 Coding Theory  
*Joachim Rosenthal and Paul Weiner* ..... 61-1

62 Quantum Computation  
*Zijian Diao* ..... 62-1

63 Information Retrieval and Web Search  
*Amy Langville and Carl Meyer* ..... 63-1

64 Signal Processing  
*Michael Stewart* ..... 64-1

**Applications to Geometry**

65 Geometry  
*Mark Hunacek* ..... 65-1

66	Some Applications of Matrices and Graphs in Euclidean Geometry <i>Miroslav Fiedler</i> .....	66-1
----	---	------

# Preface

---

It is no exaggeration to say that linear algebra is a subject of central importance in both mathematics and a variety of other disciplines. It is used by virtually all mathematicians and by statisticians, physicists, biologists, computer scientists, engineers, and social scientists. Just as the basic idea of first semester differential calculus (approximating the graph of a function by its tangent line) provides information about the function, the process of linearization often allows difficult problems to be approximated by more manageable linear ones. This can provide insight into, and, thanks to ever-more-powerful computers, approximate solutions of the original problem. For this reason, people working in all the disciplines referred to above should find the *Handbook of Linear Algebra* an invaluable resource.

The *Handbook* is the first resource that presents complete coverage of linear algebra, combinatorial linear algebra, and numerical linear algebra, combined with extensive applications to a variety of fields and information on software packages for linear algebra in an easy to use handbook format.

## Content

---

The *Handbook* covers the major topics of linear algebra at both the graduate and undergraduate level as well as its offshoots (numerical linear algebra and combinatorial linear algebra), its applications, and software packages for linear algebra computations. The *Handbook* takes the reader from the very elementary aspects of the subject to the frontiers of current research, and its format (consisting of a number of independent chapters each organized in the same standard way) should make this book accessible to readers with divergent backgrounds.

## Format

---

There are five main parts in this book. The first part (Chapters 1 through Chapter 26) covers linear algebra; the second (Chapter 27 through Chapter 36) and third (Chapter 37 through Chapter 49) cover, respectively, combinatorial and numerical linear algebra, two important branches of the subject. Applications of linear algebra to other disciplines, both inside and outside of mathematics, comprise the fourth part of the book (Chapter 50 through Chapter 70). Part five (Chapter 71 through Chapter 77) addresses software packages useful for linear algebra computations.

Each chapter is written by a different author or team of authors, who are experts in the area covered. Each chapter is divided into sections, which are organized into the following uniform format:

- Definitions
- Facts
- Examples

Most relevant definitions appear within the Definitions segment of each chapter, but some terms that are used throughout linear algebra are not redefined in each chapter. The Glossary, covering the terminology of linear algebra, combinatorial linear algebra, and numerical linear algebra, is available at the end of the book to provide definitions of terms that appear in different chapters. In addition to the definition, the Glossary also provides the number of the chapter (and section, thereof) where the term is defined. The Notation Index serves the same purpose for symbols.

The Facts (which elsewhere might be called theorems, lemmas, etc.) are presented in list format, which allows the reader to locate desired information quickly. In lieu of proofs, references are provided for all facts. The references will also, of course, supply a source of additional information about the subject of the chapter. In this spirit, we have encouraged the authors to use texts or survey articles on the subject as references, where available.

The Examples illustrate the definitions and facts. Each section is short enough that it is easy to go back and forth between the Definitions/Facts and the Examples to see the illustration of a fact or definition. Some sections also contain brief applications following the Examples (major applications are treated in their own chapters).

## Feedback

---

To see updates and provide feedback and errata reports, please consult the web page for this book: <http://www.public.iastate.edu/~lhogben/HLA.html> or contact the editor via email, [LHogben@iastate.edu](mailto:LHogben@iastate.edu), with *HLA* in the subject heading.

# Preliminaries

---

This chapter contains a variety of definitions of terms that are used throughout the rest of the book, but are not part of linear algebra and/or do not fit naturally into another chapter. Since these definitions have little connection with each other, a different organization is followed; the definitions are (loosely) alphabetized and each definition is followed by an example.

## Algebra

---

An (**associative**) **algebra** is a vector space  $A$  over a field  $F$  together with a **multiplication**  $(\mathbf{x}, \mathbf{y}) \mapsto \mathbf{xy}$  from  $A \times A$  to  $A$  satisfying two *distributive* properties and *associativity*, i.e., for all  $a, b \in F$  and all  $\mathbf{x}, \mathbf{y}, \mathbf{z} \in A$ :

$$(a\mathbf{x} + b\mathbf{y})\mathbf{z} = a(\mathbf{xz}) + b(\mathbf{yz}), \quad \mathbf{x}(a\mathbf{y} + b\mathbf{z}) = a(\mathbf{xy}) + b(\mathbf{xz}) \quad (\mathbf{xy})\mathbf{z} = \mathbf{x}(\mathbf{yz}).$$

Except in Chapter 69 and Chapter 70 the term *algebra* means associative algebra. In these two chapters, associativity is not assumed.

### Examples:

The vector space of  $n \times n$  matrices over a field  $F$  with matrix multiplication is an (associative) algebra.

## Boundary

---

The **boundary**  $\partial S$  of a subset  $S$  of the real numbers or the complex numbers is the intersection of the closure of  $S$  and the closure of the complement of  $S$ .

### Examples:

The boundary of  $S = \{x \in \mathbb{C} : |z| \leq 1\}$  is  $\partial S = \{x \in \mathbb{C} : |z| = 1\}$ .

## Complement

---

The **complement** of the set  $X$  in universe  $S$ , denoted  $S \setminus X$ , is all elements of  $S$  that are not in  $X$ . When the universe is clear (frequently the universe is  $\{1, \dots, n\}$ ) then this can be denoted  $X^c$ .

### Examples:

For  $S = \{1, 2, 3, 4, 5\}$  and  $X = \{1, 3\}$ ,  $S \setminus X = \{2, 4, 5\}$ .

## Complex Numbers

---

Let  $a, b \in \mathbb{R}$ . The symbol  $i$  denotes  $\sqrt{-1}$ .

The **complex conjugate** of a complex number  $c = a + bi$  is  $\bar{c} = a - bi$ .

The **imaginary part** of  $a + bi$  is  $\text{im}(a + bi) = b$  and the **real part** is  $\text{re}(a + bi) = a$ .

The **absolute value** of  $c = a + bi$  is  $|c| = \sqrt{a^2 + b^2}$ .

The **argument** of the nonzero complex number  $re^{i\theta}$  is  $\theta$  (with  $r, \theta \in \mathbb{R}$  and  $0 < r$  and  $0 \leq \theta < 2\pi$ ).  
 The **open right half plane**  $\mathbb{C}^+$  is  $\{z \in \mathbb{C} : \operatorname{re}(z) > 0\}$ .  
 The **closed right half plane**  $\mathbb{C}_0^+$  is  $\{z \in \mathbb{C} : \operatorname{re}(z) \geq 0\}$ .  
 The **open left half plane**  $\mathbb{C}^-$  is  $\{z \in \mathbb{C} : \operatorname{re}(z) < 0\}$ .  
 The **closed left half plane**  $\mathbb{C}_0^-$  is  $\{z \in \mathbb{C} : \operatorname{re}(z) \leq 0\}$ .

**Facts:**

1.  $|c| = c\bar{c}$
2.  $|re^{i\theta}| = r$
3.  $re^{i\theta} = r \cos \theta + r \sin \theta i$
4.  $\overline{re^{i\theta}} = re^{-i\theta}$

**Examples:**

$$\overline{2 + 3i} = 2 - 3i, \overline{1.4} = 1.4, 1 + i = \sqrt{2}e^{i\pi/4}.$$

## Conjugate Partition

---

Let  $v = (u_1, u_2, \dots, u_n)$  be a sequence of integers such that  $u_1 \geq u_2 \geq \dots \geq u_n \geq 0$ . The **conjugate partition** of  $v$  is  $v^* = (u_1^*, \dots, u_t^*)$ , where  $u_i^*$  is the number of  $j$ s such that  $u_j \geq i$ .  $t$  is sometimes taken to be  $u_1$ , but is sometimes greater (obtained by extending with 0s).

**Facts:** If  $t$  is chosen to be the minimum, and  $u_n > 0$ ,  $v^{**} = v$ .

**Examples:**

$$(4, 3, 2, 2, 1)^* = (5, 4, 2, 1).$$

## Convexity

---

Let  $V$  be a real or complex vector space.

Let  $\{v_1, v_2, \dots, v_k\} \in V$ . A vector of the form  $a_1v_1 + a_2v_2 + \dots + a_kv_k$  with all the coefficients  $a_i$  nonnegative and  $\sum a_i = 1$  is a **convex combination** of  $\{v_1, v_2, \dots, v_k\}$ .

A set  $S \subseteq V$  is **convex** if any convex combination of vectors in  $S$  is in  $S$ .

The **convex hull** of  $S$  is the set of all convex combinations of  $S$  and is denoted by  $\operatorname{Con}(S)$ .

An **extreme point** of a closed convex set  $S$  is a point  $v \in S$  that is not a nontrivial convex combination of other points in  $S$ , i.e.,  $ax + (1 - a)y = v$  and  $0 \leq a \leq 1$  implies  $x = y = v$ .

A **convex polytope** is the convex hull of a finite set of vectors in  $\mathbb{R}^n$ .

Let  $S \subseteq V$  be convex. A function  $f : S \rightarrow \mathbb{R}$  is **convex** if for all  $a \in \mathbb{R}$ ,  $0 < a < 1$ ,  $x, y \in S$ ,  $f(ax + (1 - a)y) \leq af(x) + (1 - a)f(y)$ .

**Facts:**

1. A set  $S \subseteq V$  is convex if and only if  $\operatorname{Con}(S) = S$ .
2. The extreme points of  $\operatorname{Con}(S)$  are contained in  $S$ .
3. [HJ85] *Krein-Milman Theorem*: A compact convex set is the convex hull of its extreme points.

**Examples:**

1.  $[1.9, 0.8]^T$  is a convex combination of  $[1, -1]^T$  and  $[2, 1]^T$ , since  $[1.9, 0.8]^T = 0.1[1, -1]^T + 0.9[2, 1]^T$ .
2. The set  $K$  of all  $v \in \mathbb{R}^3$  such that  $v_i \geq 0, i = 1, 2, 3$  is a convex set. Its only extreme point is the zero vector.

## Elementary Symmetric Function

---

The  $k$ th elementary symmetric function of  $\alpha_i, i = 1, \dots, n$  is

$$S_k(\alpha_1, \dots, \alpha_n) = \sum_{1 < i_1 < i_2 < \dots < i_k < n} \alpha_{i_1} \alpha_{i_2} \dots \alpha_{i_k}.$$

**Examples:**

$$S_2(\alpha_1, \alpha_2, \alpha_3) = \alpha_1 \alpha_2 + \alpha_1 \alpha_3 + \alpha_2 \alpha_3,$$

$$S_1(\alpha_1, \dots, \alpha_n) = \alpha_1 + \alpha_2 + \dots + \alpha_n, S_n(\alpha_1, \dots, \alpha_n) = \alpha_1 \alpha_2 \dots \alpha_n.$$

## Equivalence Relation

---

A binary relation  $\equiv$  in a nonempty set  $S$  is an **equivalence relation** if it satisfies the following conditions:

1. (Reflexive) For all  $a \in S, a \equiv a$ .
2. (Symmetric) For all  $a, b \in S, a \equiv b$  implies  $b \equiv a$ .
3. (Transitive) For all  $a, b, c \in S, a \equiv b$  and  $a \equiv b$  imply  $a \equiv c$ .

**Examples:**

Congruence mod  $n$  is an equivalence relation on the integers.

## Field

---

A **field** is a set  $F$  with at least two elements together with a function  $F \times F \rightarrow F$  called addition, denoted  $(a, b) \rightarrow a + b$ , and a function  $F \times F \rightarrow F$  called multiplication, denoted  $(a, b) \rightarrow ab$ , which satisfy the following axioms:

1. (Commutativity) For each  $a, b \in F, a + b = b + a$  and  $ab = ba$ .
2. (Associativity) For each  $a, b, c \in F, (a + b) + c = a + (b + c)$  and  $(ab)c = a(bc)$ .
3. (Identities) There exist two elements 0 and 1 in  $F$  such that  $0 + a = a$  and  $1a = a$  for each  $a \in F$ .
4. (Inverses) For each  $a \in F$ , there exists an element  $-a \in F$  such that  $(-a) + a = 0$ . For each nonzero  $a \in F$ , there exists an element  $a^{-1} \in F$  such that  $a^{-1}a = 1$ .
5. (Distributivity) For each  $a, b, c \in F, a(b + c) = ab + ac$ .

**Examples:**

The real numbers,  $\mathbb{R}$ , the complex numbers,  $\mathbb{C}$ , and the rational numbers,  $\mathbb{Q}$ , are all fields. The set of integers,  $\mathbb{Z}$ , is not a field.

## Greatest Integer Function

---

The **greatest integer** or **floor** function  $\lfloor x \rfloor$  (defined on the real numbers) is the greatest integer less than or equal to  $x$ .

**Examples:**

$$\lfloor 1.5 \rfloor = 1, \lfloor 1 \rfloor = 1, \lfloor -1.5 \rfloor = -2.$$

# Group

---

(See also Chapter 67 and Chapter 68.)

A **group** is a nonempty set  $G$  with a function  $G \times G \rightarrow G$  denoted  $(a, b) \rightarrow ab$ , which satisfies the following axioms:

1. (Associativity) For each  $a, b, c \in G$ ,  $(ab)c = a(bc)$ .
2. (Identity) There exists an element  $e \in G$  such that  $ea = a = ae$  for each  $a \in G$ .
3. (Inverses) For each  $a \in G$ , there exists an element  $a^{-1} \in G$  such that  $a^{-1}a = e = aa^{-1}$ .

A group is **abelian** if  $ab = ba$  for all  $a, b \in G$ .

## Examples:

1. Any vector space is an abelian group under  $+$ .
2. The set of invertible  $n \times n$  real matrices is a group under matrix multiplication.
3. The set of all permutations of a set is a group under composition.

# Interlaces

---

Let  $a_1 \geq a_2 \geq \dots \geq a_n$  and  $b_1 \geq b_2 \geq \dots \geq b_{n-1}$ , two sequences of real numbers arranged in decreasing order. Then the sequence  $\{b_i\}$  **interlaces** the sequence  $\{a_i\}$  if  $a_n \leq b_{n-1} \leq a_{n-1} \leq \dots \leq b_1 \leq a_1$ . Further, if all of the above inequalities can be taken to be strict, the sequence  $\{b_i\}$  **strictly interlaces** the sequence  $\{a_i\}$ . Analogous definitions are given when the numbers are in increasing order.

## Examples:

$7 \geq 2.2 \geq -1$  strictly interlaces  $11 \geq \pi \geq 0 \geq -2.6$ .

# Majorization

---

Let  $\alpha = (a_1, a_2, \dots, a_n)$ ,  $\beta = (b_1, b_2, \dots, b_n)$  be sequences of real numbers.

$\alpha^\downarrow = (a_1^\downarrow, a_2^\downarrow, \dots, a_n^\downarrow)$  is the permutation of  $\alpha$  with entries in nonincreasing order, i.e.,  $a_1^\downarrow \geq a_2^\downarrow \geq \dots \geq a_n^\downarrow$ .  
 $\alpha^\uparrow = (a_1^\uparrow, a_2^\uparrow, \dots, a_n^\uparrow)$  is the permutation of  $\alpha$  with entries in nondecreasing order, i.e.,  $a_1^\uparrow \leq a_2^\uparrow \leq \dots \leq a_n^\uparrow$ .

$\alpha$  **weakly majorizes**  $\beta$ , written  $\alpha \succeq_w \beta$  or  $\beta \preceq_w \alpha$ , if:

$$\sum_{i=1}^k a_i^\downarrow \geq \sum_{i=1}^k b_i^\downarrow \quad \text{for all } k = 1, \dots, n.$$

$\alpha$  **majorizes**  $\beta$ , written  $\alpha \succeq \beta$  or  $\beta \preceq \alpha$ , if  $\alpha \succeq_w \beta$  and  $\sum_{i=1}^n a_i = \sum_{i=1}^n b_i$ .

## Examples:

1. If  $\alpha = (2, 2, -1.3, 8, 7.7)$ , then  $\alpha^\downarrow = (8, 7.7, 2, 2, -1.3)$  and  $\alpha^\uparrow = (-1.3, 2, 2, 7.7, 8)$ .
2.  $(5, 3, 1.5, 1.5, 1) \succeq (4, 3, 2, 2, 1)$  and  $(6, 5, 0) \succeq_w (4, 3, 2)$ .

# Metric

---

A **metric** on a set  $S$  is a real-valued function  $f : S \times S \rightarrow \mathbb{R}$  satisfying the following conditions:

1. For all  $x, y \in S$ ,  $f(x, y) \geq 0$ .
2. For all  $x \in S$ ,  $f(x, x) = 0$ .
3. For all  $x, y \in S$ ,  $f(x, y) = 0$  implies  $x = y$ .
4. For all  $x, y \in S$ ,  $f(x, y) = f(y, x)$ .
5. For all  $x, y, z \in S$ ,  $f(x, y) + f(y, z) \geq f(x, z)$ .

A metric is intended as a measure of distance between elements of the set.

**Examples:**

If  $\|\cdot\|$  is a norm on a vector space, then  $f(x, y) = \|\mathbf{x} - \mathbf{y}\|$  is a metric.

## Multiset

---

A **multiset** is an unordered list of elements that allows repetition.

**Examples:**

Any set is a multiset, but  $\{1, 1, 3, -2, -2, -2\}$  is a multiset that is not a set.

## O and o

---

Let,  $f, g$  be real valued functions of  $\mathbb{N}$  or  $\mathbb{R}$ , i.e.,  $f, g : \mathbb{N} \rightarrow \mathbb{R}$  or  $f, g : \mathbb{R} \rightarrow \mathbb{R}$ .

$f$  is  $O(g)$  (**big-oh** of  $g$ ) if there exist constants  $C, k$  such that  $|f(x)| \leq C|g(x)|$  for all  $x \geq k$ .

$f$  is  $o(g)$  (**little-oh** of  $g$ ) if  $\lim_{x \rightarrow \infty} \left| \frac{f(x)}{g(x)} \right| = 0$ .

**Examples:**

$x^2 + x$  is  $O(x^2)$  and  $\ln x$  is  $o(x)$ .

## Path-connected

---

A subset  $S$  of the complex numbers is **path-connected** if for any  $x, y \in S$  there exists a continuous function  $p : [0, 1] \rightarrow S$  with  $p(0) = x$  and  $p(1) = y$ .

**Examples:**

$S = \{z \in \mathbb{C} : 1 \leq |z| \leq 2\}$  and the line  $\{a + bi : a = 2b + 3\}$  are path-connected.

## Permutations

---

A **permutation** is a one-to-one onto function from a set to itself.

The set of permutations of  $\{1, \dots, n\}$  is denoted  $S_n$ . The identity permutation is denoted  $\varepsilon_n$ . In this book, permutations are generally assumed to be elements of  $S_n$  for some  $n$ .

A **cycle** or  $k$ -**cycle** is a permutation  $\tau$  such that there is a subset  $\{a_1, \dots, a_k\}$  of  $\{1, \dots, n\}$  satisfying  $\tau(a_i) = a_{i+1}$  and  $\tau(a_k) = a_1$ ; this is denoted  $\tau = (a_1, a_2, \dots, a_k)$ . The **length** of this cycle is  $k$ .

A **transposition** is a 2-cycle.

A permutation is **even** (respectively, **odd**) if it can be written as the product of an even (odd) number of transpositions.

The **sign** of a permutation  $\tau$ , denoted  $\text{sgn } \tau$ , is  $+1$  if  $\tau$  is even and  $-1$  if  $\tau$  is odd.

*Note:* Permutations are functions and act from the left (see Examples).

**Facts:**

1. Every permutation can be expressed as a product of disjoint cycles. This expression is unique up to the order of the cycles in the decomposition and cyclic permutation within a cycle.
2. Every permutation can be written as a product of transpositions. If some such expression includes an even number of transpositions, then every such expression includes an even number of transpositions.
3.  $S_n$  with the operation of composition is a group.

### Examples:

1. If  $\tau = (1523) \in S_6$ , then  $\tau(1) = 5, \tau(2) = 3, \tau(3) = 1, \tau(4) = 4, \tau(5) = 2, \tau(6) = 6$ .
2.  $(123)(12) = (13)$ .
3.  $\text{sgn}(1234) = -1$ , because  $(1234) = (14)(13)(12)$ .

## Ring

---

(See also Section 23.1)

A **ring** is a set  $R$  together with a function  $R \times R \rightarrow R$  called addition, denoted  $(a, b) \rightarrow a + b$ , and a function  $R \times R \rightarrow R$  called multiplication, denoted  $(a, b) \rightarrow ab$ , which satisfy the following axioms:

1. (Commutativity of +) For each  $a, b \in R, a + b = b + a$ .
2. (Associativity) For each  $a, b, c \in R, (a + b) + c = a + (b + c)$  and  $(ab)c = a(bc)$ .
3. (+ identity) There exists an element  $0$  in  $R$  such that  $0 + a = a$ .
4. (+ inverse) For each  $a \in R$ , there exists an element  $-a \in R$  such that  $(-a) + a = 0$ .
5. (Distributivity) For each  $a, b, c \in R, a(b + c) = ab + ac$  and  $(a + b)c = ac + bc$ .

A **zero divisor** in a ring  $R$  is a nonzero element  $a \in R$  such that there exists a nonzero  $b \in R$  with  $ab = 0$  or  $ba = 0$ .

### Examples:

- The set of integers,  $\mathbb{Z}$ , is a ring.
- Any field is a ring.
- Let  $F$  be a field. Then  $F^{n \times n}$ , with matrix addition and matrix multiplication as the operations, is a ring.  $E_{11} = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}$  and  $E_{22} = \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}$  are zero divisors since  $E_{11}E_{22} = 0_2$ .

## Sign

---

(For sign of a permutation, see *permutation*.)

The **sign** of a complex number is defined by:

$$\text{sign}(z) = \begin{cases} z/|z|, & \text{if } z \neq 0; \\ 1, & \text{if } z = 0. \end{cases}$$

If  $z$  is a real number, this sign function yields 1 or  $-1$ .

This sign function is used in numerical linear algebra.

The **sign** of a real number (as used in sign patterns) is defined by:

$$\text{sgn}(a) = \begin{cases} +, & \text{if } a > 0; \\ 0, & \text{if } a = 0; \\ -, & \text{if } a < 0. \end{cases}$$

This sign function is used in combinatorial linear algebra, and the product of a sign and a real number is interpreted in the obvious way as a real number.

*Warning:* The two sign functions disagree on the sign of 0.

### Examples:

$\text{sgn}(-1.3) = -, \text{sign}(-1.3) = -1, \text{sgn}(0) = 0, \text{sign}(0) = 1,$

$\text{sign}(1+i) = \frac{(1+i)}{\sqrt{2}}.$

Throughout this chapter,  $F$  will denote a field. The references [Lay03], [Leo02], and [SIF00] are good sources for more detail about much of the material in this chapter. They discuss primarily the field of real numbers, but the proofs are usually valid for any field.

### 1.1 Vector Spaces

---

Vectors are used in many applications. They often represent quantities that have both direction and magnitude, such as velocity or position, and can appear as functions, as  $n$ -tuples of scalars, or in other disguises. Whenever objects can be added and multiplied by scalars, they may be elements of some vector space. In this section, we formulate a general definition of vector space and establish its basic properties. An element of a field, such as the real numbers or the complex numbers, is called a scalar to distinguish it from a vector.

#### Definitions:

A **vector space over**  $F$  is a set  $V$  together with a function  $V \times V \rightarrow V$  called **addition**, denoted  $(\mathbf{x}, \mathbf{y}) \rightarrow \mathbf{x} + \mathbf{y}$ , and a function  $F \times V \rightarrow V$  called **scalar multiplication** and denoted  $(c, \mathbf{x}) \rightarrow c\mathbf{x}$ , which satisfy the following axioms:

1. (Commutativity) For each  $\mathbf{x}, \mathbf{y} \in V$ ,  $\mathbf{x} + \mathbf{y} = \mathbf{y} + \mathbf{x}$ .
2. (Associativity) For each  $\mathbf{x}, \mathbf{y}, \mathbf{z} \in V$ ,  $(\mathbf{x} + \mathbf{y}) + \mathbf{z} = \mathbf{x} + (\mathbf{y} + \mathbf{z})$ .
3. (Additive identity) There exists a **zero vector** in  $V$ , denoted  $\mathbf{0}$ , such that  $\mathbf{0} + \mathbf{x} = \mathbf{x}$  for each  $\mathbf{x} \in V$ .
4. (Additive inverse) For each  $\mathbf{x} \in V$ , there exists  $-\mathbf{x} \in V$  such that  $(-\mathbf{x}) + \mathbf{x} = \mathbf{0}$ .
5. (Distributivity) For each  $a \in F$  and  $\mathbf{x}, \mathbf{y} \in V$ ,  $a(\mathbf{x} + \mathbf{y}) = a\mathbf{x} + a\mathbf{y}$ .
6. (Distributivity) For each  $a, b \in F$  and  $\mathbf{x} \in V$ ,  $(a + b)\mathbf{x} = a\mathbf{x} + b\mathbf{x}$ .

7. (Associativity) For each  $a, b \in F$  and  $\mathbf{x} \in V$ ,  $(ab)\mathbf{x} = a(b\mathbf{x})$ .
8. For each  $\mathbf{x} \in V$ ,  $1\mathbf{x} = \mathbf{x}$ .

The properties that for all  $\mathbf{x}, \mathbf{y} \in V$ , and  $a \in F$ ,  $\mathbf{x} + \mathbf{y} \in V$  and  $a\mathbf{x} \in V$ , are called **closure under addition** and **closure under scalar multiplication**, respectively. The elements of a vector space  $V$  are called **vectors**. A vector space is called **real** if  $F = \mathbb{R}$ , **complex** if  $F = \mathbb{C}$ .

If  $n$  is a positive integer,  $F^n$  denotes the set of all ordered  $n$ -tuples (written as columns). These are

sometimes written instead as rows  $[x_1 \ \cdots \ x_n]$  or  $(x_1, \dots, x_n)$ . For  $\mathbf{x} = \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix}, \mathbf{y} = \begin{bmatrix} y_1 \\ \vdots \\ y_n \end{bmatrix} \in F^n$  and  $c \in F$ ,

define addition and scalar multiplication coordinate-wise:  $\mathbf{x} + \mathbf{y} = \begin{bmatrix} x_1 + y_1 \\ \vdots \\ x_n + y_n \end{bmatrix}$  and  $c\mathbf{x} = \begin{bmatrix} cx_1 \\ \vdots \\ cx_n \end{bmatrix}$ . Let  $\mathbf{0}$

denote the  $n$ -tuple of zeros. For  $\mathbf{x} \in F^n$ ,  $x_j$  is called the  $j^{\text{th}}$  **coordinate** of  $\mathbf{x}$ .

A **subspace** of vector space  $V$  over field  $F$  is a subset of  $V$ , which is itself a vector space over  $F$  when the addition and scalar multiplication of  $V$  are used. If  $S_1$  and  $S_2$  are subsets of vector space  $V$ , define  $S_1 + S_2 = \{\mathbf{x} + \mathbf{y} : \mathbf{x} \in S_1 \text{ and } \mathbf{y} \in S_2\}$ .

### Facts:

Let  $V$  be a vector space over  $F$ .

1.  $F^n$  is a vector space over  $F$ .
2. [FIS03, pp. 11–12] (Basic properties of a vector space):
  - The vector  $\mathbf{0}$  is the only additive identity in  $V$ .
  - For each  $\mathbf{x} \in V$ ,  $-\mathbf{x}$  is the only additive inverse for  $\mathbf{x}$  in  $V$ .
  - For each  $\mathbf{x} \in V$ ,  $-\mathbf{x} = (-1)\mathbf{x}$ .
  - If  $a \in F$  and  $\mathbf{x} \in V$ , then  $a\mathbf{x} = \mathbf{0}$  if and only if  $a = 0$  or  $\mathbf{x} = \mathbf{0}$ .
  - (Cancellation) If  $\mathbf{x}, \mathbf{y}, \mathbf{z} \in V$  and  $\mathbf{x} + \mathbf{y} = \mathbf{x} + \mathbf{z}$ , then  $\mathbf{y} = \mathbf{z}$ .
3. [FIS03, pp. 16–17] Let  $W$  be a subset of  $V$ . The following are equivalent:
  - $W$  is a subspace of  $V$ .
  - $W$  is nonempty and closed under addition and scalar multiplication.
  - $\mathbf{0} \in W$  and for any  $\mathbf{x}, \mathbf{y} \in W$  and  $a, b \in F$ ,  $a\mathbf{x} + b\mathbf{y} \in W$ .
4. For any vector space  $V$ ,  $\{\mathbf{0}\}$  and  $V$  itself are subspaces of  $V$ .
5. [FIS03, p. 19] The intersection of any nonempty collection of subspaces of  $V$  is a subspace of  $V$ .
6. [FIS03, p. 22] Let  $W_1$  and  $W_2$  be subspaces of  $V$ . Then  $W_1 + W_2$  is a subspace of  $V$  containing  $W_1$  and  $W_2$ . It is the smallest subspace that contains them in the sense that any subspace that contains both  $W_1$  and  $W_2$  must contain  $W_1 + W_2$ .

### Examples:

1. The set  $\mathbb{R}^n$  of all ordered  $n$ -tuples of real numbers is a vector space over  $\mathbb{R}$ , and the set  $\mathbb{C}^n$  of all ordered  $n$ -tuples of complex numbers is a vector space over  $\mathbb{C}$ . For instance,  $\mathbf{x} = \begin{bmatrix} 3 \\ 0 \\ -1 \end{bmatrix}$  and

$$\mathbf{y} = \begin{bmatrix} 2i \\ 4 \\ 2 - 3i \end{bmatrix} \text{ are elements of } \mathbb{C}^3; \mathbf{x} + \mathbf{y} = \begin{bmatrix} 3 + 2i \\ 4 \\ 1 - 3i \end{bmatrix}, -\mathbf{y} = \begin{bmatrix} -2i \\ -4 \\ -2 + 3i \end{bmatrix}, \text{ and } i\mathbf{y} = \begin{bmatrix} -2 \\ 4i \\ 3 + 2i \end{bmatrix}.$$

2. Notice  $\mathbb{R}^n$  is a subset of  $\mathbb{C}^n$  but not a subspace of  $\mathbb{C}^n$ , since  $\mathbb{R}^n$  is not closed under multiplication by nonreal numbers.

3. The vector spaces  $\mathbb{R}$ ,  $\mathbb{R}^2$ , and  $\mathbb{R}^3$  are the usual Euclidean spaces of analytic geometry. There are three types of subspaces of  $\mathbb{R}^2$ :  $\{\mathbf{0}\}$ , a line through the origin, and  $\mathbb{R}^2$  itself. There are four types of subspaces of  $\mathbb{R}^3$ :  $\{\mathbf{0}\}$ , a line through the origin, a plane through the origin, and  $\mathbb{R}^3$  itself. For instance, let  $\mathbf{v} = (5, -1, -1)$  and  $\mathbf{w} = (0, 3, -2)$ . The lines  $W_1 = \{s\mathbf{v} : s \in \mathbb{R}\}$  and  $W_2 = \{s\mathbf{w} : s \in \mathbb{R}\}$  are subspaces of  $\mathbb{R}^3$ . The subspace  $W_1 + W_2 = \{s\mathbf{v} + t\mathbf{w} : s, t \in \mathbb{R}\}$  is a plane. The set  $\{s\mathbf{v} + \mathbf{w} : s \in \mathbb{R}\}$  is a line parallel to  $W_1$ , but is not a subspace. (For more information on geometry, see Chapter 65.)
4. Let  $F[x]$  be the set of all polynomials in the single variable  $x$ , with coefficients from  $F$ . To add polynomials, add coefficients of like powers; to multiply a polynomial by an element of  $F$ , multiply each coefficient by that scalar. With these operations,  $F[x]$  is a vector space over  $F$ . The zero polynomial  $z$ , with all coefficients 0, is the additive identity of  $F[x]$ . For  $f \in F[x]$ , the function  $-f$  defined by  $-f(x) = (-1)f(x)$  is the additive inverse of  $f$ .
5. In  $F[x]$ , the constant polynomials have degree 0. For  $n > 0$ , the polynomials with highest power term  $x^n$  are said to have degree  $n$ . For a nonnegative integer  $n$ , let  $F[x; n]$  be the subset of  $F[x]$  consisting of all polynomials of degree  $n$  or less. Then  $F[x; n]$  is a subspace of  $F[x]$ .
6. When  $n > 0$ , the set of all polynomials of degree exactly  $n$  is not a subspace of  $F[x]$  because it is not closed under addition or scalar multiplication. The set of all polynomials in  $\mathbb{R}[x]$  with rational coefficients is not a subspace of  $\mathbb{R}[x]$  because it is not closed under scalar multiplication.
7. Let  $V$  be the set of all infinite sequences  $(a_1, a_2, a_3, \dots)$ , where each  $a_j \in F$ . Define addition and scalar multiplication coordinate-wise. Then  $V$  is a vector space over  $F$ .
8. Let  $X$  be a nonempty set and let  $\mathcal{F}(X, F)$  be the set of all functions  $f: X \rightarrow F$ . Let  $f, g \in \mathcal{F}(X, F)$  and define  $f + g$  and  $cf$  pointwise, as  $(f + g)(x) = f(x) + g(x)$  and  $(cf)(x) = cf(x)$  for all  $x \in X$ . With these operations,  $\mathcal{F}(X, F)$  is a vector space over  $F$ . The zero function is the additive identity and  $(-1)f = -f$ , the additive inverse of  $f$ .
9. Let  $X$  be a nonempty subset of  $\mathbb{R}^n$ . The set  $C(X)$  of all continuous functions  $f: X \rightarrow \mathbb{R}$  is a subspace of  $\mathcal{F}(X, \mathbb{R})$ . The set  $\mathcal{D}(X)$  of all differentiable functions  $f: X \rightarrow \mathbb{R}$  is a subspace of  $C(X)$  and also of  $\mathcal{F}(X, \mathbb{R})$ .

## 1.2 Matrices

Matrices are rectangular arrays of scalars that are used in a great variety of ways, such as to solve linear systems, model linear behavior, and approximate nonlinear behavior. They are standard tools in almost every discipline, from sociology to physics and engineering.

### Definitions:

An  $m \times p$  **matrix** over  $F$  is an  $m \times p$  rectangular array  $A = \begin{bmatrix} a_{11} & \cdots & a_{1p} \\ \vdots & \cdots & \vdots \\ a_{m1} & \cdots & a_{mp} \end{bmatrix}$ , with entries from  $F$ . The

notation  $A = [a_{ij}]$  that displays a typical entry is also used. The element  $a_{ij}$  of the matrix  $A$  is called the  $(i, j)$  **entry** of  $A$  and can also be denoted  $(A)_{ij}$ . The **shape** (or **size**) of  $A$  is  $m \times p$ , and  $A$  is **square** if  $m = p$ ; in this case,  $m$  is also called the size of  $A$ . Two matrices  $A = [a_{ij}]$  and  $B = [b_{ij}]$  are said to be **equal** if they have the same shape and  $a_{ij} = b_{ij}$  for all  $i, j$ . Let  $A = [a_{ij}]$  and  $B = [b_{ij}]$  be  $m \times p$  matrices, and let  $c$  be a scalar. Define **addition** and **scalar multiplication** on the set of all  $m \times p$  matrices over  $F$  entrywise, as  $A + B = [a_{ij} + b_{ij}]$  and  $cA = [ca_{ij}]$ . The set of all  $m \times p$  matrices over  $F$  with these operations is denoted  $F^{m \times p}$ .

If  $A$  is  $m \times p$ , **row**  $i$  is  $[a_{i1}, \dots, a_{ip}]$  and **column**  $j$  is  $\begin{bmatrix} a_{1j} \\ \vdots \\ a_{mj} \end{bmatrix}$ . These are called a **row vector** and a **column vector** respectively, and they belong to  $F^{n \times 1}$  and  $F^{1 \times n}$ , respectively. The elements of  $F^n$  are identified with the elements of  $F^{n \times 1}$  (or sometimes with the elements of  $F^{1 \times n}$ ). Let  $\mathbf{0}_{mp}$  denote the  $m \times p$  matrix of zeros, often shortened to  $\mathbf{0}$  when the size is clear. Define  $-A = (-1)A$ .

Let  $A = [\mathbf{a}_1 \ \dots \ \mathbf{a}_p] \in F^{m \times p}$ , where  $\mathbf{a}_j$  is the  $j$ th column of  $A$ , and let  $\mathbf{b} = \begin{bmatrix} b_1 \\ \vdots \\ b_p \end{bmatrix} \in F^{p \times 1}$ . The

**matrix–vector product** of  $A$  and  $\mathbf{b}$  is  $\mathbf{Ab} = b_1\mathbf{a}_1 + \dots + b_p\mathbf{a}_p$ . Notice  $\mathbf{Ab}$  is  $m \times 1$ .

If  $A \in F^{m \times p}$  and  $C = [\mathbf{c}_1 \ \dots \ \mathbf{c}_n] \in F^{p \times n}$ , define the **matrix product** of  $A$  and  $C$  as  $AC = [A\mathbf{c}_1 \ \dots \ A\mathbf{c}_n]$ . Notice  $AC$  is  $m \times n$ .

Square matrices  $A$  and  $B$  **commute** if  $AB = BA$ . When  $i = j$ ,  $a_{ii}$  is a **diagonal entry** of  $A$  and the set of all its diagonal entries is the **main diagonal** of  $A$ . When  $i \neq j$ ,  $a_{ij}$  is an **off-diagonal entry**.

The **trace** of  $A$  is the sum of all the diagonal entries of  $A$ ,  $\text{tr } A = \sum_{i=1}^n a_{ii}$ .

A matrix  $A = [a_{ij}]$  is **diagonal** if  $a_{ij} = 0$  whenever  $i \neq j$ , **lower triangular** if  $a_{ij} = 0$  whenever  $i < j$ , and **upper triangular** if  $a_{ij} = 0$  whenever  $i > j$ . A **unit triangular** matrix is a lower or upper triangular matrix in which each diagonal entry is 1.

The **identity matrix**  $I_n$ , often shortened to  $I$  when the size is clear, is the  $n \times n$  matrix with main diagonal entries 1 and other entries 0.

A **scalar matrix** is a scalar multiple of the identity matrix.

A **permutation matrix** is one whose rows are some rearrangement of the rows of an identity matrix.

Let  $A \in F^{m \times p}$ . The **transpose** of  $A$ , denoted  $A^T$ , is the  $p \times m$  matrix whose  $(i, j)$  entry is the  $(j, i)$  entry of  $A$ .

The square matrix  $A$  is **symmetric** if  $A^T = A$  and **skew-symmetric** if  $A^T = -A$ .

When  $F = \mathbb{C}$ , that is, when  $A$  has complex entries, the **Hermitian adjoint** of  $A$  is its conjugate transpose,  $A^* = \bar{A}^T$ ; that is, the  $(i, j)$  entry of  $A^*$  is  $\bar{a}_{ji}$ . Some authors, such as [Leo02], write  $A^H$  instead of  $A^*$ .

The square matrix  $A$  is **Hermitian** if  $A^* = A$  and **skew-Hermitian** if  $A^* = -A$ .

Let  $\alpha$  be a nonempty set of row indices and  $\beta$  a nonempty set of column indices. A **submatrix** of  $A$  is a matrix  $A[\alpha, \beta]$  obtained by choosing the entries of  $A$ , which lie in rows  $\alpha$  and columns  $\beta$ . A **principal submatrix** of  $A$  is a submatrix of the form  $A[\alpha, \alpha]$ . A **leading principal submatrix** of  $A$  is one of the form  $A[\{1, \dots, k\}, \{1, \dots, k\}]$ .

### Facts:

- [SIF00, p. 5]  $F^{m \times p}$  is a vector space over  $F$ . That is, if  $\mathbf{0}, A, B, C \in F^{m \times p}$ , and  $c, d \in F$ , then:
  - $A + B = B + A$
  - $(A + B) + C = A + (B + C)$
  - $A + \mathbf{0} = \mathbf{0} + A = A$
  - $A + (-A) = (-A) + A = \mathbf{0}$
  - $c(A + B) = cA + cB$
  - $(c + d)A = cA + dA$
  - $(cd)A = c(dA)$
  - $1A = A$
- If  $A \in F^{m \times p}$  and  $C \in F^{p \times n}$ , the  $(i, j)$  entry of  $AC$  is  $(AC)_{ij} = \sum_{k=1}^p a_{ik}a_{kj}$ . This is the matrix product of row  $i$  of  $A$  and column  $j$  of  $C$ .
- [SIF00, p. 88] Let  $c \in F$ , let  $A$  and  $B$  be matrices over  $F$ , let  $I$  denote an identity matrix, and assume the shapes allow the following sums and products to be calculated. Then:
  - $AI = IA = A$
  - $A\mathbf{0} = \mathbf{0}$  and  $\mathbf{0}A = \mathbf{0}$
  - $A(BC) = (AB)C$
  - $A(B + C) = AB + AC$
  - $(A + B)C = AC + BC$
  - $c(AB) = A(cB) = (cA)B$  for any scalar  $c$

4. [SIF00, p. 5 and p. 20] Let  $c \in F$ , let  $A$  and  $B$  be matrices over  $F$ , and assume the shapes allow the following sums and products to be calculated. Then:
  - $(A^T)^T = A$
  - $(A + B)^T = A^T + B^T$
  - $(cA)^T = cA^T$
  - $(AB)^T = B^T A^T$
5. [Leo02, pp. 321–323] Let  $c \in \mathbb{C}$ , let  $A$  and  $B$  be matrices over  $\mathbb{C}$ , and assume the shapes allow the following sums and products to be calculated. Then:
  - $(A^*)^* = A$
  - $(A + B)^* = A^* + B^*$
  - $(cA)^* = \bar{c}A^*$
  - $(AB)^* = B^*A^*$
6. If  $A$  and  $B$  are  $n \times n$  and upper (lower) triangular, then  $AB$  is upper (lower) triangular.

**Examples:**

1. Let  $A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix}$  and  $\mathbf{b} = \begin{bmatrix} 7 \\ 8 \\ -9 \end{bmatrix}$ . By definition,  $\mathbf{Ab} = 7 \begin{bmatrix} 1 \\ 4 \end{bmatrix} + 8 \begin{bmatrix} 2 \\ 5 \end{bmatrix} - 9 \begin{bmatrix} 3 \\ 6 \end{bmatrix} = \begin{bmatrix} -4 \\ 14 \end{bmatrix}$ . Hand

calculation of  $\mathbf{Ab}$  can be done more quickly using Fact 2:  $\mathbf{Ab} = \begin{bmatrix} 1 \cdot 7 + 2 \cdot 8 - 3 \cdot 9 \\ 4 \cdot 7 + 5 \cdot 8 - 6 \cdot 9 \end{bmatrix} = \begin{bmatrix} -4 \\ 14 \end{bmatrix}$ .

2. Let  $A = \begin{bmatrix} 1 & -3 & 4 \\ 2 & 0 & 8 \end{bmatrix}$ ,  $B = \begin{bmatrix} -3 & 8 & 0 \\ 1 & 2 & -5 \end{bmatrix}$ , and  $C = \begin{bmatrix} 1 & -1 & 8 \\ 1 & 3 & 0 \\ 1 & 2 & -2 \end{bmatrix}$ . Then  $A + B = \begin{bmatrix} -2 & 5 & 4 \\ 3 & 2 & 3 \end{bmatrix}$  and  $2A = \begin{bmatrix} 2 & -6 & 8 \\ 4 & 0 & 16 \end{bmatrix}$ . The matrices  $A + C$ ,  $BA$ , and  $AB$  are not defined, but

$$AC = \begin{bmatrix} A \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} & A \begin{bmatrix} -1 \\ 3 \\ 2 \end{bmatrix} & A \begin{bmatrix} 8 \\ 0 \\ -2 \end{bmatrix} \end{bmatrix} = \begin{bmatrix} 2 & -2 & 0 \\ 10 & 14 & 0 \end{bmatrix}.$$

3. Even when the shapes of  $A$  and  $B$  allow both  $AB$  and  $BA$  to be calculated,  $AB$  and  $BA$  are not usually equal. For instance, let  $A = \begin{bmatrix} 1 & 0 \\ 0 & 2 \end{bmatrix}$  and  $B = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$ ; then  $AB = \begin{bmatrix} a & b \\ 2c & 2d \end{bmatrix}$  and  $BA = \begin{bmatrix} a & 2b \\ c & 2d \end{bmatrix}$ , which will be equal only if  $b = c = 0$ .

4. The product of matrices can be a zero matrix even if neither has any zero entries. For example, if  $A = \begin{bmatrix} 1 & -1 \\ 2 & -2 \end{bmatrix}$  and  $B = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}$ , then  $AB = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$ . Notice that  $BA$  is also defined but has no zero entries:  $BA = \begin{bmatrix} 3 & -3 \\ 3 & -3 \end{bmatrix}$ .

5. The matrices  $\begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -9 \end{bmatrix}$  and  $\begin{bmatrix} 1 & 0 & 0 \\ 0 & -3 & 0 \end{bmatrix}$  are diagonal,  $\begin{bmatrix} 1 & 0 & 0 \\ 2 & 0 & 0 \\ 1 & 5 & -9 \end{bmatrix}$  and  $\begin{bmatrix} 1 & 0 & 0 \\ 2 & -3 & 0 \end{bmatrix}$  are

lower triangular, and  $\begin{bmatrix} 1 & -4 & 7 \\ 0 & 1 & 2 \\ 0 & 0 & -9 \end{bmatrix}$  and  $\begin{bmatrix} 1 & 2 & 3 \\ 0 & 4 & 5 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$  are upper triangular. The matrix  $\begin{bmatrix} 1 & 0 & 0 \\ 2 & 1 & 0 \\ 1 & 5 & 1 \end{bmatrix}$

is unit lower triangular, and its transpose is unit upper triangular.

6. Examples of permutation matrices include every identity matrix,  $\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$ ,  $\begin{bmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{bmatrix}$ , and  $\begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}$ .

7. Let  $A = \begin{bmatrix} 1+i & -3i & 4 \\ 1+2i & 5i & 0 \end{bmatrix}$ . Then  $A^T = \begin{bmatrix} 1+i & 1+2i \\ -3i & 5i \\ 4 & 0 \end{bmatrix}$  and  $A^* = \begin{bmatrix} 1-i & 1-2i \\ 3i & -5i \\ 4 & 0 \end{bmatrix}$ .

8. The matrices  $\begin{bmatrix} 1 & 2 & 3 \\ 2 & 4 & 5 \\ 3 & 5 & 6 \end{bmatrix}$  and  $\begin{bmatrix} i & 2 & 3+2i \\ 2 & 4-i & 5i \\ 3+2i & 5i & 6 \end{bmatrix}$  are symmetric.

9. The matrices  $\begin{bmatrix} 0 & 2 & 3 \\ -2 & 0 & 5 \\ -3 & -5 & 0 \end{bmatrix}$  and  $\begin{bmatrix} 0 & 2 & 3+2i \\ -2 & 0 & -5 \\ -3-2i & 5 & 0 \end{bmatrix}$  are skew-symmetric.

10. The matrix  $\begin{bmatrix} 1 & 2+i & 1-3i \\ 2-i & 0 & 1 \\ 1+3i & 1 & 6 \end{bmatrix}$  is Hermitian, and any real symmetric matrix, such as

$$\begin{bmatrix} 4 & 2 & 3 \\ 2 & 0 & 5 \\ 3 & 5 & -1 \end{bmatrix}, \text{ is also Hermitian.}$$

11. The matrix  $\begin{bmatrix} i & 2 & -3+2i \\ -2 & 4i & 5 \\ 3+2i & -5 & 0 \end{bmatrix}$  is skew-Hermitian, and any real skew-symmetric matrix,

$$\text{such as } \begin{bmatrix} 0 & 2 & -3 \\ -2 & 0 & 5 \\ 3 & -5 & 0 \end{bmatrix}, \text{ is also skew-Hermitian.}$$

12. Let  $A = \begin{bmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \\ 9 & 10 & 11 & 12 \\ 13 & 14 & 15 & 16 \end{bmatrix}$ . Row 1 of  $A$  is  $[1 \ 2 \ 3 \ 4]$ , column 3 is  $\begin{bmatrix} 3 \\ 7 \\ 11 \\ 15 \end{bmatrix}$ , and the submatrix

$$\text{in rows } \{1, 2, 4\} \text{ and columns } \{2, 3, 4\} \text{ is } A[\{1, 2, 4\}, \{2, 3, 4\}] = \begin{bmatrix} 2 & 3 & 4 \\ 6 & 7 & 8 \\ 14 & 15 & 16 \end{bmatrix}. \text{ A principal}$$

$$\text{submatrix of } A \text{ is } A[\{1, 2, 4\}, \{1, 2, 4\}] = \begin{bmatrix} 1 & 2 & 4 \\ 5 & 6 & 8 \\ 13 & 14 & 16 \end{bmatrix}. \text{ The leading principal submatrices of}$$

$$A \text{ are } [1], \begin{bmatrix} 1 & 2 \\ 5 & 6 \end{bmatrix}, \begin{bmatrix} 1 & 2 & 3 \\ 5 & 6 & 7 \\ 9 & 10 & 11 \end{bmatrix}, \text{ and } A \text{ itself.}$$

## 1.3 Gaussian and Gauss–Jordan Elimination

---

### Definitions:

Let  $A$  be a matrix with  $m$  rows.

When a row of  $A$  is not zero, its first nonzero entry is the **leading entry** of the row. The matrix  $A$  is in **row echelon form** (REF) when the following two conditions are met:

1. Any zero rows are below all nonzero rows.
2. For each nonzero row  $i$ ,  $i \leq m - 1$ , either row  $i + 1$  is zero or the leading entry of row  $i + 1$  is in a column to the right of the column of the leading entry in row  $i$ .

The matrix  $A$  is in **reduced row echelon form** (RREF) if it is in row echelon form and the following third condition is also met:

3. If  $a_{ik}$  is the leading entry in row  $i$ , then  $a_{ik} = 1$ , and every entry of column  $k$  other than  $a_{ik}$  is zero.

**Elementary row operations** on a matrix are operations of the following types:

1. Add a multiple of one row to a different row.
2. Exchange two different rows.
3. Multiply one row by a nonzero scalar.

The matrix  $A$  is **row equivalent** to the matrix  $B$  if there is a sequence of elementary row operations that transforms  $A$  into  $B$ . The **reduced row echelon form** of  $A$ ,  $\text{RREF}(A)$ , is the matrix in reduced row echelon form that is row equivalent to  $A$ . A **row echelon form** of  $A$  is any matrix in row echelon form that is row equivalent to  $A$ . The **rank** of  $A$ , denoted  $\text{rank } A$  or  $\text{rank}(A)$ , is the number of leading entries in  $\text{RREF}(A)$ . If  $A$  is in row echelon form, the positions of the leading entries in its nonzero rows are called **pivot positions** and the entries in those positions are called **pivots**. A column (row) that contains a pivot position is a **pivot column** (**pivot row**).

**Gaussian Elimination** is a process that uses elementary row operations in a particular way to change, or reduce, a matrix to row echelon form. **Gauss–Jordan Elimination** is a process that uses elementary row operations in a particular way to reduce a matrix to RREF. See Algorithm 1 below.

### Facts:

Let  $A \in F^{m \times p}$ .

1. [Lay03, p. 15] The reduced row echelon form of  $A$ ,  $\text{RREF}(A)$ , exists and is unique.
2. A matrix in REF or RREF is upper triangular.
3. Every elementary row operation is reversible by an elementary row operation of the same type.
4. If  $A$  is row equivalent to  $B$ , then  $B$  is row equivalent to  $A$ .
5. If  $A$  is row equivalent to  $B$ , then  $\text{RREF}(A) = \text{RREF}(B)$  and  $\text{rank } A = \text{rank } B$ .
6. The number of nonzero rows in any row echelon form of  $A$  equals  $\text{rank } A$ .
7. If  $B$  is any row echelon form of  $A$ , the positions of the leading entries in  $B$  are the same as the positions of the leading entries of  $\text{RREF}(A)$ .
8. [Lay03, pp. 17–20] (Gaussian and Gauss–Jordan Elimination Algorithms) When one or more pivots are relatively small, using the algorithms below in floating point arithmetic can yield inaccurate results. (See Chapter 38 for more accurate variations of them, and Chapter 75 for information on professional software implementations of such variations.)

**Algorithm 1. Gaussian and Gauss-Jordan Elimination**

Let  $A \in F^{m \times p}$ . Steps 1 to 4 below do Gaussian Elimination, reducing  $A$  to a matrix that is in row echelon form. Steps 1 to 6 do Gauss-Jordan Elimination, reducing  $A$  to  $\text{RREF}(A)$ .

1. Let  $U = A$  and  $r = 1$ . If  $U = \mathbf{0}$ ,  $U$  is in RREF.
2. If  $U \neq \mathbf{0}$ , search the submatrix of  $U$  in rows  $r$  to  $m$  to find its first nonzero column,  $k$ , and the first nonzero entry,  $a_{ik}$ , in this column. If  $i > r$ , exchange rows  $r$  and  $i$  in  $U$ , thus getting a nonzero entry in position  $(r, k)$ . Let  $U$  be the matrix created by this row exchange.
3. Add multiples of row  $r$  to the rows below it, to create zeros in column  $k$  below row  $r$ . Let  $U$  denote the new matrix.
4. If either  $r = m - 1$  or rows  $r + 1, \dots, m$  are all zero,  $U$  is now in REF. Otherwise, let  $r = r + 1$  and repeat steps 2, 3, and 4.
5. Let  $k_1, \dots, k_s$  be the pivot columns of  $U$ , so  $(1, k_1), \dots, (s, k_s)$  are the pivot positions. For  $i = s, s - 1, \dots, 2$ , add multiples of row  $i$  to the rows above it to create zeros in column  $k_i$  above row  $i$ .
6. For  $i = 1, \dots, s$ , divide row  $s$  by its leading entry. The resulting matrix is  $\text{RREF}(A)$ .

**Examples:**

1. The RREF of a zero matrix is itself, and its rank is zero.

2. Let  $A = \begin{bmatrix} 1 & 3 & 4 & -8 \\ 0 & 0 & 2 & 4 \\ 0 & 0 & 0 & 0 \end{bmatrix}$  and  $B = \begin{bmatrix} 1 & 3 & 4 & -8 \\ 0 & 0 & 0 & 4 \\ 0 & 0 & 1 & 0 \end{bmatrix}$ . Both are upper triangular, but  $A$  is in REF

and  $B$  is not. Use Gauss-Jordan Elimination to calculate  $\text{RREF}(A)$  and  $\text{RREF}(B)$ .

For  $A$ , add  $(-2)(\text{row } 2)$  to row 1 and multiply row 2 by  $\frac{1}{2}$ . This yields  $\text{RREF}(A) = \begin{bmatrix} 1 & 3 & 0 & -16 \\ 0 & 0 & 1 & 2 \\ 0 & 0 & 0 & 0 \end{bmatrix}$ .

For  $B$ , exchange rows 2 and 3 to get  $\begin{bmatrix} 1 & 3 & 4 & -8 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 4 \end{bmatrix}$ , which is in REF. Then add  $2(\text{row } 3)$  to

row 1 to get a new matrix. In this new matrix, add  $(-4)(\text{row } 2)$  to row 1, and multiply row 3 by  $\frac{1}{4}$ .

This yields  $\text{RREF}(B) = \begin{bmatrix} 1 & 3 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$ .

Observe that  $\text{rank}(A) = 2$  and  $\text{rank}(B) = 3$ .

3. Apply Gauss-Jordan Elimination to  $A = \begin{bmatrix} 2 & 6 & 4 & 4 \\ -4 & -12 & -8 & -7 \\ 0 & 0 & -1 & -4 \\ 1 & 3 & 1 & -2 \end{bmatrix}$ .

Step 1. Let  $U^{(1)} = A$  and  $r = 1$ .

Step 2. No row exchange is needed since  $a_{11} \neq 0$ .

Step 3. Add  $(2)(\text{row } 1)$  to row 2, and  $(-\frac{1}{2})(\text{row } 1)$  to row 4 to get  $U^{(2)} = \begin{bmatrix} 2 & 6 & 4 & 4 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 4 \\ 0 & 0 & -1 & -4 \end{bmatrix}$ .

Step 4. The submatrix in rows 2, 3, 4 is not zero, so let  $r = 2$  and return to Step 2.

Step 2. Search the submatrix in rows 2 to 4 of  $U^{(2)}$  to see that its first nonzero column is column 3 and the first nonzero entry in this column is in row 3 of  $U^{(2)}$ . Exchange rows 2 and 3 in  $U^{(2)}$  to get

$$U^{(3)} = \begin{bmatrix} 2 & 6 & 4 & 4 \\ 0 & 0 & 1 & 4 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & -4 \end{bmatrix}.$$

Step 3. Add row 2 to row 4 in  $U^{(3)}$  to get  $U^{(4)} = \begin{bmatrix} 2 & 6 & 4 & 4 \\ 0 & 0 & 1 & 4 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}$ .

Step 4. Now  $U^{(4)}$  is in REF, so Gaussian Elimination is finished.

Step 5. The pivot positions are (1, 1), (2, 3), and (3, 4). Add  $-4(\text{row } 3)$  to rows 1 and 2 of  $U^{(4)}$  to get

$$U^{(5)} = \begin{bmatrix} 2 & 6 & 4 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}. \text{ Add } -4(\text{row } 2) \text{ of } U^{(5)} \text{ to row 1 of } U^{(5)} \text{ to get } U^{(6)} = \begin{bmatrix} 2 & 6 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}.$$

Step 6. Multiply row 1 of  $U^{(6)}$  by  $\frac{1}{2}$ , obtaining  $U^{(7)} = \begin{bmatrix} 1 & 3 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}$ , which is RREF( $A$ ).

## 1.4 Systems of Linear Equations

### Definitions:

A **linear equation** is an equation of the form  $a_1x_1 + \cdots + a_px_p = b$  where  $a_1, \dots, a_p, b \in F$  and  $x_1, \dots, x_p$  are **variables**. The scalars  $a_j$  are **coefficients** and the scalar  $b$  is the **constant term**.

A **system of linear equations**, or **linear system**, is a set of one or more linear equations in the same

variables, such as 
$$\begin{aligned} a_{11}x_1 + \cdots + a_{1p}x_p &= b_1 \\ a_{21}x_1 + \cdots + a_{2p}x_p &= b_2 \\ \dots \end{aligned}$$
 . A **solution** of the system is a  $p$ -tuple  $(c_1, \dots, c_p)$  such that

$$a_{m1}x_1 + \cdots + a_{mp}x_p = b_m$$

letting  $x_j = c_j$  for each  $j$  satisfies every equation. The **solution set** of the system is the set of all solutions. A system is **consistent** if there exists at least one solution; otherwise it is **inconsistent**. Systems are **equivalent** if they have the same solution set. If  $b_j = 0$  for all  $j$ , the system is **homogeneous**. A formula that describes a general vector in the solution set is called the **general solution**.

For the system 
$$\begin{aligned} a_{11}x_1 + \cdots + a_{1p}x_p &= b_1 \\ a_{21}x_1 + \cdots + a_{2p}x_p &= b_2 \\ \dots \\ a_{m1}x_1 + \cdots + a_{mp}x_p &= b_m \end{aligned}$$
, the  $m \times p$  matrix  $A = \begin{bmatrix} a_{11} & \cdots & a_{1p} \\ \vdots & \dots & \vdots \\ a_{m1} & \cdots & a_{mp} \end{bmatrix}$  is the **coefficient**

**matrix**,  $\mathbf{b} = \begin{bmatrix} b_1 \\ \vdots \\ b_m \end{bmatrix}$  is the **constant vector**, and  $\mathbf{x} = \begin{bmatrix} x_1 \\ \vdots \\ x_p \end{bmatrix}$  is the **unknown vector**. The  $m \times (p + 1)$  matrix

$[A \ \mathbf{b}]$  is the **augmented matrix** of the system. It is customary to identify the system of linear equations

with the matrix-vector equation  $A\mathbf{x} = \mathbf{b}$ . This is valid because a column vector  $\mathbf{x} = \begin{bmatrix} c_1 \\ \vdots \\ c_p \end{bmatrix}$  satisfies  $A\mathbf{x} =$

$\mathbf{b}$  if and only if  $(c_1, \dots, c_p)$  is a solution of the linear system.

Observe that the coefficients of  $x_k$  are stored in column  $k$  of  $A$ . If  $A\mathbf{x} = \mathbf{b}$  is equivalent to  $C\mathbf{x} = \mathbf{d}$  and column  $k$  of  $C$  is a pivot column, then  $x_k$  is a **basic variable**; otherwise,  $x_k$  is a **free variable**.

### Facts:

Let  $A\mathbf{x} = \mathbf{b}$  be a linear system, where  $A$  is an  $m \times p$  matrix.

- [SIF00, pp. 27, 118] If elementary row operations are done to the augmented matrix  $[A \ \mathbf{b}]$ , obtaining a new matrix  $[C \ \mathbf{d}]$ , the new system  $C\mathbf{x} = \mathbf{d}$  is equivalent to  $A\mathbf{x} = \mathbf{b}$ .
- [SIF00, p. 24] There are three possibilities for the solution set of  $A\mathbf{x} = \mathbf{b}$ : either there are no solutions or there is exactly one solution or there is more than one solution. If there is more than one solution and  $F$  is infinite (such as the real numbers or complex numbers), then there are infinitely many solutions. If there is more than one solution and  $F$  is finite, then there are at least  $|F|$  solutions.
- A homogeneous system is always consistent (the zero vector  $\mathbf{0}$  is always a solution).
- The set of solutions to the homogeneous system  $A\mathbf{x} = \mathbf{0}$  is a subspace of the vector space  $F^p$ .
- [SIF00, p. 44] The system  $A\mathbf{x} = \mathbf{b}$  is consistent if and only if  $\mathbf{b}$  is not a pivot column of  $[A \ \mathbf{b}]$ , that is, if and only if  $\text{rank}([A \ \mathbf{b}]) = \text{rank } A$ .
- [SIF00, pp. 29–32] Suppose  $A\mathbf{x} = \mathbf{b}$  is consistent. It has a unique solution if and only if there is a pivot position in each column of  $A$ , that is, if and only if there are no free variables in the equation  $A\mathbf{x} = \mathbf{b}$ . Suppose there are  $t \geq 1$  nonpivot columns in  $A$ . Then there are  $t$  free variables in the system. If  $\text{RREF}([A \ \mathbf{b}]) = [C \ \mathbf{d}]$ , then the general solution of  $C\mathbf{x} = \mathbf{d}$ , hence of  $A\mathbf{x} = \mathbf{b}$ , can be written in the form  $\mathbf{x} = s_1\mathbf{v}_1 + \cdots + s_t\mathbf{v}_t + \mathbf{w}$  where  $\mathbf{v}_1, \dots, \mathbf{v}_t, \mathbf{w}$  are column vectors and  $s_1, \dots, s_t$  are parameters, each representing one of the free variables. Thus  $\mathbf{x} = \mathbf{w}$  is one solution of  $A\mathbf{x} = \mathbf{b}$ . Also, the general solution of  $A\mathbf{x} = \mathbf{0}$  is  $\mathbf{x} = s_1\mathbf{v}_1 + \cdots + s_t\mathbf{v}_t$ .
- [SIF00, pp. 29–32] (General solution of a linear system algorithm)

### Algorithm 2: General Solution of a Linear System $A\mathbf{x} = \mathbf{b}$

This algorithm is intended for small systems using rational arithmetic. It is not the most efficient and when some pivots are relatively small, using this algorithm in floating point arithmetic can yield inaccurate results. (For more accurate and efficient algorithms, see Chapter 38.) Let  $A \in F^{m \times p}$  and  $\mathbf{b} \in F^{p \times 1}$ .

- Calculate  $\text{RREF}([A \ \mathbf{b}])$ , obtaining  $[C \ \mathbf{d}]$ .
- If there is a pivot in the last column of  $[C \ \mathbf{d}]$ , stop. There is no solution.
- Assume the last column of  $[C \ \mathbf{d}]$  is not a pivot column, and let  $\mathbf{d} = [d_1, \dots, d_m]^T$ .
  - If  $\text{rank}(C) = p$ , so there exists a pivot in each column of  $C$ , then  $\mathbf{x} = \mathbf{d}$  is the unique solution of the system.
  - Suppose  $\text{rank } C = r < p$ .
    - Write the system of linear equations represented by the nonzero rows of  $[C \ \mathbf{d}]$ . In each equation, the first nonzero term will be a basic variable, and each basic variable appears in only one of these equations.
    - Solve each equation for its basic variable and substitute parameter names for the  $p - r$  free variables, say  $s_1, \dots, s_{p-r}$ . This is the general solution of  $C\mathbf{x} = \mathbf{d}$  and, thus, the general solution of  $A\mathbf{x} = \mathbf{b}$ .
    - To write the general solution in vector form, as  $\mathbf{x} = s_1\mathbf{v}^{(1)} + \cdots + s_{p-r}\mathbf{v}^{(p-r)} + \mathbf{w}$ , let  $(i, k_i)$  be the  $i^{\text{th}}$  pivot position of  $C$ . Define  $\mathbf{w} \in F^p$  by  $w_{k_i} = d_i$  for  $i = 1, \dots, r$ , and all other entries of  $\mathbf{w}$  are 0. Let  $x_{u_j}$  be the  $j^{\text{th}}$  free variable, and define the vectors  $\mathbf{v}^{(j)} \in F^p$  as follows:

For  $j = 1, \dots, p - r$ ,  
 the  $u_j$ -entry of  $\mathbf{v}^{(j)}$  is 1,  
 for  $i = 1, \dots, r$ , the  $k_i$ -entry of  $\mathbf{v}^{(j)}$  is  $-c_{iu_j}$ ,  
 and all other entries of  $\mathbf{v}^{(j)}$  are 0.

**Examples:**

1. The linear system  $\begin{matrix} x_1 + x_2 = 0 \\ -x_1 + x_2 = 0 \end{matrix}$  has augmented matrix  $\begin{bmatrix} 1 & 1 & 0 \\ -1 & 1 & 0 \end{bmatrix}$ . The RREF of this is  $\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}$ ,

which is the augmented matrix for the equivalent system  $\begin{matrix} x_1 = 0 \\ x_2 = 0 \end{matrix}$ . Thus, the original system has a

unique solution in  $\mathbb{R}^2$ ,  $(0,0)$ . In vector form the solution is  $\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$ .

2. The system  $\begin{matrix} x_1 + x_2 = 2 \\ x_1 - x_2 = 0 \end{matrix}$  has a unique solution in  $\mathbb{R}^2$ ,  $(1, 1)$ , or  $\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$ .

3. The system  $\begin{matrix} x_1 + x_2 + x_3 = 2 \\ x_2 + x_3 = 2 \\ x_3 = 0 \end{matrix}$  has a unique solution in  $\mathbb{R}^3$ ,  $(0, 2, 0)$ , or  $\mathbf{x} = \begin{bmatrix} 0 \\ 2 \\ 0 \end{bmatrix}$ .

4. The system  $\begin{matrix} x_1 + x_2 = 2 \\ 2x_1 + 2x_2 = 4 \end{matrix}$  has infinitely many solutions in  $\mathbb{R}^2$ . The augmented matrix reduces

to  $\begin{bmatrix} 1 & 1 & 2 \\ 0 & 0 & 0 \end{bmatrix}$ , so the only equation left is  $x_1 + x_2 = 2$ . Thus  $x_1$  is basic and  $x_2$  is free. Solving

for  $x_1$  and letting  $x_2 = s$  gives  $x_1 = -s + 2$ . Then the general solution is  $\begin{matrix} x_1 = -s + 2 \\ x_2 = s \end{matrix}$ , or all

vectors of the form  $(-s + 2, s)$ . Letting  $\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$ , the vector form of the general solution is

$$\mathbf{x} = \begin{bmatrix} -s + 2 \\ s \end{bmatrix} = s \begin{bmatrix} -1 \\ 1 \end{bmatrix} + \begin{bmatrix} 2 \\ 0 \end{bmatrix}.$$

5. The system  $\begin{matrix} x_1 + x_2 + x_3 + x_4 = 1 \\ x_2 + x_3 - x_4 = 3 \end{matrix}$  has infinitely many solutions in  $\mathbb{R}^4$ . Its augmented matrix

$\begin{bmatrix} 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 1 & -1 & 3 \end{bmatrix}$  reduces to  $\begin{bmatrix} 1 & 0 & 0 & 2 & -2 \\ 0 & 1 & 1 & -1 & 3 \end{bmatrix}$ . Thus,  $x_1$  and  $x_2$  are the basic variables, and  $x_3$  and  $x_4$  are free. Write each of the new equations and solve it for its basic variable

to see  $\begin{matrix} x_1 = -2x_4 - 2 \\ x_2 = -x_3 + x_4 + 3 \end{matrix}$ . Let  $x_3 = s_1$  and  $x_4 = s_2$  to get the general solution

$$\begin{matrix} x_1 = -2s_2 - 2 \\ x_2 = -s_1 + s_2 + 3 \\ x_3 = s_1 \\ x_4 = s_2 \end{matrix}, \text{ or } \mathbf{x} = s_1 \mathbf{v}^{(1)} + s_2 \mathbf{v}^{(2)} + \mathbf{w} = s_1 \begin{bmatrix} 0 \\ -1 \\ 1 \\ 0 \end{bmatrix} + s_2 \begin{bmatrix} -2 \\ 1 \\ 0 \\ 1 \end{bmatrix} + \begin{bmatrix} -2 \\ 3 \\ 0 \\ 0 \end{bmatrix}.$$

6. These systems have no solutions:  $\begin{matrix} x_1 + x_2 = 0 \\ x_1 + x_2 = 1 \end{matrix}$  and  $\begin{matrix} x_1 + x_2 + x_3 = 0 \\ x_1 - x_2 - x_3 = 0 \\ x_2 + x_3 = 1 \end{matrix}$ . This can be verified by

inspection, or by calculating the RREF of the augmented matrix of each and observing that each has a pivot in its last column.

## 1.5 Matrix Inverses and Elementary Matrices

Invertibility is a strong and useful property. For example, when a linear system  $A\mathbf{x} = \mathbf{b}$  has an invertible coefficient matrix  $A$ , it has a unique solution. The various characterizations of invertibility in Fact 10 below are also quite useful. Throughout this section,  $F$  will denote a field.

**Definitions:**

An  $n \times n$  matrix  $A$  is **invertible**, or **nonsingular**, if there exists another  $n \times n$  matrix  $B$ , called the **inverse** of  $A$ , such that  $AB = BA = I_n$ . The inverse of  $A$  is denoted  $A^{-1}$  (cf. Fact 1). If no such  $B$  exists,  $A$  is **not invertible**, or **singular**.

For an  $n \times n$  matrix and a positive integer  $m$ , the  **$m$ th power** of  $A$  is  $A^m = \underbrace{AA \dots A}_m$ . It is also convenient to define  $A^0 = I_n$ . If  $A$  is invertible, then  $A^{-m} = (A^{-1})^m$ .

An **elementary matrix** is a square matrix obtained by doing one elementary row operation to an identity matrix. Thus, there are three types:

1. A multiple of one row of  $I_n$  has been added to a different row.
2. Two different rows of  $I_n$  have been exchanged.
3. One row of  $I_n$  has been multiplied by a nonzero scalar.

**Facts:**

1. [SIF00, pp. 114–116] If  $A \in F^{n \times n}$  is invertible, then its inverse is unique.
2. [SIF00, p. 128] (Method to compute  $A^{-1}$ ) Suppose  $A \in F^{n \times n}$ . Create the matrix  $[A \ I_n]$  and calculate its RREF, which will be of the form  $[\text{RREF}(A) \ X]$ . If  $\text{RREF}(A) = I_n$ , then  $A$  is invertible and  $X = A^{-1}$ . If  $\text{RREF}(A) \neq I_n$ , then  $A$  is not invertible. As with the Gaussian algorithm, this method is theoretically correct, but more accurate and efficient methods for calculating inverses are used in professional computer software. (See Chapter 75.)
3. [SIF00, pp. 114–116] If  $A \in F^{n \times n}$  is invertible, then  $A^{-1}$  is invertible and  $(A^{-1})^{-1} = A$ .
4. [SIF00, pp. 114–116] If  $A, B \in F^{n \times n}$  are invertible, then  $AB$  is invertible and  $(AB)^{-1} = B^{-1}A^{-1}$ .
5. [SIF00, pp. 114–116] If  $A \in F^{n \times n}$  is invertible, then  $A^T$  is invertible and  $(A^T)^{-1} = (A^{-1})^T$ .
6. If  $A \in F^{n \times n}$  is invertible, then for each  $\mathbf{b} \in F^{n \times 1}$ ,  $A\mathbf{x} = \mathbf{b}$  has a unique solution, and it is  $\mathbf{x} = A^{-1}\mathbf{b}$ .
7. [SIF00, p. 124] If  $A \in F^{n \times n}$  and there exists  $C \in F^{n \times n}$  such that either  $AC = I_n$  or  $CA = I_n$ , then  $A$  is invertible and  $A^{-1} = C$ . That is, a left or right inverse for a square matrix is actually its unique two-sided inverse.
8. [SIF00, p. 117] Let  $E$  be an elementary matrix obtained by doing one elementary row operation to  $I_n$ . If that same row operation is done to an  $n \times p$  matrix  $A$ , the result equals  $EA$ .
9. [SIF00, p. 117] An elementary matrix is invertible and its inverse is another elementary matrix of the same type.
10. [SIF00, pp. 126] (Invertible Matrix Theorem) (See Section 2.5.) When  $A \in F^{n \times n}$ , the following are equivalent:
  - $A$  is invertible.
  - $\text{RREF}(A) = I_n$ .
  - $\text{Rank}(A) = n$ .
  - The only solution of  $A\mathbf{x} = \mathbf{0}$  is  $\mathbf{x} = \mathbf{0}$ .
  - For every  $\mathbf{b} \in F^{n \times 1}$ ,  $A\mathbf{x} = \mathbf{b}$  has a unique solution.
  - For every  $\mathbf{b} \in F^{n \times 1}$ ,  $A\mathbf{x} = \mathbf{b}$  has a solution.
  - There exists  $B \in F^{n \times n}$  such that  $AB = I_n$ .
  - There exists  $C \in F^{n \times n}$  such that  $CA = I_n$ .
  - $A^T$  is invertible.
  - There exist elementary matrices whose product equals  $A$ .
11. [SIF00, p. 148] and [Lay03, p.132] Let  $A \in F^{n \times n}$  be upper (lower) triangular. Then  $A$  is invertible if and only if each diagonal entry is nonzero. If  $A$  is invertible, then  $A^{-1}$  is also upper (lower) triangular, and the diagonal entries of  $A^{-1}$  are the reciprocals of those of  $A$ . In particular, if  $L$  is a unit upper (lower) triangular matrix, then  $L^{-1}$  is also a unit upper (lower) triangular matrix.

12. Matrix powers obey the usual rules of exponents, i.e., when  $A^s$  and  $A^t$  are defined for integers  $s$  and  $t$ , then  $A^s A^t = A^{s+t}$ ,  $(A^s)^t = A^{st}$ .

**Examples:**

1. For any  $n$ , the identity matrix  $I_n$  is invertible and is its own inverse. If  $P$  is a permutation matrix, it is invertible and  $P^{-1} = P^T$ .
2. If  $A = \begin{bmatrix} 7 & 3 \\ 2 & 1 \end{bmatrix}$  and  $B = \begin{bmatrix} 1 & -3 \\ -2 & 7 \end{bmatrix}$ , then calculation shows  $AB = BA = I_2$ , so  $A$  is invertible and  $A^{-1} = B$ .
3. If  $A = \begin{bmatrix} 0.2 & 4 & 1 \\ 0 & 2 & 1 \\ 0 & 0 & -1 \end{bmatrix}$ , then  $A^{-1} = \begin{bmatrix} 5 & -10 & -5 \\ 0 & 0.5 & 0.5 \\ 0 & 0 & -1 \end{bmatrix}$ , as can be verified by multiplication.
4. The matrix  $A = \begin{bmatrix} 1 & 2 \\ 2 & 4 \end{bmatrix}$  is not invertible since  $\text{RREF}(A) \neq I_2$ . Alternatively, if  $B$  is any  $2 \times 2$  matrix,  $AB$  is of the form  $\begin{bmatrix} r & s \\ 2r & 2s \end{bmatrix}$ , which cannot equal  $I_2$ .
5. Let  $A$  be an  $n \times n$  matrix  $A$  with a zero row (zero column). Then  $A$  is not invertible since  $\text{RREF}(A) \neq I_n$ . Alternatively, if  $B$  is any  $n \times n$  matrix,  $AB$  has a zero row ( $BA$  has a zero column), so  $B$  is not an inverse for  $A$ .
6. If  $A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$  is any  $2 \times 2$  matrix, then  $A$  is invertible if and only if  $ad - bc \neq 0$ ; further, when  $ad - bc \neq 0$ ,  $A^{-1} = \frac{1}{ad - bc} \begin{bmatrix} d & -b \\ -c & a \end{bmatrix}$ . The scalar  $ad - bc$  is called the determinant of  $A$ . (The determinant is defined for any  $n \times n$  matrix in Section 4.1.) Using this formula, the matrix  $A = \begin{bmatrix} 7 & 3 \\ 2 & 1 \end{bmatrix}$  from Example 2 (above) has determinant 1, so  $A$  is invertible and  $A^{-1} = \begin{bmatrix} 1 & -3 \\ -2 & 7 \end{bmatrix}$ , as noted above. The matrix  $\begin{bmatrix} 1 & 2 \\ 2 & 4 \end{bmatrix}$  from Example 3 (above) is not invertible since its determinant is 0.
7. Let  $A = \begin{bmatrix} 1 & 3 & 0 \\ 2 & 7 & 0 \\ 1 & 1 & 1 \end{bmatrix}$ . Then  $\text{RREF}([A \ I_n]) = \begin{bmatrix} 1 & 0 & 0 & 7 & -3 & 0 \\ 0 & 1 & 0 & -2 & 1 & 0 \\ 0 & 0 & 1 & -5 & 2 & 1 \end{bmatrix}$ , so  $A^{-1}$  exists and equals  $\begin{bmatrix} 7 & -3 & 0 \\ -2 & 1 & 0 \\ -5 & 2 & 1 \end{bmatrix}$ .

## 1.6 LU Factorization

This section discusses the *LU* and *PLU* factorizations of a matrix that arise naturally when Gaussian Elimination is done. Several other factorizations are widely used for real and complex matrices, such as the QR, Singular Value, and Cholesky Factorizations. (See Chapter 5 and Chapter 38.) Throughout this section,  $F$  will denote a field and  $A$  will denote a matrix over  $F$ . The material in this section and additional background can be found in [GV96, Sec. 3.2].

**Definitions:**

Let  $A$  be a matrix of any shape.

An ***LU factorization***, or ***triangular factorization***, of  $A$  is a factorization  $A = LU$  where  $L$  is a square unit lower triangular matrix and  $U$  is upper triangular. A ***PLU factorization*** of  $A$  is a factorization of

the form  $PA = LU$  where  $P$  is a permutation matrix,  $L$  is square unit lower triangular, and  $U$  is upper triangular. An **LDU factorization** of  $A$  is a factorization  $A = LDU$  where  $L$  is a square unit lower triangular matrix,  $D$  is a square diagonal matrix, and  $U$  is a unit upper triangular matrix.

A **PLDU factorization** of  $A$  is a factorization  $PA = LDU$  where  $P$  is a permutation matrix,  $L$  is a square unit lower triangular matrix,  $D$  is a square diagonal matrix, and  $U$  is a unit upper triangular matrix.

**Facts:** [GV96, Sec. 3.2]

1. Let  $A$  be square. If each leading principal submatrix of  $A$ , except possibly  $A$  itself, is invertible, then  $A$  has an  $LU$  factorization. When  $A$  is invertible,  $A$  has an  $LU$  factorization if and only if each leading principal submatrix of  $A$  is invertible; in this case, the  $LU$  factorization is unique and there is also a unique  $LDU$  factorization of  $A$ .
2. Any matrix  $A$  has a  $PLU$  factorization. Algorithm 1 (Section 1.3) performs the addition of multiples of pivot rows to lower rows and perhaps row exchanges to obtain an REF matrix  $U$ . If instead, the same series of row exchanges are done to  $A$  before any pivoting, this creates  $PA$  where  $P$  is a permutation matrix, and then  $PA$  can be reduced to  $U$  without row exchanges. That is, there exist unit lower triangular matrices  $E_j$  such that  $E_k \dots E_1(PA) = U$ . It follows that  $PA = LU$ , where  $L = (E_k \dots E_1)^{-1}$  is unit lower triangular and  $U$  is upper triangular.
3. In most professional software packages, the standard method for solving a square linear system  $A\mathbf{x} = \mathbf{b}$ , for which  $A$  is invertible, is to reduce  $A$  to an REF matrix  $U$  as in Fact 2 above, choosing row exchanges by a strategy to reduce pivot size. By keeping track of the exchanges and pivot operations done, this produces a  $PLU$  factorization of  $A$ . Then  $A = P^T LU$  and  $P^T LU\mathbf{x} = \mathbf{b}$  is the equation to be solved. Using forward substitution,  $P^T L\mathbf{y} = \mathbf{b}$  can be solved quickly for  $\mathbf{y}$ , and then  $U\mathbf{x} = \mathbf{y}$  can either be solved quickly for  $\mathbf{x}$  by back substitution, or be seen to be inconsistent. This method gives accurate results for most problems. There are other types of solution methods that can work more accurately or efficiently for special types of matrices. (See Chapter 7.)

**Examples:**

1. Calculate a  $PLU$  factorization for  $A = \begin{bmatrix} 1 & 1 & 2 & 3 \\ -1 & -1 & -3 & 1 \\ 0 & 1 & 1 & 1 \\ -1 & 0 & -1 & 1 \end{bmatrix}$ . If Gaussian Elimination is performed

on  $A$ , after adding row 1 to rows 2 and 4, rows 2 and 3 must be exchanged and the final result is

$$U = E_3 P E_2 E_1 A = \begin{bmatrix} 1 & 1 & 2 & 3 \\ 0 & 1 & 1 & 1 \\ 0 & 0 & -1 & 4 \\ 0 & 0 & 0 & 3 \end{bmatrix} \text{ where } E_1, E_2, \text{ and } E_3 \text{ are lower triangular unit matrices and}$$

$P$  is a permutation matrix. This will not yield an  $LU$  factorization of  $A$ . But if the row exchange

$$\text{is done to } A \text{ first, by multiplying } A \text{ by } P = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \text{ one gets } PA = \begin{bmatrix} 1 & 1 & 2 & 3 \\ 0 & 1 & 1 & 1 \\ -1 & -1 & -3 & 1 \\ -1 & 0 & -1 & 1 \end{bmatrix};$$

then Gaussian Elimination can proceed without any row exchanges. Add row 1 to rows 3 and 4 to get

$$F_2 F_1 PA = \begin{bmatrix} 1 & 1 & 2 & 3 \\ 0 & 1 & 1 & 1 \\ 0 & 0 & -1 & 4 \\ 0 & 1 & 1 & 4 \end{bmatrix} \text{ where } F_1 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \text{ and } F_2 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 \end{bmatrix}. \text{ Then add}$$

$$(-1)(\text{row } 2) \text{ to row } 4 \text{ to get } U = F_3 F_2 F_1 PA = \begin{bmatrix} 1 & 1 & 2 & 3 \\ 0 & 1 & 1 & 1 \\ 0 & 0 & -1 & 4 \\ 0 & 0 & 0 & 3 \end{bmatrix}, \text{ where } F_3 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 1 \end{bmatrix}.$$

Note that  $U$  is the same upper triangular matrix as before. Finally,  $L = (F_3 F_2 F_1)^{-1}$  is unit lower triangular and  $PA = LU$  is true, so this is a  $PLU$  factorization of  $A$ . To get a  $PLDU$  factorization,

use the same  $P$  and  $L$ , and define  $D = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 3 \end{bmatrix}$  and  $U = \begin{bmatrix} 1 & 1 & 2 & 3 \\ 0 & 1 & 1 & 1 \\ 0 & 0 & 1 & -4 \\ 0 & 0 & 0 & 1 \end{bmatrix}$ .

2. Let  $A = LU = \begin{bmatrix} 1 & 3 & 4 \\ -1 & -1 & -5 \\ 2 & 12 & 3 \end{bmatrix}$ . Each leading principal submatrix of  $A$  is invertible so  $A$  has

both  $LU$  and  $LDU$  factorizations:

$A = LU = \begin{bmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ 2 & 3 & 1 \end{bmatrix} \begin{bmatrix} 1 & 3 & 4 \\ 0 & 2 & -1 \\ 0 & 0 & -2 \end{bmatrix}$ . This yields an  $LDU$  factorization of  $A$ ,  $\begin{bmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ 2 & 3 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & -2 \end{bmatrix}$

$\begin{bmatrix} 1 & 3 & 4 \\ 0 & 1 & -0.5 \\ 0 & 0 & 1 \end{bmatrix}$ . With the  $LU$  factorization, an equation such as  $A\mathbf{x} = \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$  can be solved efficiently

as follows. Use forward substitution to solve  $L\mathbf{y} = \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$ , getting  $\mathbf{y} = \begin{bmatrix} 1 \\ 2 \\ -8 \end{bmatrix}$ , and then backward

substitution to solve  $U\mathbf{x} = \mathbf{y}$ , getting  $\mathbf{x} = \begin{bmatrix} -24 \\ 3 \\ 4 \end{bmatrix}$ .

3. Any invertible matrix whose  $(1, 1)$  entry is zero, such as  $\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$  or  $\begin{bmatrix} 0 & -1 & 5 \\ 1 & 1 & 1 \\ 1 & 0 & 3 \end{bmatrix}$ , does not have an  $LU$  factorization.

4. The matrix  $A = \begin{bmatrix} 1 & 3 & 4 \\ -1 & -3 & -5 \\ 2 & 6 & 6 \end{bmatrix}$  is not invertible, nor is its leading principal  $2 \times 2$  submatrix,

but it does have an  $LU$  factorization:  $A = LU = \begin{bmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ 2 & 3 & 1 \end{bmatrix} \begin{bmatrix} 1 & 3 & 4 \\ 0 & 0 & -1 \\ 0 & 0 & 1 \end{bmatrix}$ . To find out if an

equation such as  $A\mathbf{x} = \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$  is consistent, notice  $L\mathbf{y} = \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$  yields  $\mathbf{y} = \begin{bmatrix} 1 \\ 2 \\ -8 \end{bmatrix}$ , but  $U\mathbf{x} = \mathbf{y}$  is

inconsistent, hence  $A\mathbf{x} = \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}$  has no solution.

5. The matrix  $A = \begin{bmatrix} 0 & -1 & 5 \\ 1 & 1 & 1 \\ 1 & 0 & 2 \end{bmatrix}$  has no  $LU$  factorization, but does have a  $PLU$  factorization with

$P = \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}$ ,  $L = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 1 & 1 & 1 \end{bmatrix}$ , and  $U = \begin{bmatrix} 1 & 1 & 1 \\ 0 & -1 & 5 \\ 0 & 0 & -4 \end{bmatrix}$ .

### 2.1 Span and Linear Independence

---

Let  $V$  be a vector space over a field  $F$ .

#### Definitions:

A **linear combination** of the vectors  $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_k \in V$  is a sum of scalar multiples of these vectors; that is,  $c_1\mathbf{v}_1 + c_2\mathbf{v}_2 + \dots + c_k\mathbf{v}_k$ , for some scalar coefficients  $c_1, c_2, \dots, c_k \in F$ . If  $S$  is a set of vectors in  $V$ , a linear combination of vectors in  $S$  is a vector of the form  $c_1\mathbf{v}_1 + c_2\mathbf{v}_2 + \dots + c_k\mathbf{v}_k$  with  $k \in \mathbb{N}, \mathbf{v}_i \in S, c_i \in F$ . Note that  $S$  may be finite or infinite, but a linear combination is, by definition, a finite sum. The zero vector is defined to be a linear combination of the empty set.

When all the scalar coefficients in a linear combination are 0, it is a **trivial linear combination**. A sum over the empty set is also a trivial linear combination.

The **span** of the vectors  $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_k \in V$  is the set of all linear combinations of these vectors, denoted by  $\text{Span}(\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_k)$ . If  $S$  is a (finite or infinite) set of vectors in  $V$ , then the span of  $S$ , denoted by  $\text{Span}(S)$ , is the set of all linear combinations of vectors in  $S$ .

If  $V = \text{Span}(S)$ , then  $S$  **spans** the vector space  $V$ .

A (finite or infinite) set of vectors  $S$  in  $V$  is **linearly independent** if the only linear combination of distinct vectors in  $S$  that produces the zero vector is a trivial linear combination. That is, if  $\mathbf{v}_i$  are distinct vectors in  $S$  and  $c_1\mathbf{v}_1 + c_2\mathbf{v}_2 + \dots + c_k\mathbf{v}_k = \mathbf{0}$ , then  $c_1 = c_2 = \dots = c_k = 0$ . Vectors that are not linearly independent are **linearly dependent**. That is, there exist distinct vectors  $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_k \in S$  and  $c_1, c_2, \dots, c_k$  not all 0 such that  $c_1\mathbf{v}_1 + c_2\mathbf{v}_2 + \dots + c_k\mathbf{v}_k = \mathbf{0}$ .

**Facts:** The following facts can be found in [Lay03, Sections 4.1 and 4.3].

1.  $\text{Span}(\emptyset) = \{\mathbf{0}\}$ .
2. A linear combination of a single vector  $\mathbf{v}$  is simply a scalar multiple of  $\mathbf{v}$ .
3. In a vector space  $V$ ,  $\text{Span}(\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_k)$  is a subspace of  $V$ .
4. Suppose the set of vectors  $S = \{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_k\}$  spans the vector space  $V$ . If one of the vectors, say  $\mathbf{v}_i$ , is a linear combination of the remaining vectors, then the set formed from  $S$  by removing  $\mathbf{v}_i$  still spans  $V$ .
5. Any single nonzero vector is linearly independent.
6. Two nonzero vectors are linearly independent if and only if neither is a scalar multiple of the other.
7. If  $S$  spans  $V$  and  $S \subseteq T$ , then  $T$  spans  $V$ .
8. If  $T$  is a linearly independent subset of  $V$  and  $S \subseteq T$ , then  $S$  is linearly independent.
9. Vectors  $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_k$  are linearly dependent if and only if  $\mathbf{v}_i = c_1\mathbf{v}_1 + \dots + c_{i-1}\mathbf{v}_{i-1} + c_{i+1}\mathbf{v}_{i+1} + \dots + c_k\mathbf{v}_k$ , for some  $1 \leq i \leq k$  and some scalars  $c_1, \dots, c_{i-1}, c_{i+1}, \dots, c_k$ . A set  $S$  of vectors in  $V$  is linearly dependent if and only if there exists  $\mathbf{v} \in S$  such that  $\mathbf{v}$  is a linear combination of other vectors in  $S$ .
10. Any set of vectors that includes the zero vector is linearly dependent.

**Examples:**

1. Linear combinations of  $\begin{bmatrix} 1 \\ -1 \end{bmatrix}, \begin{bmatrix} 0 \\ 3 \end{bmatrix} \in \mathbb{R}^2$  are vectors of the form  $c_1 \begin{bmatrix} 1 \\ -1 \end{bmatrix} + c_2 \begin{bmatrix} 0 \\ 3 \end{bmatrix} = \begin{bmatrix} c_1 \\ -c_1 + 3c_2 \end{bmatrix}$ , for any scalars  $c_1, c_2 \in \mathbb{R}$ . Any vector of this form is in  $\text{Span}\left(\begin{bmatrix} 1 \\ -1 \end{bmatrix}, \begin{bmatrix} 0 \\ 3 \end{bmatrix}\right)$ . In fact,  $\text{Span}\left(\begin{bmatrix} 1 \\ -1 \end{bmatrix}, \begin{bmatrix} 0 \\ 3 \end{bmatrix}\right) = \mathbb{R}^2$  and these vectors are linearly independent.
2. If  $\mathbf{v} \in \mathbb{R}^n$  and  $\mathbf{v} \neq \mathbf{0}$ , then geometrically  $\text{Span}(\mathbf{v})$  is a line in  $\mathbb{R}^n$  through the origin.
3. Suppose  $n \geq 2$  and  $\mathbf{v}_1, \mathbf{v}_2 \in \mathbb{R}^n$  are linearly independent vectors. Then geometrically  $\text{Span}(\mathbf{v}_1, \mathbf{v}_2)$  is a plane in  $\mathbb{R}^n$  through the origin.
4. Any polynomial  $p(x) \in \mathbb{R}[x]$  of degree less than or equal to 2 can easily be seen to be a linear combination of 1,  $x$ , and  $x^2$ . However,  $p(x)$  is also a linear combination of 1,  $1 + x$ , and  $1 + x^2$ . So  $\text{Span}(1, x, x^2) = \text{Span}(1, 1 + x, 1 + x^2) = \mathbb{R}[x; 2]$ .
5. The  $n$  vectors  $\mathbf{e}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix}, \mathbf{e}_2 = \begin{bmatrix} 0 \\ 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix}, \dots, \mathbf{e}_n = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix}$  span  $F^n$ , for any field  $F$ . These vectors are also linearly independent.
6. In  $\mathbb{R}^2$ ,  $\begin{bmatrix} 1 \\ -1 \end{bmatrix}$  and  $\begin{bmatrix} 0 \\ 3 \end{bmatrix}$  are linearly independent. However,  $\begin{bmatrix} 1 \\ -1 \end{bmatrix}, \begin{bmatrix} 0 \\ 3 \end{bmatrix}$ , and  $\begin{bmatrix} 1 \\ 5 \end{bmatrix}$  are linearly dependent, because  $\begin{bmatrix} 1 \\ 5 \end{bmatrix} = \begin{bmatrix} 1 \\ -1 \end{bmatrix} + 2 \begin{bmatrix} 0 \\ 3 \end{bmatrix}$ .
7. The infinite set  $\{1, x, x^2, \dots, x^n, \dots\}$  is linearly independent in  $F[x]$ , for any field  $F$ .
8. In the vector space of continuous real-valued functions on the real line,  $\mathcal{C}(\mathbb{R})$ , the set  $\{\sin(x), \sin(2x), \dots, \sin(nx), \cos(x), \cos(2x), \dots, \cos(nx)\}$  is linearly independent for any  $n \in \mathbb{N}$ . The infinite set  $\{\sin(x), \sin(2x), \dots, \sin(nx), \dots, \cos(x), \cos(2x), \dots, \cos(nx), \dots\}$  is also linearly independent in  $\mathcal{C}(\mathbb{R})$ .

**Applications:**

1. The homogeneous differential equation  $\frac{d^2y}{dx^2} - 3\frac{dy}{dx} + 2y = 0$  has as solutions  $y_1(x) = e^{2x}$  and  $y_2(x) = e^x$ . Any linear combination  $y(x) = c_1y_1(x) + c_2y_2(x)$  is a solution of the differential equation, and so  $\text{Span}(e^{2x}, e^x)$  is contained in the set of solutions of the differential equation (called the solution space for the differential equation). In fact, the solution space is spanned by  $e^{2x}$  and  $e^x$ , and so is a subspace of the vector space of functions. In general, the solution space for a homogeneous differential equation is a vector space, meaning that any linear combination of solutions is again a solution.

## 2.2 Basis and Dimension of a Vector Space

---

Let  $V$  be a vector space over a field  $F$ .

**Definitions:**

A set of vectors  $\mathcal{B}$  in a vector space  $V$  is a **basis** for  $V$  if

- $\mathcal{B}$  is a linearly independent set, and
- $\text{Span}(\mathcal{B}) = V$ .

The set  $\mathcal{E}_n = \left\{ \mathbf{e}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix}, \mathbf{e}_2 = \begin{bmatrix} 0 \\ 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix}, \dots, \mathbf{e}_n = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix} \right\}$  is the **standard basis** for  $F^n$ .

The number of vectors in a basis for a vector space  $V$  is the **dimension** of  $V$ , denoted by  $\dim(V)$ . If a basis for  $V$  contains a finite number of vectors, then  $V$  is **finite dimensional**. Otherwise,  $V$  is **infinite dimensional**, and we write  $\dim(V) = \infty$ .

**Facts:** All the following facts, except those with a specific reference, can be found in [Lay03, Sections 4.3 and 4.5].

1. Every vector space has a basis.
2. The standard basis for  $F^n$  is a basis for  $F^n$ , and so  $\dim F^n = n$ .
3. A basis  $\mathcal{B}$  in a vector space  $V$  is the largest set of linearly independent vectors in  $V$  that contains  $\mathcal{B}$ , and it is the smallest set of vectors in  $V$  that contains  $\mathcal{B}$  and spans  $V$ .
4. The empty set is a basis for the trivial vector space  $\{\mathbf{0}\}$ , and  $\dim(\{\mathbf{0}\}) = 0$ .
5. If the set  $S = \{\mathbf{v}_1, \dots, \mathbf{v}_p\}$  spans a vector space  $V$ , then some subset of  $S$  forms a basis for  $V$ . In particular, if one of the vectors, say  $\mathbf{v}_i$ , is a linear combination of the remaining vectors, then the set formed from  $S$  by removing  $\mathbf{v}_i$  will be “closer” to a basis for  $V$ . This process can be continued until the remaining vectors form a basis for  $V$ .
6. If  $S$  is a linearly independent set in a vector space  $V$ , then  $S$  can be expanded, if necessary, to a basis for  $V$ .
7. No nontrivial vector space over a field with more than two elements has a unique basis.
8. If a vector space  $V$  has a basis containing  $n$  vectors, then every basis of  $V$  must contain  $n$  vectors. Similarly, if  $V$  has an infinite basis, then every basis of  $V$  must be infinite. So the dimension of  $V$  is unique.
9. Let  $\dim(V) = n$  and let  $S$  be a set containing  $n$  vectors. The following are equivalent:
  - $S$  is a basis for  $V$ .
  - $S$  spans  $V$ .
  - $S$  is linearly independent.

10. If  $\dim(V) = n$ , then any subset of  $V$  containing more than  $n$  vectors is linearly dependent.
11. If  $\dim(V) = n$ , then any subset of  $V$  containing fewer than  $n$  vectors does not span  $V$ .
12. [Lay03, Section 4.4] If  $\mathcal{B} = \{\mathbf{b}_1, \dots, \mathbf{b}_p\}$  is a basis for a vector space  $V$ , then each  $\mathbf{x} \in V$  can be expressed as a unique linear combination of the vectors in  $\mathcal{B}$ . That is, for each  $\mathbf{x} \in V$  there is a unique set of scalars  $c_1, c_2, \dots, c_p$  such that  $\mathbf{x} = c_1\mathbf{b}_1 + c_2\mathbf{b}_2 + \dots + c_p\mathbf{b}_p$ .

### Examples:

1. In  $\mathbb{R}^2$ ,  $\begin{bmatrix} 1 \\ -1 \end{bmatrix}$  and  $\begin{bmatrix} 0 \\ 3 \end{bmatrix}$  are linearly independent, and they span  $\mathbb{R}^2$ . So they form a basis for  $\mathbb{R}^2$  and  $\dim(\mathbb{R}^2) = 2$ .
2. In  $F[x]$ , the set  $\{1, x, x^2, \dots, x^n\}$  is a basis for  $F[x; n]$  for any  $n \in \mathbb{N}$ . The infinite set  $\{1, x, x^2, x^3, \dots\}$  is a basis for  $F[x]$ , meaning  $\dim(F[x]) = \infty$ .
3. The set of  $m \times n$  matrices  $E_{ij}$  having a 1 in the  $i, j$ -entry and zeros everywhere else forms a basis for  $F^{m \times n}$ . Since there are  $mn$  such matrices,  $\dim(F^{m \times n}) = mn$ .

4. The set  $S = \left\{ \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \begin{bmatrix} 1 \\ 2 \end{bmatrix} \right\}$  clearly spans  $\mathbb{R}^2$ , but it is not a linearly independent set. However, removing any single vector from  $S$  will cause the remaining vectors to be a basis for  $\mathbb{R}^2$ , because any pair of vectors is linearly independent and still spans  $\mathbb{R}^2$ .

5. The set  $S = \left\{ \begin{bmatrix} 1 \\ 1 \\ 0 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 0 \\ 1 \\ 1 \end{bmatrix} \right\}$  is linearly independent, but it cannot be a basis for  $\mathbb{R}^4$  since it does

not span  $\mathbb{R}^4$ . However, we can start expanding it to a basis for  $\mathbb{R}^4$  by first adding a vector that is not

in the span of  $S$ , such as  $\begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$ . Then since these three vectors still do not span  $\mathbb{R}^4$ , we can add a

vector that is not in their span, such as  $\begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \end{bmatrix}$ . These four vectors now span  $\mathbb{R}^4$  and they are linearly

independent, so they form a basis for  $\mathbb{R}^4$ .

6. Additional techniques for determining whether a given finite set of vectors is linearly independent or spans a given subspace can be found in Sections 2.5 and 2.6.

### Applications:

1. Because  $y_1(x) = e^{2x}$  and  $y_2(x) = e^x$  are linearly independent and span the solution space for the homogeneous differential equation  $\frac{d^2y}{dx^2} - 3\frac{dy}{dx} + 2y = 0$ , they form a basis for the solution space and the solution space has dimension 2.

## 2.3 Direct Sum Decompositions

Throughout this section,  $V$  will be a vector space over a field  $F$ , and  $W_i$ , for  $i = 1, \dots, k$ , will be subspaces of  $V$ . For facts and general reading for this section, see [HK71].

**Definitions:**

The **sum** of subspaces  $W_i$ , for  $i = 1, \dots, k$ , is  $\sum_{i=1}^k W_i = W_1 + \dots + W_k = \{\mathbf{w}_1 + \dots + \mathbf{w}_k \mid \mathbf{w}_i \in W_i\}$ . The sum  $W_1 + \dots + W_k$  is a **direct sum** if for all  $i = 1, \dots, k$ , we have  $W_i \cap \sum_{j \neq i} W_j = \{\mathbf{0}\}$ .  $W = W_1 \oplus \dots \oplus W_k$  denotes that  $W = W_1 + \dots + W_k$  and the sum is direct. The subspaces  $W_i$ , for  $i = 1, \dots, k$ , are **independent** if for  $\mathbf{w}_i \in W_i$ ,  $\mathbf{w}_1 + \dots + \mathbf{w}_k = \mathbf{0}$  implies  $\mathbf{w}_i = \mathbf{0}$  for all  $i = 1, \dots, k$ . Let  $V_i$ , for  $i = 1, \dots, k$ , be vector spaces over  $F$ . The **external direct sum** of the  $V_i$ , denoted  $V_1 \times \dots \times V_k$ , is the cartesian product of  $V_i$ , for  $i = 1, \dots, k$ , with coordinate-wise operations. Let  $W$  be a subspace of  $V$ . An **additive coset** of  $W$  is a subset of the form  $v + W = \{v + w \mid w \in W\}$  with  $v \in V$ . The **quotient** of  $V$  by  $W$ , denoted  $V/W$ , is the set of additive cosets of  $W$  with operations  $(v_1 + W) + (v_2 + W) = (v_1 + v_2) + W$  and  $c(v + W) = (cv) + W$ , for any  $c \in F$ . Let  $V = W \oplus U$ , let  $\mathcal{B}_W$  and  $\mathcal{B}_U$  be bases for  $W$  and  $U$  respectively, and let  $\mathcal{B} = \mathcal{B}_W \cup \mathcal{B}_U$ . The **induced basis** of  $\mathcal{B}$  in  $V/W$  is the set of vectors  $\{u + W \mid u \in \mathcal{B}_U\}$ .

**Facts:**

1.  $W = W_1 \oplus W_2$  if and only if  $W = W_1 + W_2$  and  $W_1 \cap W_2 = \{\mathbf{0}\}$ .
2. If  $W$  is a subspace of  $V$ , then there exists a subspace  $U$  of  $V$  such that  $V = W \oplus U$ . Note that  $U$  is not usually unique.
3. Let  $W = W_1 + \dots + W_k$ . The following are equivalent:
  - $W = W_1 \oplus \dots \oplus W_k$ . That is, for all  $i = 1, \dots, k$ , we have  $W_i \cap \sum_{j \neq i} W_j = \{\mathbf{0}\}$ .
  - $W_i \cap \sum_{j=1}^{i-1} W_j = \{\mathbf{0}\}$ , for all  $i = 2, \dots, k$ .
  - For each  $\mathbf{w} \in W$ ,  $\mathbf{w}$  can be expressed in exactly one way as a sum of vectors in  $W_1, \dots, W_k$ . That is, there exist unique  $\mathbf{w}_i \in W_i$ , such that  $\mathbf{w} = \mathbf{w}_1 + \dots + \mathbf{w}_k$ .
  - The subspaces  $W_i$ , for  $i = 1, \dots, k$ , are independent.
  - If  $\mathcal{B}_i$  is an (ordered) basis for  $W_i$ , then  $\mathcal{B} = \bigcup_{i=1}^k \mathcal{B}_i$  is an (ordered) basis for  $W$ .
4. If  $\mathcal{B}$  is a basis for  $V$  and  $\mathcal{B}$  is partitioned into disjoint subsets  $\mathcal{B}_i$ , for  $i = 1, \dots, k$ , then  $V = \text{Span}(\mathcal{B}_1) \oplus \dots \oplus \text{Span}(\mathcal{B}_k)$ .
5. If  $S$  is a linearly independent subset of  $V$  and  $S$  is partitioned into disjoint subsets  $S_i$ , for  $i = 1, \dots, k$ , then the subspaces  $\text{Span}(S_1), \dots, \text{Span}(S_k)$  are independent.
6. If  $V$  is finite dimensional and  $V = W_1 + \dots + W_k$ , then  $\dim(V) = \dim(W_1) + \dots + \dim(W_k)$  if and only if  $V = W_1 \oplus \dots \oplus W_k$ .
7. Let  $V_i$ , for  $i = 1, \dots, k$ , be vector spaces over  $F$ .
  - $V_1 \times \dots \times V_k$  is a vector space over  $F$ .
  - $\widehat{V}_i = \{(0, \dots, 0, v_i, 0, \dots, 0) \mid v_i \in V_i\}$  (where  $v_i$  is the  $i$ th coordinate) is a subspace of  $V_1 \times \dots \times V_k$ .
  - $V_1 \times \dots \times V_k = \widehat{V}_1 \oplus \dots \oplus \widehat{V}_k$ .
  - If  $V_i$ , for  $i = 1, \dots, k$ , are finite dimensional, then  $\dim \widehat{V}_i = \dim V_i$  and  $\dim(V_1 \times \dots \times V_k) = \dim V_1 + \dots + \dim V_k$ .
8. If  $W$  is a subspace of  $V$ , then the quotient  $V/W$  is a vector space over  $F$ .
9. Let  $V = W \oplus U$ , let  $\mathcal{B}_W$  and  $\mathcal{B}_U$  be bases for  $W$  and  $U$  respectively, and let  $\mathcal{B} = \mathcal{B}_W \cup \mathcal{B}_U$ . The induced basis of  $\mathcal{B}$  in  $V/W$  is a basis for  $V/W$  and  $\dim(V/W) = \dim U$ .

**Examples:**

1. Let  $\mathcal{B} = \{\mathbf{v}_1, \dots, \mathbf{v}_n\}$  be a basis for  $V$ . Then  $V = \text{Span}(\mathbf{v}_1) \oplus \dots \oplus \text{Span}(\mathbf{v}_n)$ .
2. Let  $X = \left\{ \begin{bmatrix} x \\ 0 \end{bmatrix} \mid x \in \mathbb{R} \right\}$ ,  $Y = \left\{ \begin{bmatrix} 0 \\ y \end{bmatrix} \mid y \in \mathbb{R} \right\}$ , and  $Z = \left\{ \begin{bmatrix} z \\ z \end{bmatrix} \mid z \in \mathbb{R} \right\}$ . Then  $\mathbb{R}^2 = X \oplus Y = Y \oplus Z = X \oplus Z$ .

3. In  $F^{n \times n}$ , let  $W_1$  be the subspace of symmetric matrices and  $W_2$  be the subspace of skew-symmetric matrices. Clearly,  $W_1 \cap W_2 = \{\mathbf{0}\}$ . For any  $A \in F^{n \times n}$ ,  $A = \frac{A + A^T}{2} + \frac{A - A^T}{2}$ , where  $\frac{A + A^T}{2} \in W_1$  and  $\frac{A - A^T}{2} \in W_2$ . Therefore,  $F^{n \times n} = W_1 \oplus W_2$ .
4. Recall that the function  $f \in \mathcal{C}(\mathbb{R})$  is even if  $f(-x) = f(x)$  for all  $x$ , and  $f$  is odd if  $f(-x) = -f(x)$  for all  $x$ . Let  $W_1$  be the subspace of even functions and  $W_2$  be the subspace of odd functions. Clearly,  $W_1 \cap W_2 = \{\mathbf{0}\}$ . For any  $f \in \mathcal{C}(\mathbb{R})$ ,  $f = f_1 + f_2$ , where  $f_1(x) = \frac{f(x) + f(-x)}{2} \in W_1$  and  $f_2(x) = \frac{f(x) - f(-x)}{2} \in W_2$ . Therefore,  $\mathcal{C}(\mathbb{R}) = W_1 \oplus W_2$ .
5. Given a subspace  $W$  of  $V$ , we can find a subspace  $U$  such that  $V = W \oplus U$  by choosing a basis for  $W$ , extending this linearly independent set to a basis for  $V$ , and setting  $U$  equal to the span of the basis vectors not in  $W$ . For example, in  $\mathbb{R}^3$ , Let  $W = \left\{ \begin{bmatrix} a \\ -2a \\ a \end{bmatrix} \mid a \in \mathbb{R} \right\}$ . If  $\mathbf{w} = \begin{bmatrix} 1 \\ -2 \\ 1 \end{bmatrix}$ , then  $\{\mathbf{w}\}$  is a basis for  $W$ . Extend this to a basis for  $\mathbb{R}^3$ , for example by adjoining  $\mathbf{e}_1$  and  $\mathbf{e}_2$ . Thus,  $V = W \oplus U$ , where  $U = \text{Span}(\mathbf{e}_1, \mathbf{e}_2)$ . Note: there are many other ways to extend the basis, and many other possible  $U$ .
6. In the external direct sum  $\mathbb{R}[x; 2] \times \mathbb{R}^{2 \times 2}$ ,  $\left( 2x^2 + 7, \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix} \right) + 3 \left( x^2 + 4x - 2, \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \right) = \left( 5x^2 + 12x + 1, \begin{bmatrix} 1 & 5 \\ 0 & 4 \end{bmatrix} \right)$ .
7. The subspaces  $X, Y, Z$  of  $\mathbb{R}^2$  in Example 2 have bases  $\mathcal{B}_X = \left\{ \begin{bmatrix} 1 \\ 0 \end{bmatrix} \right\}$ ,  $\mathcal{B}_Y = \left\{ \begin{bmatrix} 0 \\ 1 \end{bmatrix} \right\}$ ,  $\mathcal{B}_Z = \left\{ \begin{bmatrix} 1 \\ 1 \end{bmatrix} \right\}$ , respectively. Then  $\mathcal{B}_{XY} = \mathcal{B}_X \cup \mathcal{B}_Y$  and  $\mathcal{B}_{XZ} = \mathcal{B}_X \cup \mathcal{B}_Z$  are bases for  $\mathbb{R}^2$ . In  $\mathbb{R}^2/X$ , the induced bases of  $\mathcal{B}_{XY}$  and  $\mathcal{B}_{XZ}$  are  $\left\{ \begin{bmatrix} 0 \\ 1 \end{bmatrix} + X \right\}$  and  $\left\{ \begin{bmatrix} 1 \\ 1 \end{bmatrix} + X \right\}$ , respectively. These are equal because  $\begin{bmatrix} 1 \\ 1 \end{bmatrix} + X = \begin{bmatrix} 0 \\ 1 \end{bmatrix} + \begin{bmatrix} 1 \\ 0 \end{bmatrix} + X = \begin{bmatrix} 0 \\ 1 \end{bmatrix} + X$ .

## 2.4 Matrix Range, Null Space, Rank, and the Dimension Theorem

### Definitions:

For any matrix  $A \in F^{m \times n}$ , the **range** of  $A$ , denoted by  $\text{range}(A)$ , is the set of all linear combinations of the columns of  $A$ . If  $A = [\mathbf{m}_1 \ \mathbf{m}_2 \ \dots \ \mathbf{m}_n]$ , then  $\text{range}(A) = \text{Span}(\mathbf{m}_1, \mathbf{m}_2, \dots, \mathbf{m}_n)$ . The range of  $A$  is also called the **column space** of  $A$ .

The **row space** of  $A$ , denoted by  $\text{RS}(A)$ , is the set of all linear combinations of the rows of  $A$ . If  $A = [\mathbf{v}_1 \ \mathbf{v}_2 \ \dots \ \mathbf{v}_m]^T$ , then  $\text{RS}(A) = \text{Span}(\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_m)$ .

The **kernel** of  $A$ , denoted by  $\ker(A)$ , is the set of all solutions to the homogeneous equation  $A\mathbf{x} = \mathbf{0}$ . The kernel of  $A$  is also called the **null space** of  $A$ , and its dimension is called the **nullity** of  $A$ , denoted by  $\text{null}(A)$ .

The **rank** of  $A$ , denoted by  $\text{rank}(A)$ , is the number of leading entries in the reduced row echelon form of  $A$  (or any row echelon form of  $A$ ). (See Section 1.3 for more information.)

$A, B \in F^{m \times n}$  are **equivalent** if  $B = C_1^{-1}AC_2$  for some invertible matrices  $C_1 \in F^{m \times m}$  and  $C_2 \in F^{n \times n}$ .  $A, B \in F^{n \times n}$  are **similar** if  $B = C^{-1}AC$  for some invertible matrix  $C \in F^{n \times n}$ . For square matrices  $A_1 \in F^{n_1 \times n_1}, \dots, A_k \in F^{n_k \times n_k}$ , the **matrix direct sum**  $A = A_1 \oplus \dots \oplus A_k$  is the block diagonal matrix

with the matrices  $A_i$  down the diagonal. That is,  $A = \begin{bmatrix} A_1 & & \mathbf{0} \\ & \ddots & \\ \mathbf{0} & & A_k \end{bmatrix}$ , where  $A \in F^{n \times n}$  with  $n = \sum_{i=1}^k n_i$ .

**Facts:** Unless specified otherwise, the following facts can be found in [Lay03, Sections 2.8, 4.2, 4.5, and 4.6].

1. The range of an  $m \times n$  matrix  $A$  is a subspace of  $F^m$ .
2. The columns of  $A$  corresponding to the pivot columns in the reduced row echelon form of  $A$  (or any row echelon form of  $A$ ) give a basis for  $\text{range}(A)$ . Let  $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_k \in F^m$ . If matrix  $A = [\mathbf{v}_1 \ \mathbf{v}_2 \ \dots \ \mathbf{v}_k]$ , then a basis for  $\text{range}(A)$  will be a linearly independent subset of  $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_k$  having the same span.
3.  $\dim(\text{range}(A)) = \text{rank}(A)$ .
4. The kernel of an  $m \times n$  matrix  $A$  is a subspace of  $F^n$ .
5. If the reduced row echelon form of  $A$  (or any row echelon form of  $A$ ) has  $k$  pivot columns, then  $\text{null}(A) = n - k$ .
6. If two matrices  $A$  and  $B$  are row equivalent, then  $\text{RS}(A) = \text{RS}(B)$ .
7. The row space of an  $m \times n$  matrix  $A$  is a subspace of  $F^n$ .
8. The pivot rows in the reduced row echelon form of  $A$  (or any row echelon form of  $A$ ) give a basis for  $\text{RS}(A)$ .
9.  $\dim(\text{RS}(A)) = \text{rank}(A)$ .
10.  $\text{rank}(A) = \text{rank}(A^T)$ .
11. (Dimension Theorem) For any  $A \in F^{m \times n}$ ,  $n = \text{rank}(A) + \text{null}(A)$ . Similarly,  $m = \dim(\text{RS}(A)) + \text{null}(A^T)$ .
12. A vector  $\mathbf{b} \in F^m$  is in  $\text{range}(A)$  if and only if the equation  $A\mathbf{x} = \mathbf{b}$  has a solution. So  $\text{range}(A) = F^m$  if and only if the equation  $A\mathbf{x} = \mathbf{b}$  has a solution for every  $\mathbf{b} \in F^m$ .
13. A vector  $\mathbf{a} \in F^n$  is in  $\text{RS}(A)$  if and only if the equation  $A^T\mathbf{y} = \mathbf{a}$  has a solution. So  $\text{RS}(A) = F^n$  if and only if the equation  $A^T\mathbf{y} = \mathbf{a}$  has a solution for every  $\mathbf{a} \in F^n$ .
14. If  $\mathbf{a}$  is a solution to the equation  $A\mathbf{x} = \mathbf{b}$ , then  $\mathbf{a} + \mathbf{v}$  is also a solution for any  $\mathbf{v} \in \ker(A)$ .
15. [HJ85, p. 14] If  $A \in F^{m \times n}$  is rank 1, then there are vectors  $\mathbf{v} \in F^m$  and  $\mathbf{u} \in F^n$  so that  $A = \mathbf{v}\mathbf{u}^T$ .
16. If  $A \in F^{m \times n}$  is rank  $k$ , then  $A$  is a sum of  $k$  rank 1 matrices. That is, there exist  $A_1, \dots, A_k$  with  $A = A_1 + \dots + A_k$  and  $\text{rank}(A_i) = 1$ , for  $i = 1, \dots, k$ .
17. [HJ85, p. 13] The following are all equivalent statements about a matrix  $A \in F^{m \times n}$ .
  - (a) The rank of  $A$  is  $k$ .
  - (b)  $\dim(\text{range}(A)) = k$ .
  - (c) The reduced row echelon form of  $A$  has  $k$  pivot columns.
  - (d) A row echelon form of  $A$  has  $k$  pivot columns.
  - (e) The largest number of linearly independent columns of  $A$  is  $k$ .
  - (f) The largest number of linearly independent rows of  $A$  is  $k$ .
18. [HJ85, p. 13] (Rank Inequalities) (Unless specified otherwise, assume that  $A, B \in F^{m \times n}$ .)
  - (a)  $\text{rank}(A) \leq \min(m, n)$ .
  - (b) If a new matrix  $B$  is created by deleting rows and/or columns of matrix  $A$ , then  $\text{rank}(B) \leq \text{rank}(A)$ .
  - (c)  $\text{rank}(A + B) \leq \text{rank}(A) + \text{rank}(B)$ .
  - (d) If  $A$  has a  $p \times q$  submatrix of 0s, then  $\text{rank}(A) \leq (m - p) + (n - q)$ .

(e) If  $A \in F^{m \times k}$  and  $B \in F^{k \times n}$ , then

$$\text{rank}(A) + \text{rank}(B) - k \leq \text{rank}(AB) \leq \min\{\text{rank}(A), \text{rank}(B)\}.$$

19. [HJ85, pp. 13–14] (Rank Equalities)

(a) If  $A \in \mathbb{C}^{m \times n}$ , then  $\text{rank}(A^*) = \text{rank}(A^T) = \text{rank}(\overline{A}) = \text{rank}(A)$ .

(b) If  $A \in \mathbb{C}^{m \times n}$ , then  $\text{rank}(A^*A) = \text{rank}(A)$ . If  $A \in \mathbb{R}^{m \times n}$ , then  $\text{rank}(A^T A) = \text{rank}(A)$ .

(c) Rank is unchanged by left or right multiplication by a nonsingular matrix. That is, if  $A \in F^{n \times n}$  and  $B \in F^{m \times m}$  are nonsingular, and  $M \in F^{m \times n}$ , then

$$\text{rank}(AM) = \text{rank}(M) = \text{rank}(MB) = \text{rank}(AMB).$$

(d) If  $A, B \in F^{m \times n}$ , then  $\text{rank}(A) = \text{rank}(B)$  if and only if there exist nonsingular matrices  $X \in F^{m \times m}$  and  $Y \in F^{n \times n}$  such that  $A = XBY$  (i.e., if and only if  $A$  is equivalent to  $B$ ).

(e) If  $A \in F^{m \times n}$  has rank  $k$ , then  $A = XBY$ , for some  $X \in F^{m \times k}$ ,  $Y \in F^{k \times n}$ , and nonsingular  $B \in F^{k \times k}$ .

(f) If  $A_1 \in F^{n_1 \times m_1}, \dots, A_k \in F^{n_k \times m_k}$ , then  $\text{rank}(A_1 \oplus \dots \oplus A_k) = \text{rank}(A_1) + \dots + \text{rank}(A_k)$ .

20. Let  $A, B \in F^{n \times n}$  with  $A$  similar to  $B$ .

(a)  $A$  is equivalent to  $B$ .

(b)  $\text{rank}(A) = \text{rank}(B)$ .

(c)  $\text{tr } A = \text{tr } B$ .

21. Equivalence of matrices is an equivalence relation on  $F^{m \times n}$ .

22. Similarity of matrices is an equivalence relation on  $F^{n \times n}$ .

23. If  $A \in F^{m \times n}$  and  $\text{rank}(A) = k$ , then  $A$  is equivalent to  $\begin{bmatrix} I_k & 0 \\ 0 & 0 \end{bmatrix}$ , and so any two matrices of the same size and rank are equivalent.

24. (For information on the determination of whether two matrices are similar, see Chapter 6.)

25. [Lay03, Sec. 6.1] If  $A \in \mathbb{R}^{n \times n}$ , then for any  $\mathbf{x} \in \text{RS}(A)$  and any  $\mathbf{y} \in \ker(A)$ ,  $\mathbf{x}^T \mathbf{y} = 0$ . So the row space and kernel of a real matrix are orthogonal to one another. (See Chapter 5 for more on orthogonality.)

### Examples:

1. If  $A = \begin{bmatrix} 1 & 7 & -2 \\ 0 & -1 & 1 \\ 2 & 13 & -3 \end{bmatrix} \in \mathbb{R}^{3 \times 3}$ , then any vector of the form  $\begin{bmatrix} a + 7b - 2c \\ -b + c \\ 2a + 13b - 3c \end{bmatrix} = \begin{bmatrix} 1 & 7 & -2 \\ 0 & -1 & 1 \\ 2 & 13 & -3 \end{bmatrix} \begin{bmatrix} a \\ b \\ c \end{bmatrix}$

is in  $\text{range}(A)$ , for any  $a, b, c \in \mathbb{R}$ . Since a row echelon form of  $A$  is  $\begin{bmatrix} 1 & 7 & -2 \\ 0 & 1 & -1 \\ 0 & 0 & 0 \end{bmatrix}$ , we know that

the set  $\left\{ \begin{bmatrix} 1 \\ 0 \\ 2 \end{bmatrix}, \begin{bmatrix} 7 \\ -1 \\ 13 \end{bmatrix} \right\}$  is a basis for  $\text{range}(A)$ , and the set  $\left\{ \begin{bmatrix} 1 \\ 7 \\ -2 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \\ -1 \end{bmatrix} \right\}$  is a basis for

$\text{RS}(A)$ . Since its reduced row echelon form is  $\begin{bmatrix} 1 & 0 & 5 \\ 0 & 1 & -1 \\ 0 & 0 & 0 \end{bmatrix}$ , the set  $\left\{ \begin{bmatrix} 1 \\ 0 \\ 5 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \\ -1 \end{bmatrix} \right\}$  is another

basis for  $\text{RS}(A)$ .

2. If  $A = \begin{bmatrix} 1 & 7 & -2 \\ 0 & -1 & 1 \\ 2 & 13 & -3 \end{bmatrix} \in \mathbb{R}^{3 \times 3}$ , then using the reduced row echelon form given in the previ-

ous example, solutions to  $A\mathbf{x} = \mathbf{0}$  have the form  $\mathbf{x} = c \begin{bmatrix} -5 \\ 1 \\ 1 \end{bmatrix}$ , for any  $c \in \mathbb{R}$ . So  $\ker(A) =$

$$\text{Span} \left( \begin{bmatrix} -5 \\ 1 \\ 1 \end{bmatrix} \right).$$

3. If  $A \in \mathbb{R}^{3 \times 5}$  has the reduced row echelon form  $\begin{bmatrix} 1 & 0 & 3 & 0 & 2 \\ 0 & 1 & -2 & 0 & 7 \\ 0 & 0 & 0 & 1 & -1 \end{bmatrix}$ , then any solution to

$A\mathbf{x} = \mathbf{0}$  has the form

$$\mathbf{x} = c_1 \begin{bmatrix} -3 \\ 2 \\ 1 \\ 0 \\ 0 \end{bmatrix} + c_2 \begin{bmatrix} -2 \\ -7 \\ 0 \\ 1 \\ 1 \end{bmatrix}$$

for some  $c_1, c_2 \in \mathbb{R}$ . So,

$$\ker(A) = \text{Span} \left( \begin{bmatrix} -3 \\ 2 \\ 1 \\ 0 \\ 0 \end{bmatrix}, \begin{bmatrix} -2 \\ -7 \\ 0 \\ 1 \\ 1 \end{bmatrix} \right).$$

4. Example 1 above shows that  $\left\{ \begin{bmatrix} 1 \\ 0 \\ 2 \end{bmatrix}, \begin{bmatrix} 7 \\ -1 \\ 13 \end{bmatrix} \right\}$  is a linearly independent set having the same span

as the set  $\left\{ \begin{bmatrix} 1 \\ 0 \\ 2 \end{bmatrix}, \begin{bmatrix} 7 \\ -1 \\ 13 \end{bmatrix}, \begin{bmatrix} -2 \\ 1 \\ -3 \end{bmatrix} \right\}$ .

5.  $\begin{bmatrix} 1 & 7 \\ 2 & -3 \end{bmatrix}$  is similar to  $\begin{bmatrix} 37 & -46 \\ 31 & -39 \end{bmatrix}$  because  $\begin{bmatrix} 37 & -46 \\ 31 & -39 \end{bmatrix} = \begin{bmatrix} -2 & 3 \\ 3 & -4 \end{bmatrix}^{-1} \begin{bmatrix} 1 & 7 \\ 2 & -3 \end{bmatrix} \begin{bmatrix} -2 & 3 \\ 3 & -4 \end{bmatrix}$ .

## 2.5 Nonsingularity Characterizations

From the previous discussion, we can add to the list of nonsingularity characterizations of a square matrix that was started in the previous chapter.

**Facts:** The following facts can be found in [HJ85, p. 14] or [Lay03, Sections 2.3 and 4.6].

1. If  $A \in F^{n \times n}$ , then the following are equivalent.
  - (a)  $A$  is nonsingular.
  - (b) The columns of  $A$  are linearly independent.
  - (c) The dimension of  $\text{range}(A)$  is  $n$ .

- (d) The range of  $A$  is  $F^n$ .
- (e) The equation  $A\mathbf{x} = \mathbf{b}$  is consistent for each  $\mathbf{b} \in F^n$ .
- (f) If the equation  $A\mathbf{x} = \mathbf{b}$  is consistent, then the solution is unique.
- (g) The equation  $A\mathbf{x} = \mathbf{b}$  has a unique solution for each  $\mathbf{b} \in F^n$ .
- (h) The rows of  $A$  are linearly independent.
- (i) The dimension of  $\text{RS}(A)$  is  $n$ .
- (j) The row space of  $A$  is  $F^n$ .
- (k) The dimension of  $\ker(A)$  is 0.
- (l) The only solution to  $A\mathbf{x} = \mathbf{0}$  is  $\mathbf{x} = \mathbf{0}$ .
- (m) The rank of  $A$  is  $n$ .
- (n) The determinant of  $A$  is nonzero. (See Section 4.1 for the definition of the determinant.)

## 2.6 Coordinates and Change of Basis

Coordinates are used to transform a problem in a more abstract vector space (e.g., the vector space of polynomials of degree less than or equal to 3) to a problem in  $F^n$ .

### Definitions:

Suppose that  $\mathcal{B} = (\mathbf{b}_1, \mathbf{b}_2, \dots, \mathbf{b}_n)$  is an ordered basis for a vector space  $V$  over a field  $F$  and  $\mathbf{x} \in V$ . The **coordinates of  $\mathbf{x}$  relative to the ordered basis  $\mathcal{B}$**  (or the  **$\mathcal{B}$ -coordinates of  $\mathbf{x}$** ) are the scalar coefficients  $c_1, c_2, \dots, c_n \in F$  such that  $\mathbf{x} = c_1\mathbf{x}_1 + c_2\mathbf{x}_2 + \dots + c_n\mathbf{x}_n$ . Whenever coordinates are involved, the vector space is assumed to be nonzero and finite dimensional.

If  $c_1, c_2, \dots, c_n$  are the  $\mathcal{B}$ -coordinates of  $\mathbf{x}$ , then the vector in  $F^n$ ,

$$[\mathbf{x}]_{\mathcal{B}} = \begin{bmatrix} c_1 \\ c_2 \\ \vdots \\ c_n \end{bmatrix},$$

is the **coordinate vector of  $\mathbf{x}$  relative to  $\mathcal{B}$**  or the  **$\mathcal{B}$ -coordinate vector of  $\mathbf{x}$** .

The mapping  $\mathbf{x} \rightarrow [\mathbf{x}]_{\mathcal{B}}$  is the **coordinate mapping determined by  $\mathcal{B}$** .

If  $\mathcal{B}$  and  $\mathcal{B}'$  are ordered bases for the vector space  $F^n$ , then the **change-of-basis matrix** from  $\mathcal{B}$  to  $\mathcal{B}'$  is the matrix whose columns are the  $\mathcal{B}'$ -coordinate vectors of the vectors in  $\mathcal{B}$  and is denoted by  ${}_{\mathcal{B}'}[I]_{\mathcal{B}}$ . Such a matrix is also called a **transition matrix**.

**Facts:** The following facts can be found in [Lay03, Sections 4.4 and 4.7] or [HJ85, Section 0.10]:

1. For any vector  $\mathbf{x} \in F^n$  with the standard ordered basis  $\mathcal{E}_n = (\mathbf{e}_1, \mathbf{e}_2, \dots, \mathbf{e}_n)$ , we have  $\mathbf{x} = [\mathbf{x}]_{\mathcal{E}_n}$ .
2. For any ordered basis  $\mathcal{B} = (\mathbf{b}_1, \dots, \mathbf{b}_n)$  of a vector space  $V$ , we have  $[\mathbf{b}_i]_{\mathcal{B}} = \mathbf{e}_i$ .
3. If  $\dim(V) = n$ , then the coordinate mapping is a one-to-one linear transformation from  $V$  onto  $F^n$ . (See Chapter 3 for the definition of linear transformation.)
4. If  $\mathcal{B}$  is an ordered basis for a vector space  $V$  and  $\mathbf{v}_1, \mathbf{v}_2 \in V$ , then  $\mathbf{v}_1 = \mathbf{v}_2$  if and only if  $[\mathbf{v}_1]_{\mathcal{B}} = [\mathbf{v}_2]_{\mathcal{B}}$ .
5. Let  $V$  be a vector space over a field  $F$ , and suppose  $\mathcal{B}$  is an ordered basis for  $V$ . Then for any  $\mathbf{x}, \mathbf{v}_1, \dots, \mathbf{v}_k \in V$  and  $c_1, \dots, c_k \in F$ ,  $\mathbf{x} = c_1\mathbf{v}_1 + \dots + c_k\mathbf{v}_k$  if and only if  $[\mathbf{x}]_{\mathcal{B}} = c_1[\mathbf{v}_1]_{\mathcal{B}} + \dots + c_k[\mathbf{v}_k]_{\mathcal{B}}$ . So, for any  $\mathbf{x}, \mathbf{v}_1, \dots, \mathbf{v}_k \in V$ ,  $\mathbf{x} \in \text{Span}(\mathbf{v}_1, \dots, \mathbf{v}_k)$  if and only if  $[\mathbf{x}]_{\mathcal{B}} \in \text{Span}([\mathbf{v}_1]_{\mathcal{B}}, \dots, [\mathbf{v}_k]_{\mathcal{B}})$ .
6. Suppose  $\mathcal{B}$  is an ordered basis for an  $n$ -dimensional vector space  $V$  over a field  $F$  and  $\mathbf{v}_1, \dots, \mathbf{v}_k \in V$ . The set  $S = \{\mathbf{v}_1, \dots, \mathbf{v}_k\}$  is linearly independent in  $V$  if and only if the set  $S' = \{[\mathbf{v}_1]_{\mathcal{B}}, \dots, [\mathbf{v}_k]_{\mathcal{B}}\}$  is linearly independent in  $F^n$ .

7. Let  $V$  be a vector space over a field  $F$  with  $\dim(V) = n$ , and suppose  $\mathcal{B}$  is an ordered basis for  $V$ . Then  $\text{Span}(\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_k) = V$  for some  $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_k \in V$  if and only if  $\text{Span}([\mathbf{v}_1]_{\mathcal{B}}, [\mathbf{v}_2]_{\mathcal{B}}, \dots, [\mathbf{v}_k]_{\mathcal{B}}) = F^n$ .
8. Suppose  $\mathcal{B}$  is an ordered basis for a vector space  $V$  over a field  $F$  with  $\dim(V) = n$ , and let  $S = \{\mathbf{v}_1, \dots, \mathbf{v}_n\}$  be a subset of  $V$ . Then  $S$  is a basis for  $V$  if and only if  $\{[\mathbf{v}_1]_{\mathcal{B}}, \dots, [\mathbf{v}_n]_{\mathcal{B}}\}$  is a basis for  $F^n$  if and only if the matrix  $[[\mathbf{v}_1]_{\mathcal{B}}, \dots, [\mathbf{v}_n]_{\mathcal{B}}]$  is invertible.
9. If  $\mathcal{B}$  and  $\mathcal{B}'$  are ordered bases for a vector space  $V$ , then  $[\mathbf{x}]_{\mathcal{B}'} = {}_{\mathcal{B}'}[I]_{\mathcal{B}} [\mathbf{x}]_{\mathcal{B}}$  for any  $\mathbf{x} \in V$ . Furthermore,  ${}_{\mathcal{B}'}[I]_{\mathcal{B}}$  is the only matrix such that for any  $\mathbf{x} \in V$ ,  $[\mathbf{x}]_{\mathcal{B}'} = {}_{\mathcal{B}'}[I]_{\mathcal{B}} [\mathbf{x}]_{\mathcal{B}}$ .
10. Any change-of-basis matrix is invertible.
11. If  $B$  is invertible, then  $B$  is a change-of-basis matrix. Specifically, if  $B = [\mathbf{b}_1 \cdots \mathbf{b}_n] \in F^{n \times n}$ , then  $B = {}_{\mathcal{E}_n}[I]_{\mathcal{B}}$ , where  $\mathcal{B} = (\mathbf{b}_1, \dots, \mathbf{b}_n)$  is an ordered basis for  $F^n$ .
12. If  $\mathcal{B} = (\mathbf{b}_1, \dots, \mathbf{b}_n)$  is an ordered basis for  $F^n$ , then  ${}_{\mathcal{E}_n}[I]_{\mathcal{B}} = [\mathbf{b}_1 \cdots \mathbf{b}_n]$ .
13. If  $\mathcal{B}$  and  $\mathcal{B}'$  are ordered bases for a vector space  $V$ , then  ${}_{\mathcal{B}}[I]_{\mathcal{B}'} = ({}_{\mathcal{B}'}[I]_{\mathcal{B}})^{-1}$ .
14. If  $\mathcal{B}$  and  $\mathcal{B}'$  are ordered bases for  $F^n$ , then  ${}_{\mathcal{B}'}[I]_{\mathcal{B}} = ({}_{\mathcal{B}'}[I]_{\mathcal{E}_n})({}_{\mathcal{E}_n}[I]_{\mathcal{B}})$ .

**Examples:**

1. If  $p(x) = a_n x^n + a_{n-1} x^{n-1} + \cdots + a_1 x + a_0 \in F[x; n]$  with the standard ordered basis

$$\mathcal{B} = (1, x, x^2, \dots, x^n), \text{ then } [p(x)]_{\mathcal{B}} = \begin{bmatrix} a_0 \\ a_1 \\ \vdots \\ a_n \end{bmatrix}.$$

2. The set  $\mathcal{B} = \left( \begin{bmatrix} 1 \\ -1 \end{bmatrix}, \begin{bmatrix} 0 \\ 3 \end{bmatrix} \right)$  forms an ordered basis for  $\mathbb{R}^2$ . If  $\mathcal{E}_2$  is the standard ordered basis

for  $\mathbb{R}^2$ , then the change-of-basis matrix from  $\mathcal{B}$  to  $\mathcal{E}_2$  is  ${}_{\mathcal{E}_2}[T]_{\mathcal{B}} = \begin{bmatrix} 1 & 0 \\ -1 & 3 \end{bmatrix}$ , and  $({}_{\mathcal{E}_2}[T]_{\mathcal{B}})^{-1} =$

$$\begin{bmatrix} 1 & 0 \\ \frac{1}{3} & \frac{1}{3} \end{bmatrix}. \text{ So for } \mathbf{v} = \begin{bmatrix} 3 \\ 1 \end{bmatrix} \text{ in the standard ordered basis, we find that } [\mathbf{v}]_{\mathcal{B}} = ({}_{\mathcal{E}_2}[T]_{\mathcal{B}})^{-1} \mathbf{v} = \begin{bmatrix} 3 \\ \frac{4}{3} \end{bmatrix}.$$

To check this, we can easily see that  $\mathbf{v} = \begin{bmatrix} 3 \\ 1 \end{bmatrix} = 3 \begin{bmatrix} 1 \\ -1 \end{bmatrix} + \frac{4}{3} \begin{bmatrix} 0 \\ 3 \end{bmatrix}$ .

3. The set  $\mathcal{B}' = (1, 1 + x, 1 + x^2)$  is an ordered basis for  $\mathbb{R}[x; 2]$ , and using the standard ordered basis

$$\mathcal{B} = (1, x, x^2) \text{ for } \mathbb{R}[x; 2] \text{ we have } {}_{\mathcal{B}}[P]_{\mathcal{B}'} = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}. \text{ So, } ({}_{\mathcal{B}}[P]_{\mathcal{B}'} )^{-1} = \begin{bmatrix} 1 & -1 & -1 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

$$\text{and } [5 - 2x + 3x^2]_{\mathcal{B}'} = ({}_{\mathcal{B}}[P]_{\mathcal{B}'} )^{-1} \begin{bmatrix} 5 \\ -2 \\ 3 \end{bmatrix} = \begin{bmatrix} 4 \\ -2 \\ 3 \end{bmatrix}. \text{ Of course, we can see } 5 - 2x + 3x^2 =$$

$$4(1) - 2(1 + x) + 3(1 + x^2).$$

4. If we want to change from the ordered basis  $\mathcal{B}_1 = \left( \begin{bmatrix} 1 \\ -1 \end{bmatrix}, \begin{bmatrix} 0 \\ 3 \end{bmatrix} \right)$  in  $\mathbb{R}^2$  to the ordered basis  $\mathcal{B}_2 =$

$\left( \begin{bmatrix} 2 \\ 1 \end{bmatrix}, \begin{bmatrix} 5 \\ 0 \end{bmatrix} \right)$ , then the resulting change-of-basis matrix is  ${}_{\mathcal{B}_2}[T]_{\mathcal{B}_1} = ({}_{\mathcal{E}_2}[T]_{\mathcal{B}_2})^{-1} ({}_{\mathcal{E}_2}[T]_{\mathcal{B}_1}) =$

$$\begin{bmatrix} 2 & 5 \\ 1 & 0 \end{bmatrix}^{-1} \begin{bmatrix} 1 & 0 \\ -1 & 3 \end{bmatrix} = \begin{bmatrix} -1 & 3 \\ \frac{3}{5} & -\frac{6}{5} \end{bmatrix}.$$

5. Let  $S = \{5 - 2x + 3x^2, 3 - x + 2x^2, 8 + 3x\}$  in  $\mathbb{R}[x; 2]$  with the standard ordered basis  $\mathcal{B} = (1, x, x^2)$ . The matrix  $A = \begin{bmatrix} 5 & 3 & 8 \\ -2 & -1 & 3 \\ 3 & 2 & 0 \end{bmatrix}$  contains the  $\mathcal{B}$ -coordinate vectors for the polynomials in  $S$  and it has row echelon form  $\begin{bmatrix} 5 & 3 & 8 \\ 0 & 1 & 31 \\ 0 & 0 & 1 \end{bmatrix}$ . Since this row echelon form shows that  $A$  is nonsingular, we know by Fact 8 above that  $S$  is a basis for  $\mathbb{R}[x; 2]$ .

## 2.7 Idempotence and Nilpotence

---

### Definitions:

$A$  is an **idempotent** if  $A^2 = A$ .

$A$  is **nilpotent** if, for some  $k \geq 0$ ,  $A^k = 0$ .

**Facts:** All of the following facts except those with a specific reference are immediate from the definitions.

1. Every idempotent except the identity matrix is singular.
2. Let  $A \in F^{n \times n}$ . The following statements are equivalent.
  - (a)  $A$  is an idempotent.
  - (b)  $I - A$  is an idempotent.
  - (c) If  $\mathbf{v} \in \text{range}(A)$ , then  $A\mathbf{v} = \mathbf{v}$ .
  - (d)  $F^n = \ker A \oplus \text{range} A$ .
  - (e) [HJ85, p. 37 and p. 148]  $A$  is similar to  $\begin{bmatrix} I_k & 0 \\ 0 & 0 \end{bmatrix}$ , for some  $k \leq n$ .
3. If  $A_1$  and  $A_2$  are idempotents of the same size and commute, then  $A_1 A_2$  is an idempotent.
4. If  $A_1$  and  $A_2$  are idempotents of the same size and  $A_1 A_2 = A_2 A_1 = 0$ , then  $A_1 + A_2$  is an idempotent.
5. If  $A \in F^{n \times n}$  is nilpotent, then  $A^n = 0$ .
6. If  $A$  is nilpotent and  $B$  is of the same size and commutes with  $A$ , then  $AB$  is nilpotent.
7. If  $A_1$  and  $A_2$  are nilpotent matrices of the same size and  $A_1 A_2 = A_2 A_1 = 0$ , then  $A_1 + A_2$  is nilpotent.

### Examples:

1.  $\begin{bmatrix} -8 & 12 \\ -6 & 9 \end{bmatrix}$  is an idempotent.  $\begin{bmatrix} 1 & -1 \\ 1 & -1 \end{bmatrix}$  is nilpotent.

### 3.1 Basic Concepts

---

Let  $V, W$  be vector spaces over a field  $F$ .

#### Definitions:

A **linear transformation** (or **linear mapping**) is a mapping  $T: V \rightarrow W$  such that, for each  $\mathbf{u}, \mathbf{v} \in V$ , and for each  $c \in F$ ,  $T(\mathbf{u} + \mathbf{v}) = T(\mathbf{u}) + T(\mathbf{v})$ , and  $T(c\mathbf{u}) = cT(\mathbf{u})$ .

$V$  is called the **domain** of the linear transformation  $T: V \rightarrow W$ .

$W$  is called the **codomain** of the linear transformation  $T: V \rightarrow W$ .

The **identity** transformation  $I_V: V \rightarrow V$  is defined by  $I_V(\mathbf{v}) = \mathbf{v}$  for each  $\mathbf{v} \in V$ .  $I_V$  is also denoted by  $I$ .

The **zero** transformation  $0: V \rightarrow W$  is defined by  $0(\mathbf{v}) = \mathbf{0}_W$  for each  $\mathbf{v} \in V$ .

A **linear operator** is a linear transformation  $T: V \rightarrow V$ .

#### Facts:

Let  $T: V \rightarrow W$  be a linear transformation. The following facts can be found in almost any elementary linear algebra text, including [Lan70, IV§1], [Sta69, §3.1], [Goo03, Chapter 4], and [Lay03, §1.8].

1.  $T(\sum_1^n a_i \mathbf{v}_i) = \sum_1^n a_i T(\mathbf{v}_i)$ , for any  $a_i \in F$ ,  $\mathbf{v}_i \in V$ ,  $i = 1, \dots, n$ .
2.  $T(\mathbf{0}_V) = \mathbf{0}_W$ .
3.  $T(-\mathbf{v}) = -T(\mathbf{v})$ , for each  $\mathbf{v} \in V$ .
4. The identity transformation is a linear transformation.
5. The zero transformation is a linear transformation.

6. If  $\mathcal{B} = \{\mathbf{v}_1, \dots, \mathbf{v}_n\}$  is a basis for  $V$ , and  $\mathbf{w}_1, \dots, \mathbf{w}_n \in W$ , then there exists a unique  $T: V \rightarrow W$  such that  $T(\mathbf{v}_i) = \mathbf{w}_i$  for each  $i$ .

### Examples:

Examples 1 to 9 are linear transformations.

1.  $T: \mathbb{R}^3 \rightarrow \mathbb{R}^2$  where  $T \left( \begin{bmatrix} x \\ y \\ z \end{bmatrix} \right) = \begin{bmatrix} x + y \\ 2x - z \end{bmatrix}$ .
2.  $T: V \rightarrow V$ , defined by  $T(\mathbf{v}) = -\mathbf{v}$  for each  $\mathbf{v} \in V$ .
3. If  $A \in F^{m \times n}$ ,  $T: F^n \rightarrow F^m$ , where  $T(\mathbf{v}) = A\mathbf{v}$ .
4.  $T: F^{m \times n} \rightarrow F$ , where  $T(A) = \text{tr}A$ .
5. Let  $\mathcal{C}([0, 1])$  be the vector space of all continuous functions on  $[0, 1]$  into  $\mathbb{R}$ , and let  $T: \mathcal{C}([0, 1]) \rightarrow \mathbb{R}$  be defined by  $T(f) = \int_0^1 f(t) dt$ .
6. Let  $V$  be the vector space of all functions  $f: \mathbb{R} \rightarrow \mathbb{R}$  that have derivatives of all orders, and  $D: V \rightarrow V$  be defined by  $D(f) = f'$ .
7. The transformation, which rotates every vector in the plane  $\mathbb{R}^2$  through an angle  $\theta$ .
8. The projection  $T$  onto the  $xy$ -plane of  $\mathbb{R}^3$ , i.e.,  $T \left( \begin{bmatrix} x \\ y \\ z \end{bmatrix} \right) = \begin{bmatrix} x \\ y \\ 0 \end{bmatrix}$ .
9.  $T: \mathbb{R}^3 \rightarrow \mathbb{R}^3$ , where  $T(\mathbf{v}) = \mathbf{b} \times \mathbf{v}$ , for some  $\mathbf{b} \in \mathbb{R}^3$ .

Examples 10 and 11 are not linear transformations.

10.  $f: \mathbb{R}^2 \rightarrow \mathbb{R}^2$ , where  $f \left( \begin{bmatrix} x \\ y \end{bmatrix} \right) = \begin{bmatrix} y + 1 \\ x - y - 2 \end{bmatrix}$  is not a linear transformation because  $f(\mathbf{0}) \neq \mathbf{0}$ .
11.  $f: \mathbb{R}^2 \rightarrow \mathbb{R}$ , where  $f \left( \begin{bmatrix} x \\ y \end{bmatrix} \right) = x^2$  is not a linear transformation because  $f \left( 2 \begin{bmatrix} 1 \\ 0 \end{bmatrix} \right) = 4 \neq 2 = 2f \left( \begin{bmatrix} 1 \\ 0 \end{bmatrix} \right)$ .

## 3.2 The Spaces $L(V, W)$ and $L(V, V)$

---

Let  $V, W$  be vector spaces over  $F$ .

### Definitions:

$L(V, W)$  denotes the set of all linear transformations of  $V$  into  $W$ .

For each  $T_1, T_2 \in L(V, W)$  the **sum**  $T_1 + T_2$  is defined by  $(T_1 + T_2)(\mathbf{v}) = T_1(\mathbf{v}) + T_2(\mathbf{v})$ .

For each  $c \in F, T \in L(V, W)$  the **scalar multiple**  $cT$  is defined by  $(cT)(\mathbf{v}) = cT(\mathbf{v})$ .

For each  $T_1, T_2 \in L(V, V)$  the **product**  $T_1 T_2$  is the composite mapping defined by  $(T_1 T_2)(\mathbf{v}) = T_1(T_2(\mathbf{v}))$ .

$T_1, T_2 \in L(V, V)$  **commute** if  $T_1 T_2 = T_2 T_1$ .

$T \in L(V, V)$  is a **scalar transformation** if, for some  $c \in F, T(\mathbf{v}) = c\mathbf{v}$  for each  $\mathbf{v} \in V$ .

### Facts:

Let  $T, T_1, T_2 \in L(V, W)$ . The following facts can be found in almost any elementary linear algebra text, including [Fin60, §3.2], [Lan70, IV §4], [Sta69, §3.6], [SW68, §4.3], and [Goo03, Chap. 4].

1.  $T_1 + T_2 \in L(V, W)$ .
2.  $cT \in L(V, W)$ .

3. If  $T_1, T_2 \in L(V, V)$ , then  $T_1 T_2 \in L(V, V)$ .
4.  $L(V, W)$ , with sum and scalar multiplication, is a vector space over  $F$ .
5.  $L(V, V)$ , with sum, scalar multiplication, and composition, is a linear algebra over  $F$ .
6. Let  $\dim V = n$  and  $\dim W = m$ . Then  $\dim L(V, W) = mn$ .
7. If  $\dim V > 1$ , then there exist  $T_1, T_2 \in L(V, V)$ , which do not commute.
8.  $T_0 \in L(V, V)$  commutes with all  $T \in L(V, V)$  if and only if  $T_0$  is a scalar transformation.

**Examples:**

1. For each  $j = 1, \dots, n$  let  $T_j \in L(F^n, F^n)$  be defined by  $T_j(\mathbf{x}) = x_j \mathbf{e}_j$ . Then  $\sum_{i=1}^n T_j$  is the identity transformation in  $V$ .
2. Let  $T_1$  and  $T_2$  be the transformations that rotates every vector in  $\mathbb{R}^2$  through an angle  $\theta_1$  and  $\theta_2$  respectively. Then  $T_1 T_2$  is the rotation through the angle  $\theta_1 + \theta_2$ .
3. Let  $T_1$  be the rotation through an angle  $\theta$  in  $\mathbb{R}^2$  and let  $T_2$  be the reflection on the horizontal axis, that is,  $T_2(x, y) = (x, -y)$ . Then  $T_1$  and  $T_2$  do not commute.

### 3.3 Matrix of a Linear Transformation

---

Let  $V, W$  be nonzero finite dimensional vector spaces over  $F$ .

**Definitions:**

The **linear transformation associated to a matrix**  $A \in F^{m \times n}$  is  $T_A: F^n \rightarrow F^m$  defined by  $T_A(\mathbf{v}) = A\mathbf{v}$ .

The **matrix associated to a linear transformation**  $T \in L(V, W)$  and relative to the ordered bases  $\mathcal{B} = (\mathbf{b}_1, \dots, \mathbf{b}_n)$  of  $V$ , and  $\mathcal{C}$  of  $W$ , is the matrix  ${}_C[T]_B = [ [T(\mathbf{b}_1)]_C \cdots [T(\mathbf{b}_n)]_C ]$ .

If  $T \in L(F^n, F^m)$ , then the **standard matrix** of  $T$  is  $[T] = {}_{\mathcal{E}_m}[T]_{\mathcal{E}_n}$ , where  $\mathcal{E}_n$  is the standard basis for  $F^n$ .

*Note:* If  $V = W$  and  $\mathcal{B} = \mathcal{C}$ , the matrix  ${}_B[T]_B$  will be denoted by  $[T]_B$ .

If  $T \in L(V, V)$  and  $\mathcal{B}$  is an ordered basis for  $V$ , then the **trace** of  $T$  is  $\text{tr } T = \text{tr } [T]_B$ .

**Facts:**

Let  $\mathcal{B}$  and  $\mathcal{C}$  be ordered bases  $V$  and  $W$ , respectively. The following facts can be found in almost any elementary linear algebra text, including [Lan70, V §2], [Sta69, §3.4–3.6], [SW68, §4.3], and [Goo03, Chap. 4].

1. The trace of  $T \in L(V, V)$  is independent of the ordered basis of  $V$  used to define it.
2. For  $A, B \in F^{m \times n}$ ,  $T_A = T_B$  if and only if  $A = B$ .
3. For any  $T_1, T_2 \in L(V, W)$ ,  ${}_C[T_1]_B = {}_C[T_2]_B$  if and only if  $T_1 = T_2$ .
4. If  $T \in L(F^n, F^m)$ , then  $[T] = [T(\mathbf{e}_1) \cdots T(\mathbf{e}_n)]$ .
5. The change-of-basis matrix from basis  $\mathcal{B}$  to  $\mathcal{C}$ ,  ${}_C[I]_B$ , as defined in Chapter 2.6, is the same matrix as the matrix of the identity transformation with respect to  $\mathcal{B}$  and  $\mathcal{C}$ .
6. Let  $A \in F^{m \times n}$  and let  $T_A$  be the linear transformation associated to  $A$ . Then  $[T_A] = A$ .
7. If  $T \in L(F^n, F^m)$ , then  $T_{[T]} = T$ .
8. For any  $T_1, T_2 \in L(V, W)$ ,  ${}_C[T_1 + T_2]_B = {}_C[T_1]_B + {}_C[T_2]_B$ .
9. For any  $T \in L(V, W)$ , and  $c \in F$ ,  ${}_C[cT]_B = c {}_C[T]_B$ .
10. For any  $T_1, T_2 \in L(V, V)$ ,  $[T_1 T_2]_B = [T_1]_B [T_2]_B$ .
11. If  $T \in L(V, W)$ , then, for each  $\mathbf{v} \in V$ ,  $[T(\mathbf{v})]_C = {}_C[T]_B [\mathbf{v}]_B$ . Furthermore  ${}_C[T]_B$  is the only matrix  $A$  such that, for each  $\mathbf{v} \in V$ ,  $[T(\mathbf{v})]_C = A[\mathbf{v}]_B$ .

**Examples:**

1. Let  $T$  be the projection of  $\mathbb{R}^3$  onto the  $xy$ -plane of  $\mathbb{R}^3$ . Then

$$[T] = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

2. Let  $T$  be the identity in  $F^n$ . Then  $[T]_{\mathcal{B}} = I_n$ .
3. Let  $T$  be the rotation by  $\theta$  in  $\mathbb{R}^2$ . Then

$$[T] = \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix}.$$

4. Let  $D: \mathbb{R}[x; n] \rightarrow \mathbb{R}[x; n-1]$  be the derivative transformation, and let  $\mathcal{B} = \{1, x, \dots, x^n\}$ ,  $\mathcal{C} = \{1, x, \dots, x^{n-1}\}$ . Then

$$c[T]_{\mathcal{B}} = \begin{bmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 2 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & n-1 \end{bmatrix}.$$

### 3.4 Change of Basis and Similarity

---

Let  $V, W$  be nonzero finite dimensional vector spaces over  $F$ .

**Facts:**

The following facts can be found in [Gan60, III §5–6] and [Goo03, Chap. 4].

1. Let  $T \in L(V, W)$  and let  $\mathcal{B}, \mathcal{B}'$  be bases of  $V, \mathcal{C}, \mathcal{C}'$  be bases of  $W$ . Then

$$c'[T]_{\mathcal{B}'} = c'[I]_{\mathcal{C}'} c[T]_{\mathcal{B}} c[I]_{\mathcal{B}'}$$

2. Two  $m \times n$  matrices are equivalent if and only if they represent the same linear transformation  $T \in L(V, W)$ , but possibly in different bases, as in Fact 1.
3. Any  $m \times n$  matrix  $A$  of rank  $r$  is equivalent to the  $m \times n$  matrix

$$\tilde{I}_r = \begin{bmatrix} I_r & 0 \\ 0 & 0 \end{bmatrix}.$$

4. Two  $m \times n$  matrices are equivalent if and only if they have the same rank.
5. Two  $n \times n$  matrices are similar if and only if they represent the same linear transformation  $T \in L(V, V)$ , but possibly in different bases, i.e., if  $A_1$  is similar to  $A_2$ , then there is  $T \in L(V, V)$  and ordered bases  $\mathcal{B}_1, \mathcal{B}_2$  of  $V$  such that  $A_i = [T]_{\mathcal{B}_i}$  and conversely.

**Examples:**

1. Let  $T$  be the projection on the  $x$ -axis of  $\mathbb{R}^2$ , i.e.,  $T(x, y) = (x, 0)$ . If  $\mathcal{B} = \{\mathbf{e}_1, \mathbf{e}_2\}$  and  $\mathcal{C} = \{\mathbf{e}_1 + \mathbf{e}_2, \mathbf{e}_1 - \mathbf{e}_2\}$ , then  $[T]_{\mathcal{B}} = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}$ ,  $[T]_{\mathcal{C}} = \begin{bmatrix} 1/2 & 1/2 \\ 1/2 & 1/2 \end{bmatrix}$ , and  $[T]_{\mathcal{C}} = Q^{-1}[T]_{\mathcal{B}}Q$  with

$$Q = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}.$$

### 3.5 Kernel and Range

Let  $V, W$  be vector spaces over  $F$  and let  $T \in L(V, W)$ .

**Definitions:**

$T$  is **one-to-one** (or **injective**) if  $\mathbf{v}_1 \neq \mathbf{v}_2$  implies  $T(\mathbf{v}_1) \neq T(\mathbf{v}_2)$ .

The **kernel** (or **null space**) of  $T$  is the set  $\ker T = \{\mathbf{v} \in V \mid T(\mathbf{v}) = \mathbf{0}\}$ .

The **nullity** of  $T$ , denoted by  $\text{null } T$ , is the dimension of  $\ker T$ .

$T$  is **onto** (or **surjective**) if, for each  $\mathbf{w} \in W$ , there exists  $\mathbf{v} \in V$  such that  $T(\mathbf{v}) = \mathbf{w}$ .

The **range** (or **image**) of  $T$  is the set  $\text{range } T = \{\mathbf{w} \in W \mid \exists \mathbf{v}, \mathbf{w} = T(\mathbf{v})\}$ .

The **rank** of  $T$ , denoted by  $\text{rank } T$ , is the dimension of  $\text{range } T$ .

**Facts:**

The following facts can be found in [Fin60, §3.3], [Lan70, IV §3], [Sta69, §3.1–3.2], and [Goo03, Chap. 4].

1.  $\ker T$  is a subspace of  $V$ .
2. The following statements are equivalent.
  - (a)  $T$  is one-to-one.
  - (b)  $\ker T = \{\mathbf{0}\}$ .
  - (c) Each linearly independent set is mapped to a linearly independent set.
  - (d) Each basis is mapped to a linearly independent set.
  - (e) Some basis is mapped to a linearly independent set.
3.  $\text{range } T$  is a subspace of  $W$ .
4.  $\text{rank } T = \text{rank } {}_C[T]_B$  for any finite nonempty ordered bases  $B, C$ .
5. For  $A \in F^{m \times n}$ ,  $\ker T_A = \ker A$  and  $\text{range } T_A = \text{range } A$ .
6. (Dimension Theorem) Let  $T \in L(V, W)$  where  $V$  has finite dimension. Then  $\text{null } T + \text{rank } T = \dim V$ .
7. Let  $T \in L(V, V)$ , where  $V$  has finite dimension, then  $T$  is one-to-one if and only if  $T$  is onto.
8. Let  $T(\mathbf{v}) = \mathbf{w}$ . Then  $\{\mathbf{u} \in V \mid T(\mathbf{u}) = \mathbf{w}\} = \mathbf{v} + \ker T$ .
9. Let  $V = \text{Span}\{\mathbf{v}_1, \dots, \mathbf{v}_n\}$ . Then  $\text{range } T = \text{Span}\{T(\mathbf{v}_1), \dots, T(\mathbf{v}_n)\}$ .
10. Let  $T_1, T_2 \in L(V, V)$ . Then  $\ker T_1 T_2 \supseteq \ker T_2$  and  $\text{range } T_1 T_2 \subseteq \text{range } T_1$ .
11. Let  $T \in L(V, V)$ . Then

$$\{\mathbf{0}\} \subseteq \ker T \subseteq \ker T^2 \subseteq \dots \subseteq \ker T^k \subseteq \dots$$

$$V \supseteq \text{range } T \supseteq \text{range } T^2 \supseteq \dots \supseteq \text{range } T^k \supseteq \dots$$

Furthermore, if, for some  $k$ ,  $\text{range } T^{k+1} = \text{range } T^k$ , then, for each  $i \geq 1$ ,  $\text{range } T^{k+i} = \text{range } T^k$ .  
 If, for some  $k$ ,  $\ker T^{k+1} = \ker T^k$ , then, for each  $i \geq 1$ ,  $\ker T^{k+i} = \ker T^k$ .

**Examples:**

1. Let  $T$  be the projection of  $\mathbb{R}^3$  onto the  $xy$ -plane of  $\mathbb{R}^3$ . Then  $\ker T = \{(0, 0, z) : z \in \mathbb{R}\}$ ;  $\text{range } T = \{(x, y, 0) : x, y \in \mathbb{R}\}$ ;  $\text{null } T = 1$ ; and  $\text{rank } T = 2$ .
2. Let  $T$  be the linear transformation in Example 1 of Section 3.1. Then  $\ker T = \text{Span}\{[1 \ -1 \ 2]^T\}$ , while  $\text{range } T = \mathbb{R}^2$ .
3. Let  $D \in L(\mathbb{R}[x], \mathbb{R}[x])$  be the derivative transformation, then  $\ker D$  consists of all constant polynomials, while  $\text{range } D = \mathbb{R}[x]$ . In particular,  $D$  is onto but is not one-to-one. Note that  $\mathbb{R}[x]$  is not finite dimensional.

4. Let  $T_1, T_2 \in L(F^{n \times n}, F^{n \times n})$  where  $T_1(A) = \frac{1}{2}(A - A^T)$ ,  $T_2(A) = \frac{1}{2}(A + A^T)$ , then

$$\ker T_1 = \text{range } T_2 = \{n \times n \text{ symmetric matrices}\};$$

$$\ker T_2 = \text{range } T_1 = \{n \times n \text{ skew-symmetric matrices}\};$$

$$\text{null } T_1 = \text{rank } T_2 = \frac{n(n+1)}{2}; \quad \text{null } T_2 = \text{rank } T_1 = \frac{n(n-1)}{2}.$$

5. Let  $T(\mathbf{v}) = \mathbf{b} \times \mathbf{v}$  as in Example 9 of Section 3.1. Then  $\ker T = \text{Span}\{\mathbf{b}\}$ .

### 3.6 Invariant Subspaces and Projections

Let  $V$  be a vector space over  $F$ , and let  $V = V_1 \oplus V_2$  for some  $V_1, V_2$  subspaces of  $V$ . For each  $\mathbf{v} \in V$ , let  $\mathbf{v}_i \in V_i$  denote the (unique) vector such that  $\mathbf{v} = \mathbf{v}_1 + \mathbf{v}_2$  (see Section 2.3). Finally, let  $T \in L(V, V)$ .

#### Definitions:

For  $i, j \in \{1, 2\}$ ,  $i \neq j$ , the **projection** onto  $V_i$  along  $V_j$  is the operator  $\text{proj}_{V_i, V_j} : V \rightarrow V$  defined by  $\text{proj}_{V_i, V_j}(\mathbf{v}) = \mathbf{v}_i$  for each  $\mathbf{v} \in V$  (see also Chapter 5).

The **complementary projection** of the projection  $\text{proj}_{V_i, V_j}$  is the projection  $\text{proj}_{V_j, V_i}$ .

$T$  is an **idempotent** if  $T^2 = T$ .

A subspace  $V_0$  of  $V$  is **invariant** under  $T$  or  **$T$ -invariant** if  $T(V_0) \subseteq V_0$ .

The **fixed space** of  $T$  is  $\text{fix } T = \{\mathbf{v} \in V \mid T(\mathbf{v}) = \mathbf{v}\}$ .

$T$  is **nilpotent** if, for some  $k \geq 0$ ,  $T^k = 0$ .

#### Facts:

The following facts can be found in [Mal63, §43–44].

- $\text{proj}_{V_i, V_j} \in L(V, V)$ .
- $\text{proj}_{V_1, V_2} + \text{proj}_{V_2, V_1} = I$ , the identity linear operator in  $V$ .
- $\text{range}(\text{proj}_{V_i, V_j}) = \ker(\text{proj}_{V_j, V_i}) = V_i$ .
- Sum and intersection of invariant subspaces are invariant subspaces.
- If  $V$  has a nonzero subspace different from  $V$  that is invariant under  $T$ , then there exists a suitable ordered basis  $\mathcal{B}$  of  $V$  such that  $[T]_{\mathcal{B}} = \begin{bmatrix} A_{11} & A_{12} \\ 0 & A_{22} \end{bmatrix}$ . Conversely, if  $[T]_{\mathcal{B}} = \begin{bmatrix} A_{11} & A_{12} \\ 0 & A_{22} \end{bmatrix}$ , where  $A_{11}$  is an  $m$ -by- $m$  block, then the subspace spanned by the first  $m$  vectors in  $\mathcal{B}$  is a  $T$ -invariant subspace.
- Let  $T$  have two nonzero finite dimensional invariant subspaces  $V_1$  and  $V_2$ , with ordered bases  $\mathcal{B}_1$  and  $\mathcal{B}_2$ , respectively, such that  $V_1 \oplus V_2 = V$ . Let  $T_1 \in L(V_1, V_1)$ ,  $T_2 \in L(V_2, V_2)$  be the restrictions of  $T$  on  $V_1$  and  $V_2$ , respectively, and let  $\mathcal{B} = \mathcal{B}_1 \cup \mathcal{B}_2$ . Then  $[T]_{\mathcal{B}} = [T_1]_{\mathcal{B}_1} \oplus [T_2]_{\mathcal{B}_2}$ .

The following facts can be found in [Hoh64, §6.15; §6.20].

- Every idempotent except the identity is singular.
- The statements 8a through 8e are equivalent. If  $V$  is finite dimensional, statement 8f is also equivalent to these statements.
  - $T$  is an idempotent.
  - $I - T$  is an idempotent.
  - $\text{fix } T = \text{range } T$ .
  - $V = \ker T \oplus \text{fix } T$ .

- (e)  $T$  is the projection onto  $V_1$  along  $V_2$  for some  $V_1, V_2$ , with  $V = V_1 \oplus V_2$ .
  - (f) There exists a basis  $\mathcal{B}$  of  $V$  such that  $[T]_{\mathcal{B}} = \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix}$ .
9. If  $T_1$  and  $T_2$  are idempotents on  $V$  and commute, then  $T_1 T_2$  is an idempotent.
  10. If  $T_1$  and  $T_2$  are idempotents on  $V$  and  $T_1 T_2 = T_2 T_1 = 0$ , then  $T_1 + T_2$  is an idempotent.
  11. If  $\dim V = n$  and  $T \in L(V, V)$  is nilpotent, then  $T^n = 0$ .

**Examples:**

1. Example 8 of Section 3.1,  $T : \mathbb{R}^3 \rightarrow \mathbb{R}^3$ , where  $T \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} x \\ y \\ 0 \end{pmatrix}$  is the projection onto  $\text{Span}\{\mathbf{e}_1, \mathbf{e}_2\}$  along  $\text{Span}\{\mathbf{e}_3\}$ .
2. The zero subspace is  $T$ -invariant for any  $T$ .
3.  $T_1$  and  $T_2$ , defined in Example 4 of Section 3.5, are the projection of  $F^{n \times n}$  onto the subspace of  $n$ -by- $n$  symmetric matrices along the subspace of  $n$ -by- $n$  skew-symmetric matrices, and the projection of  $F^{n \times n}$  onto the skew-symmetric matrices along the symmetric matrices, respectively.
4. Let  $T$  be a nilpotent linear transformation on  $V$ . Let  $T^p = 0$  and  $T^{p-1}(\mathbf{v}) \neq 0$ . Then  $S = \text{Span}\{\mathbf{v}, T(\mathbf{v}), T^2(\mathbf{v}), \dots, T^{p-1}(\mathbf{v})\}$  is a  $T$ -invariant subspace.

### 3.7 Isomorphism and Nonsingularity Characterization

---

Let  $U, V, W$  be vector spaces over  $F$  and let  $T \in L(V, W)$ .

**Definitions:**

$T$  is **invertible** (or an **isomorphism**) if there exists a function  $S: W \rightarrow V$  such that  $ST = I_V$  and  $TS = I_W$ .  $S$  is called the **inverse** of  $T$  and is denoted by  $T^{-1}$ .

$V$  and  $W$  are **isomorphic** if there exists an isomorphism of  $V$  onto  $W$ .

$T$  is **nonsingular** if  $\ker T = \{\mathbf{0}\}$ ; otherwise  $T$  is **singular**.

**Facts:**

The following facts can be found in [Fin60, §3.4], [Hoh64, §6.11], and [Lan70, IV §4]:

1. The inverse is unique.
2.  $T^{-1}$  is a linear transformation, invertible, and  $(T^{-1})^{-1} = T$ .
3. If  $T_1 \in L(V, W)$  and  $T_2 \in L(U, V)$ , then  $T_1 T_2$  is invertible if and only if  $T_1$  and  $T_2$  are invertible.
4. If  $T_1 \in L(V, W)$  and  $T_2 \in L(U, V)$ , then  $(T_1 T_2)^{-1} = T_2^{-1} T_1^{-1}$ .
5. Let  $T \in L(V, W)$ , and let  $\dim V = \dim W = n$ . The following statements are equivalent:
  - (a)  $T$  is invertible.
  - (b)  $T$  is nonsingular.
  - (c)  $T$  is one-to-one.
  - (d)  $\ker T = \{\mathbf{0}\}$ .
  - (e)  $\text{null } T = 0$ .
  - (f)  $T$  is onto.
  - (g)  $\text{range } T = W$ .

- (h)  $\text{rank } T = n$ .
- (i)  $T$  maps some bases of  $V$  to bases of  $W$ .
6. If  $V$  and  $W$  are isomorphic, then  $\dim V = \dim W$ .
  7. If  $\dim V = n > 0$ , then  $V$  is isomorphic to  $F^n$  through  $\varphi$  defined by  $\varphi(\mathbf{v}) = [\mathbf{v}]_{\mathcal{B}}$  for any ordered basis  $\mathcal{B}$  of  $V$ .
  8. Let  $\dim V = n > 0$ ,  $\dim W = m > 0$ , and let  $\mathcal{B}$  and  $\mathcal{C}$  be ordered bases of  $V$  and  $W$ , respectively. Then  $L(V, W)$  and  $F^{m \times n}$  are isomorphic through  $\varphi$  defined by  $\varphi(T) = {}_c[T]_{\mathcal{B}}$ .

**Examples:**

1.  $V = F[x; n]$  and  $W = F^{n+1}$  are isomorphic through  $T \in L(V, W)$  defined by  $T(\sum_0^n a_i x^i) = [a_0 \dots a_n]^T$ .
2. If  $V$  is an infinite dimensional vector space, a nonsingular linear operator  $T \in L(V, V)$  need not be invertible. For example, let  $T \in L(\mathbb{R}[x], \mathbb{R}[x])$  be defined by  $T(p(x)) = xp(x)$ . Then  $T$  is nonsingular but not invertible since  $T$  is not onto. For matrices, nonsingular and invertible are equivalent, since an  $n \times n$  matrix over  $F$  is an operator on the finite dimensional vector  $F^n$ .

### 3.8 Linear Functionals and Annihilator

---

Let  $V, W$  be vector spaces over  $F$ .

**Definitions:**

A **linear functional** (or **linear form**) on  $V$  is a linear transformation from  $V$  to  $F$ .

The **dual space** of  $V$  is the vector space  $V^* = L(V, F)$  of all linear functionals on  $V$ .

If  $V$  is nonzero and finite dimensional, the **dual basis** of a basis  $\mathcal{B} = \{\mathbf{v}_1, \dots, \mathbf{v}_n\}$  of  $V$  is the set  $\mathcal{B}^* = \{f_1, \dots, f_n\} \subseteq V^*$ , such that  $f_i(\mathbf{v}_j) = \delta_{ij}$  for each  $i, j$ .

The **bidual space** is the vector space  $V^{**} = (V^*)^* = L(V^*, F)$ .

The **annihilator** of a set  $S \subseteq V$  is  $S^a = \{f \in V^* \mid f(\mathbf{v}) = 0, \forall \mathbf{v} \in S\}$ .

The **transpose** of  $T \in L(V, W)$  is the mapping  $T^T \in L(W^*, V^*)$  defined by setting, for each  $g \in W^*$ ,

$$\begin{aligned} T^T(g) : V &\rightarrow F \\ \mathbf{v} &\mapsto g(T(\mathbf{v})). \end{aligned}$$

**Facts:**

The following facts can be found in [Hoh64, §6.19] and [SW68, §4.4].

1. For each  $\mathbf{v} \in V, \mathbf{v} \neq 0$ , there exists  $f \in V^*$  such that  $f(\mathbf{v}) \neq 0$ .
2. For each  $\mathbf{v} \in V$  define  $h_{\mathbf{v}} \in L(V^*, F)$  by setting  $h_{\mathbf{v}}(f) = f(\mathbf{v})$ . Then the mapping

$$\begin{aligned} \varphi : V &\rightarrow V^{**} \\ \mathbf{v} &\mapsto h_{\mathbf{v}} \end{aligned}$$

is a one-to-one linear transformation. If  $V$  is finite dimensional,  $\varphi$  is an isomorphism of  $V$  onto  $V^{**}$ .

3.  $S^a$  is a subspace of  $V^*$ .
4.  $\{0\}^a = V^*$ ;  $V^a = \{0\}$ .
5.  $S^a = (\text{Span}\{S\})^a$ .

The following facts hold for finite dimensional vector spaces.

6. If  $V$  is nonzero, for each basis  $\mathcal{B}$  of  $V$ , the dual basis exists, is uniquely determined, and is a basis for  $V^*$ .
7.  $\dim V = \dim V^*$ .
8. If  $V$  is nonzero, each basis of  $V^*$  is the dual basis of some basis of  $V$ .

9. Let  $\mathcal{B}$  be a basis for the nonzero vector space  $V$ . For each  $\mathbf{v} \in V$ ,  $f \in V^*$ ,  $f(\mathbf{v}) = [f]_{\mathcal{B}^*}^T [\mathbf{v}]_{\mathcal{B}}$ .
10. If  $S$  is a subspace of  $V$ , then  $\dim S + \dim S^a = \dim V$ .
11. If  $S$  is a subspace of  $V$ , then, by identifying  $V$  and  $V^{**}$ ,  $S = (S^a)^a$ .
12. Let  $S_1, S_2$  be subspaces of  $V$  such that  $S_1^a = S_2^a$ . Then  $S_1 = S_2$ .
13. Any subspace of  $V^*$  is the annihilator of some subspace  $S$  of  $V$ .
14. Let  $S_1, S_2$  be subspaces of  $V$ . Then  $(S_1 \cap S_2)^a = S_1^a + S_2^a$  and  $(S_1 + S_2)^a = S_1^a \cap S_2^a$ .
15.  $\ker T^T = (\text{range } T)^a$ .
16.  $\text{rank } T = \text{rank } T^T$ .
17. If  $\mathcal{B}$  and  $\mathcal{C}$  are nonempty bases of  $V$  and  $W$ , respectively, then  ${}_{\mathcal{B}^*}[T^T]_{\mathcal{C}^*} = (c[T]_{\mathcal{B}})^T$ .

### Examples:

1. Let  $V = \mathcal{C}[a, b]$  be the vector space of continuous functions  $\varphi: [a, b] \rightarrow \mathbb{R}$ , and let  $c \in [a, b]$ . Then  $f(\varphi) = \varphi(c)$  is a linear functional on  $V$ .
2. Let  $V = \mathcal{C}[a, b]$ ,  $\psi \in V$ , and  $f(\varphi) = \int_a^b \varphi(t)\psi(t)dt$ . Then  $f$  is a linear functional.
3. The trace is a linear functional on  $F^{n \times n}$ .
4. Let  $V = F^{m \times n}$ .  $\mathcal{B} = \{E_{ij}: 1 \leq i \leq m, 1 \leq j \leq n\}$  is a basis for  $V$ . The dual basis  $\mathcal{B}^*$  consists of the linear functionals  $f_{ij}$ ,  $1 \leq i \leq m, 1 \leq j \leq n$ , defined by  $f_{ij}(A) = a_{ij}$ .

### 4.1 Determinants

#### Definitions:

The **determinant**,  $\det A$ , of a matrix  $A = [a_{ij}] \in F^{n \times n}$  is an element in  $F$  defined inductively:

- $\det [a] = a$ .
- For  $i, j \in \{1, 2, \dots, n\}$ , the  **$ij$ th minor** of  $A$  corresponding to  $a_{ij}$  is defined by  $m_{ij} = \det A(\{i\}, \{j\})$ .
- The  **$ij$ th cofactor** of  $a_{ij}$  is  $c_{ij} = (-1)^{i+j} m_{ij}$ .
- $\det A = \sum_{j=1}^n (-1)^{i+j} a_{ij} m_{ij} = \sum_{j=1}^n a_{ij} c_{ij}$  for  $i \in \{1, 2, \dots, n\}$ .

This method of computing the determinant of a matrix is called **Laplace expansion of the determinant by minors along the  $i$ th row**.

The **determinant of a linear operator**  $T : V \rightarrow V$  on a finite dimensional vector space,  $V$ , is defined as  $\det(T) = \det([T]_{\mathcal{B}})$ , where  $\mathcal{B}$  is a basis for  $V$ .

#### Facts:

All matrices are assumed to be in  $F^{n \times n}$ , unless otherwise stated. All the following facts except those with a specific reference can be found in [Lay03, pp. 185–213] or [Goo03, pp. 167–193].

$$1. \det \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} = a_{11}a_{22} - a_{12}a_{21}.$$

$$2. \det A = \det \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} = a_{11}a_{22}a_{33} + a_{21}a_{13}a_{32} + a_{31}a_{12}a_{23} - a_{31}a_{13}a_{22} - a_{21}a_{12}a_{33} - a_{11}a_{32}a_{23}.$$

3. The determinant is independent of the row  $i$  used to evaluate it.
4. (Expansion of the determinant by minors along the  $j$ th column) Let  $j \in \{1, 2, \dots, n\}$ . Then  $\det A = \sum_{i=1}^n (-1)^{i+j} a_{ij} m_{ij} = \sum_{i=1}^n a_{ij} c_{ij}$ .
5.  $\det I_n = 1$ .
6. If  $A$  is a triangular matrix, then  $\det A = a_{11}a_{22} \cdots a_{nn}$ .

7. If  $B$  is a matrix obtained from  $A$  by interchanging two rows (or columns), then  $\det B = -\det A$ .
8. If  $B$  is a matrix obtained from  $A$  by multiplying one row (or column) by a nonzero constant  $r$ , then  $\det B = r \det A$ .
9. If  $B$  is a matrix obtained from  $A$  by adding to a row (or column) a multiple of another row (or column), then  $\det B = \det A$ .
10. If  $A$ ,  $B$ , and  $C$  differ only in the  $r$ th row (or column), and the  $r$ th row (or column) of  $C$  is the sum of the  $r$ th rows (or columns) of  $A$  and  $B$ , then  $\det C = \det A + \det B$ .
11. If  $A$  is a matrix with a row (or column) of zeros, then  $\det A = 0$ .
12. If  $A$  is a matrix with two identical rows (or columns), then  $\det A = 0$ .
13. Let  $B$  be a row echelon form of  $A$  obtained by Gaussian elimination, using  $k$  row interchange operations and adding multiples of one row to another (see Algorithm 1 in Section 1.3). Then  $\det A = (-1)^k \det B = (-1)^k b_{11} b_{22} \cdots b_{nn}$ .
14.  $\det A^T = \det A$ .
15. If  $A \in \mathbb{C}^{n \times n}$ , then  $\det A^* = \overline{\det A}$ .
16.  $\det AB = \det A \det B$ .
17. If  $c \in F$ , then  $\det(cA) = c^n \det A$ .
18.  $A$  is nonsingular, that is  $A^{-1}$  exists, if and only if  $\det A \neq 0$ .
19. If  $A$  is nonsingular, then  $\det(A^{-1}) = \frac{1}{\det A}$ .
20. If  $S$  is nonsingular, then  $\det(S^{-1}AS) = \det A$ .
21. [HJ85]  $\det A = \sum_{\sigma} \operatorname{sgn} \sigma a_{1\sigma(1)} a_{2\sigma(2)} \cdots a_{n\sigma(n)}$ , where summation is over the  $n!$  permutations,  $\sigma$ , of the  $n$  indices  $\{1, 2, \dots, n\}$ . The weight “ $\operatorname{sgn} \sigma$ ” is 1 when  $\sigma$  is even and  $-1$  when  $\sigma$  is odd. (See Preliminaries for more information on permutations.)
22. If  $\mathbf{x}, \mathbf{y} \in F^n$ , then  $\det(I + \mathbf{xy}^T) = 1 + \mathbf{y}^T \mathbf{x}$ .
23. [FIS89] Let  $T$  be a linear operator on a finite dimensional vector space  $V$ . Let  $\mathcal{B}$  and  $\mathcal{B}'$  be bases for  $V$ . Then  $\det(T) = \det([T]_{\mathcal{B}}) = \det([T]_{\mathcal{B}'})$ .
24. [FIS89] Let  $T$  be a linear operator on a finite dimensional vector space  $V$ . Then  $T$  is invertible if and only if  $\det(T) \neq 0$ .
25. [FIS89] Let  $T$  be an invertible linear operator on a finite dimensional vector space  $V$ . Then  $\det(T^{-1}) = \frac{1}{\det(T)}$ .
26. [FIS89] Let  $T$  and  $U$  be linear operators on a finite dimensional vector space  $V$ . Then  $\det(TU) = \det(T) \cdot \det(U)$ .

### Examples:

1. Let  $A = \begin{bmatrix} 3 & -2 & 4 \\ 2 & 5 & -6 \\ -3 & 1 & 5 \end{bmatrix}$ . Expanding the determinant of  $A$  along the second column:  $\det A =$

$$2 \cdot \det \begin{bmatrix} 2 & -6 \\ -3 & 5 \end{bmatrix} + 5 \cdot \det \begin{bmatrix} 3 & 4 \\ -3 & 5 \end{bmatrix} - \det \begin{bmatrix} 3 & 4 \\ 2 & -6 \end{bmatrix} = 2 \cdot (-8) + 5 \cdot 27 + 26 = 145.$$

2. Let  $A = \begin{bmatrix} -1 & 3 & -2 & 4 \\ 2 & 5 & 8 & 1 \\ 7 & -4 & 0 & -6 \\ 0 & 3 & 1 & 5 \end{bmatrix}$ . Expanding the determinant of  $A$  along the third row:  $\det A =$

$$7 \cdot \det \begin{bmatrix} 3 & -2 & 4 \\ 5 & 8 & 1 \\ 3 & 1 & 5 \end{bmatrix} + 4 \cdot \det \begin{bmatrix} -1 & -2 & 4 \\ 2 & 8 & 1 \\ 0 & 1 & 5 \end{bmatrix} + 6 \cdot \det \begin{bmatrix} -1 & 3 & -2 \\ 2 & 5 & 8 \\ 0 & 3 & 1 \end{bmatrix} = 557.$$

3. Let  $T: \mathbb{R}^2 \rightarrow \mathbb{R}^2$  defined by  $T \left( \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \right) = \begin{bmatrix} 2x_1 - 3x_2 \\ x_1 + 6x_2 \end{bmatrix}$ . With  $\mathcal{B} = \left\{ \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \end{bmatrix} \right\}$ , then  $\det([T]_{\mathcal{B}}) =$
- $$\det \begin{bmatrix} 2 & -3 \\ 1 & 6 \end{bmatrix} = 15. \text{ Now let } \mathcal{B}' = \left\{ \begin{bmatrix} 1 \\ 1 \end{bmatrix}, \begin{bmatrix} 1 \\ 0 \end{bmatrix} \right\}. \text{ Then } \det([T]_{\mathcal{B}'}) = \det \begin{bmatrix} 7 & 1 \\ -8 & 1 \end{bmatrix} = 15.$$

**Applications:**

- (Cramer’s Rule) If  $A \in F^{n \times n}$  is nonsingular, then the equation  $A\mathbf{x} = \mathbf{b}$ , where  $\mathbf{x}, \mathbf{b} \in F^n$ , has the

unique solution  $\mathbf{s} = \begin{bmatrix} s_1 \\ s_2 \\ \vdots \\ s_n \end{bmatrix}$ , where  $s_i = \frac{\det A_i}{\det A}$  and  $A_i$  is the matrix obtained from  $A$  by replacing the  $i$ th column with  $\mathbf{b}$ .

- [Mey00, p. 486] (Vandermonde Determinant)  $\det \begin{bmatrix} 1 & 1 & \cdots & 1 \\ x_1 & x_2 & \cdots & x_n \\ x_1^2 & x_2^2 & \cdots & x_n^2 \\ \vdots & \vdots & \ddots & \vdots \\ x_1^{n-1} & x_2^{n-1} & \cdots & x_n^{n-1} \end{bmatrix} = \prod_{1 \leq i < j \leq n} (x_i - x_j)$ .

- [FB90, pp. 220–235] (Volume) Let  $\mathbf{a}_1, \mathbf{a}_2, \dots, \mathbf{a}_n$  be linearly independent vectors in  $\mathbb{R}^m$ . The volume,  $V$ , of the  $n$ -dimensional solid in  $\mathbb{R}^m$ , defined by  $S = \{\sum_{i=1}^n t_i \mathbf{a}_i, 0 \leq t_i \leq 1, i = 1, 2, \dots, n\}$ , is given by  $V = \sqrt{\det(A^T A)}$ , where  $A$  is the matrix whose  $i$ th column is the vector  $\mathbf{a}_i$ .

Let  $m \geq n$  and  $T: \mathbb{R}^n \rightarrow \mathbb{R}^m$  be a linear transformation whose standard matrix representation is the  $m \times n$  matrix  $A$ . Let  $S$  be a region in  $\mathbb{R}^n$  of volume  $V_S$ . Then the volume of the image of  $S$  under the transformation  $T$  is  $V_{T(S)} = \sqrt{\det(A^T A)} \cdot V_S$ .

- [Uhl02, pp. 247–248] (Wronskian) Let  $f_1, f_2, \dots, f_n$  be  $n - 1$  times differentiable functions of the real variable  $x$ . The determinant

$$W(f_1, f_2, \dots, f_n)(x) = \det \begin{bmatrix} f_1(x) & f_2(x) & \cdots & f_n(x) \\ f_1'(x) & f_2'(x) & \cdots & f_n'(x) \\ \vdots & \vdots & \ddots & \vdots \\ f_1^{(n-1)}(x) & f_2^{(n-1)}(x) & \cdots & f_n^{(n-1)}(x) \end{bmatrix}$$

is called the **Wronskian** of  $f_1, f_2, \dots, f_n$ . If  $W(f_1, f_2, \dots, f_n)(x) \neq 0$  for some  $x \in \mathbb{R}$ , then the functions  $f_1, f_2, \dots, f_n$  are linearly independent.

## 4.2 Determinants: Advanced Results

**Definitions:**

A **principal minor** is the determinant of a principal submatrix. (See Section 1.2.)

A **leading principal minor** is the determinant of a leading principal submatrix.

The sum of all the  $k \times k$  principal minors of  $A$  is denoted  $S_k(A)$ .

The  **$k$ th compound matrix** of  $A \in F^{m \times n}$  is the  $\binom{m}{k} \times \binom{n}{k}$  matrix  $C_k(A)$  whose entries are the  $k \times k$  minors of  $A$ , usually in lexicographical order.

The **adjugate** of  $A \in F^{n \times n}$  is the matrix  $\text{adj } A = [c_{ji}] = [c_{ij}]^T$ , where  $c_{ij}$  is the  $ij$ th-cofactor.

The  **$k$ th adjugate** of  $A \in F^{n \times n}$  is the  $\binom{n}{k} \times \binom{n}{k}$  matrix  $\text{adj}^{(k)} A$ , whose  $a_{ji}$  entry is the cofactor, in  $A$ , of the  $(n - k)$ th minor, of  $A$ , in the  $ij$ th position of the compound.

Let  $\alpha \subseteq \{1, 2, \dots, n\}$  and  $A \in F^{n \times n}$  with  $A[\alpha]$  nonsingular. The matrix

$$A/A[\alpha] = A[\alpha^c] - A[\alpha^c, \alpha]A[\alpha]^{-1}A[\alpha, \alpha^c]$$

is called the **Schur complement** of  $A[\alpha]$ .

**Facts:**

All matrices are assumed to be in  $F^{n \times n}$ , unless otherwise stated. All the following facts except those with a specific reference can be found in [Lay03, pp. 185–213] or [Goo03, pp. 167–193].

1.  $A(\text{adj } A) = (\text{adj } A)A = (\det A)I_n$ .
2.  $\det(\text{adj } A) = (\det A)^{n-1}$ .
3. If  $\det A \neq 0$ , then  $\text{adj } A$  is nonsingular, and  $(\text{adj } A)^{-1} = (\det A)^{-1}A$ .

4. [Ait56] (Method of Condensation) Let  $A = \begin{bmatrix} a_{11} & a_{12} & a_{13} & \cdots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \cdots & a_{2n} \\ a_{31} & a_{32} & a_{33} & \cdots & a_{3n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & a_{n3} & \cdots & a_{nn} \end{bmatrix}$ , and assume without

loss of generality that  $a_{11} \neq 0$ , otherwise a nonzero element can be brought to the (1, 1) position by interchanging two rows, which will change the sign of the determinant. Multiply all the rows of  $A$  except the first by  $a_{11}$ . For  $i = 2, 3, \dots, n$ , perform the row operations: replace row  $i$  with row  $i - a_{i1}$ .

row 1. Thus  $a_{11}^{n-1} \det A = \det \begin{bmatrix} a_{11} & a_{12} & a_{13} & \cdots & a_{1n} \\ 0 & a_{11}a_{22} - a_{21}a_{12} & a_{11}a_{23} - a_{21}a_{13} & \cdots & a_{11}a_{2n} - a_{21}a_{1n} \\ 0 & a_{11}a_{32} - a_{31}a_{12} & a_{11}a_{33} - a_{31}a_{13} & \cdots & a_{11}a_{3n} - a_{31}a_{1n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & a_{11}a_{n2} - a_{n1}a_{12} & a_{11}a_{n3} - a_{n1}a_{13} & \cdots & a_{11}a_{nn} - a_{n1}a_{1n} \end{bmatrix}$ .

So,  $\det A = \frac{1}{a_{11}^{n-1}} \cdot \det \begin{bmatrix} \det \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} & \det \begin{bmatrix} a_{11} & a_{13} \\ a_{21} & a_{23} \end{bmatrix} & \cdots & \det \begin{bmatrix} a_{11} & a_{1n} \\ a_{21} & a_{2n} \end{bmatrix} \\ \det \begin{bmatrix} a_{11} & a_{12} \\ a_{31} & a_{32} \end{bmatrix} & \det \begin{bmatrix} a_{11} & a_{13} \\ a_{31} & a_{33} \end{bmatrix} & \cdots & \det \begin{bmatrix} a_{11} & a_{1n} \\ a_{31} & a_{3n} \end{bmatrix} \\ \vdots & \vdots & \ddots & \vdots \\ \det \begin{bmatrix} a_{11} & a_{12} \\ a_{n1} & a_{n2} \end{bmatrix} & \det \begin{bmatrix} a_{11} & a_{12} \\ a_{n1} & a_{n3} \end{bmatrix} & \cdots & \det \begin{bmatrix} a_{11} & a_{1n} \\ a_{n1} & a_{nn} \end{bmatrix} \end{bmatrix}$ .

5. [Ait56]  $A^{(k)}(\text{adj } A) = (\text{adj } A)A^{(k)} = (\det A)I_n$ .
6. [Ait56]  $\det(A^{(k)}) = \det(A^r)$ , where  $r = \binom{n-1}{k-1}$ .
7. [Ait56]  $\det(A^{(n-k)}) = \det(\text{adj } A)$ .
8. [HJ85] If  $A \in F^{n \times n}$ ,  $B \in F^{m \times m}$ , then  $\det(A \otimes B) = (\det A)^m (\det B)^n$ . (See Section 10.5 for the definition of  $A \otimes B$ .)
9. [Uhl02] For  $A \in F^{n \times n}$ ,  $\det A$  is the unique normalized, alternating, and multilinear function  $d: F^{n \times n} \rightarrow F$ . That is,  $d(I_n) = 1$ ,  $d(A) = -d(A')$ , where  $A'$  denotes the matrix obtained from  $A$ , by interchanging two rows, and  $d$  is linear in each row of  $A$ , if the remaining rows of  $A$  are held fixed.
10. [HJ85] (Cauchy–Binet) Let  $A \in F^{n \times k}$ ,  $B \in F^{k \times n}$ , and  $C = AB$ . Then

$$\det C[\alpha, \beta] = \sum_{\gamma} \det A[\alpha, \gamma] \det B[\gamma, \beta],$$

where  $\alpha \subseteq \{1, 2, \dots, m\}$ ,  $\beta \subseteq \{1, 2, \dots, n\}$ , with  $|\alpha| = |\beta| = r$ ,  $1 \leq r \leq \min\{m, k, n\}$ , and the sum is taken over all sets  $\gamma \subseteq \{1, 2, \dots, k\}$  with  $|\gamma| = r$ .

11. [HJ85] (Schur Complement). Let  $A[\alpha]$  be nonsingular. Then

$$\det A = \det A[\alpha] \det (A[\alpha^c] - A[\alpha^c, \alpha] A[\alpha]^{-1} A[\alpha, \alpha^c]).$$

12. [HJ85] (Jacobi's Theorem) Let  $A$  be nonsingular and let  $\alpha, \beta \subseteq \{1, 2, \dots, n\}$ , with  $|\alpha| = |\beta|$ . Then

$$\det A^{-1}[\alpha^c, \beta^c] = (-1)^{(\sum_{i \in \alpha} i + \sum_{j \in \beta} j)} \frac{\det A[\beta, \alpha]}{\det A}.$$

In particular, if  $\alpha = \beta$ . Then  $\det A^{-1}[\alpha^c] = \frac{\det A[\alpha]}{\det A}$ .

13. [HJ85] (Sylvester's Identity) Let  $\alpha \subseteq \{1, 2, \dots, n\}$  with  $|\alpha| = k$ , and  $i, j \in \{1, 2, \dots, n\}$ , with  $i, j \notin \alpha$ . For  $A \in F^{n \times n}$ , let  $B = [b_{ij}] \in F^{(n-k) \times (n-k)}$  be defined by  $b_{ij} = \det A[\alpha \cup \{i\}, \alpha \cup \{j\}]$ . Then

$$\det B = (\det A[\alpha])^{n-k-1} \det A.$$

**Examples:**

1. Let  $A = \begin{bmatrix} 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & -3 & 2 \\ 0 & -1 & -2 & -4 \end{bmatrix}$ .  $S_3(A) = 23$  because  $\det A[\{1, 2, 3\}] = \det \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -3 \end{bmatrix} = -3$ ,

$\det A[\{1, 2, 4\}] = \det \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 0 & -1 & -4 \end{bmatrix} = -3$ ,  $\det A[\{1, 3, 4\}] = \det \begin{bmatrix} 1 & 0 & 0 \\ 0 & -3 & 2 \\ 0 & -2 & -4 \end{bmatrix} = 16$ , and

$\det A[\{2, 3, 4\}] = \det \begin{bmatrix} 1 & 0 & 1 \\ 0 & -3 & 2 \\ -1 & -2 & -4 \end{bmatrix} = 13$ . From the Laplace expansion on the first column

and  $\det A[\{2, 3, 4\}] = 13$ , it follows that  $S_4(A) = \det A = 13$ . Clearly,  $S_1(A) = \text{tr } A = -5$ .

2. ( $k$ th compound) Let  $A = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 0 & 1 & 4 \\ 1 & 1 & 0 & 1 \\ 1 & 4 & 0 & 1 \end{bmatrix}$ . Then  $\det A = 9$ ,  $C_2(A) = \begin{bmatrix} -1 & 0 & 3 & 1 & 4 & 3 \\ 0 & -1 & 0 & -1 & 0 & 1 \\ 3 & -1 & 0 & -4 & -3 & 1 \\ 1 & -1 & -3 & -1 & -4 & 1 \\ 4 & -1 & -3 & -4 & -16 & 1 \\ 3 & 0 & 0 & 0 & -3 & 0 \end{bmatrix}$ ,

and  $\det(C_2(A)) = 729$ .

3. (Cauchy-Binet) Let  $A = \begin{bmatrix} -1 & 3 & -1 \\ 2 & 0 & 0 \\ i & -4 & 0 \\ 0 & 1+i & 1 \end{bmatrix}$ ,  $B = \begin{bmatrix} 3 & 2 & -3 & 0 \\ 0 & -4 & 4 & 3i \\ 7 & -6i & 5 & 4 \end{bmatrix}$ , and  $C = AB$ .

Then  $\det C[\{2, 4\}, \{2, 3\}] = \det A[\{2, 4\}, \{1, 2\}] \det B[\{1, 2\}, \{2, 3\}] + \det A[\{2, 4\}, \{1, 3\}] \det B[\{1, 3\}, \{2, 3\}] + \det A[\{2, 4\}, \{2, 3\}] \det B[\{2, 3\}, \{2, 3\}] = 12 - 44i$ .

4. (Schur Complement) Let  $A = \begin{bmatrix} a & \mathbf{b}^* \\ \mathbf{b} & C \end{bmatrix}$ , where  $a \in \mathbb{C}$ ,  $\mathbf{b} \in \mathbb{C}^{n-1}$ , and  $C \in \mathbb{C}^{(n-1) \times (n-1)}$ . If  $C$  is nonsingular, then  $\det A = (a - \mathbf{b}^* C^{-1} \mathbf{b}) \det C$ . If  $a \neq 0$ , then  $\det A = a \det(C - \frac{1}{a} \mathbf{b} \mathbf{b}^*)$ .

5. (Jacobi's Theorem) Let  $A = \begin{bmatrix} 1 & -2 & 0 \\ 3 & 4 & 0 \\ -1 & 0 & 5 \end{bmatrix}$  and  $\alpha = \{2\} = \beta$ . By Jacobi's formula,  $\det A^{-1}(2) =$

$\frac{\det A[2]}{\det A} = \frac{4}{50} = \frac{2}{25}$ . This can be readily verified by computing  $A^{-1} = \begin{bmatrix} \frac{2}{5} & \frac{1}{5} & 0 \\ -\frac{3}{10} & \frac{1}{10} & 0 \\ \frac{2}{25} & \frac{1}{25} & \frac{1}{5} \end{bmatrix}$ , and verifying

$\det A^{-1}[\{1, 3\}] = \frac{2}{25}$ .

6. (Sylvester's Identity) Let  $A = \begin{bmatrix} -7 & i & -3 \\ -i & -2 & 1+4i \\ -3 & 1-4i & 5 \end{bmatrix}$  and  $\alpha = \{1\}$ . Define  $B \in \mathbb{C}^{2 \times 2}$ , with entries

$b_{11} = \det A[\{1, 2\}] = 13$ ,  $b_{12} = \det A[\{1, 2\}, \{1, 3\}] = -7 - 31i$ ,  $b_{21} = \det A[\{1, 3\}, \{1, 2\}] = -7 + 31i$ ,  $b_{22} = \det A[\{1, 3\}] = -44$ . Then  $-1582 = \det B = (\det A[\{1\}]) \det A = (-7) \det A$ , so  $\det A = 226$ .

### 4.3 Eigenvalues and Eigenvectors

#### Definitions:

An element  $\lambda \in F$  is an **eigenvalue** of a matrix  $A \in F^{n \times n}$  if there exists a nonzero vector  $\mathbf{x} \in F^n$  such that  $A\mathbf{x} = \lambda\mathbf{x}$ . The vector  $\mathbf{x}$  is said to be an **eigenvector** of  $A$  corresponding to the eigenvalue  $\lambda$ . A nonzero row vector  $\mathbf{y}$  is a **left eigenvector** of  $A$ , corresponding to the eigenvalue  $\lambda$ , if  $\mathbf{y}A = \lambda\mathbf{y}$ .

For  $A \in F^{n \times n}$ , the **characteristic polynomial** of  $A$  is given by  $p_A(x) = \det(xI - A)$ .

The **algebraic multiplicity**,  $\alpha(\lambda)$ , of  $\lambda \in \sigma(A)$  is the number of times the eigenvalue occurs as a root in the characteristic polynomial of  $A$ .

The **spectrum** of  $A \in F^{n \times n}$ ,  $\sigma(A)$ , is the multiset of all eigenvalues of  $A$ , with eigenvalue  $\lambda$  appearing  $\alpha(\lambda)$  times in  $\sigma(A)$ .

The **spectral radius** of  $A \in \mathbb{C}^{n \times n}$  is  $\rho(A) = \max\{|\lambda| : \lambda \in \sigma(A)\}$ .

Let  $p(x) = c_n x^n + c_{n-1} x^{n-1} + \cdots + c_2 x^2 + c_1 x + c_0$  be a polynomial with coefficients in  $F$ . Then  $p(A) = c_n A^n + c_{n-1} A^{n-1} + \cdots + c_2 A^2 + c_1 A + c_0 I$ .

For  $A \in F^{n \times n}$ , the **minimal polynomial** of  $A$ ,  $q_A(x)$ , is the unique monic polynomial of least degree for which  $q_A(A) = 0$ .

The vector space  $\ker(A - \lambda I)$ , for  $\lambda \in \sigma(A)$ , is the **eigenspace** of  $A \in F^{n \times n}$  corresponding to  $\lambda$ , and is denoted by  $E_\lambda(A)$ .

The **geometric multiplicity**,  $\gamma(\lambda)$ , of an eigenvalue  $\lambda$  is the dimension of the eigenspace  $E_\lambda(A)$ .

An eigenvalue  $\lambda$  is **simple** if  $\alpha(\lambda) = 1$ .

An eigenvalue  $\lambda$  is **semisimple** if  $\alpha(\lambda) = \gamma(\lambda)$ .

For  $K = \mathbb{C}$  or any other algebraically closed field, a matrix  $A \in K^{n \times n}$  is **nonderogatory** if  $\gamma(\lambda) = 1$  for all  $\lambda \in \sigma(A)$ , otherwise  $A$  is **derogatory**. Over an arbitrary field  $F$ , a matrix is nonderogatory (derogatory) if it is nonderogatory (derogatory) over the algebraic closure of  $F$ .

For  $K = \mathbb{C}$  or any other algebraically closed field, a matrix  $A \in K^{n \times n}$  is **nondefective** if every eigenvalue of  $A$  is semisimple, otherwise  $A$  is **defective**. Over an arbitrary field  $F$ , a matrix is nondefective (defective) if it is nondefective (defective) over the algebraic closure of  $F$ .

A matrix  $A \in F^{n \times n}$  is **diagonalizable** if there exists a nonsingular matrix  $B \in F^{n \times n}$ , such that  $A = BDB^{-1}$  for some diagonal matrix  $D \in F^{n \times n}$ .

For a monic polynomial  $p(x) = x^n + c_{n-1} x^{n-1} + \cdots + c_2 x^2 + c_1 x + c_0$  with coefficients in  $F$ , the  $n \times n$  matrix  $C(p) = \begin{bmatrix} 0 & 0 & 0 & \cdots & 0 & -c_0 \\ 1 & 0 & 0 & \cdots & 0 & -c_1 \\ 0 & 1 & 0 & \cdots & 0 & -c_2 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 1 & -c_{n-1} \end{bmatrix}$  is called the **companion matrix** of  $p(x)$ .

Let  $T$  be a linear operator on a finite dimensional vector space,  $V$ , over a field  $F$ . An element  $\lambda \in F$  is an **eigenvalue** of  $T$  if there exists a nonzero vector  $\mathbf{v} \in V$  such that  $T(\mathbf{v}) = \lambda\mathbf{v}$ . The vector  $\mathbf{v}$  is said to be an **eigenvector** of  $T$  corresponding to the eigenvalue  $\lambda$ .

For a linear operator,  $T$ , on a finite dimensional vector space,  $V$ , with a basis,  $\mathcal{B}$ , the **characteristic polynomial** of  $T$  is given by  $p_T(x) = \det([T]_{\mathcal{B}})$ .

A linear operator  $T$  on a finite dimensional vector space,  $V$ , is **diagonalizable** if there exists a basis,  $\mathcal{B}$ , for  $V$  such that  $[T]_{\mathcal{B}}$  is diagonalizable.

**Facts:**

These facts are grouped into the following categories: Eigenvalues and Eigenvectors, Diagonalization, Polynomials, Other Facts. All matrices are assumed to be in  $F^{n \times n}$  unless otherwise stated. All the following facts, except those with a specific reference, can be found in [Mey00, pp. 489–660] or [Lay03, pp. 301–342].

**Eigenvalues and Eigenvectors**

1.  $\lambda \in \sigma(A)$  if and only if  $p_A(\lambda) = 0$ .
2. For each eigenvalue  $\lambda$  of a matrix  $A$ ,  $1 \leq \gamma(\lambda) \leq \alpha(\lambda)$ .
3. A simple eigenvalue is semisimple.
4. For any  $F$ ,  $|\sigma(A)| \leq n$ . If  $F = \mathbb{C}$  or any algebraically closed field, then  $|\sigma(A)| = n$ .
5. If  $F = \mathbb{C}$  or any algebraically closed field, then  $\det A = \prod_{i=1}^n \lambda_i, \lambda_i \in \sigma(A)$ .
6. If  $F = \mathbb{C}$  or any algebraically closed field, then  $\text{tr } A = \sum_{i=1}^n \lambda_i, \lambda_i \in \sigma(A)$ .
7. For  $A \in \mathbb{C}^{n \times n}, \lambda \in \sigma(A)$  if and only if  $\bar{\lambda} \in \sigma(A^*)$ .
8. For  $A \in \mathbb{R}^{n \times n}$ , viewing  $A \in \mathbb{C}^{n \times n}, \lambda \in \sigma(A)$  if and only if  $\bar{\lambda} \in \sigma(A)$ .
9. If  $A \in \mathbb{C}^{n \times n}$  is Hermitian (e.g.,  $A \in \mathbb{R}^{n \times n}$  is symmetric), then  $A$  has real eigenvalues and  $A$  can be diagonalized. (See also Section 7.2.)
10.  $A$  and  $A^T$  have the same eigenvalues with same algebraic multiplicities.
11. If  $A = [a_{ij}]$  is triangular, then  $\sigma(A) = \{a_{11}, a_{22}, \dots, a_{nn}\}$ .
12. If  $A$  has all row (column) sums equal to  $r$ , then  $r$  is an eigenvalue of  $A$ .
13.  $A$  is singular if and only if  $\det A = 0$ , if and only if  $0 \in \sigma(A)$ .
14. If  $A$  is nonsingular and  $\lambda$  is an eigenvalue of  $A$  of algebraic multiplicity  $\alpha(\lambda)$ , with corresponding eigenvector  $\mathbf{x}$ , then  $\lambda^{-1}$  is an eigenvalue of  $A^{-1}$  with algebraic multiplicity  $\alpha(\lambda)$  and corresponding eigenvector  $\mathbf{x}$ .
15. Let  $\lambda_1, \lambda_2, \dots, \lambda_s$  be distinct eigenvalues of  $A$ . For each  $i = 1, 2, \dots, s$  let  $\mathbf{x}_{i1}, \mathbf{x}_{i2}, \dots, \mathbf{x}_{ir_i}$  be linearly independent eigenvectors corresponding to  $\lambda_i$ . Then the vectors  $\mathbf{x}_{11}, \dots, \mathbf{x}_{1r_1}, \mathbf{x}_{21}, \dots, \mathbf{x}_{2r_2}, \dots, \mathbf{x}_{s1}, \dots, \mathbf{x}_{sr_s}$  are linearly independent.
16. [FIS89] Let  $T$  be a linear operator on a finite dimensional vector space over a field  $F$ , with basis  $\mathcal{B}$ . Then  $\lambda \in F$  is an eigenvalue of  $T$  if and only if  $\lambda$  is an eigenvalue of  $[T]_{\mathcal{B}}$ .
17. [FIS89] Let  $\lambda_1, \lambda_2, \dots, \lambda_s$  be distinct eigenvalues of the linear operator  $T$ , on a finite dimensional space  $V$ . For each  $i = 1, 2, \dots, s$  let  $\mathbf{x}_{i1}, \mathbf{x}_{i2}, \dots, \mathbf{x}_{ir_i}$  be linearly independent eigenvectors corresponding to  $\lambda_i$ . Then the vectors  $\mathbf{x}_{11}, \dots, \mathbf{x}_{1r_1}, \mathbf{x}_{21}, \dots, \mathbf{x}_{2r_2}, \dots, \mathbf{x}_{s1}, \dots, \mathbf{x}_{sr_s}$  are linearly independent.
18. Let  $T$  be linear operator on a finite dimensional vector space  $V$  over a field  $F$ . Then  $\lambda \in F$  is an eigenvalue of  $T$  if and only if  $p_T(\lambda) = 0$ .

**Diagonalization**

19. [Lew91, pp. 135–136] Let  $\lambda_1, \lambda_2, \dots, \lambda_s$  be distinct eigenvalues of  $A$ . If  $A \in \mathbb{C}^{n \times n}$ , then  $A$  is diagonalizable if and only if  $\alpha(\lambda_i) = \gamma(\lambda_i)$  for  $i = 1, 2, \dots, s$ . If  $A \in \mathbb{R}^{n \times n}$ , then  $A$  is diagonalizable by a nonsingular matrix  $B \in \mathbb{R}^{n \times n}$  if and only if all the eigenvalues of  $A$  are real and  $\alpha(\lambda_i) = \gamma(\lambda_i)$  for  $i = 1, 2, \dots, s$ .
20. Method for Diagonalization of  $A$  over  $\mathbb{C}$ : This is a theoretical method using exact arithmetic and is undesirable in decimal arithmetic with rounding errors. See Chapter 43 for information on appropriate numerical methods.
  - Find the eigenvalues of  $A$ .
  - Find a basis  $\mathbf{x}_{i1}, \dots, \mathbf{x}_{ir_i}$  for  $E_{\lambda_i}(A)$  for each of the distinct eigenvalues  $\lambda_1, \dots, \lambda_k$  of  $A$ .
  - If  $r_1 + \dots + r_k = n$ , then let  $B = [\mathbf{x}_{11} \dots \mathbf{x}_{1r_1} \dots \mathbf{x}_{k1} \dots \mathbf{x}_{kr_k}]$ .  $B$  is invertible and  $D = B^{-1}AB$  is a diagonal matrix, whose diagonal entries are the eigenvalues of  $A$ , in the order that corresponds to the order of the columns of  $B$ . Else  $A$  is not diagonalizable.
21.  $A$  is diagonalizable if and only if  $A$  has  $n$  linearly independent eigenvectors.

22.  $A$  is diagonalizable if and only if  $|\sigma(A)| = n$  and  $A$  is nondefective.
23. If  $A$  has  $n$  distinct eigenvalues, then  $A$  is diagonalizable.
24.  $A$  is diagonalizable if and only if  $q_A(x)$  can be factored into distinct linear factors.
25. If  $A$  is diagonalizable, then so are  $A^T, A^k, k \in \mathbb{N}$ .
26. If  $A$  is nonsingular and diagonalizable, then  $A^{-1}$  is diagonalizable.
27. If  $A$  is an idempotent, then  $A$  is diagonalizable and  $\sigma(A) \subseteq \{0, 1\}$ .
28. If  $A$  is nilpotent, then  $\sigma(A) = \{0\}$ . If  $A$  is nilpotent and is not the zero matrix, then  $A$  is not diagonalizable.
29. [FIS89] Let  $T$  be a linear operator on a finite dimensional vector space  $V$  with a basis  $\mathcal{B}$ . Then  $T$  is diagonalizable if and only if  $[T]_{\mathcal{B}}$  is diagonalizable.
30. [FIS89] A linear operator,  $T$ , on a finite dimensional vector space  $V$  is diagonalizable if and only if there exists a basis  $\mathcal{B} = \{\mathbf{v}_1, \dots, \mathbf{v}_n\}$  for  $V$ , and scalars  $\lambda_1, \dots, \lambda_n$ , such that  $T(\mathbf{v}_i) = \lambda_i \mathbf{v}_i$ , for  $1 \leq i \leq n$ .
31. [FIS89] If a linear operator,  $T$ , on a vector space,  $V$ , of dimension  $n$ , has  $n$  distinct eigenvalues, then it is diagonalizable.
32. [FIS89] The characteristic polynomial of a diagonalizable linear operator on a finite dimensional vector space can be factored into linear terms.

### Polynomials

33. [HJ85] (Cayley–Hamilton Theorem) Let  $p_A(x) = x^n + a_{n-1}x^{n-1} + \dots + a_1x + a_0$  be the characteristic polynomial of  $A$ . Then  $p_A(A) = A^n + a_{n-1}A^{n-1} + \dots + a_1A + a_0I_n = 0$ .
34. [FIS89] (Cayley–Hamilton Theorem for a Linear Operator) Let  $p_T(x) = x^n + a_{n-1}x^{n-1} + \dots + a_1x + a_0$  be the characteristic polynomial of a linear operator,  $T$ , on a finite dimensional vector space,  $V$ . Then  $p_T(T) = T^n + a_{n-1}T^{n-1} + \dots + a_1T + a_0I_n = T_0$ , where  $T_0$  is the zero linear operator on  $V$ .
35.  $p_{A^T}(x) = p_A(x)$ .
36. The minimal polynomial  $q_A(x)$  of a matrix  $A$  is a factor of the characteristic polynomial  $p_A(x)$  of  $A$ .
37. If  $\lambda$  is an eigenvalue of  $A$  associated with the eigenvector  $\mathbf{x}$ , then  $p(\lambda)$  is an eigenvalue of the matrix  $p(A)$  associated with the eigenvector  $\mathbf{x}$ , where  $p(x)$  is a polynomial with coefficients in  $F$ .
38. If  $B$  is nonsingular,  $p_A(x) = p_{B^{-1}AB}(x)$ , therefore,  $A$  and  $B^{-1}AB$  have the same eigenvalues.
39. Let  $p_A(x) = x^n + a_{n-1}x^{n-1} + \dots + a_1x + a_0$  be the characteristic polynomial of  $A$ . If  $|\sigma(A)| = n$ , then  $a_k = (-1)^{n-k} S_{n-k}(\lambda_1, \dots, \lambda_n)$ ,  $k = 0, 1, \dots, n-1$ , where  $S_k(\lambda_1, \dots, \lambda_n)$  is the  $k$ th symmetric function of the eigenvalues of  $A$ .
40. Let  $p_A(x) = x^n + a_{n-1}x^{n-1} + \dots + a_1x + a_0$  be the characteristic polynomial of  $A$ . Then  $a_k = (-1)^{n-k} S_{n-k}(A)$ ,  $k = 0, 1, \dots, n-1$ .
41. If  $|\sigma(A)| = n$ , then  $S_k(A) = S_k(\lambda_1, \dots, \lambda_n)$ .
42. If  $C(p)$  is the companion matrix of the polynomial  $p(x)$ , then  $p(x) = p_{C(p)}(x) = q_{C(p)}(x)$ .
43. [HJ85, p. 135] If  $|\sigma(A)| = n$ ,  $A$  is nonderogatory, and  $B$  commutes with  $A$ , then there exists a polynomial  $f(x)$  of degree less than  $n$  such that  $B = f(A)$ .

### Other Facts:

44. If  $A$  is nonsingular and  $\lambda$  is an eigenvalue of  $A$  of algebraic multiplicity  $\alpha(\lambda)$ , with corresponding eigenvector  $\mathbf{x}$ , then  $\det(A)\lambda^{-1}$  is an eigenvalue of  $\text{adj } A$  with algebraic multiplicity  $\alpha(\lambda)$  and corresponding eigenvector  $\mathbf{x}$ .
45. [Lew91] If  $\lambda \in \sigma(A)$ , then any nonzero column of  $\text{adj}(A - \lambda I)$  is an eigenvector of  $A$  corresponding to  $\lambda$ .
46. If  $AB = BA$ , then  $A$  and  $B$  have a common eigenvector.
47. If  $A \in F^{m \times n}$  and  $B \in F^{n \times m}$ , then  $\sigma(AB) = \sigma(BA)$  except for the zero eigenvalues.

48. If  $A \in F^{m \times m}$  and  $B \in F^{n \times n}$ ,  $\lambda \in \sigma(A)$ ,  $\mu \in \sigma(B)$ , with corresponding eigenvectors  $\mathbf{u}$  and  $\mathbf{v}$ , respectively, then  $\lambda\mu \in \sigma(A \otimes B)$ , with corresponding eigenvector  $\mathbf{u} \otimes \mathbf{v}$ . (See Section 10.5 for the definition of  $A \otimes B$ .)

**Examples:**

1. Let  $A = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$ . Then, viewing  $A \in \mathbb{C}^{n \times n}$ ,  $\sigma(A) = \{-i, i\}$ . That is,  $A$  has no eigenvalues over the reals.

2. Let  $A = \begin{bmatrix} -3 & 7 & -1 \\ 6 & 8 & -2 \\ 72 & -28 & 19 \end{bmatrix}$ . Then  $p_A(x) = (x + 6)(x - 15)^2 = q_A(x)$ ,  $\lambda_1 = -6$ ,  $\alpha(\lambda_1) = 1$ ,  $\gamma(\lambda_1) = 1$ ,  $\lambda_2 = 15$ ,  $\alpha(\lambda_2) = 2$ ,  $\gamma(\lambda_2) = 1$ . Also, a set of linearly independent eigenvectors is  $\left\{ \begin{bmatrix} -1 \\ -2 \\ 4 \end{bmatrix}, \begin{bmatrix} -1 \\ 1 \\ 4 \end{bmatrix} \right\}$ . So,  $A$  is not diagonalizable.

3. Let  $A = \begin{bmatrix} 57 & -21 & 21 \\ -14 & 22 & -7 \\ -140 & 70 & -55 \end{bmatrix}$ . Then  $p_A(x) = (x + 6)(x - 15)^2$ ,  $q_A(x) = (x + 6)(x - 15)$ ,  $\lambda_1 = -6$ ,  $\alpha(\lambda_1) = 1$ ,  $\gamma(\lambda_1) = 1$ ,  $\lambda_2 = 15$ ,  $\alpha(\lambda_2) = 2$ ,  $\gamma(\lambda_2) = 2$ . Also, a set of linearly independent eigenvectors is  $\left\{ \begin{bmatrix} -1 \\ 0 \\ 2 \end{bmatrix}, \begin{bmatrix} 1 \\ 2 \\ 0 \end{bmatrix}, \begin{bmatrix} -3 \\ 1 \\ 10 \end{bmatrix} \right\}$ . So,  $A$  is diagonalizable.

4. Let  $A = \begin{bmatrix} -5 + 4i & 1 & i \\ 2 + 8i & -4 & 2i \\ 20 - 4i & -4 & -i \end{bmatrix}$ . Then  $\sigma(A) = \{-6, -3, 3i\}$ . If  $B = \frac{1}{9}A^2 + 2A - 4I$ , then  $\sigma(B) = \{-12, -9, -5 + 6i\}$ .

5. Let  $A = \begin{bmatrix} -2 & 1 & 0 \\ 0 & -3i & 0 \\ 0 & 0 & 1 \end{bmatrix}$  and  $B = \begin{bmatrix} -2 & 1 & 0 \\ 3 & -1 & 1 \\ 4 & 0 & 1 \end{bmatrix}$ .  $B$  is nonsingular, so  $A$  and  $B^{-1}AB = \begin{bmatrix} -1 + 3i & 1 - i & i \\ 5 + 6i & -1 - 2i & 1 + 2i \\ 8 - 12i & -4 + 4i & 1 - 4i \end{bmatrix}$  have the same eigenvalues, which are given in the diagonal of  $A$ .

6. Let  $A = \begin{bmatrix} 2 & -1 & 0 \\ 0 & 3 & 1 \end{bmatrix}$  and  $B = \begin{bmatrix} 3 & 0 \\ 2 & 1 \\ 1 & 0 \end{bmatrix}$ . Then  $AB = \begin{bmatrix} 4 & -1 \\ 7 & 3 \end{bmatrix}$ ,  $\sigma(AB) = \left\{ \frac{1}{2}(7 + 3\sqrt{3}i), \frac{1}{2}(7 - 3\sqrt{3}i) \right\}$ ,  $BA = \begin{bmatrix} 6 & -3 & 0 \\ 4 & 1 & 1 \\ 2 & -1 & 0 \end{bmatrix}$ , and  $\sigma(BA) = \left\{ \frac{1}{2}(7 + 3\sqrt{3}i), \frac{1}{2}(7 - 3\sqrt{3}i), 0 \right\}$ .

7. Let  $A = \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -3i \end{bmatrix}$  and  $B = \begin{bmatrix} -2 & 7 & 0 \\ 0 & -2 & 0 \\ 0 & 0 & i \end{bmatrix}$ . Then  $AB = BA = \begin{bmatrix} -2 & 5 & 0 \\ 0 & -2 & 0 \\ 0 & 0 & 3 \end{bmatrix}$ .  $A$  and  $B$

share the eigenvector  $\mathbf{x} = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$ , corresponding to the eigenvalues  $\lambda = 1$  of  $A$  and  $\mu = -2$  of  $B$ .

8. Let  $A = \begin{bmatrix} 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & -3 & 2 \\ 0 & -1 & -2 & -4 \end{bmatrix}$ . Then  $p_A(x) = x^4 + 5x^3 + 4x^2 - 23x + 13$ .  $S_4(A)$ ,  $S_3(A)$ , and  $S_1(A)$

were computed in Example 1 of Section 4.2, and it is straightforward to verify that  $S_2(A) = 4$ . Comparing these values to the characteristic polynomial,  $S_4(A) = 13 = (-1)^4 13$ ,  $S_3(A) = 23 = (-1)^3(-23)$ ,  $S_2(A) = (-1)^2 4$ , and  $S_1(A) = (-1)(5)$ . It follows that  $S_4(\lambda_1, \lambda_2, \lambda_3, \lambda_4) = \lambda_1 \lambda_2 \lambda_3 \lambda_4 = 13$ ,  $S_3(\lambda_1, \lambda_2, \lambda_3, \lambda_4) = 23$ ,  $S_2(\lambda_1, \lambda_2, \lambda_3, \lambda_4) = 4$ , and  $S_1(\lambda_1, \lambda_2, \lambda_3, \lambda_4) = \lambda_1 + \lambda_2 + \lambda_3 + \lambda_4 = -5$  (these values can also be verified with a computer algebra system or numerical software).

9. Let  $p(x) = x^3 - 7x^2 - 3x + 2$ ,  $C = C(p) = \begin{bmatrix} 0 & 0 & -2 \\ 1 & 0 & 3 \\ 0 & 1 & 7 \end{bmatrix}$ . Then  $p_C(x) = x^3 - 7x^2 - 3x + 2 =$

$$p(x). \text{ Also, } p_C(C) = -C^3 + 7C^2 + 3C - 2I = - \begin{bmatrix} -2 & -14 & -104 \\ 3 & 19 & 142 \\ 7 & 52 & 383 \end{bmatrix} + 7 \begin{bmatrix} 0 & -2 & -14 \\ 0 & 3 & 19 \\ 1 & 7 & 52 \end{bmatrix} \\ + 3 \begin{bmatrix} 0 & 0 & -2 \\ 1 & 0 & 3 \\ 0 & 1 & 7 \end{bmatrix} - 2 \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

### Applications:

- (Markov Chains) (See also Chapter 54 for more information.) A Markov Chain describes a process in which a system can be in any one of  $n$  states:  $s_1, s_2, \dots, s_n$ . The probability of entering state  $s_i$  depends only on the state previously occupied by the system. The **transition probability** of entering state  $j$ , given that the system is in state  $i$ , is denoted by  $p_{ij}$ . The **transition matrix** is the matrix  $P = [p_{ij}]$ ; its rows have sum 1. A (row or column) vector is a **probability vector** if its entries are nonnegative and sum to 1. The probability row vector  $\pi^{(k)} = (\pi_1^{(k)}, \pi_2^{(k)}, \dots, \pi_n^{(k)})$ ,  $k \geq 0$ , is called the **state vector** of the system at time  $k$  if its  $i$ th entry is the probability that the system is in state  $s_i$  at time  $k$ . In particular, when  $k = 0$ , the state vector is called the **initial state vector** and its  $i$ th entry is the probability that the system begins at state  $s_i$ . It follows from probability theory that  $\pi^{(k+1)} = \pi^{(k)} P$ , and thus inductively that  $\pi^{(k)} = \pi^{(0)} P^k$ . If the entries of some power of  $P$  are all positive, then  $P$  is said to be

**regular**. If  $P$  is a regular transition matrix, then as  $n \rightarrow \infty$ ,  $P^n \rightarrow \begin{bmatrix} \pi_1 & \pi_2 & \cdots & \pi_n \\ \pi_1 & \pi_2 & \cdots & \pi_n \\ \vdots & \vdots & \ddots & \vdots \\ \pi_1 & \pi_2 & \cdots & \pi_n \end{bmatrix}$ . The

row vector  $\pi = (\pi_1, \pi_2, \dots, \pi_n)$  is called the **steady state vector**,  $\pi$  is a probability vector, and as  $n \rightarrow \infty$ ,  $\pi^{(n)} \rightarrow \pi$ . The vector  $\pi$  is the unique probability row vector with the property that  $\pi P = \pi$ . That is,  $\pi$  is the unique probability row vector that is a left eigenvector of  $P$  for eigenvalue 1.

- (Differential Equations) [Mey00, pp. 541–546] Consider the system of linear differential equations
 
$$\begin{cases} x_1' = a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n \\ x_2' = a_{21}x_1 + a_{22}x_2 + \dots + a_{2n}x_n \\ \vdots \\ x_n' = a_{n1}x_1 + a_{n2}x_2 + \dots + a_{nn}x_n \end{cases}, \text{ where each of the unknowns } x_1, x_2, \dots, x_n$$

is a differentiable function of the real variable  $t$ . This system of linear differential equations can

be written in matrix form as  $\mathbf{x}' = A\mathbf{x}$ , where  $A = [a_{ij}]$ ,  $\mathbf{x} = \begin{bmatrix} x_1(t) \\ x_2(t) \\ \vdots \\ x_n(t) \end{bmatrix}$ , and  $\mathbf{x}' = \begin{bmatrix} x_1'(t) \\ x_2'(t) \\ \vdots \\ x_n'(t) \end{bmatrix}$ . If  $A$

is diagonalizable, there exists a nonsingular matrix  $B$  (the columns of the matrix  $B$  are linearly independent eigenvectors of  $A$ ), such that  $B^{-1}AB = D$  is a diagonal matrix, so  $\mathbf{x}' = BDB^{-1}\mathbf{x}$ , or  $B^{-1}\mathbf{x}' = DB^{-1}\mathbf{x}$ . Let  $\mathbf{u} = B^{-1}\mathbf{x}$ . The linear system of differential equations  $\mathbf{u}' = D\mathbf{u}$  has solution

$\mathbf{u} = \begin{bmatrix} k_1 e^{\lambda_1 t} \\ k_2 e^{\lambda_2 t} \\ \vdots \\ k_n e^{\lambda_n t} \end{bmatrix}$ , where  $\lambda_1, \lambda_2, \dots, \lambda_n$  are the eigenvalues of  $A$ . It follows that  $\mathbf{x} = B\mathbf{u}$ . (See also

Chapter 55.)

- (Dynamical Systems) [Lay03, pp. 315–316] Consider the dynamical system given by  $\mathbf{u}_{k+1} = A\mathbf{u}_k$ ,

where  $A = [a_{ij}]$ ,  $\mathbf{u}_0 = \begin{bmatrix} a_1 \\ a_2 \\ \vdots \\ a_n \end{bmatrix}$ . If  $A$  is diagonalizable, there exist  $n$  linearly independent eigenvectors,

$\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_n$ , of  $A$ . The vector  $\mathbf{u}_0$  can then be written as a linear combination of the eigenvectors, that is,  $\mathbf{u}_0 = c_1\mathbf{x}_1 + c_2\mathbf{x}_2 + \dots + c_n\mathbf{x}_n$ . Then  $\mathbf{u}_1 = A\mathbf{u}_0 = A(c_1\mathbf{x}_1 + c_2\mathbf{x}_2 + \dots + c_n\mathbf{x}_n) = c_1\lambda_1\mathbf{x}_1 + c_2\lambda_2\mathbf{x}_2 + \dots + c_n\lambda_n\mathbf{x}_n$ . Inductively,  $\mathbf{u}_{k+1} = A\mathbf{u}_k = c_1\lambda_1^{k+1}\mathbf{x}_1 + c_2\lambda_2^{k+1}\mathbf{x}_2 + \dots + c_n\lambda_n^{k+1}\mathbf{x}_n$ . Thus, the long-term behavior of the dynamical system can be studied using the eigenvalues of the matrix  $A$ . (See also Chapter 56.)

### 5.1 Inner Product Spaces

---

#### Definitions:

Let  $V$  be a vector space over the field  $F$ , where  $F = \mathbb{R}$  or  $F = \mathbb{C}$ . An **inner product** on  $V$  is a function  $\langle \cdot, \cdot \rangle: V \times V \rightarrow F$  such that for all  $\mathbf{u}, \mathbf{v}, \mathbf{w} \in V$  and  $a, b \in F$ , the following hold:

- $\langle \mathbf{v}, \mathbf{v} \rangle \geq 0$  and  $\langle \mathbf{v}, \mathbf{v} \rangle = 0$  if and only if  $\mathbf{v} = \mathbf{0}$ .
- $\langle a\mathbf{u} + b\mathbf{v}, \mathbf{w} \rangle = a\langle \mathbf{u}, \mathbf{w} \rangle + b\langle \mathbf{v}, \mathbf{w} \rangle$ .
- For  $F = \mathbb{R}$ :  $\langle \mathbf{u}, \mathbf{v} \rangle = \langle \mathbf{v}, \mathbf{u} \rangle$ ; For  $F = \mathbb{C}$ :  $\langle \mathbf{u}, \mathbf{v} \rangle = \overline{\langle \mathbf{v}, \mathbf{u} \rangle}$  (where bar denotes complex conjugation).

A real (or complex) **inner product space** is a vector space  $V$  over  $\mathbb{R}$  (or  $\mathbb{C}$ ), together with an inner product defined on it.

In an inner product space  $V$ , the **norm**, or **length**, of a vector  $\mathbf{v} \in V$  is  $\|\mathbf{v}\| = \sqrt{\langle \mathbf{v}, \mathbf{v} \rangle}$ .

A vector  $\mathbf{v} \in V$  is a **unit vector** if  $\|\mathbf{v}\| = 1$ .

The **angle** between two nonzero vectors  $\mathbf{u}$  and  $\mathbf{v}$  in a real inner product space is the real number  $\theta$ ,  $0 \leq \theta \leq \pi$ , such that  $\langle \mathbf{u}, \mathbf{v} \rangle = \|\mathbf{u}\| \|\mathbf{v}\| \cos \theta$ . See the Cauchy–Schwarz inequality (Fact 9 below).

Let  $V$  be an inner product space. The **distance** between two vectors  $\mathbf{u}$  and  $\mathbf{v}$  is  $d(\mathbf{u}, \mathbf{v}) = \|\mathbf{u} - \mathbf{v}\|$ .

A Hermitian matrix  $A$  is **positive definite** if  $\mathbf{x}^* A \mathbf{x} > 0$  for all nonzero  $\mathbf{x} \in \mathbb{C}^n$ . (See Chapter 8 for more information on positive definite matrices.)

### Facts:

All the following facts except those with a specific reference can be found in [Rom92, pp. 157–164].

1. The vector space  $\mathbb{R}^n$  is an inner product space under the **standard inner product**, or **dot product**, defined by

$$\langle \mathbf{u}, \mathbf{v} \rangle = \mathbf{u}^T \mathbf{v} = \sum_{i=1}^n u_i v_i.$$

This inner product space is often called  $n$ -dimensional **Euclidean space**.

2. The vector space  $\mathbb{C}^n$  is an inner product space under the **standard inner product**, defined by

$$\langle \mathbf{u}, \mathbf{v} \rangle = \mathbf{v}^* \mathbf{u} = \sum_{i=1}^n u_i \bar{v}_i.$$

This inner product space is often called  $n$ -dimensional **unitary space**.

3. [HJ85, p. 410] In  $\mathbb{R}^n$ , a function  $\langle \cdot, \cdot \rangle: \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$  is an inner product if and only if there exists a real symmetric positive definite matrix  $G$  such that  $\langle \mathbf{u}, \mathbf{v} \rangle = \mathbf{u}^T G \mathbf{v}$ , for all  $\mathbf{u}, \mathbf{v} \in \mathbb{R}^n$ .
4. [HJ85, p. 410] In  $\mathbb{C}^n$ , a function  $\langle \cdot, \cdot \rangle: \mathbb{C}^n \times \mathbb{C}^n \rightarrow \mathbb{C}$  is an inner product if and only if there exists a Hermitian positive definite matrix  $H$  such that  $\langle \mathbf{u}, \mathbf{v} \rangle = \mathbf{v}^* H \mathbf{u}$ , for all  $\mathbf{u}, \mathbf{v} \in \mathbb{C}^n$ .
5. Let  $l^2$  be the vector space of all infinite complex sequences  $\mathbf{v} = (v_n)$  with the property that  $\sum_{n=1}^{\infty} |v_n|^2 < \infty$ . Then  $l^2$  is an inner product space under the inner product

$$\langle \mathbf{u}, \mathbf{v} \rangle = \sum_{n=1}^{\infty} u_n \bar{v}_n.$$

6. The vector space  $C[a, b]$  of all continuous real-valued functions on the closed interval  $[a, b]$  is an inner product space under the inner product

$$\langle f, g \rangle = \int_a^b f(x)g(x)dx.$$

7. If  $V$  is an inner product space and  $\langle \mathbf{u}, \mathbf{w} \rangle = \langle \mathbf{v}, \mathbf{w} \rangle$  for all  $\mathbf{w} \in V$ , then  $\mathbf{u} = \mathbf{v}$ .
8. The inner product on an inner product space  $V$ , when restricted to vectors in a subspace  $S$  of  $V$ , is an inner product on  $S$ .
9. Let  $V$  be an inner product space. Then the norm function  $\| \cdot \|$  on  $V$  has the following basic properties for all  $\mathbf{u}, \mathbf{v} \in V$ :
  - $\|\mathbf{v}\| \geq 0$  and  $\|\mathbf{v}\| = 0$  if and only if  $\mathbf{v} = \mathbf{0}$ .
  - $\|a\mathbf{v}\| = |a|\|\mathbf{v}\|$ , for all  $a \in F$ .
  - (The triangle inequality)  $\|\mathbf{u} + \mathbf{v}\| \leq \|\mathbf{u}\| + \|\mathbf{v}\|$  with equality if and only if  $\mathbf{v} = a\mathbf{u}$ , for some  $a \in F$ .
  - (The Cauchy–Schwarz inequality)  $|\langle \mathbf{u}, \mathbf{v} \rangle| \leq \|\mathbf{u}\|\|\mathbf{v}\|$  with equality if and only if  $\mathbf{v} = a\mathbf{u}$ , for some  $a \in F$ .
  - $|\|\mathbf{u}\| - \|\mathbf{v}\|| \leq \|\mathbf{u} - \mathbf{v}\|$ .

- (The parallelogram law)  $\|\mathbf{u} + \mathbf{v}\|^2 + \|\mathbf{u} - \mathbf{v}\|^2 = 2\|\mathbf{u}\|^2 + 2\|\mathbf{v}\|^2$ .
- (Polarization identities)

$$4\langle \mathbf{u}, \mathbf{v} \rangle = \begin{cases} \|\mathbf{u} + \mathbf{v}\|^2 - \|\mathbf{u} - \mathbf{v}\|^2, & \text{if } F = \mathbb{R}. \\ \|\mathbf{u} + \mathbf{v}\|^2 - \|\mathbf{u} - \mathbf{v}\|^2 + i\|\mathbf{u} + i\mathbf{v}\|^2 - i\|\mathbf{u} - i\mathbf{v}\|^2, & \text{if } F = \mathbb{C}. \end{cases}$$

**Examples:**

- Let  $\mathbb{R}^4$  be the Euclidean space with the inner product  $\langle \mathbf{u}, \mathbf{v} \rangle = \mathbf{u}^T \mathbf{v}$ . Let  $\mathbf{x} = [1, 2, 3, 4]^T \in \mathbb{R}^4$  and  $\mathbf{y} = [3, -1, 0, 2]^T \in \mathbb{R}^4$  be two vectors. Then
  - $\langle \mathbf{x}, \mathbf{y} \rangle = 9$ ,  $\|\mathbf{x}\| = \sqrt{30}$ , and  $\|\mathbf{y}\| = \sqrt{14}$ .
  - The distance between  $\mathbf{x}$  and  $\mathbf{y}$  is  $d(\mathbf{x}, \mathbf{y}) = \|\mathbf{x} - \mathbf{y}\| = \sqrt{26}$ .
  - The angle between  $\mathbf{x}$  and  $\mathbf{y}$  is  $\theta = \arccos \frac{9}{\sqrt{30}\sqrt{14}} = \arccos \frac{9}{2\sqrt{105}} \approx 1.116$  radians.
- $\langle \mathbf{u}, \mathbf{v} \rangle = u_1v_1 + 2u_1v_2 + 2u_2v_1 + 6u_2v_2 = \mathbf{u}^T \begin{bmatrix} 1 & 2 \\ 2 & 6 \end{bmatrix} \mathbf{v}$  is an inner product on  $\mathbb{R}^2$ , as the matrix  $G = \begin{bmatrix} 1 & 2 \\ 2 & 6 \end{bmatrix}$  is symmetric positive definite.
- Let  $C[-1, 1]$  be the vector space with the inner product  $\langle f, g \rangle = \int_{-1}^1 f(x)g(x)dx$  and let  $f(x) = 1$  and  $g(x) = x^2$  be two functions in  $C[-1, 1]$ . Then  $\langle f, g \rangle = \int_{-1}^1 x^2 dx = 2/3$ ,  $\langle f, f \rangle = \int_{-1}^1 1 dx = 2$ , and  $\langle g, g \rangle = \int_{-1}^1 x^4 dx = 2/5$ . The angle between  $f$  and  $g$  is  $\arccos(\sqrt{5}/3) \approx 0.730$  radians.
- [Mey00, p. 286]  $\langle A, B \rangle = \text{tr}(AB^*)$  is an inner product on  $\mathbb{C}^{m \times n}$ .

## 5.2 Orthogonality

---

**Definitions:**

Let  $V$  be an inner product space. Two vectors  $\mathbf{u}, \mathbf{v} \in V$  are **orthogonal** if  $\langle \mathbf{u}, \mathbf{v} \rangle = 0$ , and this is denoted by  $\mathbf{u} \perp \mathbf{v}$ .

A subset  $S$  of an inner product space  $V$  is an **orthogonal set** if  $\mathbf{u} \perp \mathbf{v}$ , for all  $\mathbf{u}, \mathbf{v} \in S$  such that  $\mathbf{u} \neq \mathbf{v}$ .

A subset  $S$  of an inner product space  $V$  is an **orthonormal set** if  $S$  is an orthogonal set and each  $\mathbf{v} \in S$  is a unit vector.

Two subsets  $S$  and  $W$  of an inner product space  $V$  are **orthogonal** if  $\mathbf{u} \perp \mathbf{v}$ , for all  $\mathbf{u} \in S$  and  $\mathbf{v} \in W$ , and this is denoted by  $S \perp W$ .

The **orthogonal complement** of a subset  $S$  of an inner product space  $V$  is  $S^\perp = \{\mathbf{w} \in V \mid \langle \mathbf{w}, \mathbf{v} \rangle = 0 \text{ for all } \mathbf{v} \in S\}$ .

A **complete orthonormal set**  $M$  in an inner product space  $V$  is an orthonormal set of vectors in  $V$  such that for  $\mathbf{v} \in V$ ,  $\mathbf{v} \perp M$  implies that  $\mathbf{v} = \mathbf{0}$ .

An **orthogonal basis** for an inner product space  $V$  is an orthogonal set that is also a basis for  $V$ .

An **orthonormal basis** for  $V$  is an orthonormal set that is also a basis for  $V$ .

A matrix  $U$  is **unitary** if  $U^*U = I$ .

A real matrix  $Q$  is **orthogonal** if  $Q^T Q = I$ .

**Facts:**

1. [Mey00, p. 298] An orthogonal set of nonzero vectors is linearly independent. An orthonormal set of vectors is linearly independent.
2. [Rom92, p. 164] If  $S$  is a subset of an inner product space  $V$ , then  $S^\perp$  is a subspace of  $V$ . Moreover, if  $S$  is a subspace of  $V$ , then  $S \cap S^\perp = \{\mathbf{0}\}$ .
3. [Mey00, p. 409] In an inner product space  $V$ ,  $\{\mathbf{0}\}^\perp = V$  and  $V^\perp = \{\mathbf{0}\}$ .
4. [Rom92, p. 168] If  $S$  is a finite dimensional subspace of an inner product space  $V$ , then for any  $\mathbf{v} \in V$ ,
  - There are unique vectors  $\mathbf{s} \in S$  and  $\mathbf{t} \in S^\perp$  such that  $\mathbf{v} = \mathbf{s} + \mathbf{t}$ . This implies  $V = S \oplus S^\perp$ .
  - There is a unique linear operator  $P$  such that  $P(\mathbf{v}) = \mathbf{s}$ .
5. [Mey00, p. 404] If  $S$  is a subspace of an  $n$ -dimensional inner product space  $V$ , then
  - $(S^\perp)^\perp = S$ .
  - $\dim(S^\perp) = n - \dim(S)$ .
6. [Rom92, p. 174] If  $S$  is a subspace of an infinite dimensional inner product space, then  $S \subseteq (S^\perp)^\perp$ , but the two sets need not be equal.
7. [Rom92, p. 166] An orthonormal basis is a complete orthonormal set.
8. [Rom92, p. 166] In a finite-dimensional inner product space, a complete orthonormal set is a basis.
9. [Rom92, p. 165] In an infinite-dimensional inner product space, a complete orthonormal set may not be a basis.
10. [Rom92, p. 166] Every finite-dimensional inner product space has an orthonormal basis.
11. [Mey00, p. 299] Let  $\mathcal{B} = \{\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_n\}$  be an orthonormal basis for  $V$ . Every vector  $\mathbf{v} \in V$  can be uniquely expressed as

$$\mathbf{v} = \sum_{i=1}^n \langle \mathbf{v}, \mathbf{u}_i \rangle \mathbf{u}_i.$$

The expression on the right is called the **Fourier expansion** of  $\mathbf{v}$  with respect to  $\mathcal{B}$  and the scalars  $\langle \mathbf{v}, \mathbf{u}_i \rangle$  are called the **Fourier coefficients**.

12. [Mey00, p. 305] (Pythagorean Theorem) If  $\{\mathbf{v}_i\}_{i=1}^k$  is an orthogonal set of vectors in  $V$ , then  $\|\sum_{i=1}^k \mathbf{v}_i\|^2 = \sum_{i=1}^k \|\mathbf{v}_i\|^2$ .
13. [Rom92, p. 167] (Bessel's Inequality) If  $\{\mathbf{u}_i\}_{i=1}^k$  is an orthonormal set of vectors in  $V$ , then  $\|\mathbf{v}\|^2 \geq \sum_{i=1}^k |\langle \mathbf{v}, \mathbf{u}_i \rangle|^2$ .
14. [Mey00, p. 305] (Parseval's Identity) Let  $\mathcal{B} = \{\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_n\}$  be an orthonormal basis for  $V$ . Then for each  $\mathbf{v} \in V$ ,  $\|\mathbf{v}\|^2 = \sum_{i=1}^n |\langle \mathbf{v}, \mathbf{u}_i \rangle|^2$ .
15. [Mey00, p. 405] Let  $A \in F^{m \times n}$ , where  $F = \mathbb{R}$  or  $\mathbb{C}$ . Then
  - $\ker(A)^\perp = \text{range}(A^*)$ ,  $\text{range}(A)^\perp = \ker(A^*)$ .
  - $F^m = \text{range}(A) \oplus \text{range}(A)^\perp = \text{range}(A) \oplus \ker(A^*)$ .
  - $F^n = \ker(A) \oplus \ker(A)^\perp = \ker(A) \oplus \text{range}(A^*)$ .
16. [Mey00, p. 321] (See also Section 7.1.) The following statements for a real matrix  $Q \in \mathbb{R}^{n \times n}$  are equivalent:
  - $Q$  is orthogonal.
  - $Q$  has orthonormal columns.
  - $Q$  has orthonormal rows.
  - $QQ^T = I$ , where  $I$  is the identity matrix of order  $n$ .
  - For all  $\mathbf{v} \in \mathbb{R}^n$ ,  $\|Q\mathbf{v}\| = \|\mathbf{v}\|$ .

17. [Mey00, p. 321] (See also Section 7.1.) The following statements for a complex matrix  $U \in \mathbb{C}^{n \times n}$  are equivalent:

- $U$  is unitary.
- $U$  has orthonormal columns.
- $U$  has orthonormal rows.
- $UU^* = I$ , where  $I$  is the identity matrix of order  $n$ .
- For all  $\mathbf{v} \in \mathbb{C}^n$ ,  $\|U\mathbf{v}\| = \|\mathbf{v}\|$ .

**Examples:**

1. Let  $C[-1, 1]$  be the vector space with the inner product  $\langle f, g \rangle = \int_{-1}^1 f(x)g(x)dx$  and let  $f(x) = 1$  and  $g(x) = x$  be two functions in  $C[-1, 1]$ . Then  $\langle f, g \rangle = \int_{-1}^1 x dx = 0$ . Thus,  $f \perp g$ .
2. The standard basis  $\{\mathbf{e}_1, \mathbf{e}_2, \dots, \mathbf{e}_n\}$  is an orthonormal basis for the unitary space  $\mathbb{C}^n$ .
3. If  $\{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_n\}$  is an orthogonal basis for  $\mathbb{C}^n$  and  $S = \text{span}\{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_k\}$  ( $1 \leq k \leq n-1$ ), then  $S^\perp = \text{span}\{\mathbf{v}_{k+1}, \dots, \mathbf{v}_n\}$ .
4. The vectors  $\mathbf{v}_1 = [2, 2, 1]^T$ ,  $\mathbf{v}_2 = [1, -1, 0]^T$ , and  $\mathbf{v}_3 = [-1, -1, 4]^T$  are mutually orthogonal. They can be normalized to  $\mathbf{u}_1 = \mathbf{v}_1/\|\mathbf{v}_1\| = [2/3, 2/3, 1/3]^T$ ,  $\mathbf{u}_2 = \mathbf{v}_2/\|\mathbf{v}_2\| = [1/\sqrt{2}, -1/\sqrt{2}, 0]^T$ , and  $\mathbf{u}_3 = \mathbf{v}_3/\|\mathbf{v}_3\| = [-\sqrt{2}/6, -\sqrt{2}/6, 2\sqrt{2}/3]^T$ . The set  $\mathbb{B} = \{\mathbf{u}_1, \mathbf{u}_2, \mathbf{u}_3\}$  forms an orthonormal basis for the Euclidean space  $\mathbb{R}^3$ .

- If  $\mathbf{v} = [v_1, v_2, v_3]^T \in \mathbb{R}^3$ , then  $\mathbf{v} = \langle \mathbf{v}, \mathbf{u}_1 \rangle \mathbf{u}_1 + \langle \mathbf{v}, \mathbf{u}_2 \rangle \mathbf{u}_2 + \langle \mathbf{v}, \mathbf{u}_3 \rangle \mathbf{u}_3$ , that is,

$$\mathbf{v} = \frac{2v_1 + 2v_2 + v_3}{3} \mathbf{u}_1 + \frac{v_1 - v_2}{\sqrt{2}} \mathbf{u}_2 + \frac{-v_1 - v_2 + 4v_3}{3\sqrt{2}} \mathbf{u}_3.$$

- The matrix  $Q = [\mathbf{u}_1, \mathbf{u}_2, \mathbf{u}_3] \in \mathbb{R}^{3 \times 3}$  is an orthogonal matrix.
5. Let  $S$  be the subspace of  $\mathbb{C}^3$  spanned by the vectors  $\mathbf{u} = [i, 1, 1]^T$  and  $\mathbf{v} = [1, i, 1]^T$ . Then the orthogonal complement of  $S$  is

$$S^\perp = \{\mathbf{w} | \mathbf{w} = \alpha[1, 1, -1 + i]^T, \text{ where } \alpha \in \mathbb{C}\}.$$

6. Consider the inner product space  $l^2$  from Fact 5 in Section 5.1. Let  $\mathcal{E} = \{\mathbf{e}_i | i = 1, 2, \dots\}$ , where  $\mathbf{e}_i$  has a 1 on  $i$ th place and 0s elsewhere. It is clear that  $\mathcal{E}$  is an orthonormal set. If  $\mathbf{v} = (v_n) \perp \mathcal{E}$ , then for each  $n$ ,  $v_n = \langle \mathbf{v}, \mathbf{e}_n \rangle = 0$ . This implies  $\mathbf{v} = \mathbf{0}$ . Therefore,  $\mathcal{E}$  is a complete orthonormal set. However,  $\mathcal{E}$  is not a basis for  $l^2$  as  $S = \text{span}\{\mathcal{E}\} \neq l^2$ . Further,  $S^\perp = \{\mathbf{0}\}$ . Thus,  $(S^\perp)^\perp = l^2 \not\subseteq S$  and  $l^2 \neq S \oplus S^\perp$ .

### 5.3 Adjoins of Linear Operators on Inner Product Spaces

Let  $V$  be a finite dimensional (real or complex) inner product space and let  $T$  be a linear operator on  $V$ .

**Definitions:**

A linear operator  $T^*$  on  $V$  is called the **adjoint** of  $T$  if  $\langle T(\mathbf{u}), \mathbf{v} \rangle = \langle \mathbf{u}, T^*(\mathbf{v}) \rangle$  for all  $\mathbf{u}, \mathbf{v} \in V$ .

The linear operator  $T$  is **self-adjoint**, or **Hermitian**, if  $T = T^*$ ;  $T$  is **unitary** if  $T^*T = I_V$ .

**Facts:**

The following facts can be found in [HK71].

1. Let  $f$  be a linear functional on  $V$ . Then there exists a unique  $\mathbf{v} \in V$  such that  $f(\mathbf{w}) = \langle \mathbf{w}, \mathbf{v} \rangle$  for all  $\mathbf{w} \in V$ .
2. The adjoint  $T^*$  of  $T$  exists and is unique.
3. Let  $\mathcal{B} = (\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_n)$  be an ordered, orthonormal basis of  $V$ . Let  $A = [T]_{\mathcal{B}}$ . Then

$$a_{ij} = \langle T(\mathbf{u}_j), \mathbf{u}_i \rangle, \quad i, j = 1, 2, \dots, n.$$

Moreover,  $[T^*]_{\mathcal{B}} = A^*$ , the Hermitian adjoint of  $A$ .

4. (Properties of the adjoint operator)
  - (a)  $(T^*)^* = T$  for every linear operator  $T$  on  $V$ .
  - (b)  $(aT)^* = \bar{a}T^*$  for every linear operator  $T$  on  $V$  and every  $a \in F$ .
  - (c)  $(T + T_1)^* = T^* + T_1^*$  for every linear operators  $T, T_1$  on  $V$ .
  - (d)  $(TT_1)^* = T_1^*T^*$  for every linear operators  $T, T_1$  on  $V$ .
5. Let  $\mathcal{B}$  be an ordered orthonormal basis of  $V$  and let  $A = [T]_{\mathcal{B}}$ . Then
  - (a)  $T$  is self-adjoint if and only if  $A$  is a Hermitian matrix.
  - (b)  $T$  is unitary if and only if  $A$  is a unitary matrix.

**Examples:**

1. Consider the space  $\mathbb{R}^3$  equipped with the standard inner product and let  $f(\mathbf{w}) = 3w_1 - 2w_3$ . Then with  $\mathbf{v} = [3, 0, -2]^T$ ,  $f(\mathbf{w}) = \langle \mathbf{w}, \mathbf{v} \rangle$ .
2. Consider the space  $\mathbb{R}^3$  equipped with the standard inner product. Let  $\mathbf{v} = \begin{bmatrix} x \\ y \\ z \end{bmatrix}$  and  $T(\mathbf{v}) = \begin{bmatrix} 2x + y \\ y - 3z \\ x + y + z \end{bmatrix}$ . Then  $[T] = \begin{bmatrix} 2 & 1 & 0 \\ 0 & 1 & -3 \\ 1 & 1 & 1 \end{bmatrix}$ , so  $[T]^* = \begin{bmatrix} 2 & 0 & 1 \\ 1 & 1 & 1 \\ 0 & -3 & 1 \end{bmatrix}$ , and  $T^*(\mathbf{v}) = \begin{bmatrix} 2x + z \\ x + y + z \\ -3y + z \end{bmatrix}$ .
3. Consider the space  $\mathbb{C}^{n \times n}$  equipped with the inner product in Example 4 of section 5.1. Let  $A, B \in \mathbb{C}^{n \times n}$  and let  $T$  be the linear operator on  $\mathbb{C}^{n \times n}$  defined by  $T(X) = AX + XB$ ,  $X \in \mathbb{C}^{n \times n}$ . Then  $T^*(X) = A^*X + XB^*$ ,  $X \in \mathbb{C}^{n \times n}$ .
4. Let  $V$  be an inner product space and let  $T$  be a linear operator on  $V$ . For a fixed  $\mathbf{u} \in V$ ,  $f(\mathbf{w}) = \langle T(\mathbf{w}), \mathbf{u} \rangle$  is a linear functional. By Fact 1, there is a unique vector  $\mathbf{v}$  such that  $f(\mathbf{w}) = \langle \mathbf{w}, \mathbf{v} \rangle$ . Then  $T^*(\mathbf{u}) = \mathbf{v}$ .

## 5.4 Orthogonal Projection

---

**Definitions:**

Let  $S$  be a finite-dimensional subspace of an inner product space  $V$ . Then according to Fact 4 in Section 5.2, each  $\mathbf{v} \in V$  can be written uniquely as  $\mathbf{v} = \mathbf{s} + \mathbf{t}$ , where  $\mathbf{s} \in S$  and  $\mathbf{t} \in S^\perp$ . The vector  $\mathbf{s}$  is called the **orthogonal projection** of  $\mathbf{v}$  onto  $S$  and is often written as  $\text{Proj}_S \mathbf{v}$ , where the linear operator  $\text{Proj}_S$  is called the **orthogonal projection** onto  $S$  along  $S^\perp$ . When  $V = \mathbb{C}^n$  or  $V = \mathbb{R}^n$  with the standard inner product, the linear operator  $\text{Proj}_S$  is often identified with its standard matrix  $[\text{Proj}_S]$  and  $\text{Proj}_S$  is used to denote both the operator and the matrix.

**Facts:**

1. An orthogonal projection is a projection (as defined in Section 3.6).
2. [Mey00, p. 433] Suppose that  $P$  is a projection. The following statements are equivalent:
  - $P$  is an orthogonal projection.
  - $P^* = P$ .
  - $\text{range}(P) \perp \ker(P)$ .
3. [Mey00, p. 430] If  $S$  is a subspace of a finite dimensional inner product space  $V$ , then

$$\text{Proj}_{S^\perp} = I - \text{Proj}_S.$$

4. [Mey00, p. 430] Let  $S$  be a  $p$ -dimensional subspace of the standard inner product space  $\mathbb{C}^n$ , and let the columns of matrices  $M \in \mathbb{C}^{n \times p}$  and  $N \in \mathbb{C}^{n \times (n-p)}$  be bases for  $S$  and  $S^\perp$ , respectively. Then the orthogonal projections onto  $S$  and  $S^\perp$  are

$$\text{Proj}_S = M(M^*M)^{-1}M^* \quad \text{and} \quad \text{Proj}_{S^\perp} = N(N^*N)^{-1}N^*.$$

If  $M$  and  $N$  contain orthonormal bases for  $S$  and  $S^\perp$ , then  $\text{Proj}_S = MM^*$  and  $\text{Proj}_{S^\perp} = NN^*$ .

5. [Lay03, p. 399] If  $\{\mathbf{u}_1, \dots, \mathbf{u}_p\}$  is an orthonormal basis for a subspace  $S$  of  $\mathbb{C}^n$ , then for any  $\mathbf{v} \in \mathbb{C}^n$ ,

$$\text{Proj}_S \mathbf{v} = (\mathbf{u}_1^* \mathbf{v}) \mathbf{u}_1 + \dots + (\mathbf{u}_p^* \mathbf{v}) \mathbf{u}_p.$$

6. [TB97, p. 46] Let  $\mathbf{v} \in \mathbb{C}^n$  be a nonzero vector. Then
  - $\text{Proj}_{\mathbf{v}} = \frac{\mathbf{v}\mathbf{v}^*}{\mathbf{v}^*\mathbf{v}}$  is the orthogonal projection onto the line  $L = \text{span}\{\mathbf{v}\}$ .
  - $\text{Proj}_{\perp \mathbf{v}} = I - \frac{\mathbf{v}\mathbf{v}^*}{\mathbf{v}^*\mathbf{v}}$  is the orthogonal projection onto  $L^\perp$ .
7. [Mey00, p. 435] (The Best Approximation Theorem) Let  $S$  be a finite dimensional subspace of an inner product space  $V$  and let  $\mathbf{b}$  be a vector in  $V$ . Then  $\text{Proj}_S \mathbf{b}$  is the unique vector in  $S$  that is closest to  $\mathbf{b}$  in the sense that

$$\min_{\mathbf{s} \in S} \|\mathbf{b} - \mathbf{s}\| = \|\mathbf{b} - \text{Proj}_S \mathbf{b}\|.$$

The vector  $\text{Proj}_S \mathbf{b}$  is called **the best approximation to  $\mathbf{b}$  by the elements of  $S$** .

**Examples:**

1. Generally, an orthogonal projection  $P \in \mathbb{C}^{n \times n}$  is not a unitary matrix.
2. Let  $\{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_n\}$  be an orthogonal basis for  $\mathbb{R}^n$  and let  $S$  the subspace of  $\mathbb{R}^n$  spanned by  $\{\mathbf{v}_1, \dots, \mathbf{v}_k\}$ , where  $1 \leq k \leq n - 1$ . Then  $\mathbf{w} = c_1 \mathbf{v}_1 + c_2 \mathbf{v}_2 + \dots + c_n \mathbf{v}_n \in \mathbb{R}^n$  can be written as  $\mathbf{w} = \mathbf{s} + \mathbf{t}$ , where  $\mathbf{s} = c_1 \mathbf{v}_1 + \dots + c_k \mathbf{v}_k \in S$  and  $\mathbf{t} = c_{k+1} \mathbf{v}_{k+1} + \dots + c_n \mathbf{v}_n \in S^\perp$ .
3. Let  $\mathbf{u}_1 = [2/3, 2/3, 1/3]^T$ ,  $\mathbf{u}_2 = [1/3, -2/3, 2/3]^T$ , and  $\mathbf{x} = [2, 3, 5]^T$ . Then  $\{\mathbf{u}_1, \mathbf{u}_2\}$  is an orthonormal basis for the subspace  $S = \text{span}\{\mathbf{u}_1, \mathbf{u}_2\}$  of  $\mathbb{R}^3$ .
  - The orthogonal projection of  $\mathbf{x}$  onto  $S$  is

$$\text{Proj}_S \mathbf{x} = \left(\mathbf{u}_1^T\right) \mathbf{x} \mathbf{u}_1 + \left(\mathbf{u}_2^T \mathbf{x}\right) \mathbf{u}_2 = [4, 2, 3]^T.$$

- The orthogonal projection of  $\mathbf{x}$  onto  $S^\perp$  is  $\mathbf{y} = \mathbf{x} - \text{Proj}_S \mathbf{x} = [-2, 1, 2]^T$ .
- The vector in  $S$  that is closest to  $\mathbf{x}$  is  $\text{Proj}_S \mathbf{x} = [4, 2, 3]^T$ .

- Let  $M = [\mathbf{u}_1, \mathbf{u}_2]$ . Then the orthogonal projection onto  $S$  is

$$\text{Proj}_S = MM^T = \frac{1}{9} \begin{bmatrix} 5 & 2 & 4 \\ 2 & 8 & -2 \\ 4 & -2 & 5 \end{bmatrix}.$$

- The orthogonal projection of any  $\mathbf{v} \in \mathbb{R}^3$  onto  $S$  can be computed by  $\text{Proj}_S \mathbf{v} = MM^T \mathbf{v}$ . In particular,  $MM^T \mathbf{x} = [4, 2, 3]^T$ .
4. Let  $\mathbf{w}_1 = [1, 1, 0]^T$  and  $\mathbf{w}_2 = [1, 0, 1]^T$ . Consider the subspace  $W = \text{span}\{\mathbf{w}_1, \mathbf{w}_2\}$  of  $\mathbb{R}^3$ . Define

the matrix  $M = [\mathbf{w}_1, \mathbf{w}_2] = \begin{bmatrix} 1 & 1 \\ 1 & 0 \\ 0 & 1 \end{bmatrix}$ . Then  $M^T M = \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix}$ .

- The orthogonal projection onto  $W$  is  $\text{Proj}_W = M(M^T M)^{-1} M^T =$

$$\begin{bmatrix} 1 & 1 \\ 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix}^{-1} \begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \end{bmatrix} = \frac{1}{3} \begin{bmatrix} 2 & 1 & 1 \\ 1 & 2 & -1 \\ 1 & -1 & 2 \end{bmatrix}.$$

- The orthogonal projection of any  $\mathbf{v} \in \mathbb{R}^3$  onto  $W$  can be computed by  $\text{Proj}_W \mathbf{v}$ . For  $\mathbf{v} = [1, 2, 3]^T$ ,  $\text{Proj}_W \mathbf{v} = \text{Proj}_W [1, 2, 3]^T = [7/3, 2/3, 5/3]^T$ .

## 5.5 Gram–Schmidt Orthogonalization and QR Factorization

### Definitions:

Let  $\{\mathbf{a}_1, \mathbf{a}_2, \dots, \mathbf{a}_n\}$  be a basis for a subspace  $S$  of an inner product space  $V$ . An orthonormal basis  $\{\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_n\}$  for  $S$  can be constructed using the following Gram–Schmidt orthogonalization process:

$$\mathbf{u}_1 = \frac{\mathbf{a}_1}{\|\mathbf{a}_1\|} \quad \text{and} \quad \mathbf{u}_k = \frac{\mathbf{a}_k - \sum_{i=1}^{k-1} \langle \mathbf{a}_k, \mathbf{u}_i \rangle \mathbf{u}_i}{\|\mathbf{a}_k - \sum_{i=1}^{k-1} \langle \mathbf{a}_k, \mathbf{u}_i \rangle \mathbf{u}_i\|}, \quad \text{for } k = 2, \dots, n.$$

A **reduced QR factorization** of  $A \in \mathbb{C}^{m \times n}$  ( $m \geq n$ ) is a factorization  $A = \hat{Q}\hat{R}$ , where  $\hat{Q} \in \mathbb{C}^{m \times n}$  has orthonormal columns and  $\hat{R} \in \mathbb{C}^{n \times n}$  is an upper triangular matrix.

A **QR factorization** of  $A \in \mathbb{C}^{m \times n}$  ( $m \geq n$ ) is a factorization  $A = QR$ , where  $Q \in \mathbb{C}^{m \times m}$  is a unitary matrix and  $R \in \mathbb{C}^{m \times n}$  is an upper triangular matrix with the last  $m - n$  rows of  $R$  being zero.

### Facts:

- [TB97, p. 51] Each  $A \in \mathbb{C}^{m \times n}$  ( $m \geq n$ ) has a full QR factorization  $A = QR$ . If  $A \in \mathbb{R}^{m \times n}$ , then both  $Q$  and  $R$  may be taken to be real.
- [TB97, p. 52] Each  $A \in \mathbb{C}^{m \times n}$  ( $m \geq n$ ) has a reduced QR factorization  $A = \hat{Q}\hat{R}$ . If  $A \in \mathbb{R}^{m \times n}$ , then both  $\hat{Q}$  and  $\hat{R}$  may be taken to be real.
- [TB97, p. 52] Each  $A \in \mathbb{C}^{m \times n}$  ( $m \geq n$ ) of full rank has a unique reduced QR factorization  $A = \hat{Q}\hat{R}$ , where  $\hat{Q} \in \mathbb{C}^{m \times n}$  and  $\hat{R} \in \mathbb{C}^{n \times n}$  with real  $r_{ii} > 0$ .
- [TB97, p. 48] The orthonormal basis  $\{\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_n\}$  generated via the Gram–Schmidt orthogonalization process has the property

$$\text{Span}(\{\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_k\}) = \text{Span}(\{\mathbf{a}_1, \mathbf{a}_2, \dots, \mathbf{a}_k\}),$$

for  $k = 1, 2, \dots, n$ .

5. [TB97, p. 51]

**Algorithm 1:** Classical Gram–Schmidt Orthogonalization:

input: a basis  $\{\mathbf{a}_1, \mathbf{a}_2, \dots, \mathbf{a}_n\}$  for a subspace  $S$

output: an orthonormal basis  $\{\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_n\}$  for  $S$

for  $j = 1 : n$

$\mathbf{u}_j := \mathbf{a}_j$

    for  $i = 1 : j - 1$

$r_{ij} := \langle \mathbf{a}_j, \mathbf{u}_i \rangle$

$\mathbf{u}_j := \mathbf{u}_j - r_{ij}\mathbf{u}_i$

    end

$r_{jj} := \|\mathbf{u}_j\|$

$\mathbf{u}_j := \mathbf{u}_j / r_{jj}$

end

6. [TB97, p. 58]

**Algorithm 2:** Modified Gram–Schmidt Orthogonalization

input: a basis  $\{\mathbf{a}_1, \mathbf{a}_2, \dots, \mathbf{a}_n\}$  for a subspace  $S$

output: an orthonormal basis  $\{\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_n\}$  for  $S$

$\mathbf{w}_i := \mathbf{a}_i, i = 1 : n$

for  $i = 1 : n$

$r_{ii} := \|\mathbf{w}_i\|$

$\mathbf{u}_i := \mathbf{w}_i / r_{ii}$

    for  $j = i + 1 : n$

$r_{ij} := \langle \mathbf{w}_j, \mathbf{u}_i \rangle$

$\mathbf{w}_j := \mathbf{w}_j - r_{ij}\mathbf{u}_i$

    end

end

7. [Mey00, p. 315] If exact arithmetic is used, then Algorithms 1 and 2 generate the same orthonormal basis  $\{\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_n\}$  and the same  $r_{ij}$ , for  $j \geq i$ .
8. [GV96, pp. 230–232] If  $A = [\mathbf{a}_1, \mathbf{a}_2, \dots, \mathbf{a}_n] \in \mathbb{C}^{m \times n}$  ( $m \geq n$ ) is of full rank  $n$ , then the classic or modified Gram–Schmidt process leads to a reduced QR factorization  $A = \hat{Q}\hat{R}$ , with  $\hat{Q} = [\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_n]$  and  $\hat{R}_{ij} = r_{ij}$ , for  $j \geq i$ , and  $\hat{R}_{ij} = 0$ , for  $j < i$ .
9. [GV96, p. 232] The costs of Algorithm 1 and Algorithm 2 are both  $2mn^2$  flops when applied to compute a reduced QR factorization of a matrix  $A \in \mathbb{R}^{m \times n}$ .
10. [Mey00, p. 317 and p. 349] For the QR factorization, Algorithm 1 and Algorithm 2 are not numerically stable. However, Algorithm 2 often yields better numerical results than Algorithm 1.
11. [Mey00, p. 349] Algorithm 2 is numerically stable when it is used to solve least squares problems.
12. (Numerically stable algorithms for computing the QR factorization using Householder reflections and Givens rotations are given in Chapter 38.)
13. [TB97, p. 54] (See also Chapter 38.) If  $A = QR$  is a QR factorization of the rank  $n$  matrix  $A \in \mathbb{C}^{n \times n}$ , then the linear system  $A\mathbf{x} = \mathbf{b}$  can be solved as follows:
  - Compute the factorization  $A = QR$ .
  - Compute the vector  $\mathbf{c} = Q^*\mathbf{b}$ .
  - Solve  $R\mathbf{x} = \mathbf{c}$  by performing back substitution.

**Examples:**

1. Consider the matrix  $A = \begin{bmatrix} 1 & 2 \\ 2 & 0 \\ 0 & 2 \end{bmatrix}$ .

- $A$  has a (full) QR factorization  $A = QR$ :

$$\begin{bmatrix} 1 & 2 \\ 2 & 0 \\ 0 & 2 \end{bmatrix} = \begin{bmatrix} \frac{1}{\sqrt{5}} & \frac{4}{3\sqrt{5}} & -\frac{2}{3} \\ \frac{2}{\sqrt{5}} & -\frac{2}{3\sqrt{5}} & \frac{1}{3} \\ 0 & \frac{\sqrt{5}}{3} & \frac{2}{3} \end{bmatrix} \begin{bmatrix} \sqrt{5} & \frac{2}{\sqrt{5}} \\ 0 & \frac{6}{\sqrt{5}} \\ 0 & 0 \end{bmatrix}.$$

- $A$  has a reduced QR factorization  $A = \hat{Q}\hat{R}$ :

$$\begin{bmatrix} 1 & 2 \\ 2 & 0 \\ 0 & 2 \end{bmatrix} = \begin{bmatrix} \frac{1}{\sqrt{5}} & \frac{4}{3\sqrt{5}} \\ \frac{2}{\sqrt{5}} & -\frac{2}{3\sqrt{5}} \\ 0 & \frac{\sqrt{5}}{3} \end{bmatrix} \begin{bmatrix} \sqrt{5} & \frac{2}{\sqrt{5}} \\ 0 & \frac{6}{\sqrt{5}} \end{bmatrix}.$$

2. Consider the matrix  $A = \begin{bmatrix} 3 & 1 & -2 \\ 3 & -4 & 1 \\ 3 & -4 & -1 \\ 3 & 1 & 0 \end{bmatrix}$ . Using the classic or modified Gram–Schmidt process

gives the following reduced QR factorization:

$$\begin{bmatrix} 3 & 1 & -2 \\ 3 & -4 & 1 \\ 3 & -4 & -1 \\ 3 & 1 & 0 \end{bmatrix} = \begin{bmatrix} \frac{1}{2} & \frac{1}{2} & -\frac{1}{2} \\ \frac{1}{2} & -\frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & -\frac{1}{2} & -\frac{1}{2} \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix} \begin{bmatrix} 6 & -3 & -1 \\ 0 & 5 & -1 \\ 0 & 0 & 2 \end{bmatrix}.$$

## 5.6 Singular Value Decomposition

---

**Definitions:**

A **singular value decomposition (SVD)** of a matrix  $A \in \mathbb{C}^{m \times n}$  is a factorization

$$A = U\Sigma V^*, \quad \Sigma = \text{diag}(\sigma_1, \sigma_2, \dots, \sigma_p) \in \mathbb{R}^{m \times n}, \quad p = \min\{m, n\},$$

where  $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_p \geq 0$  and both  $U = [\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_m] \in \mathbb{C}^{m \times m}$  and  $V = [\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_n] \in \mathbb{C}^{n \times n}$  are unitary. The diagonal entries of  $\Sigma$  are called the **singular values** of  $A$ . The columns of  $U$  are called **left singular vectors** of  $A$  and the columns of  $V$  are called **right singular vectors** of  $A$ .

Let  $A \in \mathbb{C}^{m \times n}$  with  $\text{rank } r \leq p = \min\{m, n\}$ . A **reduced singular value decomposition (reduced SVD)** of  $A$  is a factorization

$$A = \hat{U}\hat{\Sigma}\hat{V}^*, \quad \hat{\Sigma} = \text{diag}(\sigma_1, \sigma_2, \dots, \sigma_r) \in \mathbb{R}^{r \times r},$$

where  $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_r > 0$  and the columns of  $\hat{U} = [\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_r] \in \mathbb{C}^{m \times r}$  and the columns of  $\hat{V} = [\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_r] \in \mathbb{C}^{n \times r}$  are both orthonormal.

(See §8.4 and §3.7 for more information on singular value decomposition.)

**Facts:**

All the following facts except those with a specific reference can be found in [TB97, pp. 25–37].

1. Every  $A \in \mathbb{C}^{m \times n}$  has a singular value decomposition  $A = U\Sigma V^*$ . If  $A \in \mathbb{R}^{m \times n}$ , then  $U$  and  $V$  may be taken to be real.
2. The singular values of a matrix are uniquely determined.
3. If  $A \in \mathbb{C}^{m \times n}$  has a singular value decomposition  $A = U\Sigma V^*$ , then

$$A\mathbf{v}_j = \sigma_j \mathbf{u}_j, \quad A^* \mathbf{u}_j = \sigma_j \mathbf{v}_j, \quad \mathbf{u}_j^* A \mathbf{v}_j = \sigma_j,$$

for  $j = 1, 2, \dots, p = \min\{m, n\}$ .

4. If  $U\Sigma V^*$  is a singular value decomposition of  $A$ , then  $V\Sigma^T U^*$  is a singular value decomposition of  $A^*$ .
5. If  $A \in \mathbb{C}^{m \times n}$  has  $r$  nonzero singular values, then
  - $\text{rank}(A) = r$ .
  - $A = \sum_{j=1}^r \sigma_j \mathbf{u}_j \mathbf{v}_j^*$ .
  - $\ker(A) = \text{span}\{\mathbf{v}_{r+1}, \dots, \mathbf{v}_n\}$ .
  - $\text{range}(A) = \text{span}\{\mathbf{u}_1, \dots, \mathbf{u}_r\}$ .
6. Any  $A \in \mathbb{C}^{m \times n}$  of rank  $r \leq p = \min\{m, n\}$  has a **reduced singular value decomposition**,

$$A = \hat{U} \hat{\Sigma} \hat{V}^*, \quad \hat{\Sigma} = \text{diag}(\sigma_1, \sigma_2, \dots, \sigma_r) \in \mathbb{R}^{r \times r},$$

where  $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_r > 0$  and the columns of  $\hat{U} = [\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_r] \in \mathbb{C}^{m \times r}$  and the columns of  $\hat{V} = [\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_r] \in \mathbb{C}^{n \times r}$  are both orthonormal. If  $A \in \mathbb{R}^{m \times n}$ , then  $\hat{U}$  and  $\hat{V}$  may be taken to be real.

7. If  $\text{rank}(A) = r$ , then  $A$  has  $r$  nonzero singular values.
8. The nonzero singular values of  $A$  are the square roots of the nonzero eigenvalues of  $A^*A$  or  $AA^*$ .
9. [HJ85, p. 414] If  $U\Sigma V^*$  is a singular value decomposition of  $A$ , then the columns of  $V$  are eigenvectors of  $A^*A$ ; the columns of  $U$  are eigenvectors of  $AA^*$ .
10. [HJ85, p. 418] Let  $A \in \mathbb{C}^{m \times n}$  and  $p = \min\{m, n\}$ . Define

$$G = \begin{bmatrix} 0 & A \\ A^* & 0 \end{bmatrix} \in \mathbb{C}^{(m+n) \times (m+n)}.$$

If the singular values of  $A$  are  $\sigma_1, \dots, \sigma_p$ , then the eigenvalues of  $G$  are  $\sigma_1, \dots, \sigma_p, -\sigma_1, \dots, -\sigma_p$  and additional  $|n - m|$  zeros.

11. If  $A \in \mathbb{C}^{n \times n}$  is Hermitian with eigenvalues  $\lambda_1, \lambda_2, \dots, \lambda_n$ , then the singular values of  $A$  are  $|\lambda_1|, |\lambda_2|, \dots, |\lambda_n|$ .
12. For  $A \in \mathbb{C}^{n \times n}$ ,  $|\det A| = \sigma_1 \sigma_2 \dots \sigma_n$ .
13. [Aut15; Sch07] (**Eckart–Young Low Rank Approximation Theorem**)

Let  $A = U\Sigma V^*$  be an SVD of  $A \in \mathbb{C}^{m \times n}$  and  $r = \text{rank}(A)$ . For  $k < r$ , define  $A_k = \sum_{j=1}^k \sigma_j \mathbf{u}_j \mathbf{v}_j^*$ . Then

- $\|A - A_k\|_2 = \min_{\text{rank}(B) \leq k} \|A - B\|_2 = \sigma_{k+1}$ ;
- $\|A - A_k\|_F = \min_{\text{rank}(B) \leq k} \|A - B\|_F = \sqrt{\sum_{j=k+1}^r \sigma_j^2}$ ,

where  $\|M\|_2 = \max_{\|x\|_2=1} \|Mx\|_2$  and  $\|M\|_F = \sqrt{\sum_{i=1}^m \sum_{j=1}^n m_{ij}^2}$  are the 2-norm and Frobenius norm of matrix  $M$ , respectively. (See Chapter 37 for more information on matrix norms.)

**Examples:**

Consider the matrices  $A = \begin{bmatrix} 1 & 2 \\ 2 & 0 \\ 0 & 2 \end{bmatrix}$  and  $B = A^T = \begin{bmatrix} 1 & 2 & 0 \\ 2 & 0 & 2 \end{bmatrix}$ .

1. The eigenvalues of  $A^T A = \begin{bmatrix} 5 & 2 \\ 2 & 8 \end{bmatrix}$  are 9 and 4. So, the singular values of  $A$  are 3 and 2.

2. Normalized eigenvectors for  $A^T A$  are  $\mathbf{v}_1 = \begin{bmatrix} \frac{1}{\sqrt{5}} \\ \frac{2}{\sqrt{5}} \end{bmatrix}$  and  $\mathbf{v}_2 = \begin{bmatrix} \frac{2}{\sqrt{5}} \\ -\frac{1}{\sqrt{5}} \end{bmatrix}$ .

3.  $\mathbf{u}_1 = \frac{1}{3} A \mathbf{v}_1 = \begin{bmatrix} \frac{\sqrt{5}}{3} \\ \frac{2}{3\sqrt{5}} \\ \frac{4}{3\sqrt{5}} \end{bmatrix}$  and  $\mathbf{u}_2 = \frac{1}{2} A \mathbf{v}_2 = \begin{bmatrix} 0 \\ \frac{2}{\sqrt{5}} \\ -\frac{1}{\sqrt{5}} \end{bmatrix}$ . Application of the Gram–Schmidt process to

$\mathbf{u}_1$ ,  $\mathbf{u}_2$ , and  $\mathbf{e}_1$  produces  $\mathbf{u}_3 = \begin{bmatrix} \frac{2}{3} \\ -\frac{1}{3} \\ -\frac{2}{3} \end{bmatrix}$ .

4.  $A$  has the singular value decomposition  $A = U \Sigma V^T$ , where

$$U = \frac{1}{3\sqrt{5}} \begin{bmatrix} 5 & 0 & 2\sqrt{5} \\ 2 & 6 & -\sqrt{5} \\ 4 & -3 & -2\sqrt{5} \end{bmatrix}, \quad \Sigma = \begin{bmatrix} 3 & 0 \\ 0 & 2 \\ 0 & 0 \end{bmatrix}, \quad V = \frac{1}{\sqrt{5}} \begin{bmatrix} 1 & 2 \\ 2 & -1 \end{bmatrix}.$$

5.  $A$  has the reduced singular value decomposition  $A = \hat{U} \hat{\Sigma} \hat{V}^T$ , where

$$\hat{U} = \frac{1}{3\sqrt{5}} \begin{bmatrix} 5 & 0 \\ 2 & 6 \\ 4 & -3 \end{bmatrix}, \quad \hat{\Sigma} = \begin{bmatrix} 3 & 0 \\ 0 & 2 \end{bmatrix}, \quad \hat{V} = \frac{1}{\sqrt{5}} \begin{bmatrix} 1 & 2 \\ 2 & -1 \end{bmatrix}.$$

6.  $B$  has the singular value decomposition  $B = U_B \Sigma_B V_B^T$ , where

$$U_B = V_A = \frac{1}{\sqrt{5}} \begin{bmatrix} 1 & 2 \\ 2 & -1 \end{bmatrix}, \quad \Sigma_B = \begin{bmatrix} 3 & 0 & 0 \\ 0 & 2 & 0 \end{bmatrix}, \quad V_B = U_A = \frac{1}{3\sqrt{5}} \begin{bmatrix} 5 & 0 & 2\sqrt{5} \\ 2 & 6 & -\sqrt{5} \\ 4 & -3 & -2\sqrt{5} \end{bmatrix}.$$

( $U_A = U$  and  $V_A = V$  for  $A$  were given in Example 4.)

## 5.7 Pseudo-Inverse

---

**Definitions:**

A **Moore–Penrose pseudo-inverse** of a matrix  $A \in \mathbb{C}^{m \times n}$  is a matrix  $A^\dagger \in \mathbb{C}^{n \times m}$  that satisfies the following four **Penrose** conditions:

$$AA^\dagger A = A; \quad A^\dagger AA^\dagger = A^\dagger; \quad (AA^\dagger)^* = AA^\dagger; \quad (A^\dagger A)^* = A^\dagger A.$$

**Facts:**

All the following facts except those with a specific reference can be found in [Gra83, pp. 105–141].

1. Every  $A \in \mathbb{C}^{m \times n}$  has a unique pseudo-inverse  $A^\dagger$ . If  $A \in \mathbb{R}^{m \times n}$ , then  $A^\dagger$  is real.

2. [LH95, p. 38] If  $A \in \mathbb{C}^{m \times n}$  of rank  $r \leq \min\{m, n\}$  has an SVD  $A = U\Sigma V^*$ , then its pseudo-inverse is  $A^\dagger = V\Sigma^\dagger U^*$ , where

$$\Sigma^\dagger = \text{diag}(1/\sigma_1, \dots, 1/\sigma_r, 0, \dots, 0) \in \mathbb{R}^{n \times m}.$$

3.  $\mathbf{0}_{mn}^\dagger = \mathbf{0}_{nm}$  and  $J_{mn}^\dagger = \frac{1}{mn} J_{nm}$ , where  $\mathbf{0}_{mn} \in \mathbb{C}^{m \times n}$  is the all 0s matrix and  $J_{mn} \in \mathbb{C}^{m \times n}$  is the all 1s matrix.
4.  $(A^\dagger)^* = (A^*)^\dagger$ ;  $(A^\dagger)^\dagger = A$ .
5. If  $A$  is a nonsingular square matrix, then  $A^\dagger = A^{-1}$ .
6. If  $U$  has orthonormal columns or orthonormal rows, then  $U^\dagger = U^*$ .
7. If  $A = A^*$  and  $A = A^2$ , then  $A^\dagger = A$ .
8.  $A^\dagger = A^*$  if and only if  $A^*A$  is idempotent.
9. If  $A = A^*$ , then  $AA^\dagger = A^\dagger A$ .
10. If  $U \in \mathbb{C}^{m \times n}$  is of rank  $n$  and satisfies  $U^\dagger = U^*$ , then  $U$  has orthonormal columns.
11. If  $U \in \mathbb{C}^{m \times m}$  and  $V \in \mathbb{C}^{n \times n}$  are unitary matrices, then  $(UAV)^\dagger = V^*A^\dagger U^*$ .
12. If  $A \in \mathbb{C}^{m \times n}$  ( $m \geq n$ ) has full rank  $n$ , then  $A^\dagger = (A^*A)^{-1}A^*$ .
13. If  $A \in \mathbb{C}^{m \times n}$  ( $m \leq n$ ) has full rank  $m$ , then  $A^\dagger = A^*(AA^*)^{-1}$ .
14. Let  $A \in \mathbb{C}^{m \times n}$ . Then
  - $A^\dagger A$ ,  $AA^\dagger$ ,  $I_n - A^\dagger A$ , and  $I_m - AA^\dagger$  are orthogonal projections.
  - $\text{rank}(A) = \text{rank}(A^\dagger) = \text{rank}(AA^\dagger) = \text{rank}(A^\dagger A)$ .
  - $\text{rank}(I_n - A^\dagger A) = n - \text{rank}(A)$ .
  - $\text{rank}(I_m - AA^\dagger) = m - \text{rank}(A)$ .
15. If  $A = A_1 + A_2 + \dots + A_k$ ,  $A_i^*A_j = 0$ , and  $A_iA_j^* = 0$ , for all  $i, j = 1, \dots, k$ ,  $i \neq j$ , then  $A^\dagger = A_1^\dagger + A_2^\dagger + \dots + A_k^\dagger$ .
16. If  $A$  is an  $m \times r$  matrix of rank  $r$  and  $B$  is an  $r \times n$  matrix of rank  $r$ , then  $(AB)^\dagger = B^\dagger A^\dagger$ .
17.  $(A^*A)^\dagger = A^\dagger(A^*)^\dagger$ ;  $(AA^*)^\dagger = (A^*)^\dagger A^\dagger$ .
18. [Gre66] Each one of the following conditions is necessary and sufficient for  $(AB)^\dagger = B^\dagger A^\dagger$ :
  - $\text{range}(BB^*A^*) \subseteq \text{range}(A^*)$  and  $\text{range}(A^*AB) \subseteq \text{range}(B)$ .
  - $A^\dagger ABB^*$  and  $A^*ABB^\dagger$  are both Hermitian matrices.
  - $A^\dagger ABB^*A^* = BB^*A^*$  and  $BB^\dagger A^*AB = A^*AB$ .
  - $A^\dagger ABB^*A^*ABB^\dagger = BB^*A^*$ .
  - $A^\dagger AB = B(AB)^\dagger AB$  and  $BB^\dagger A^* = A^*AB(AB)^\dagger$ .
19. Let  $A \in \mathbb{C}^{m \times n}$  and  $\mathbf{b} \in \mathbb{C}^m$ . Then the system of equations  $A\mathbf{x} = \mathbf{b}$  is consistent if and only if  $AA^\dagger\mathbf{b} = \mathbf{b}$ . Moreover, if  $A\mathbf{x} = \mathbf{b}$  is consistent, then any solution to the system can be expressed as  $\mathbf{x} = A^\dagger\mathbf{b} + (I_n - A^\dagger A)\mathbf{y}$  for some  $\mathbf{y} \in \mathbb{C}^n$ .

**Examples:**

1. The pseudo-inverse of the matrix  $A = \begin{bmatrix} 1 & 2 \\ 2 & 0 \\ 0 & 2 \end{bmatrix}$  is  $A^\dagger = \frac{1}{18} \begin{bmatrix} 2 & 8 & -2 \\ 4 & -2 & 5 \end{bmatrix}$ .
2.  $(AB)^\dagger = B^\dagger A^\dagger$  generally does not hold. For example, if

$$A = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix},$$

then

$$(AB)^\dagger = \begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix}^\dagger = \frac{1}{2} \begin{bmatrix} 1 & 0 \\ 1 & 0 \end{bmatrix}.$$

However,

$$B^\dagger A^\dagger = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}.$$

## 5.8 Least Squares Problems

---

### Definitions:

Given  $A \in F^{m \times n}$  ( $F = \mathbb{R}$  or  $\mathbb{C}$ ),  $m \geq n$ , and  $\mathbf{b} \in F^m$ , the **least squares problem** is to find an  $\mathbf{x}_0 \in F^n$  such that  $\|\mathbf{b} - A\mathbf{x}\|$  is minimized:  $\|\mathbf{b} - A\mathbf{x}_0\| = \min_{\mathbf{x} \in F^n} \|\mathbf{b} - A\mathbf{x}\|$ .

- Such an  $\mathbf{x}_0$  is called a **solution** to the least squares problem or a **least squares solution** to the linear system  $A\mathbf{x} = \mathbf{b}$ .
- The vector  $\mathbf{r} = \mathbf{b} - A\mathbf{x} \in F^m$  is called the **residual**.
- If  $\text{rank}(A) = n$ , then the least squares problem is called the **full rank least squares problem**.
- If  $\text{rank}(A) < n$ , then the least squares problem is called the **rank-deficient least squares problem**.

The system  $A^*A\mathbf{x} = A^*\mathbf{b}$  is called the **normal equation** for the least squares problem.

(See Chapter 39 for more information on least squares problems.)

### Facts:

1. [Mey00, p. 439] Let  $A \in F^{m \times n}$  ( $F = \mathbb{R}$  or  $\mathbb{C}$ ,  $m \geq n$ ) and  $\mathbf{b} \in F^m$  be given. Then the following statements are equivalent:
  - $\mathbf{x}_0$  is a solution for the least squares problem.
  - $\min_{\mathbf{x} \in F^n} \|\mathbf{b} - A\mathbf{x}\| = \|\mathbf{b} - A\mathbf{x}_0\|$ .
  - $A\mathbf{x}_0 = P\mathbf{b}$ , where  $P$  is the orthogonal projection onto  $\text{range}(A)$ .
  - $A^*\mathbf{r}_0 = \mathbf{0}$ , where  $\mathbf{r}_0 = \mathbf{b} - A\mathbf{x}_0$ .
  - $A^*A\mathbf{x}_0 = A^*\mathbf{b}$ .
  - $\mathbf{x}_0 = A^\dagger\mathbf{b} + \mathbf{y}_0$  for some  $\mathbf{y}_0 \in \ker(A)$ .
2. [LH95, p. 36] If  $A \in F^{m \times n}$  ( $F = \mathbb{R}$  or  $\mathbb{C}$ ,  $m \geq n$ ) and  $\text{rank}(A) = r \leq n$ , then  $\mathbf{x}_0 = A^\dagger\mathbf{b}$  is the unique solution of minimum length for the least squares problem.
3. [TB97, p. 81] If  $A \in F^{m \times n}$  ( $F = \mathbb{R}$  or  $\mathbb{C}$ ,  $m \geq n$ ) has full rank, then  $\mathbf{x}_0 = A^\dagger\mathbf{b} = (A^*A)^{-1}A^*\mathbf{b}$  is the unique solution for the least squares problem.
4. [TB97, p. 83]

#### Algorithm 3: Solving Full Rank Least Squares via QR Factorization

input: matrix  $A \in F^{m \times n}$  ( $F = \mathbb{R}$  or  $\mathbb{C}$ ,  $m \geq n$ ) with full rank  $n$  and vector  $\mathbf{b} \in F^m$

output: solution  $\mathbf{x}_0$  for  $\min_{\mathbf{x} \in F^n} \|\mathbf{b} - A\mathbf{x}\|$

compute the reduced QR factorization  $A = \hat{Q}\hat{R}$ ;

compute the vector  $\mathbf{c} = \hat{Q}^*\mathbf{b}$ ;

solve  $\hat{R}\mathbf{x}_0 = \mathbf{c}$  using back substitution.

5. [TB97, p. 84]

**Algorithm 4:** Solving Full Rank Least Squares via SVD  
 input: matrix  $A \in F^{m \times n}$  ( $F = \mathbb{R}$  or  $\mathbb{C}$ ,  $m \geq n$ ) with full rank  $n$  and vector  $\mathbf{b} \in F^m$   
 output : solution  $\mathbf{x}_0$  for  $\min_{\mathbf{x} \in F^n} \|\mathbf{b} - A\mathbf{x}\|$   
     compute the reduced SVD  $A = \hat{U}\hat{\Sigma}\hat{V}^*$  with  $\hat{\Sigma} = \text{diag}(\sigma_1, \sigma_2, \dots, \sigma_n)$ ;  
     compute the vector  $\mathbf{c} = \hat{U}^*\mathbf{b}$ ;  
     compute the vector  $\mathbf{y}$ :  $y_i = c_i/\sigma_i$ ,  $i = 1, 2, \dots, n$ ;  
     compute  $\mathbf{x}_0 = \hat{V}\mathbf{y}$ .

6. [TB97, p. 82]

**Algorithm 5:** Solving Full Rank Least Squares via Normal Equations  
 input: matrix  $A \in F^{m \times n}$  ( $F = \mathbb{R}$  or  $\mathbb{C}$ ,  $m \geq n$ ) with full rank  $n$  and vector  $\mathbf{b} \in F^m$   
 output : solution  $\mathbf{x}_0$  for  $\min_{\mathbf{x} \in F^n} \|\mathbf{b} - A\mathbf{x}\|$   
     compute the matrix  $A^*A$  and the vector  $\mathbf{c} = A^*\mathbf{b}$ ;  
     solve the system  $A^*A\mathbf{x}_0 = \mathbf{c}$  via the Cholesky factorization.

**Examples:**

1. Consider the inconsistent linear system  $A\mathbf{x} = \mathbf{b}$ , where

$$A = \begin{bmatrix} 1 & 2 \\ 2 & 0 \\ 0 & 2 \end{bmatrix}, \quad \mathbf{b} = \begin{bmatrix} 1 \\ 2 \\ 3 \end{bmatrix}.$$

Then the normal equations are given by  $A^T A\mathbf{x} = A^T \mathbf{b}$ , where

$$A^T A = \begin{bmatrix} 5 & 2 \\ 2 & 8 \end{bmatrix} \quad \text{and} \quad A^T \mathbf{b} = \begin{bmatrix} 5 \\ 8 \end{bmatrix}.$$

A least squares solution to the system  $A\mathbf{x} = \mathbf{b}$  can be obtained via solving the normal equations:

$$\mathbf{x}_0 = (A^T A)^{-1} A^T \mathbf{b} = A^\dagger \mathbf{b} = \begin{bmatrix} 2/3 \\ 5/6 \end{bmatrix}.$$

2. We use Algorithm 3 to find a least squares solution of the system  $A\mathbf{x} = \mathbf{b}$  given in Example 1. The reduced QR factorization  $A = \hat{Q}\hat{R}$  found in Example 1 in Section 5.5 gives

$$\hat{Q}^T \mathbf{b} = \begin{bmatrix} \frac{1}{\sqrt{5}} & \frac{4}{3\sqrt{5}} \\ \frac{2}{\sqrt{5}} & -\frac{2}{3\sqrt{5}} \\ 0 & \frac{\sqrt{5}}{3} \end{bmatrix}^T \begin{bmatrix} 1 \\ 2 \\ 3 \end{bmatrix} = \begin{bmatrix} \sqrt{5} \\ \sqrt{5} \\ 3 \end{bmatrix}.$$

Now solving  $\hat{R}\mathbf{x} = [\sqrt{5}, \sqrt{5}]^T$  gives the least squares solution  $\mathbf{x}_0 = [2/3, 5/6]^T$ .

3. We use Algorithm 4 to solve the same problem given in Example 1. Using the reduced singular value decomposition  $A = \hat{U}\hat{\Sigma}\hat{V}^T$  obtained in Example 5, Section 5.6, we have

$$\mathbf{c} = \hat{U}^T \mathbf{b} = \frac{1}{3\sqrt{5}} \begin{bmatrix} 5 & 0 \\ 2 & 6 \\ 4 & -3 \end{bmatrix}^T \begin{bmatrix} 1 \\ 2 \\ 3 \end{bmatrix} = \begin{bmatrix} \frac{7}{\sqrt{5}} \\ \frac{1}{\sqrt{5}} \end{bmatrix}.$$

Now we compute  $\mathbf{y} = [y_1, y_2]^T$ :

$$y_1 = c_1/\sigma_1 = \frac{7}{3\sqrt{5}} \quad \text{and} \quad y_2 = c_2/\sigma_2 = \frac{1}{2\sqrt{5}}.$$

Finally, the least squares solution is obtained via

$$\mathbf{x}_0 = \hat{V}\mathbf{y} = \frac{1}{\sqrt{5}} \begin{bmatrix} 1 & 2 \\ 2 & -1 \end{bmatrix} \begin{bmatrix} \frac{7}{3\sqrt{5}} \\ \frac{1}{2\sqrt{5}} \end{bmatrix} = \begin{bmatrix} 2/3 \\ 5/6 \end{bmatrix}.$$

Leslie Hogben  
*Iowa State University*

A *canonical form* of a matrix is a special form with the properties that every matrix is associated to a matrix in that form (the canonical form of the matrix), it is unique or essentially unique (typically up to some type of permutation), and it has a particularly simple form (or a form well suited to a specific purpose). A canonical form partitions the set matrices in  $F^{m \times n}$  into sets of matrices each having the same canonical form, and that canonical form matrix serves as the representative. The canonical form of a given matrix can provide important information about the matrix. For example, reduced row echelon form (RREF) is a canonical form that is useful in solving systems of linear equations; RREF partitions  $F^{m \times n}$  into sets of row equivalent matrices.

The previous definition of a canonical form is far more general than the canonical forms discussed in this chapter. Here all matrices are square, and every matrix is similar to its canonical form. This chapter discusses the two most important canonical forms for square matrices over fields, the Jordan canonical form (and its real version) and (two versions of) the rational canonical form. These canonical forms capture the eigenstructure of a matrix and play important roles in many areas, for example, in matrix functions, Chapter 11, and in differential equations, Chapter 55. These canonical forms partition  $F^{n \times n}$  into similarity classes.

The Jordan canonical form is most often used when all eigenvalues of the matrix  $A \in F^{n \times n}$  lie in the field  $F$ , such as when the field is algebraically closed (e.g.,  $\mathbb{C}$ ), or when the field is  $\mathbb{R}$ ; otherwise the rational canonical form is used (e.g., for  $\mathbb{Q}$ ). The Smith normal form is a canonical form for square matrices over principal ideal domains (see Chapter 23); it is discussed here only as it pertains to the computation of the rational canonical form. If any one of these canonical forms is known, it is straightforward to determine the others (perhaps in the algebraic closure of the field  $F$ ). Details are given in the sections on rational canonical form.

Results about each type of canonical form are presented in the section on that canonical form, which facilitates locating a result, but obscures the connections underlying the derivations of the results. The facts about all of the canonical forms discussed in this section can be derived from results about modules over a principal ideal domain; such a module-theoretic treatment is typically presented in abstract algebra texts, such as [DF04, Chap. 12].

None of the canonical forms discussed in this chapter is a continuous function of the entries of a matrix and, thus, the computation of such a canonical form is inherently unstable in finite precision arithmetic. (For information about perturbation theory of eigenvalues see Chapter 15; for information specifically about numerical computation of the Jordan canonical form, see [GV96, Chapter 7.6.5].)

## 6.1 Generalized Eigenvectors

The reader is advised to consult Section 4.3 for information about eigenvalues and eigenvectors. In this section and the next,  $F$  is taken to be an algebraically closed field to ensure that an  $n \times n$  matrix has  $n$  eigenvalues, but many of the results could be rephrased for a matrix that has all its eigenvalues in  $F$ , without the assumption that  $F$  is algebraically closed. The real versions of the definitions and results are presented in Section 6.3.

### Definitions:

Let  $F$  be an algebraically closed field (e.g.,  $\mathbb{C}$ ), let  $A \in F^{n \times n}$ , let  $\mu_1, \dots, \mu_r$  be the distinct eigenvalues of  $A$ , and let  $\lambda$  be any eigenvalue of  $A$ .

For  $k$  a nonnegative integer, the  $k$ -**eigenspace** of  $A$  at  $\lambda$ , denoted  $N_\lambda^k(A)$ , is  $\ker(A - \lambda I)^k$ .

The **index** of  $A$  at  $\lambda$ , denoted  $v_\lambda(A)$ , is the smallest integer  $k$  such that  $N_\lambda^k(A) = N_\lambda^{k+1}(A)$ . When  $\lambda$  and  $A$  are clear from the context,  $v_\lambda(A)$  will be abbreviated to  $v$ , and  $v_{\mu_i}(A)$  to  $v_i$ .

The **generalized eigenspace** of  $A$  at  $\lambda$  is the set  $N_\lambda^v(A)$ , where  $v$  is the index of  $A$  at  $\lambda$ .

The vector  $\mathbf{x} \in F^n$  is a **generalized eigenvector** of  $A$  for  $\lambda$  if  $\mathbf{x} \neq \mathbf{0}$  and  $\mathbf{x} \in N_\lambda^v(A)$ .

Let  $V$  be a finite dimensional vector space over  $F$ , and let  $T$  be a linear operator on  $V$ . The definitions of  $k$ -**eigenspace** of  $T$ , **index**, and **generalized eigenspace** of  $T$  are analogous.

### Facts:

Facts requiring proof for which no specific reference is given can be found in [HJ85, Chapter 3] or [Mey00, Chapter 7.8].

Notation:  $F$  is an algebraically closed field,  $A \in F^{n \times n}$ ,  $V$  is an  $n$  dimensional vector space over  $F$ ,  $T \in L(V, V)$ ,  $\mu_1, \dots, \mu_r$  are the distinct eigenvalues of  $A$  or  $T$ , and  $\lambda = \mu_i$  for some  $i \in \{1, \dots, r\}$ .

1. An eigenvector for eigenvalue  $\lambda$  is a generalized eigenvector for  $\lambda$ , but the converse is not necessarily true.
2. The eigenspace for  $\lambda$  is the 1-eigenspace, i.e.,  $E_\lambda(A) = N_\lambda^1(A)$ .
3. Every  $k$ -eigenspace is invariant under multiplication by  $A$ .
4. The dimension of the generalized eigenspace of  $A$  at  $\lambda$  is the algebraic multiplicity of  $\lambda$ , i.e.,  $\dim N_{\mu_i}^{v_i}(A) = \alpha_A(\mu_i)$ .
5.  $A$  is diagonalizable if and only if  $v_i = 1$  for  $i = 1, \dots, r$ .
6.  $F^n$  is the vector space direct sum of the generalized eigenspaces, i.e.,

$$F^n = N_{\mu_1}^{v_1}(A) \oplus \cdots \oplus N_{\mu_r}^{v_r}(A).$$

This is a special case of the Primary Decomposition Theorem (Fact 12 in Section 6.4).

7. Facts 1 to 6 remain true when the matrix  $A$  is replaced by the linear operator  $T$ .
8. If  $\hat{T}$  denotes  $T$  restricted to  $N_{\mu_i}^{v_i}(T)$ , then the characteristic polynomial of  $\hat{T}$  is  $p_{\hat{T}}(x) = (x - \mu_i)^{\alpha(\mu_i)}$ . In particular,  $\hat{T} - \mu_i I$  is nilpotent.

**Examples:**

$$1. \text{ Let } A = \begin{bmatrix} 65 & 18 & -21 & 4 \\ -201 & -56 & 63 & -12 \\ 67 & 18 & -23 & 4 \\ 134 & 36 & -42 & 6 \end{bmatrix} \in \mathbb{C}^{4 \times 4}. \quad p_A(x) = x^4 + 8x^3 + 24x^2 + 32x + 16 = (x + 2)^4,$$

so the only eigenvalue of  $A$  is  $-2$  with algebraic multiplicity 4. The reduced row echelon form of

$$A + 2I \text{ is } \begin{bmatrix} 1 & \frac{18}{67} & -\frac{21}{67} & \frac{4}{67} \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \text{ so } N_{-2}^1(A) = \text{Span} \left( \begin{bmatrix} -18 \\ 67 \\ 0 \\ 0 \end{bmatrix}, \begin{bmatrix} 21 \\ 0 \\ 67 \\ 0 \end{bmatrix}, \begin{bmatrix} -4 \\ 0 \\ 0 \\ 67 \end{bmatrix} \right).$$

$(A + 2I)^2 = 0$ , so  $N_{-2}^2(A) = \mathbb{C}^4$ . Any vector not in  $N_{-2}^1(A)$ , e.g.,  $\mathbf{e}_1 = [1, 0, 0, 0]^T$ , is a generalized eigenvector for  $-2$  that is not an eigenvector for  $-2$ .

## 6.2 Jordan Canonical Form

The Jordan canonical form is perhaps the single most important and widely used similarity-based canonical form for (square) matrices.

**Definitions:**

Let  $F$  be an algebraically closed field (e.g.,  $\mathbb{C}$ ), and let  $A \in F^{n \times n}$ . (The real versions of the definitions and results are presented in Section 6.3.)

For  $\lambda \in F$  and positive integer  $k$ , the **Jordan block** of size  $k$  with eigenvalue  $\lambda$  is the  $k \times k$  matrix having every diagonal entry equal to  $\lambda$ , every first superdiagonal entry equal to 1, and every other entry equal to 0, i.e.,

$$J_k(\lambda) = \begin{bmatrix} \lambda & 1 & 0 & \cdots & 0 \\ 0 & \lambda & 1 & & 0 \\ \vdots & \ddots & \ddots & \ddots & \\ 0 & \cdots & 0 & \lambda & 1 \\ 0 & \cdots & 0 & 0 & \lambda \end{bmatrix}.$$

A **Jordan matrix** (or a **matrix in Jordan canonical form**) is a block diagonal matrix having Jordan blocks as the diagonal blocks, i.e., a matrix of the form  $J_{k_1}(\lambda_1) \oplus \cdots \oplus J_{k_t}(\lambda_t)$  for some positive integers  $t, k_1, \dots, k_t$  and some  $\lambda_1, \dots, \lambda_t \in F$ . (Note: the  $\lambda_i$  need not be distinct.)

A **Jordan canonical form** of matrix  $A$ , denoted  $J_A$  or  $\text{JCF}(A)$ , is a Jordan matrix that is similar to  $A$ . It is conventional to group the blocks for the same eigenvalue together and to order the Jordan blocks with the same eigenvalue in nonincreasing size order.

The **Jordan invariants** of  $A$  are the following parameters:

- The set of distinct eigenvalues of  $A$ .
- For each eigenvalue  $\lambda$ , the number  $b_\lambda$  and sizes  $p_1, \dots, p_{b_\lambda}$  of the Jordan blocks with eigenvalue  $\lambda$  in a Jordan canonical form of  $A$ .

The **total number of Jordan blocks** in a Jordan canonical form of  $A$  is  $\sum b_\mu$ , where the sum is taken over all distinct eigenvalues  $\mu$ .

If  $J_A = C^{-1}AC$ , then the ordered set of columns of  $C$  is called a **Jordan basis** for  $A$ .

Let  $\mathbf{x}$  be an eigenvector for eigenvalue  $\lambda$  of  $A$ . If  $\mathbf{x} \in \text{range}(A - \lambda I)^h - \text{range}(A - \lambda I)^{h+1}$ . Then  $h$  is called the **depth** of  $\mathbf{x}$ .

Let  $\mathbf{x}$  be an eigenvector of depth  $h$  for eigenvalue  $\lambda$  of  $A$ . A **Jordan chain** above  $\mathbf{x}$  is a sequence of vectors  $\mathbf{x}_0 = \mathbf{x}, \mathbf{x}_1, \dots, \mathbf{x}_h$  satisfying  $\mathbf{x}_i = (A - \lambda I)\mathbf{x}_{i+1}$  for  $i = 0, \dots, h - 1$ .

Let  $V$  be a finite dimensional vector space over  $F$ , and let  $T$  be a linear operator on  $V$ .

A **Jordan basis** for  $T$  is an ordered basis  $\mathcal{B}$  of  $V$ , with respect to which the matrix  ${}_B[T]_B$  of  $T$  is a Jordan matrix. In this case,  ${}_B[T]_B$  is a Jordan canonical form of  $T$ , denoted  $\text{JCF}(T)$  or  $J_T$ , and the **Jordan invariants** of  $T$  are the Jordan invariants of  $\text{JCF}(T) =_B [T]_B$ .

### Facts:

Facts requiring proof for which no specific reference is given can be found in [HJ85, Chapter 3] or [Mey00, Chapter 7.8].

*Notation:*  $F$  is an algebraically closed field,  $A, B \in F^{n \times n}$ , and  $\lambda$  is an eigenvalue of  $A$ .

1.  $A$  has a Jordan canonical form  $J_A$ , and  $J_A$  is unique up to permutation of the Jordan blocks. In particular, the Jordan invariants of  $A$  are uniquely determined by  $A$ .
2.  $A, B$  are similar if and only if they have the same Jordan invariants.
3. The Jordan invariants and, hence, the Jordan canonical form of  $A$  can be found from the eigenvalues and the ranks of powers of  $A - \lambda I$ . Specifically, the number of Jordan blocks of size  $k$  in  $J_A$  with eigenvalue  $\lambda$  is

$$\text{rank}(A - \lambda I)^{k-1} + \text{rank}(A - \lambda I)^{k+1} - 2 \text{rank}(A - \lambda I)^k.$$

4. The total number of Jordan blocks in a Jordan canonical form of  $A$  is the maximal number of linearly independent eigenvectors of  $A$ .
5. The number  $b_\lambda$  of Jordan blocks with eigenvalue  $\lambda$  in  $J_A$  equals the geometric multiplicity  $\gamma_A(\lambda)$  of  $\lambda$ .  $A$  is nonderogatory if and only if for each eigenvalue  $\lambda$  of  $A$ ,  $J_A$  has exactly one block with  $\lambda$ .
6. The size of the largest Jordan block with eigenvalue  $\lambda$  equals the multiplicity of  $\lambda$  as a root of the minimal polynomial  $q_A(x)$  of  $A$ .
7. The size of the largest Jordan block with eigenvalue  $\lambda$  equals the size of the index  $\nu_\lambda(A)$  of  $A$  at  $\lambda$ .
8. The sum of the sizes of all the Jordan blocks with eigenvalue  $\lambda$  in  $J_A$  (i.e., the number of times  $\lambda$  appears on the diagonal of the Jordan canonical form) equals the algebraic multiplicity  $\alpha_A(\lambda)$  of  $\lambda$ .
9. Knowledge of both the characteristic and minimal polynomials suffices to determine the Jordan block sizes for any eigenvalue having algebraic multiplicity at most 3 and, hence, to determine the Jordan canonical form of  $A$  if no eigenvalue of  $A$  has algebraic multiplicity exceeding 3. This is not necessarily true when the algebraic multiplicity of an eigenvalue is 4 or greater (cf. Example 3 below).
10. Knowledge of the the algebraic multiplicity, geometric multiplicity, and index of an eigenvalue  $\lambda$  suffices to determine the Jordan block sizes for  $\lambda$  if the algebraic multiplicity of  $\lambda$  is at most 6. This is not necessarily true when the algebraic multiplicity of an eigenvalue is 7 or greater (cf. Example 4 below).
11. The following are equivalent:
  - (a)  $A$  is similar to a diagonal matrix.
  - (b) The total number of Jordan blocks of  $A$  equals  $n$ .
  - (c) The size of every Jordan block in a Jordan canonical form  $J_A$  of  $A$  is 1.
12. If  $A$  is real, then nonreal eigenvalues of  $A$  occur in conjugate pairs; furthermore, if  $\lambda$  is a nonreal eigenvalue, then each size  $k$  Jordan block with eigenvalue  $\lambda$  can be paired with a size  $k$  Jordan block for  $\bar{\lambda}$ .
13. If  $A = A_1 \oplus \dots \oplus A_m$ , then  $J_{A_1} \oplus \dots \oplus J_{A_m}$  is a Jordan canonical form of  $A$ .
14. [Mey00, Chapter 7.8] A Jordan basis and Jordan canonical form of  $A$  can be constructed by using Algorithm 1.

**Algorithm 1: Jordan Basis and Jordan Canonical Form**

Input:  $A \in F^{n \times n}$ , the distinct eigenvalues  $\mu_1, \dots, \mu_r$ , the indices  $\nu_1, \dots, \nu_r$ .

Output:  $C \in F^{n \times n}$  such that  $C^{-1}AC = J_A$ .

Initially  $C$  has no columns.

FOR  $i = 1, \dots, r$                    % working on eigenvalue  $\mu_i$

**Step 1:** Find a special basis  $\mathcal{B}_{\mu_i}$  for  $E_{\mu_i}(A)$ .

    (a) Initially  $\mathcal{B}_{\mu_i}$  has no vectors.

    (b) FOR  $k = \nu_i - 1$  down to 0

        Extend the set of vectors already found to a basis for  $\text{range}(A - \mu_i I)^k \cap E_{\mu_i}(A)$ .

    (c) Denote the vectors of  $\mathcal{B}_{\mu_i}$  by  $\mathbf{b}_j$  (ordered as found in step (b)).

**Step 2:** For each vector  $\mathbf{b}_j$  found in Step 1, build a Jordan chain above  $\mathbf{b}_j$ .

    FOR  $j = 1, \dots, \dim \ker(A - \mu_i I)$                    % working on  $\mathbf{b}_j$

    (a) Solve  $(A - \mu_i I)^{h_j} \mathbf{u}_j = \mathbf{b}_j$  for  $\mathbf{u}_j$  where  $h_j$  is the depth of  $\mathbf{b}_j$ .

    (b) Insert  $(A - \mu_i I)^{h_j} \mathbf{u}_j, (A - \mu_i I)^{h_j - 1} \mathbf{u}_j, \dots, (A - \mu_i I) \mathbf{u}_j, \mathbf{u}_j$   
        as the next  $h + 1$  columns of  $C$ .

15.  $A$  and its transpose  $A^T$  have the same Jordan canonical form (and are, therefore, similar).
16. For a nilpotent matrix, the list of block sizes determines the Jordan canonical form or, equivalently, determines the similarity class. The number of similarity classes of nilpotent matrices of size  $n$  is the number of partitions of  $n$ .
17. Let  $J_A$  be a Jordan matrix, let  $D$  be the diagonal matrix having the same diagonal as  $J_A$ , and let  $N = J_A - D$ . Then  $N$  is nilpotent.
18.  $A$  can be expressed as the sum of a diagonalizable matrix  $A_D$  and a nilpotent matrix  $A_N$ , where  $A_D$  and  $A_N$  are polynomials in  $A$  (and  $A_D$  and  $A_N$  commute).
19. Let  $V$  be an  $n$ -dimensional vector space over  $F$  and  $T$  be a linear operator on  $V$ . Facts 1, 3 to 10, 16, and 18 remain true when matrix  $A$  is replaced by linear operator  $T$ ; in particular,  $\text{JCF}(T)$  exists and is independent (up to permutation of the diagonal Jordan blocks) of the ordered basis of  $V$  used to compute it, and the Jordan invariants of  $T$  are independent of basis.

**Examples:**

$$1. J_4(3) = \begin{bmatrix} 3 & 1 & 0 & 0 \\ 0 & 3 & 1 & 0 \\ 0 & 0 & 3 & 1 \\ 0 & 0 & 0 & 3 \end{bmatrix}.$$

2. Let  $A$  be the matrix in Example 1 in Section 6.1.  $p_A(x) = x^4 + 8x^3 + 24x^2 + 32x + 16 = (x + 2)^4$ , so the only eigenvalue of  $A$  is  $-2$  with algebraic multiplicity 4. From Example 1 in section 6.1,  $A$  has 3 linearly independent eigenvectors for eigenvalue  $-2$ , so  $J_A$  has 3 Jordan blocks with eigenvalue  $-2$ .

In this case, this is enough information to completely determine that  $J_A = \begin{bmatrix} -2 & 1 & 0 & 0 \\ 0 & -2 & 0 & 0 \\ 0 & 0 & -2 & 0 \\ 0 & 0 & 0 & -2 \end{bmatrix}$ .

3. The Jordan canonical form of  $A$  is not necessarily determined by the characteristic and minimal polynomials of  $A$ . For example, the Jordan matrices  $A = J_2(0) \oplus J_1(0) \oplus J_1(0)$  and  $B = J_2(0) \oplus J_2(0)$  are not similar to each other, but have  $p_A(x) = p_B(x) = x^4, q_A(x) = q_B(x) = x^2$ .
4. The Jordan canonical form of  $A$  is not necessarily determined by the eigenvalues and the algebraic multiplicity, geometric multiplicity, and index of each eigenvalue. For example, the Jordan matrices  $A = J_3(0) \oplus J_3(0) \oplus J_1(0)$  and  $B = J_3(0) \oplus J_2(0) \oplus J_2(0)$  are not similar to each other, but have  $\alpha_A(0) = \alpha_B(0) = 7, \gamma_A(0) = \gamma_B(0) = 3, \nu_0(A) = \nu_0(B) = 3$  (and  $p_A(x) = p_B(x) = x^7, q_A(x) = q_B(x) = x^3$ ).

**TABLE 6.1**  $\text{rank}(A - \lambda I)^k$ 

$k =$	1	2	3	4	5
$\lambda = 1$	11	10	9	9	9
$\lambda = 2$	12	10	10	10	10
$\lambda = 3$	12	11	10	9	9

5. We use Algorithm 1 to find a matrix  $C$  such that  $C^{-1}AC = J_A$  for

$$A = \begin{bmatrix} -2 & 3 & 0 & 1 & -1 \\ 4 & 0 & 3 & 0 & -2 \\ 6 & -3 & 3 & -1 & -1 \\ -8 & 6 & -3 & 2 & 0 \\ 2 & 3 & 3 & 1 & -3 \end{bmatrix}. \text{ Computations show that } p_A(x) = x^5 \text{ and } \ker A = \text{Span}(\mathbf{z}_1, \mathbf{z}_2, \mathbf{z}_3),$$

where  $\mathbf{z}_1 = [3, 2, -4, 0, 0]^T$ ,  $\mathbf{z}_2 = [0, 1, 0, -3, 0]^T$ ,  $\mathbf{z}_3 = [3, 4, 0, 0, 6]^T$ .

For Step 1,  $A^3 = \mathbf{0}$ , and  $\text{range}(A^2) = \text{Span}(\mathbf{b}_1)$  where  $\mathbf{b}_1 = [-1, -1, 0, -1, -2]^T$ .

Then  $\mathcal{B} = \{\mathbf{b}_1, \mathbf{z}_1, \mathbf{z}_2\}$  is a suitable basis (any 2 of  $\{\mathbf{z}_1, \mathbf{z}_2, \mathbf{z}_3\}$  will work in this case).

For Step 2, construct a Jordan chain above  $\mathbf{b}_1$  by solving  $A^2\mathbf{u}_1 = \mathbf{b}_1$ . There are many possible solutions; we choose  $\mathbf{u}_1 = [0, 0, 0, 0, 1]^T$ . Then  $A\mathbf{u}_1 = [-1, -2, -1, 0, -3]^T$ ,

$$C = \begin{bmatrix} -1 & -1 & 0 & 3 & 0 \\ -1 & -2 & 0 & 2 & 1 \\ 0 & -1 & 0 & -4 & 0 \\ -1 & 0 & 0 & 0 & -3 \\ -2 & -3 & 1 & 0 & 0 \end{bmatrix}, \quad \text{and} \quad J_A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix} \oplus [0] \oplus [0].$$

6. We compute the Jordan canonical form of a  $14 \times 14$  matrix  $A$  by the method in Fact 3, where the necessary data about the eigenvalues of  $A$  and ranks is given in Table 6.1.

$\lambda = 1$  – The number of blocks of size 1 is  $14 + 10 - 2 \cdot 11 = 2$ .

– The number of blocks of size 2 is  $11 + 9 - 2 \cdot 10 = 0$ .

– The number of blocks of size 3 is  $10 + 9 - 2 \cdot 9 = 1$ .

So  $v_1 = 3$  and  $b_1 = 3$ .

$\lambda = 2$  – The number of blocks of size 1 is  $14 + 10 - 2 \cdot 12 = 0$ .

– The number of blocks of size 2 is  $12 + 10 - 2 \cdot 10 = 2$ .

So,  $v_2 = 2$  and  $b_2 = 2$ .

$\lambda = 3$  – The number of blocks of size 1 is  $14 + 11 - 2 \cdot 12 = 1$ .

– The number of blocks of size 2 is  $12 + 10 - 2 \cdot 11 = 0$ .

– The number of blocks of size 3 is  $11 + 9 - 2 \cdot 10 = 0$ .

– The number of blocks of size 4 is  $10 + 9 - 2 \cdot 9 = 1$ .

So,  $v_3 = 4$  and  $b_3 = 2$ .

From this information,

$$J_A = J_3(1) \oplus J_1(1) \oplus J_1(1) \oplus J_2(2) \oplus J_2(2) \oplus J_4(3) \oplus J_1(3).$$

### 6.3 Real-Jordan Canonical Form

The real-Jordan canonical form is used in applications to differential equations, dynamical systems, and control theory (see Chapter 56). The real-Jordan canonical form is discussed here only for matrices and with limited discussion of generalized eigenspaces; more generality is possible, and is readily derivable from the corresponding results for the Jordan canonical form.

**Definitions:**

Let  $A \in \mathbb{R}^{n \times n}, \alpha, \beta, \alpha_j, \beta_j \in \mathbb{R}$ .

The **real generalized eigenspace** of  $A$  at eigenvalue  $\alpha + \beta i$  is

$$E(A, \alpha + \beta i) = \begin{cases} \ker((A^2 - 2\alpha A + (\alpha^2 + \beta^2)I)^v) & \text{if } \beta \neq 0 \\ N_{\alpha}^v(A) = \ker((A - \alpha I)^v) & \text{if } \beta = 0. \end{cases}$$

The vector  $\mathbf{x} \in \mathbb{R}^n$  is a **real generalized eigenvector** of  $A$  for  $\alpha + \beta i$  if  $\mathbf{x} \neq \mathbf{0}$  and  $\mathbf{x} \in E(A, \alpha + \beta i)$ .

For  $\alpha, \beta \in \mathbb{R}$  with  $\beta \neq 0$ , and even positive integer  $2k$ , the **real-Jordan block** of size  $2k$  with eigenvalue

$\alpha + \beta i$  is the  $2k \times 2k$  matrix having  $k$  copies of  $M_2(\alpha, \beta) = \begin{bmatrix} \alpha & \beta \\ -\beta & \alpha \end{bmatrix}$  on the (block matrix) diagonal,  $k - 1$

copies of  $I_2 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$  on the first (block matrix) superdiagonal, and copies of  $0_2 = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$  everywhere else, i.e.,

$$J_{2k}^{\mathbb{R}}(\alpha + \beta i) = \begin{bmatrix} M_2(\alpha, \beta) & I_2 & 0_2 & \cdots & 0_2 \\ 0_2 & M_2(\alpha, \beta) & I_2 & \cdots & 0_2 \\ \vdots & \ddots & \ddots & & \vdots \\ 0_2 & \cdots & 0_2 & M_2(\alpha, \beta) & I_2 \\ 0_2 & \cdots & 0_2 & 0_2 & M_2(\alpha, \beta) \end{bmatrix}.$$

A **real-Jordan matrix** (or a **matrix in real-Jordan canonical form**) is a block diagonal matrix having diagonal blocks that are Jordan blocks or real-Jordan blocks, i.e., a matrix of the form  $J_{m_1}(\alpha_1) \oplus \cdots \oplus J_{m_t}(\alpha_t) \oplus J_{2k_{t+1}}^{\mathbb{R}}(\alpha_{t+1} + \beta_{t+1}i) \oplus \cdots \oplus J_{2k_s}^{\mathbb{R}}(\alpha_s + \beta_s i)$  (or a permutation of the direct summands).

A **real-Jordan canonical form** of matrix  $A$ , denoted  $J_A^{\mathbb{R}}$  or  $\text{JCF}^{\mathbb{R}}(A)$ , is a real-Jordan matrix that is similar to  $A$ . It is conventional to use  $\beta_j > 0$ , to group the blocks for the same eigenvalue together, and to order the Jordan blocks with the same eigenvalue in nonincreasing size order.

The **total number of Jordan blocks** in a real-Jordan canonical form of  $A$  is the number of blocks (Jordan or real-Jordan) in  $J_A^{\mathbb{R}}$ .

**Facts:**

Facts requiring proof for which no specific reference is given can be found in [HJ85, Chapter 3].

*Notation:*  $A, B \in \mathbb{R}^{n \times n}, \alpha, \beta, \alpha_j, \beta_j \in \mathbb{R}$ .

1. The real generalized eigenspace of a complex number  $\lambda = \alpha + \beta i$  and its conjugate  $\bar{\lambda} = \alpha - \beta i$  are equal, i.e.,  $E(A, \alpha + \beta i) = E(A, \alpha - \beta i)$ .
2. The real-Jordan blocks with a nonreal complex number and its conjugate are similar to each other.
3.  $A$  has a real-Jordan canonical form  $J_A^{\mathbb{R}}$ , and  $J_A^{\mathbb{R}}$  is unique up to permutation of the diagonal (real-) Jordan blocks.
4.  $A, B$  are similar if and only if their real-Jordan canonical forms have the same set of Jordan and real-Jordan blocks (although the order may vary).
5. If all the eigenvalues of  $A$  are real, then  $J_A^{\mathbb{R}}$  is the same as  $J_A$  (up to the order of the Jordan blocks).
6. The real-Jordan canonical form of  $A$  can be computed from the Jordan canonical form of  $A$ . The nonreal eigenvalues occur in conjugate pairs, and if  $\beta > 0$ , then each size  $k$  Jordan block with eigenvalue  $\alpha + \beta i$  can be paired with a size  $k$  Jordan block for  $\alpha - \beta i$ . Then  $J_k(\alpha + \beta i) \oplus J_k(\alpha - \beta i)$  is replaced by  $J_{2k}^{\mathbb{R}}(\alpha + \beta i)$ . The Jordan blocks of  $J_A^{\mathbb{R}}$  with real eigenvalues are the same as the those of  $J_A$ .
7. The total number of Jordan and real-Jordan blocks in a real-Jordan canonical form of  $A$  is the number of Jordan blocks with a real eigenvalue plus half the number of Jordan blocks with a nonreal eigenvalue in a Jordan canonical form of  $A$ .

8. If  $\beta \neq 0$ , the size of the largest real-Jordan block with eigenvalue  $\alpha + \beta i$  is twice the multiplicity of  $x^2 - 2\alpha x + (\alpha^2 + \beta^2)$  as a factor of the minimal polynomial  $q_A(x)$  of  $A$ .
9. If  $\beta \neq 0$ , the sum of the sizes of all the real-Jordan blocks with eigenvalue  $\alpha + \beta i$  in  $J_A$  equals twice the algebraic multiplicity  $\alpha_A(\alpha + \beta i)$ .
10. If  $\beta \neq 0$ ,  $\dim E(A, \alpha + \beta i) = \alpha_A(\alpha + \beta i)$ .
11. If  $A = A_1 \oplus \cdots \oplus A_m$ , then  $J_{A_1}^{\mathbb{R}} \oplus \cdots \oplus J_{A_m}^{\mathbb{R}}$  is a real-Jordan canonical form of  $A$ .

**Examples:**

1. Let  $a = \begin{bmatrix} -10 & 6 & -4 & 4 & 0 \\ -17 & 10 & -4 & 6 & -1 \\ -4 & 2 & -3 & 2 & 1 \\ -11 & 6 & -11 & 6 & 3 \\ -4 & 2 & -4 & 2 & 2 \end{bmatrix}$ . Since the characteristic and minimal polynomials of  $A$  are

$$\text{both } x^5 - 5x^4 + 12x^3 - 16x^2 + 12x - 4 = (x - 1)(x^2 - 2x + 2)^2,$$

$$J_A^{\mathbb{R}} = \begin{bmatrix} 1 & 1 & 1 & 0 & 0 \\ -1 & 1 & 0 & 1 & 0 \\ 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & -1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}.$$

2. The requirement that  $\beta \neq 0$  is important.  $A = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$  is *not* a real-Jordan matrix;

$$J_A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}.$$

## 6.4 Rational Canonical Form: Elementary Divisors

---

The elementary divisors rational canonical form is closely related to the Jordan canonical form (see Fact 7 below). A rational canonical form (either the elementary divisors or the invariant factors version, cf. Section 6.6) is used when it is desirable to stay within a field that is not algebraically closed, such as the rational numbers.

**Definitions:**

Let  $F$  be a field.

For a monic polynomial  $p(x) = x^n + c_{n-1}x^{n-1} + \cdots + c_2x^2 + c_1x + c_0 \in F[x]$  (with  $n \geq 1$ ), the

**companion matrix** of  $p(x)$  is the  $n \times n$  matrix  $C(p) = \begin{bmatrix} 0 & 0 & \cdots & -c_0 \\ 1 & 0 & \cdots & -c_1 \\ \vdots & \ddots & & \vdots \\ 0 & \cdots & 1 & -c_{n-1} \end{bmatrix}$ .

An **elementary divisors rational canonical form matrix (ED-RCF matrix)** (over  $F$ ) is a block diagonal matrix of the form  $C(h_1^{m_1}) \oplus \cdots \oplus C(h_t^{m_t})$  where each  $h_i(x)$  is a monic polynomial that is irreducible over  $F$ .

The **elementary divisors** of the ED-RCF matrix  $C(h_1^{m_1}) \oplus \cdots \oplus C(h_t^{m_t})$  are the polynomials  $h_i(x)^{m_i}$ ,  $i = 1, \dots, t$ .

An **elementary divisors rational canonical form** of matrix  $A \in F^{n \times n}$ , denoted  $\text{RCF}_{ED}(A)$ , is an ED-RCF matrix that is similar to  $A$ . It is conventional to group the companion matrices associated with powers of the same irreducible polynomial together, and within such a group to order the blocks in size order.

The **elementary divisors** of  $A$  are the elementary divisors of  $\text{RCF}_{ED}(A)$ .

Let  $V$  be a finite dimensional vector space over  $F$ , and let  $T$  be a linear operator on  $V$ .

An **ED-RCF basis** for  $T$  is an ordered basis  $\mathcal{B}$  of  $V$ , with respect to which the matrix  ${}_{\mathcal{B}}[T]_{\mathcal{B}}$  of  $T$  is an ED-RCF matrix. In this case,  ${}_{\mathcal{B}}[T]_{\mathcal{B}}$  is an elementary divisors rational canonical form of  $T$ , denoted  $\text{RCF}_{ED}(T)$ , and the **elementary divisors** of  $T$  are the elementary divisors of  $\text{RCF}_{ED}(T) = {}_{\mathcal{B}}[T]_{\mathcal{B}}$ .

Let  $q(x)$  be a monic polynomial over  $F$ .

A **primary decomposition** of a nonconstant monic polynomial  $q(x)$  over  $F$  is a factorization  $q(x) = (h_1(x))^{m_1} \cdots (h_r(x))^{m_r}$ , where the  $h_i(x)$ ,  $i = 1, \dots, r$  are distinct monic irreducible polynomials over  $F$ .

The factors  $(h_i(x))^{m_i}$  in a primary decomposition of  $q(x)$  are the **primary factors** of  $q(x)$ .

### Facts:

Facts requiring proof for which no specific reference is given can be found in [HK71, Chapter 7] or [DF04, Chapter 12].

1. The characteristic and minimal polynomials of the companion matrix  $C(p)$  are both equal to  $p(x)$ .
2. Whether or not a matrix is an ED-RCF matrix depends on polynomial irreducibility, which depends on the field. See Example 1 below.
3. Every matrix  $A \in F^{n \times n}$  is similar to an ED-RCF matrix,  $\text{RCF}_{ED}(A)$ , and  $\text{RCF}_{ED}(A)$  is unique up to permutation of the companion matrix blocks on the diagonal. In particular, the elementary divisors of  $A$  are uniquely determined by  $A$ .
4.  $A, B \in F^{n \times n}$  are similar if and only if they have the same elementary divisors.
5. (See Fact 3 in Section 6.2) For  $A \in F^{n \times n}$ , the elementary divisors and, hence,  $\text{RCF}_{ED}(A)$  can be found from the irreducible factors  $h_i(x)$  of the characteristic polynomial of  $A$  and the ranks of powers of  $h_i(A)$ . Specifically, the number of times  $h_i(x)^k$  appears as an elementary divisor of  $A$  is

$$\frac{1}{\deg h_i(x)} (\text{rank}(h_i(A))^{k-1} + \text{rank}(h_i(A))^{k+1} - 2 \text{rank}(h_i(A))^k).$$

6. If  $A \in F^{n \times n}$  has  $n$  eigenvalues in  $F$ , then the elementary divisors of  $A$  are the polynomials  $(x - \lambda)^k$ , where the  $J_k(\lambda)$  are the Jordan blocks of  $J_A$ .
7. There is a natural association between the diagonal blocks in the elementary divisors rational canonical form of  $A$  and the Jordan canonical form of  $A$  in  $\hat{F}^{n \times n}$ , where  $\hat{F}$  is the algebraic closure of  $F$ . Let  $h(x)^m$  be an elementary divisor of  $A$ , and factor  $h(x)$  into monic linear factors over  $\hat{F}$ ,  $h(x) = (x - \lambda_1) \cdots (x - \lambda_t)$ . If the roots of  $h(x)$  are distinct (e.g., if the characteristic of  $F$  is 0 or  $F$  is a finite field), then the ED-RCF diagonal block  $C(h^m)$  is associated with the Jordan blocks  $J_m(\lambda_i)$ ,  $i = 1, \dots, t$ . If the characteristic of  $F$  is  $p$  and  $h(x)$  has repeated roots, then all roots have the same multiplicity  $p^k$  (for some positive integer  $k$ ) and the ED-RCF diagonal block  $C(h^m)$  is associated with the Jordan blocks  $J_{p^k m}(\lambda_i)$ ,  $i = 1, \dots, t$ .
8. [HK71, Chapter 4.5] Every monic polynomial  $q(x)$  over  $F$  has a primary decomposition. The primary decomposition is unique up to the order of the monic irreducible polynomials, i.e., the set of primary factors of  $q(x)$  is unique.
9. [HK71, Chapter 6.8] Let  $q(x) \in F[x]$ , let  $h_i(x)^{m_i}$ ,  $i = 1, \dots, r$  be the primary factors, and define  $f_i(x) = \frac{q(x)}{h_i(x)^{m_i}}$ . Then there exist polynomials  $g_i(x)$  such that  $f_1(x)g_1(x) + \cdots + f_r(x)g_r(x) = 1$ . Let  $A \in F^{n \times n}$  and let  $q_A(x) = (h_1(x))^{m_1} \cdots (h_r(x))^{m_r}$  be a primary decomposition of its minimal polynomial.
10. Every primary factor  $h_i(x)^{m_i}$  of  $q_A(x)$  is an elementary divisor of  $A$ .
11. Every elementary divisor of  $A$  is of the form  $(h_i(x))^m$  with  $m \leq m_i$  for some  $i \in \{1, \dots, r\}$ .

12. [HK71, Chapter 6.8] *Primary Decomposition Theorem*

- (a)  $F^n = \ker(h_1(A)^{m_1}) \oplus \cdots \oplus \ker(h_r(A)^{m_r})$ .
- (b) Let  $f_i$  and  $g_i$  be as defined in Fact 9. Then for  $i = 1, \dots, r$ ,  $E_i = f_i(A)g_i(A)$  is the projection onto  $\ker(h_i(A)^{m_i})$  along  $\ker(h_1(A)^{m_1}) \oplus \cdots \oplus \ker(h_{i-1}(A)^{m_{i-1}}) \oplus \ker(h_{i+1}(A)^{m_{i+1}}) \oplus \cdots \oplus \ker(h_r(A)^{m_r})$ .
- (c) The  $E_i = f_i(A)g_i(A)$  are mutually orthogonal idempotents (i.e.,  $E_i^2 = E_i$  and  $E_i E_j = 0$  if  $i \neq j$ ) and  $I = E_1 + \cdots + E_r$ .

13. [HK71, Chapter 6.7] If  $A \in F^{n \times n}$  is diagonalizable, then  $A = \mu_1 E_1 + \cdots + \mu_r E_r$  where the  $E_i$  are the projections defined in Fact 12 with primary factors  $h_i(x)^{m_i} = (x - \mu_i)$  of  $q_A(x)$ .

Let  $V$  be an  $n$ -dimensional vector space over  $F$ , and let  $T$  be a linear operator on  $V$ .

- 14. Facts 3, 5 to 7, and 10 to 13 remain true when matrix  $A$  is replaced by linear operator  $T$ ; in particular,  $\text{RCF}_{ED}(T)$  exists and is independent (up to permutation of the companion matrix diagonal blocks) of the ordered basis of  $V$  used to compute it, and the elementary divisors of  $T$  are independent of basis.
- 15. If  $\hat{T}$  denotes  $T$  restricted to  $\ker(h_i(T)^{m_i})$ , then the minimal polynomial of  $\hat{T}$  is  $h_i(T)^{m_i}$ .

**Examples:**

1. Let  $A = [-1] \oplus [-1] \oplus \begin{bmatrix} 0 & 0 & -1 \\ 1 & 0 & -3 \\ 0 & 1 & -3 \end{bmatrix} \oplus \begin{bmatrix} 0 & 2 \\ 1 & 0 \end{bmatrix} \oplus \begin{bmatrix} 0 & 0 & 0 & -4 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 4 \\ 0 & 0 & 1 & 0 \end{bmatrix}$ . Over  $\mathbb{Q}$ ,  $A$  is an ED-RCF

matrix and its elementary divisors are  $x + 1, x + 1, (x + 1)^3, x^2 - 2, (x^2 - 2)^2$ .  $A$  is not an ED-RCF matrix over  $\mathbb{C}$  because  $x^2 - 2$  is not irreducible over  $\mathbb{C}$ .

$\text{JCF}(A) = [-1] \oplus [-1] \oplus \begin{bmatrix} -1 & 1 & 0 \\ 0 & -1 & 1 \\ 0 & 0 & -1 \end{bmatrix} \oplus [\sqrt{2}] \oplus [-\sqrt{2}] \oplus \begin{bmatrix} \sqrt{2} & 1 \\ 0 & \sqrt{2} \end{bmatrix} \oplus \begin{bmatrix} -\sqrt{2} & 1 \\ 0 & -\sqrt{2} \end{bmatrix}$ ,

where the order of the Jordan blocks has been chosen to emphasize the connection to  $\text{RCF}_{ED}(A) = A$ .

2. Let  $A = \begin{bmatrix} -2 & 2 & -2 & 1 & 1 \\ 6 & -2 & 2 & -2 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ -12 & 7 & -8 & 5 & 4 \\ 0 & 0 & -1 & 0 & 2 \end{bmatrix} \in \mathbb{Q}^{5 \times 5}$ . We use Fact 5 to determine the elementary divisors

rational canonical form of  $A$ . The following computations can be performed easily over  $\mathbb{Q}$  in a computer algebra system such as Mathematica, Maple, or MATLAB® (see Chapters 71, 72, 73), or on a matrix-capable calculator.  $p_A(x) = x^5 - 3x^4 + x^3 + 5x^2 - 6x + 2 = (x - 1)^3(x^2 - 2)$ . Table 6.2 gives the of ranks  $h_i(A)^k$  where  $h_i(x)$  is shown in the left column.

$h(x) = x - 1$  The number of times  $x - 1$  appears as an elementary divisor is  $5 + 2 - 2 \cdot 3 = 1$ .  
The number of  $(x - 1)^2$  appears as an elementary divisor is  $3 + 2 - 2 \cdot 2 = 1$ .

$h(x) = x^2 - 2$  The number of times  $x^2 - 2$  appears as an elementary divisor is  $(5 + 3 - 2 \cdot 3) / 2 = 1$ .

Thus,  $\text{RCF}_{ED}(A) = C(x - 1) \oplus C((x - 1)^2) \oplus C(x^2 - 2) = [1] \oplus \begin{bmatrix} 0 & -1 \\ 1 & 2 \end{bmatrix} \oplus \begin{bmatrix} 0 & 2 \\ 1 & 0 \end{bmatrix}$ .

**TABLE 6.2**  $\text{rank}(h(A)^k)$

$k =$	1	2	3
$h_1(x) = x - 1$	3	2	2
$h_2(x) = x^2 - 2$	3	3	3

3. We find the projections  $E_i, i = 1, 2$  in Fact 12 for  $A$  in the previous example. From the elementary divisors of  $A, q_A(x) = (x - 1)^2(x^2 - 2)$ . Let  $h_1(x) = (x - 1)^2, h_2(x) = x^2 - 2$ . Then  $f_1(x) = x^2 - 2, f_2(x) = (x - 1)^2$ . *Note:* normally the  $f_i(x)$  will not be primary factors; this happens here because there are only two primary factors. If we choose  $g_1(x) = -(2x - 1), g_2(x) = 2x + 3$ , then  $1 = f_1(x)g_1(x) + f_2(x)g_2(x)$  ( $g_1, g_2$  can be found by the Euclidean algorithm). Then

$$E_1 = f_1(A)g_1(A) = \begin{bmatrix} -2 & 1 & -1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ -6 & 3 & -2 & 3 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad \text{and} \quad E_2 = f_2(A)g_2(A) = \begin{bmatrix} 3 & -1 & 1 & -1 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 6 & -3 & 2 & -2 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix},$$

and it is easy to verify that  $E_1^2 = E_1, E_2^2 = E_2, E_1E_2 = E_2E_1 = 0$ , and  $E_1 + E_2 = I$ .

## 6.5 Smith Normal Form on $F[x]^{n \times n}$

For a matrix  $A \in F^{n \times n}$ , the Smith normal form of  $xI_n - A$  is an important tool for the computation of the invariant factors rational canonical form of  $A$  discussed in Section 6.6. In this section, Smith normal form is discussed only for matrices in  $F[x]^{n \times n}$ , and the emphasis is on finding the Smith normal form of  $xI_n - A$ , where  $A \in F^{n \times n}$ . Smith normal form is used more generally for matrices over principal ideal domains (see Section 23.2); it is not used extensively as a canonical form within  $F^{n \times n}$ , since the Smith normal form of a matrix  $A \in F^{n \times n}$  of rank  $k$  is  $I_k \oplus 0_{n-k}$ .

### Definitions:

Let  $F$  be a field. For  $M \in F[x]^{n \times n}$ , the following operations are the **elementary row and column operations** on  $M$ :

- Interchange rows  $i, j$ , denoted  $R_i \leftrightarrow R_j$  (analogous column operation denoted  $C_i \leftrightarrow C_j$ ).
- Add a  $p(x)$  multiple of row  $j$  to row  $i$ , denoted  $R_i + p(x)R_j \rightarrow R_i$  (analogous column operation denoted  $C_i + p(x)C_j \rightarrow C_i$ ).
- Multiply row  $i$  by a nonzero element  $b$  of  $F$ , denoted  $bR_i \rightarrow R_i$  (analogous column operation denoted  $bC_i \rightarrow C_i$ ).

A **Smith normal matrix** in  $F[x]^{n \times n}$  is a diagonal matrix  $D = \text{diag}(1, \dots, 1, a_1(x), \dots, a_s(x), 0, \dots, 0)$ , where the  $a_i(x)$  are monic nonconstant polynomials such that  $a_i(x)$  divides  $a_{i+1}(x)$  for  $i = 1, \dots, s - 1$ .

The **Smith normal form** of  $M \in F[x]^{n \times n}$  is the Smith normal matrix obtained from  $M$  by elementary row and column operations.

For  $A \in F^{n \times n}$ , the monic nonconstant polynomials of the Smith normal form of  $xI_n - A$  are the **Smith invariant factors** of  $A$ .

### Facts:

Facts requiring proof for which no specific reference is given can be found in [HK71, Chapter 7] or [DF04, Chapter 12].

- Let  $M \in F[x]^{n \times n}$ . Then  $M$  has a unique Smith normal form.
- Let  $A \in F^{n \times n}$ . There are no zeros on the diagonal of the Smith normal form of  $xI_n - A$ .
- (*Division Property*) If  $a(x), b(x) \in F[x]$  and  $b(x) \neq 0$ , then there exist polynomials  $q(x), r(x)$  such that  $a(x) = q(x)b(x) + r(x)$  and  $r(x) = 0$  or  $\deg r(x) < \deg b(x)$ .
- The Smith normal form of  $M = xI - A$  and, thus, the Smith invariant factors of  $A$  can be computed as follows:

- For  $k = 1, \dots, n - 1$ 
  - Use elementary row and column operations and the division property of  $F[x]$  to place the greatest common divisor of the entries of  $M[\{k, \dots, n\}]$  in the  $k$ th diagonal position.
  - Use elementary row and column operations to create zeros in all nondiagonal positions in row  $k$  and column  $k$ .
- Make the  $n$ th diagonal entry monic by multiplying the last column by a nonzero element of  $F$ .

This process is illustrated in Example 1 below.

### Examples:

1. Let  $A = \begin{bmatrix} 1 & 1 & 1 & -1 \\ 0 & 3 & 2 & -2 \\ 2 & 0 & 4 & -2 \\ 4 & 0 & 6 & -3 \end{bmatrix}$ . We use the method in Fact 4 above to find the Smith normal form of

$M = xI - A$  and invariant factors of  $A$ .

- $k = 1$ : Use the row and column operations on  $M$  (in the order shown):

$$R_1 \leftrightarrow R_3, -\frac{1}{2}R_1 \rightarrow R_1, R_3 + (1-x)R_1 \rightarrow R_3, R_4 + 4R_1 \rightarrow R_4, \\ C_3 + (-2 + \frac{x}{2})C_1 \rightarrow C_3, C_4 + C_1 \rightarrow C_4$$

$$\text{to obtain } M_1 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & x-3 & -2 & 2 \\ 0 & -1 & \frac{x^2}{2} - \frac{5x}{2} + 1 & x \\ 0 & 0 & 2-2x & x-1 \end{bmatrix}.$$

- $k = 2$ : Use the row and column operations on  $M_1$  (in the order shown):

$$R_3 \leftrightarrow R_2, -1R_2 \rightarrow R_2, R_3 + (3-x)R_2 \rightarrow R_3, \\ C_3 + (1 - \frac{5x}{2} + \frac{x^2}{2})C_2 \rightarrow C_3, C_4 + xC_2 \rightarrow C_4$$

$$\text{to obtain } M_2 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & \frac{x^3}{2} - 4x^2 + \frac{17x}{2} - 5 & x^2 - 3x + 2 \\ 0 & 0 & 2-2x & x-1 \end{bmatrix}.$$

- $k = 3$  (and final step): Use the row and column operations on  $M_2$  (in the order shown):

$$R_3 \leftrightarrow R_4, -\frac{1}{2}R_3 \rightarrow R_3, R_4 + \frac{-1}{2}(x-2)(x-5)R_3 \rightarrow R_4, \\ C_4 + \frac{1}{2}C_3 \rightarrow C_4, 4C_4 \rightarrow C_4$$

$$\text{to obtain the Smith normal form of } M, M_3 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & x-1 & 0 \\ 0 & 0 & 0 & x^3 - 4x^2 + 5x - 2 \end{bmatrix}.$$

The Smith invariant factors of  $A$  are  $x - 1, x^3 - 4x^2 + 5x - 2$ .

## 6.6 Rational Canonical Form: Invariant Factors

Like the elementary divisors version, the invariant factors rational canonical form does not require the field to be algebraically closed. It has two other advantages: This canonical form is unique (not just unique up to permutation), and (unlike elementary divisors rational canonical form) whether a matrix is in invariant factors rational canonical form is independent of the field (see Fact 2 below).

**Definitions:**

Let  $F$  be a field. An **invariant factors rational canonical form matrix (IF-RCF matrix)** is a block diagonal matrix of the form  $C(a_1) \oplus \cdots \oplus C(a_s)$ , where  $a_i(x)$  divides  $a_{i+1}(x)$  for  $i = 1, \dots, s - 1$ .

The **invariant factors** of the IF-RCF matrix  $C(a_1) \oplus \cdots \oplus C(a_s)$  are the polynomials  $a_i(x), i = 1, \dots, s$ .

The **invariant factors rational canonical form** of matrix  $A \in F^{n \times n}$ , denoted  $\text{RCF}_{IF}(A)$ , is the IF-RCF matrix that is similar to  $A$ .

The **invariant factors** of  $A$  are the invariant factors of  $\text{RCF}_{IF}(A)$ .

Let  $V$  be a finite dimensional vector space over  $F$  and let  $T$  be a linear operator on  $V$ .

An **IF-RCF basis** for  $T$  is an ordered basis  $\mathcal{B}$  of  $V$ , with respect to which the matrix  ${}_B[T]_B$  of  $T$  is an IF-RCF matrix. In this case,  ${}_B[T]_B$  is the **invariant factors rational canonical form of  $T$** , denoted  $\text{RCF}_{IF}(T)$ , and the **invariant factors** of  $T$  are the invariant factors of  $\text{RCF}_{IF}(T) = {}_B[T]_B$ .

**Facts:**

Facts requiring proof for which no specific reference is given can be found in [HK71, Chapter 7] or [DF04, Chapter 12]. *Notation:*  $A \in F^{n \times n}$ .

1. Every square matrix  $A$  is similar to a unique IF-RCF matrix,  $\text{RCF}_{IF}(A)$ .
2.  $\text{RCF}_{IF}(A)$  is independent of field. That is, if  $K$  is an extension field of  $F$  and  $A$  is considered as an element of  $K^{n \times n}$ ,  $\text{RCF}_{IF}(A)$  is the same as when  $A$  is considered as an element of  $F^{n \times n}$ .
3. Let  $B \in F^{n \times n}$ . Then  $A, B$  are similar if and only if  $\text{RCF}_{IF}(A) = \text{RCF}_{IF}(B)$ .
4. The characteristic polynomial is the product of the invariant factors of  $A$ , i.e.,  $p_A(x) = a_1(x) \cdots a_s(x)$ .
5. The minimal polynomial of  $A$  is the invariant factor of highest degree, i.e.,  $q_A(x) = a_s(x)$ .
6. The elementary divisors of  $A \in F^{n \times n}$  are the primary factors (over  $F$ ) of the invariant factors of  $A$ .
7. The Smith invariant factors of  $A$  are the invariant factors of  $A$ .
8. [DF04, Chapter 12.2]  $\text{RCF}_{IF}(A)$  and a nonsingular matrix  $S \in F^{n \times n}$  such that  $S^{-1}AS = \text{RCF}_{IF}(A)$  can be computed by Algorithm 2.

**Algorithm 2: Rational Canonical Form (invariant factors)**

1. Compute the Smith normal form  $D$  of  $M = xI - A$  as in Fact 4 of section 6.5, keeping track of the elementary row operations, in the order performed (column operations need not be recorded).
2. The invariant factors are the nonconstant diagonal elements  $a_1(x), \dots, a_s(x)$  of  $D$ .
3. Let  $d_1, \dots, d_s$  denote the degrees of  $a_1(x), \dots, a_s(x)$ .
4. Let  $G = I$ .
5. FOR  $k = 1, \dots$ , number of row operations performed in step 1
  - (a) If the  $k$ th row operation is  $R_i \leftrightarrow R_j$ , then perform column operation  $C_j \leftrightarrow C_i$  on  $G$ .
  - (b) If the  $k$ th row operation is  $R_i + p(x)R_j \rightarrow R_i$ , then perform column operation  $C_j - p(A)C_i \rightarrow C_j$  on  $G$  (*note index reversal*).
  - (c) If the  $k$ th row operation is  $bR_i \rightarrow R_i$ , then perform column operation  $\frac{1}{b}C_i \rightarrow C_i$  on  $G$ .
6.  $G$  will have 0s in the first  $n - s$  columns; denote the remaining columns of  $G$  by  $\mathbf{g}_1, \dots, \mathbf{g}_s$ .
7. Initially  $S$  has no columns.
8. FOR  $k = 1, \dots, s$ 
  - (a) Insert  $\mathbf{g}_k$  as the next column of  $S$  (working left to right).
  - (b) FOR  $i = 1, \dots, d_k - 1$   
 Insert  $A$  times the last column inserted as the next column of  $S$ .
9.  $\text{RCF}_{IF}(A) = S^{-1}AS$ .

9. Let  $V$  be an  $n$ -dimensional vector space over  $F$ , and let  $T$  be a linear operator on  $V$ . Facts 1, 2, 4 to 6 remain true when matrix  $A$  is replaced by linear operator  $T$ ; in particular,  $\text{RCF}_{IF}(T)$  exists and is unique (independent of the ordered basis of  $V$  used to compute it).

### Examples:

1. We can use the elementary divisors already computed to find the invariant factors and IF-RCF of  $A$  in Example 2 of Section 6.4. The elementary divisors of  $A$  are  $x - 1, (x - 1)^2, x^2 - 2$ . We combine these, working down from the highest power of each irreducible polynomial.

$a_2(x) = (x - 1)^2(x^2 - 2) = x^4 - 2x^3 - x^2 + 4x - 2, a_1(x) = x - 1$ . Then

$$\text{RCF}_{IF}(A) = C(x - 1) \oplus C(x^4 - 2x^3 - x^2 + 4x - 2) = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 2 \\ 0 & 1 & 0 & 0 & -4 \\ 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 1 & 2 \end{bmatrix}.$$

2. By Fact 7, for the matrix  $A$  in Example 1 in Section 6.5,  $\text{RCF}_{IF}(A) = C(x - 1) \oplus C(x^3 - 4x^2 + 5x - 2)$ .  
3. We can use Algorithm 2 to find a matrix  $S$  such that  $\text{RCF}_{IF}(A) = S^{-1}AS$  for the matrix  $A$  in Example 1.

- $k = 1$ : Starting with  $G = I_4$ , perform the column operations (in the order shown):

$$C_1 \leftrightarrow C_3, -2C_1 \rightarrow C_1, C_1 - (I_4 - A)C_3 \rightarrow C_1, C_1 - 4C_4 \rightarrow C_1,$$

$$\text{to obtain } G_1 = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}.$$

- $k = 2$ : Use column operations on  $G$  (in the order shown):

$$C_3 \leftrightarrow C_2, -1C_2 \rightarrow C_2, C_2 - (3I_4 - A)C_3 \rightarrow C_2,$$

$$\text{to obtain } G = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}.$$

- $k = 3$  (and final step of Fact 4 in Section 6.5):

Use column operations on  $G$  (in the order shown):

$$C_3 \leftrightarrow C_4, -2C_3 \rightarrow C_3, C_3 + \frac{1}{2}(A - 2I_4)(A - 5I_4)C_4 \rightarrow C_3,$$

$$\text{to obtain } G = [\mathbf{g}_1, \mathbf{g}_2, \mathbf{g}_3, \mathbf{g}_4] = \begin{bmatrix} 0 & 0 & -\frac{3}{2} & 0 \\ 0 & 0 & -1 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}.$$

$$\text{Then } S = [\mathbf{g}_3, \mathbf{g}_4, A\mathbf{g}_4, A^2\mathbf{g}_4] = \begin{bmatrix} -\frac{3}{2} & 0 & 1 & 4 \\ -1 & 1 & 3 & 9 \\ 1 & 0 & 0 & 2 \\ 0 & 0 & 0 & 4 \end{bmatrix} \quad \text{and} \quad \text{RCF}_{IF}(A) = S^{-1}AS = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 2 \\ 0 & 1 & 0 & -5 \\ 0 & 0 & 1 & 4 \end{bmatrix}.$$

7.1	Unitary Similarity .....	7-1
7.2	Normal Matrices and Spectral Theory .....	7-5
	References .....	7-9

Unitary transformations preserve the inner product. Hence, they preserve the metric quantities that stem from the inner product, such as length, distance, and angle. While a general similarity preserves the algebraic features of a linear transformation, such as the characteristic and minimal polynomials, the rank, and the Jordan canonical form, unitary similarities also preserve metric features such as the norm, singular values, and the numerical range. Unitary similarities are desirable in computational linear algebra for stability reasons.

Normal transformations are those which have an orthogonal basis of eigenvectors and, thus, can be represented by diagonal matrices relative to an orthonormal basis. The class of normal transformations includes Hermitian, skew-Hermitian, and unitary transformations; studying normal matrices leads to a more unified understanding of all of these special types of transformations. Often, results that are discovered first for Hermitian matrices can be generalized to the class of normal matrices. Since normal matrices are unitarily similar to diagonal matrices, things that are obviously true for diagonal matrices often hold for normal matrices as well; for example, the singular values of a normal matrix are the absolute values of the eigenvalues. Normal matrices have two important properties — diagonalizability and an orthonormal basis of eigenvectors — that tend to make life easier in both theoretical and computational situations.

### 7.1 Unitary Similarity

---

In this subsection, all matrices are over the complex numbers and are square. All vector spaces are finite dimensional complex inner product spaces.

#### Definitions:

A matrix  $U$  is **unitary** if  $U^*U = I$ .

A matrix  $Q$  is **orthogonal** if  $Q^T Q = I$ .

*Note:* This extends the definition of orthogonal matrix given earlier in Section 5.2 for real matrices.

Matrices  $A$  and  $B$  are **unitarily similar** if  $B = U^*AU$  for some unitary matrix  $U$ . The term **unitarily equivalent** is sometimes used in the literature.

The **numerical range** of  $A$  is  $W(A) = \{\mathbf{v}^*A\mathbf{v} \mid \mathbf{v}^*\mathbf{v} = 1\}$ .

The **Frobenius (Euclidean) norm** of the matrix  $A$  is  $\|A\|_F = (\sum_{i,j=1}^n |a_{ij}|^2)^{1/2} = (\text{tr}(A^*A))^{1/2}$ . (See Chapter 37 for more information on norms.)

The **operator norm** of the matrix  $A$  induced by the vector 2-norm  $\|\cdot\|_2$  is  $\|A\|_2 = \max\{\|A\mathbf{v}\| \mid \|\mathbf{v}\| = 1\}$ ; this norm is also called the **spectral norm**.

### Facts:

Most of the material in this section can be found in one or more of the following: [HJ85, Chap. 2] [Hal87, Chap. 3] [Gan59, Chap. IX] [MM64, I.4, III.5]. Specific references are also given for some facts.

1. A real, orthogonal matrix is unitary.
2. The following are equivalent:
  - $U$  is unitary.
  - $U$  is invertible and  $U^{-1} = U^*$ .
  - The columns of  $U$  are orthonormal.
  - The rows of  $U$  are orthonormal.
  - For any vectors  $\mathbf{x}$  and  $\mathbf{y}$ , we have  $\langle U\mathbf{x}, U\mathbf{y} \rangle = \langle \mathbf{x}, \mathbf{y} \rangle$ .
  - For any vector  $\mathbf{x}$ , we have  $\|U\mathbf{x}\| = \|\mathbf{x}\|$ .
3. If  $U$  is unitary, then  $U^*$ ,  $U^T$ , and  $\bar{U}$  are also unitary.
4. If  $U$  is unitary, then every eigenvalue of  $U$  has modulus 1 and  $|\det(U)| = 1$ . Also,  $\|U\|_2 = 1$ .
5. The product of two unitary matrices is unitary and the product of two orthogonal matrices is orthogonal.
6. The set of  $n \times n$  unitary matrices, denoted  $U(n)$ , is a subgroup of  $GL(n, \mathbb{C})$ , called the unitary group. The subgroup of elements of  $U(n)$  with determinant one is the special unitary group, denoted  $SU(n)$ . Similarly, the set of  $n \times n$  real orthogonal matrices, denoted  $O(n)$ , is a subgroup of  $GL(n, \mathbb{R})$ , called the real, orthogonal group, and the subgroup of real, orthogonal matrices of determinant one is  $SO(n)$ , the special orthogonal group.
7. Let  $U$  be unitary. Then
  - $\|A\|_F = \|U^*AU\|_F$ .
  - $\|A\|_2 = \|U^*AU\|_2$ .
  - $A$  and  $U^*AU$  have the same singular values, as well as the same eigenvalues.
  - $W(A) = W(U^*AU)$ .
8. [Sch09] Any square, complex matrix  $A$  is unitarily similar to a triangular matrix. If  $T = U^*AU$  is triangular, then the diagonal entries of  $T$  are the eigenvalues of  $A$ . The unitary matrix  $U$  can be chosen to get the eigenvalues in any desired order along the diagonal of  $T$ . Algorithm 1 below gives a method for finding  $U$ , assuming that one knows how to find an eigenvalue and eigenvector, e.g., by exact methods for small matrices (Section 4.3), and how to find an orthonormal basis containing the given vector, e.g., by the Gram-Schmidt process (Section 5.5). This algorithm is designed to illuminate the result, not for computation with large matrices in finite precision arithmetic; for such problems appropriate numerical methods should be used (cf. Section 43.2).

**Algorithm 1: Unitary Triangularization**Input:  $A \in \mathbb{C}^{n \times n}$ .Output: unitary  $U$  such that  $U^*AU = T$  is triangular.

1.  $A_1 = A$ .
2. FOR  $k = 1, \dots, n - 1$ 
  - (a) Find an eigenvalue and normalized eigenvector  $\mathbf{x}$  of the  $(n + 1 - k) \times (n + 1 - k)$  matrix  $A_k$ .
  - (b) Find an orthonormal basis  $\mathbf{x}, \mathbf{y}_2, \dots, \mathbf{y}_{n+1-k}$  for  $\mathbb{C}^{n+1-k}$ .
  - (c)  $U_k = [\mathbf{x}, \mathbf{y}_2, \dots, \mathbf{y}_{n+1-k}]$ .
  - (d)  $\tilde{U}_k = I_{k-1} \oplus U_k$  ( $\tilde{U}_1 = U_1$ ).
  - (e)  $B_k = U_k^* A_k U_k$ .
  - (f)  $A_{k+1} = B_k(1)$ , the  $(n - k) \times (n - k)$  matrix obtained from  $B_k$  by deleting the first row and column.
3.  $U = \tilde{U}_1 \tilde{U}_2, \dots, \tilde{U}_{n-1}$ .

9. (A strictly real version of the Schur unitary triangularization theorem) If  $A$  is a real matrix, then there is a real, orthogonal matrix  $Q$  such that  $Q^T A Q$  is block triangular, with the blocks of size  $1 \times 1$  or  $2 \times 2$ . Each real eigenvalue of  $A$  appears as a  $1 \times 1$  block of  $Q^T A Q$  and each nonreal pair of complex conjugate eigenvalues corresponds to a  $2 \times 2$  diagonal block of  $Q^T A Q$ .
10. If  $\mathcal{F}$  is a commuting family of matrices, then  $\mathcal{F}$  is simultaneously unitarily triangularizable — i.e., there is a unitary matrix  $U$  such that  $U^*AU$  is triangular for every matrix  $A$  in  $\mathcal{F}$ . This fact has the analogous real form also.
11. [Lit53] [Mit53] [Sha91] Let  $\lambda_1, \lambda_2, \dots, \lambda_t$  be the distinct eigenvalues of  $A$  with multiplicities  $m_1, m_2, \dots, m_t$ . Suppose  $U^*AU$  is block triangular with diagonal blocks  $A_1, A_2, \dots, A_t$ , where  $A_i$  is size  $m_i \times m_i$  and  $\lambda_i$  is the only eigenvalue of  $A_i$  for each  $i$ . Then the Jordan canonical form of  $A$  is the direct sum of the Jordan canonical forms of the blocks  $A_1, A_2, \dots, A_t$ . *Note:* This conclusion also holds if the unitary similarity  $U$  is replaced by an ordinary similarity.
12. Let  $\lambda_1, \lambda_2, \dots, \lambda_n$  be the eigenvalues of the  $n \times n$  matrix  $A$  and let  $T = U^*AU$  be triangular. Then  $\|A\|_F^2 = \sum_{i=1}^n |\lambda_i|^2 + \sum_{i < j} |t_{ij}|^2$ . Hence,  $\|A\|_F^2 \geq \sum_{i=1}^n |\lambda_i|^2$  and equality holds if and only if  $T$  is diagonal, or equivalently, if and only if  $A$  is normal (see Section 7.2).
13. A  $2 \times 2$  matrix  $A$  with eigenvalues  $\lambda_1, \lambda_2$  is unitarily similar to the triangular matrix  $\begin{bmatrix} \lambda_1 & r \\ 0 & \lambda_2 \end{bmatrix}$ , where  $r = \sqrt{\|A\|_F^2 - (|\lambda_1|^2 + |\lambda_2|^2)}$ . Note that  $r$  is real and nonnegative.
14. Two  $2 \times 2$  matrices,  $A$  and  $B$ , are unitarily similar if and only if they have the same eigenvalues and  $\|A\|_F = \|B\|_F$ .
15. Any square matrix  $A$  is unitarily similar to a matrix in which all of the diagonal entries are equal to  $\frac{\text{tr}(A)}{n}$ .
16. [Spe40] Two  $n \times n$  matrices,  $A$  and  $B$ , are unitarily equivalent if and only if  $\text{tr } \omega(A, A^*) = \text{tr } \omega(B, B^*)$  for every word  $\omega(s, t)$  in two noncommuting variables.
17. [Pea62] Two  $n \times n$  matrices,  $A$  and  $B$ , are unitarily equivalent if and only if  $\text{tr } \omega(A, A^*) = \text{tr } \omega(B, B^*)$  for every word  $\omega(s, t)$  in two noncommuting variables of degree at most  $2n^2$ .

**Examples:**

1. The matrix  $\frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ i & -i \end{bmatrix}$  is unitary but not orthogonal.
2. The matrix  $\frac{1}{\sqrt{1+2i}} \begin{bmatrix} 1 & 1+i \\ 1+i & -1 \end{bmatrix}$  is orthogonal but not unitary.

3. Fact 13 shows that  $A = \begin{bmatrix} 3 & 1 \\ 2 & 2 \end{bmatrix}$  is unitarily similar to  $A = \begin{bmatrix} 4 & 1 \\ 0 & 1 \end{bmatrix}$ .

4. For any nonzero  $r$ , the matrices  $\begin{bmatrix} 3 & r \\ 0 & 2 \end{bmatrix}$  and  $\begin{bmatrix} 3 & 0 \\ 0 & 2 \end{bmatrix}$  are similar, but not unitarily similar.

5. Let  $A = \begin{bmatrix} -31 & 21 & 48 \\ -4 & 4 & 6 \\ -20 & 13 & 31 \end{bmatrix}$ . Apply Algorithm 1 to  $A$ :

Step 1.  $A_1 = A$ .

Step 2. For

$k = 1$ : (a)  $p_{A_1}(x) = x^3 - 4x^2 + 5x - 2 = (x - 2)(x - 1)^2$ , so the eigenvalues are 1, 1, 2. From the reduced row echelon form of  $A - I_3$ , we see that  $[3, 0, 2]^T$  is an eigenvector for 1 and, thus,  $\mathbf{x} = [\frac{3}{\sqrt{13}}, 0, \frac{2}{\sqrt{13}}]^T$  is a normalized eigenvector.

(b) One expects to apply the Gram–Schmidt process to a basis that includes  $\mathbf{x}$  as the first vector to produce an orthonormal basis. In this example, it is obvious how to find an orthonormal basis for  $\mathbb{C}^3$ :

$$(c) U_1 = \begin{bmatrix} \frac{3}{\sqrt{13}} & 0 & -\frac{2}{\sqrt{13}} \\ 0 & 1 & 0 \\ \frac{2}{\sqrt{13}} & 0 & \frac{3}{\sqrt{13}} \end{bmatrix}.$$

(d) unnecessary.

$$(e) B_1 = U_1^* A_1 U_1 = \begin{bmatrix} 1 & \frac{89}{\sqrt{13}} & 68 \\ 0 & 4 & 2\sqrt{13} \\ 0 & -\frac{3}{\sqrt{13}} & -1 \end{bmatrix}.$$

$$(f) A_2 = \begin{bmatrix} 4 & 2\sqrt{13} \\ -\frac{3}{\sqrt{13}} & -1 \end{bmatrix}.$$

$k = 2$ : (a) 1 is still an eigenvalue of  $A_2$ . From the reduced row echelon form of  $A_2 - I_2$ , we see that  $[-2\sqrt{13}, 3]^T$  is an eigenvector for 1 and, thus,  $\mathbf{x} = [-2\sqrt{\frac{13}{61}}, \frac{3}{\sqrt{61}}]^T$  is a normalized eigenvector.

(b) Again, the orthonormal basis is obvious:

$$(c) U_2 = \begin{bmatrix} -2\sqrt{\frac{13}{61}} & \frac{3}{\sqrt{61}} \\ \frac{3}{\sqrt{61}} & 2\sqrt{\frac{13}{61}} \end{bmatrix}.$$

$$(d) \tilde{U}_2 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & -2\sqrt{\frac{13}{61}} & \frac{3}{\sqrt{61}} \\ 0 & \frac{3}{\sqrt{61}} & 2\sqrt{\frac{13}{61}} \end{bmatrix}.$$

$$(e) B_2 = \begin{bmatrix} 1 & -\frac{29}{\sqrt{13}} \\ 0 & 2 \end{bmatrix}.$$

(f) unnecessary.

$$\text{Step 3. } U = \tilde{U}_1 \tilde{U}_2 = \begin{bmatrix} \frac{3}{\sqrt{13}} & -\frac{6}{\sqrt{793}} & -\frac{4}{\sqrt{61}} \\ 0 & -2\sqrt{\frac{13}{61}} & \frac{3}{\sqrt{61}} \\ \frac{2}{\sqrt{13}} & \frac{9}{\sqrt{793}} & \frac{6}{\sqrt{61}} \end{bmatrix}, T = U^* A U = \begin{bmatrix} 1 & \frac{26}{\sqrt{61}} & \frac{2035}{\sqrt{793}} \\ 0 & 1 & -\frac{29}{\sqrt{13}} \\ 0 & 0 & 2 \end{bmatrix}.$$

6. [HJ85, p. 84] Schur's theorem tells us that every complex, square matrix is unitarily similar to a triangular matrix. However, it is not true that every complex, square matrix is similar to a triangular matrix via a complex, orthogonal similarity. For, suppose  $A = QTQ^T$ , where  $Q$  is complex orthogonal and  $T$  is triangular. Let  $\mathbf{q}$  be the first column of  $Q$ . Then  $\mathbf{q}$  is an eigenvector of  $A$  and  $\mathbf{q}^T \mathbf{q} = 1$ . However, the matrix  $A = \begin{bmatrix} 1 & i \\ i & -1 \end{bmatrix}$  has no such eigenvector;  $A$  is nilpotent and any eigenvector of  $A$  is a scalar multiple of  $\begin{bmatrix} 1 \\ i \end{bmatrix}$ .

## 7.2 Normal Matrices and Spectral Theory

In this subsection, all matrices are over the complex numbers and are square. All vector spaces are finite dimensional complex inner product spaces.

### Definitions:

The matrix  $A$  is **normal** if  $AA^* = A^*A$ .

The matrix  $A$  is **Hermitian** if  $A^* = A$ .

The matrix  $A$  is **skew-Hermitian** if  $A^* = -A$ .

The linear operator,  $T$ , on the complex inner product space  $V$  is **normal** if  $TT^* = T^*T$ .

Two orthogonal projections,  $P$  and  $Q$ , are **pairwise orthogonal** if  $PQ = QP = 0$ . (See Section 5.4 for information about orthogonal projection.)

The matrices  $A$  and  $B$  are said to have **Property L** if their eigenvalues  $\alpha_k, \beta_k, (k = 1, \dots, n)$  may be ordered in such a way that the eigenvalues of  $xA + yB$  are given by  $x\alpha_k + y\beta_k$  for all complex numbers  $x$  and  $y$ .

### Facts:

Most of the material in this section can be found in one or more of the following: [HJ85, Chap. 2] [Hal87, Chap. 3] [Gan59, Chap. IX] [MM64, I.4, III.3.5, III.5] [GJSW87]. Specific references are also given for some facts.

1. Diagonal, Hermitian, skew-Hermitian, and unitary matrices are all normal. Note that real symmetric matrices are Hermitian, real skew-symmetric matrices are skew-Hermitian, and real, orthogonal matrices are unitary, so all of these matrices are normal.
2. If  $U$  is unitary, then  $A$  is normal if and only if  $U^*AU$  is normal.
3. Let  $T$  be a linear operator on the complex inner product space  $V$ . Let  $\mathcal{B}$  be an ordered orthonormal basis of  $V$  and let  $A = [T]_{\mathcal{B}}$ . Then  $T$  is normal if and only if  $A$  is a normal matrix.
4. (Spectral Theorem) The following three versions are equivalent.
  - A matrix is normal if and only if it is unitarily similar to a diagonal matrix. (*Note:* This is sometimes taken as the definition of normal. See Fact 6 below for a strictly real version.)
  - The matrix  $A$  is normal if and only if there is an orthonormal basis of eigenvectors of  $A$ .
  - Let  $\lambda_1, \lambda_2, \dots, \lambda_t$  be the distinct eigenvalues of  $A$  with algebraic multiplicities  $m_1, m_2, \dots, m_t$ . Then  $A$  is normal if and only if there exist  $t$  pairwise orthogonal, orthogonal projections  $P_1, P_2, \dots, P_t$  such that  $\sum_{i=1}^t P_i = I$ ,  $\text{rank}(P_i) = m_i$ , and  $A = \sum_{i=1}^t \lambda_i P_i$ . (*Note:* that the two orthogonal projections  $P$  and  $Q$  are pairwise orthogonal if and only if  $\text{range}(P)$  and  $\text{range}(Q)$  are orthogonal subspaces.)
5. (Principal Axes Theorem) A real matrix  $A$  is symmetric if and only if  $A = QDQ^T$ , where  $Q$  is a real, orthogonal matrix and  $D$  is a real, diagonal matrix. Equivalently, a real matrix  $A$  is symmetric

if and only if there is a real, orthonormal basis of eigenvectors of  $A$ . Note that the eigenvalues of  $A$  appear on the diagonal of  $D$ , and the columns of  $Q$  are eigenvectors of  $A$ . The Principal Axes Theorem follows from the Spectral Theorem, and the fact that all of the eigenvalues of a Hermitian matrix are real.

6. (A strictly real version of the Spectral Theorem) If  $A$  is a real, normal matrix, then there is a real, orthogonal matrix  $Q$  such that  $Q^T A Q$  is block diagonal, with the blocks of size  $1 \times 1$  or  $2 \times 2$ . Each real eigenvalue of  $A$  appears as a  $1 \times 1$  block of  $Q^T A Q$  and each nonreal pair of complex conjugate eigenvalues corresponds to a  $2 \times 2$  diagonal block of  $Q^T A Q$ .
7. The following are equivalent. See also Facts 4 and 8. See [GJSW87] and [EI98] for more equivalent conditions.
  - $A$  is normal.
  - $A^*$  can be expressed as a polynomial in  $A$ .
  - For any  $B$ ,  $AB = BA$  implies  $A^*B = BA^*$ .
  - Any eigenvector of  $A$  is also an eigenvector of  $A^*$ .
  - Each invariant subspace of  $A$  is also an invariant subspace of  $A^*$ .
  - For each invariant subspace,  $\mathcal{V}$ , of  $A$ , the orthogonal complement,  $\mathcal{V}^\perp$ , is also an invariant subspace of  $A$ .
  - $\langle A\mathbf{x}, A\mathbf{y} \rangle = \langle A^*\mathbf{x}, A^*\mathbf{y} \rangle$  for all vectors  $\mathbf{x}$  and  $\mathbf{y}$ .
  - $\langle A\mathbf{x}, A\mathbf{x} \rangle = \langle A^*\mathbf{x}, A^*\mathbf{x} \rangle$  for every vector  $\mathbf{x}$ .
  - $\|A\mathbf{x}\| = \|A^*\mathbf{x}\|$  for every vector  $\mathbf{x}$ .
  - $A^* = UA$  for some unitary matrix  $U$ .
  - $\|A\|_F^2 = \sum_{i=1}^n |\lambda_i|^2$ , where  $\lambda_1, \lambda_2, \dots, \lambda_n$  are the eigenvalues of  $A$ .
  - The singular values of  $A$  are  $|\lambda_1|, |\lambda_2|, \dots, |\lambda_n|$ , where  $\lambda_1, \lambda_2, \dots, \lambda_n$  are the eigenvalues of  $A$ .
  - If  $A = UP$  is a polar decomposition of  $A$ , then  $UP = PU$ . (See Section 8.4.)
  - $A$  commutes with a normal matrix with distinct eigenvalues.
  - $A$  commutes with a Hermitian matrix with distinct eigenvalues.
  - The Hermitian matrix  $AA^* - A^*A$  is semidefinite (i.e., it does not have both positive and negative eigenvalues).
8. Let  $H = \frac{A + A^*}{2}$  and  $K = \frac{A - A^*}{2i}$ . Then  $H$  and  $K$  are Hermitian and  $A = H + iK$ . The matrix  $A$  is normal if and only if  $HK = KH$ .
9. If  $A$  is normal, then
  - $A$  is Hermitian if and only if all of the eigenvalues of  $A$  are real.
  - $A$  is skew-Hermitian if and only if all of the eigenvalues of  $A$  are pure imaginary.
  - $A$  is unitary if and only if all of the eigenvalues of  $A$  have modulus 1.
10. The matrix  $U$  is unitary if and only if  $U = \exp(iH)$  where  $H$  is Hermitian.
11. If  $Q$  is a real matrix with  $\det(Q) = 1$ , then  $Q$  is orthogonal if and only if  $Q = \exp(K)$ , where  $K$  is a real, skew-symmetric matrix.
12. (Cayley's Formulas/Cayley Transform) If  $U$  is unitary and does not have  $-1$  as an eigenvalue, then  $U = (I + iH)(I - iH)^{-1}$ , where  $H = i(I - U)(I + U)^{-1}$  is Hermitian.
13. (Cayley's Formulas/Cayley Transform, real version) If  $Q$  is a real, orthogonal matrix which does not have  $-1$  as an eigenvalue, then  $Q = (I - K)(I + K)^{-1}$ , where  $K = (I - Q)(I + Q)^{-1}$  is a real, skew-symmetric matrix.
14. A triangular matrix is normal if and only if it is diagonal. More generally, if the block triangular matrix,  $\begin{bmatrix} B_{11} & B_{12} \\ 0 & B_{22} \end{bmatrix}$  (where the diagonal blocks,  $B_{ii}$ ,  $i = 1, 2$ , are square), is normal, then  $B_{12} = 0$ .

15. Let  $A$  be a normal matrix. Then the diagonal entries of  $A$  are the eigenvalues of  $A$  if and only if  $A$  is diagonal.
16. If  $A$  and  $B$  are normal and commute, then  $AB$  is normal. However, the product of two noncommuting normal matrices need not be normal. (See Example 3 below.)
17. If  $A$  is normal, then  $\rho(A) = \|A\|_2$ . Consequently, if  $A$  is normal, then  $\rho(A) \geq |a_{ij}|$  for all  $i$  and  $j$ . The converses of both of these facts are false (see Example 4 below).
18. [MM64, p. 168] [MM55] [ST80] If  $A$  is normal, then  $W(A)$  is the convex hull of the eigenvalues of  $A$ . The converse of this statement holds when  $n \leq 4$ , but not for  $n \geq 5$ .
19. [WW49] [MM64, page 162] Let  $A$  be a normal matrix and suppose  $x$  is a vector such that  $(Ax)_i = 0$  whenever  $x_i = 0$ . For each nonzero component,  $x_j$ , of  $x$ , define  $\mu_j = \frac{(Ax)_j}{x_j}$ . Note that  $\mu_j$  is a complex number, which we regard as a point in the plane. Then any closed disk that contains all of the points  $\mu_j$  must contain an eigenvalue of  $A$ .
20. [HW53] Let  $A$  and  $B$  be normal matrices with eigenvalues  $\alpha_1, \dots, \alpha_n$  and  $\beta_1, \dots, \beta_n$ . Then

$$\min_{\sigma \in S_n} \sum_{i=1}^n |\alpha_i - \beta_{\sigma(i)}|^2 \leq \|A - B\|_F^2 \leq \max_{\sigma \in S_n} \sum_{i=1}^n |\alpha_i - \beta_{\sigma(i)}|^2,$$

where the minimum and maximum are over all permutations  $\sigma$  in the symmetric group  $S_n$  (i.e., the group of all permutations of  $1, \dots, n$ ).

21. [Sun82] [Bha82] Let  $A$  and  $B$  be  $n \times n$  normal matrices with eigenvalues  $\alpha_1, \dots, \alpha_n$  and  $\beta_1, \dots, \beta_n$ . Let  $\Lambda_A, \Lambda_B$  be the diagonal matrices with diagonal entries  $\alpha_1, \dots, \alpha_n$  and  $\beta_1, \dots, \beta_n$ , respectively. Let  $\|\cdot\|$  be any unitarily invariant norm. Then, if  $A - B$  is normal, we have

$$\min_P \|\Lambda_A - P^{-1} \Lambda_B P\| \leq \|A - B\| \leq \max_P \|\Lambda_A - P^{-1} \Lambda_B P\|,$$

where the maximum and minimum are over all  $n \times n$  permutation matrices  $P$ .

Observe that if  $A$  and  $B$  are Hermitian, then  $A - B$  is also Hermitian and, hence, normal, so this inequality holds for all pairs of Hermitian matrices. However, Example 6 gives a pair of  $2 \times 2$  normal matrices (with  $A - B$  not normal) for which the inequality does not hold. Note that for the Frobenius norm, we get the Hoffman–Wielandt inequality (20), which does hold for all pairs of normal matrices.

For the operator norm,  $\|\cdot\|_2$ , this gives the inequality

$$\min_{\sigma \in S_n} \max_j |\alpha_j - \beta_{\sigma(j)}| \leq \|A - B\|_2 \leq \max_{\sigma \in S_n} \max_j |\alpha_j - \beta_{\sigma(j)}|$$

(assuming  $A - B$  is normal), which, for the case of Hermitian  $A$  and  $B$ , is a classical result of Weyl [Wey12].

22. [OS90][BEK97][BDM83][BDK89][Hol92][AN86] Let  $A$  and  $B$  be normal matrices with eigenvalues  $\alpha_1, \dots, \alpha_n$  and  $\beta_1, \dots, \beta_n$ , respectively. Using  $\|A\|_2 \leq \|A\|_F \leq \sqrt{n} \|A\|_2$  together with the Hoffman–Wielandt inequality (20) yields

$$\frac{1}{\sqrt{n}} \min_{\sigma \in S_n} \max_j |\alpha_j - \beta_{\sigma(j)}| \leq \|A - B\|_2 \leq \sqrt{n} \max_{\sigma \in S_n} \max_j |\alpha_j - \beta_{\sigma(j)}|.$$

On the right-hand side, the factor  $\sqrt{n}$  may be replaced by  $\sqrt{2}$  and it is known that this constant is the best possible. On the left-hand side, the factor  $\frac{1}{\sqrt{n}}$  may be replaced by the constant  $\frac{1}{2.91}$ , but the best possible value for this constant is still unknown. Thus, we have

$$\frac{1}{2.91} \min_{\sigma \in S_n} \max_j |\alpha_j - \beta_{\sigma(j)}| \leq \|A - B\|_2 \leq \sqrt{2} \max_{\sigma \in S_n} \max_j |\alpha_j - \beta_{\sigma(j)}|.$$

See also [Bha82], [Bha87], [BH85], [Sun82], [Sund82].

23. If  $A$  and  $B$  are normal matrices, then  $AB = BA$  if and only if  $A$  and  $B$  have Property L. This was established for Hermitian matrices by Motzkin and Taussky [MT52] and then generalized to the normal case by Wiegmann [Wieg53]. For a stronger generalization see [Wiel53].
24. [Fri02] Let  $a_{ij}, i = 1, \dots, n, j = 1, \dots, n$ , be any set of  $\frac{n(n+1)}{2}$  complex numbers. Then there exists an  $n \times n$  normal matrix,  $N$ , such that  $n_{ij} = a_{ij}$  for  $i \leq j$ . Thus, any upper triangular matrix  $A$  can be completed to a normal matrix.
25. [Bha87, p. 54] Let  $A$  be a normal  $n \times n$  matrix and let  $B$  be an arbitrary  $n \times n$  matrix such that  $\|A - B\|_2 < \epsilon$ . Then every eigenvalue of  $B$  is within distance  $\epsilon$  of an eigenvalue of  $A$ . Example 7 below shows that this need not hold for an arbitrary pair of matrices.
26. There are various ways to measure the “nonnormality” of a matrix. For example, if  $A$  has eigenvalues  $\lambda_1, \lambda_2, \dots, \lambda_n$ , the quantity  $\sqrt{\|A\|_F^2 - \sum_{i=1}^n |\lambda_i|^2}$  is a natural measure of nonnormality, as is  $\|A^*A - AA^*\|_2$ . One could also consider  $\|A^*A - AA^*\|$  for other choices of norm, or look at  $\min\{\|A - N\| : N \text{ is normal}\}$ . Fact 8 above suggests  $\|HK - KH\|$  as a possible measure of nonnormality, while the polar decomposition (see Fact 7 above)  $A = UP$  of  $A$  suggests  $\|UP - PU\|$ . See [EP87] for more measures of nonnormality and comparisons between them.
27. [Lin97] [FR96] For any  $\epsilon > 0$  there is a  $\delta > 0$  such that, for any  $n \times n$  complex matrix  $A$  with  $\|AA^* - A^*A\|_2 < \delta$ , there is a normal matrix  $N$  with  $\|N - A\|_2 < \epsilon$ . Thus, a matrix which is approximately normal is close to a normal matrix.

### Examples:

1. Let  $A = \begin{bmatrix} 3 & 1 \\ 1 & 3 \end{bmatrix}$  and  $U = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$ . Then  $U^*AU = \begin{bmatrix} 4 & 0 \\ 0 & 2 \end{bmatrix}$  and  $A = 4P_1 + 2P_2$ , where the  $P_i$ 's are the pairwise orthogonal, orthogonal projection matrices

$$P_1 = U \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} U^* = \frac{1}{2} \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} \quad \text{and} \quad P_2 = U \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix} U^* = \frac{1}{2} \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix}.$$

2.  $A = \begin{bmatrix} 1 & 4+2i & 6 \\ 0 & 8+2i & 0 \\ 2 & -2i & 4i \end{bmatrix} = H + iK$ , where  $H = \begin{bmatrix} 1 & 2+i & 4 \\ 2-i & 8 & i \\ 4 & -i & 0 \end{bmatrix}$  and  $K = \begin{bmatrix} 0 & 1-2i & -2i \\ 1+2i & 2 & -1 \\ 2i & -1 & 4 \end{bmatrix}$  are Hermitian.

3.  $A = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$  and  $B = \begin{bmatrix} 0 & 1 \\ 1 & 1 \end{bmatrix}$  are both normal matrices, but the product  $AB = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$  is not normal.

4. Let  $A = \begin{bmatrix} 2 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix}$ . Then  $\rho(A) = 2 = \|A\|_2$ , but  $A$  is not normal.

5. Let  $Q = \begin{bmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{bmatrix}$ . Put  $U = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & i \\ i & 1 \end{bmatrix}$  and  $D = \begin{bmatrix} e^{i\theta} & 0 \\ 0 & e^{-i\theta} \end{bmatrix}$ . Then  $Q = UDU^*$  =  $U \left( \exp i \begin{bmatrix} \theta & 0 \\ 0 & -\theta \end{bmatrix} \right) U^* = \exp i \left( U \begin{bmatrix} \theta & 0 \\ 0 & -\theta \end{bmatrix} U^* \right)$ . Put  $H = U \begin{bmatrix} \theta & 0 \\ 0 & -\theta \end{bmatrix} U^* = \begin{bmatrix} 0 & -i\theta \\ i\theta & 0 \end{bmatrix}$ .

Then  $H$  is Hermitian and  $Q = \exp(iH)$ . Also,  $K = iH = \begin{bmatrix} 0 & \theta \\ -\theta & 0 \end{bmatrix}$  is a real, skew-symmetric matrix and  $Q = \exp(K)$ .

6. Here is an example from [Sund82] showing that the condition that  $A - B$  be normal cannot be dropped from 21. Let  $A = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$  and  $B = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$ . Then  $A$  is Hermitian with eigenvalues  $\pm 1$

and  $B$  is skew-Hermitian with eigenvalues  $\pm i$ . So, we have  $\|\Lambda_A - P^{-1}\Lambda_B P\|_2 = \sqrt{2}$ , regardless of the permutation  $P$ . However,  $A - B = \begin{bmatrix} 0 & 2 \\ 0 & 0 \end{bmatrix}$  and  $\|A - B\|_2 = 2$ .

7. This example shows that Fact 25 above does not hold for general pairs of matrices. Let  $\alpha > \beta > 0$  and put  $A = \begin{bmatrix} 0 & \alpha \\ \beta & 0 \end{bmatrix}$  and  $B = \begin{bmatrix} 0 & \alpha - \beta \\ 0 & 0 \end{bmatrix}$ . Then the eigenvalues of  $A$  are  $\pm\sqrt{\alpha\beta}$  and both eigenvalues of  $B$  are zero. We have  $A - B = \begin{bmatrix} 0 & \beta \\ \beta & 0 \end{bmatrix}$  and  $\|A - B\|_2 = \beta$ . But, since  $\alpha > \beta$ , we have  $\sqrt{\alpha\beta} > \beta = \|A - B\|_2$ .

### 8.1 Hermitian Matrices

---

All matrices in this section are either real or complex, unless explicitly stated otherwise.

#### Definitions:

A matrix  $A \in \mathbb{C}^{n \times n}$  is **Hermitian** or **self-adjoint** if  $A^* = A$ , or element-wise,  $\bar{a}_{ij} = a_{ji}$ , for  $i, j = 1, \dots, n$ . The set of Hermitian matrices of order  $n$  is denoted by  $\mathcal{H}_n$ . Note that a matrix  $A \in \mathbb{R}^{n \times n}$  is Hermitian if and only if  $A^T = A$ .

A matrix  $A \in \mathbb{C}^{n \times n}$  is **symmetric** if  $A^T = A$ , or element-wise,  $a_{ij} = a_{ji}$ , for  $i, j = 1, \dots, n$ . The set of real symmetric matrices of order  $n$  is denoted by  $\mathcal{S}_n$ . Since  $\mathcal{S}_n$  is a subset of  $\mathcal{H}_n$ , all theorems for matrices in  $\mathcal{H}_n$  apply to  $\mathcal{S}_n$  as well.

Let  $V$  be a complex inner product space with inner product  $\langle \mathbf{v}, \mathbf{w} \rangle$  and let  $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_n \in V$ . The matrix  $G = [g_{ij}] \in \mathbb{C}^{n \times n}$  defined by  $g_{ij} = \langle \mathbf{v}_i, \mathbf{v}_j \rangle$ ,  $i, j \in \{1, 2, \dots, n\}$  is called the **Gram matrix** of the vectors  $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_n$ .

The inner product  $\langle \mathbf{x}, \mathbf{y} \rangle$  of two vectors  $\mathbf{x}, \mathbf{y} \in \mathbb{C}^n$  will mean the standard inner product, i.e.,  $\langle \mathbf{x}, \mathbf{y} \rangle = \mathbf{y}^* \mathbf{x}$ , unless stated otherwise. The term orthogonal will mean orthogonal with respect to this inner product, unless stated otherwise.

#### Facts:

For facts without a specific reference, see [HJ85, pp. 38, 101–104, 169–171, 175], [Lax96, pp. 80–83], and [GR01, pp. 169–171]. Many are an immediate consequence of the definition.

1. A real symmetric matrix is Hermitian, and a real Hermitian matrix is symmetric.
2. Let  $A, B$  be Hermitian.

- (a) Then  $A + B$  is Hermitian.  
 (b) If  $AB = BA$ , then  $AB$  is Hermitian.  
 (c) If  $c \in \mathbb{R}$ , then  $cA$  is Hermitian.
- $A + A^*$ ,  $A^* + A$ ,  $AA^*$ , and  $A^*A$  are Hermitian for all  $A \in \mathbb{C}^{n \times n}$ .
  - If  $A \in \mathcal{H}_n$ , then  $\langle A\mathbf{x}, \mathbf{y} \rangle = \langle \mathbf{x}, A\mathbf{y} \rangle$  for all  $\mathbf{x}, \mathbf{y} \in \mathbb{C}^n$ .
  - If  $A \in \mathcal{H}_n$ , then  $A^k \in \mathcal{H}_n$  for all  $k \in \mathbb{N}$ .
  - If  $A \in \mathcal{H}_n$  is invertible, then  $A^{-1} \in \mathcal{H}_n$ .
  - The main diagonal entries of a Hermitian matrix are real.
  - All eigenvalues of a Hermitian matrix are real.
  - Eigenvectors corresponding to distinct eigenvalues of a Hermitian matrix are orthogonal.
  - Spectral Theorem — Diagonalization version:* If  $A \in \mathcal{H}_n$ , there is a unitary matrix  $U \in \mathbb{C}^{n \times n}$  such that  $U^*AU = D$ , where  $D$  is a real diagonal matrix whose diagonal entries are the eigenvalues of  $A$ . If  $A \in \mathcal{S}_n$ , the same conclusion holds with an orthogonal matrix  $Q \in \mathbb{R}^{n \times n}$ , i.e.,  $Q^T A Q = D$ .
  - Spectral Theorem — Orthonormal basis version:* If  $A \in \mathcal{H}_n$ , there is an orthonormal basis of  $\mathbb{C}^n$  consisting of eigenvectors of  $A$ . If  $A \in \mathcal{S}_n$ , the same conclusion holds with  $\mathbb{C}^n$  replaced by  $\mathbb{R}^n$ .
  - [Lay97, p. 447] *Spectral Theorem — Sum of rank one projections version:* Let  $A \in \mathcal{H}_n$  with eigenvalues  $\lambda_1, \lambda_2, \dots, \lambda_n$ , and corresponding orthonormal eigenvectors  $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_n$ . Then

$$A = \lambda_1 \mathbf{u}_1 \mathbf{u}_1^* + \lambda_2 \mathbf{u}_2 \mathbf{u}_2^* + \cdots + \lambda_n \mathbf{u}_n \mathbf{u}_n^*.$$

If  $A \in \mathcal{S}_n$ , then

$$A = \lambda_1 \mathbf{u}_1 \mathbf{u}_1^T + \lambda_2 \mathbf{u}_2 \mathbf{u}_2^T + \cdots + \lambda_n \mathbf{u}_n \mathbf{u}_n^T.$$

- If  $A \in \mathcal{H}_n$ , then  $\text{rank } A$  equals the number of nonzero eigenvalues of  $A$ .
- Each  $A \in \mathbb{C}^{n \times n}$  can be written uniquely as  $A = H + iK$ , where  $H, K \in \mathcal{H}_n$ .
- Given  $A \in \mathbb{C}^{n \times n}$ , then  $A \in \mathcal{H}_n$  if and only if  $\mathbf{x}^* A \mathbf{x}$  is real for all  $\mathbf{x} \in \mathbb{C}^n$ .
- Any Gram matrix is Hermitian. Some examples of how Gram matrices arise are given in Chapter 66 and [Lax96, p. 124].
- The properties given above for  $\mathcal{H}_n$  and  $\mathcal{S}_n$  are generally not true for symmetric matrices in  $\mathbb{C}^{n \times n}$ , but there is a substantial theory associated with them. (See [HJ85, sections 4.4 and 4.6].)

### Examples:

- The matrix  $\begin{bmatrix} 3 & 2-i \\ 2+i & -5 \end{bmatrix} \in \mathcal{H}_2$  and  $\begin{bmatrix} 6 & 0 & 2 \\ 0 & -1 & 5 \\ 2 & 5 & 3 \end{bmatrix} \in \mathcal{S}_3$ .
- Let  $D$  be an open set in  $\mathbb{R}^n$  containing the point  $\mathbf{x}_0$ , and let  $f : D \rightarrow \mathbb{R}$  be a twice continuously differentiable function on  $D$ . Define  $H \in \mathbb{R}^{n \times n}$  by  $h_{ij} = \frac{\partial^2 f}{\partial x_i \partial x_j}(\mathbf{x}_0)$ . Then  $H$  is a real symmetric matrix, and is called the **Hessian** of  $f$ .
- Let  $G = (V, E)$  be a simple undirected graph with vertex set  $V = \{1, 2, 3, \dots, n\}$ . The  $n \times n$  **adjacency matrix**  $A(G) = [a_{ij}]$  (see Section 28.3) is defined by

$$a_{ij} = \begin{cases} 1 & \text{if } ij \in E \\ 0 & \text{otherwise.} \end{cases}$$

In particular, all diagonal entries of  $A(G)$  are 0. Since  $ij$  is an edge of  $G$  if and only if  $ji$  is, the adjacency matrix is real symmetric. Observe that for each  $i \in V$ ,  $\sum_{j=1}^n a_{ij} = \delta(i)$ , i.e., the sum of the  $i^{\text{th}}$  row is the degree of vertex  $i$ .

## 8.2 Order Properties of Eigenvalues of Hermitian Matrices

**Definitions:**

Given  $A \in \mathcal{H}_n$ , the **Rayleigh quotient**  $R_A : \mathbb{C}^n \setminus \{0\} \rightarrow \mathbb{R}$  is  $R_A(x) = \frac{\mathbf{x}^* A \mathbf{x}}{\mathbf{x}^* \mathbf{x}} = \frac{\langle A \mathbf{x}, \mathbf{x} \rangle}{\langle \mathbf{x}, \mathbf{x} \rangle}$ .

**Facts:**

For facts without a specific reference, see [HJ85, Sections 4.2, 4.3]; however, in that source the eigenvalues are labeled from smallest to greatest and the definition of majorizes (see Preliminaries) has a similar reversal of notation.

1. *Rayleigh–Ritz Theorem:* Let  $A \in \mathcal{H}_n$ , with eigenvalues  $\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_n$ . Then

$$\lambda_n \leq \frac{\mathbf{x}^* A \mathbf{x}}{\mathbf{x}^* \mathbf{x}} \leq \lambda_1, \quad \text{for all nonzero } \mathbf{x} \in \mathbb{C}^n,$$

$$\lambda_1 = \max_{\mathbf{x} \neq 0} \frac{\mathbf{x}^* A \mathbf{x}}{\mathbf{x}^* \mathbf{x}} = \max_{\|\mathbf{x}\|_2=1} \mathbf{x}^* A \mathbf{x},$$

and

$$\lambda_n = \min_{\mathbf{x} \neq 0} \frac{\mathbf{x}^* A \mathbf{x}}{\mathbf{x}^* \mathbf{x}} = \min_{\|\mathbf{x}\|_2=1} \mathbf{x}^* A \mathbf{x}.$$

2. *Courant–Fischer Theorem:* Let  $A \in M_n$  be a Hermitian matrix with eigenvalues  $\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_n$ , and let  $k$  be a given integer with  $1 \leq k \leq n$ . Then

$$\max_{\mathbf{w}_1, \mathbf{w}_2, \dots, \mathbf{w}_{n-k} \in \mathbb{C}^n} \min_{\substack{\mathbf{x} \neq 0, \mathbf{x} \in \mathbb{C}^n \\ \mathbf{x} \perp \mathbf{w}_1, \mathbf{w}_2, \dots, \mathbf{w}_{n-k}}} \frac{\mathbf{x}^* A \mathbf{x}}{\mathbf{x}^* \mathbf{x}} = \lambda_k$$

and

$$\min_{\mathbf{w}_1, \mathbf{w}_2, \dots, \mathbf{w}_{k-1} \in \mathbb{C}^n} \max_{\substack{\mathbf{x} \neq 0, \mathbf{x} \in \mathbb{C}^n \\ \mathbf{x} \perp \mathbf{w}_1, \mathbf{w}_2, \dots, \mathbf{w}_{k-1}}} \frac{\mathbf{x}^* A \mathbf{x}}{\mathbf{x}^* \mathbf{x}} = \lambda_k.$$

3. (Also [Bha01, p. 291]) *Weyl Inequalities:* Let  $A, B \in \mathcal{H}_n$  and assume that the eigenvalues of  $A, B$  and  $A+B$  are arranged in decreasing order. Then for every pair of integers  $j, k$  such that  $1 \leq j, k \leq n$  and  $j+k \leq n+1$ ,

$$\lambda_{j+k-1}(A+B) \leq \lambda_j(A) + \lambda_k(B)$$

and for every pair of integers  $j, k$  such that  $1 \leq j, k \leq n$  and  $j+k \geq n+1$ ,

$$\lambda_{j+k-n}(A+B) \geq \lambda_j(A) + \lambda_k(B).$$

4. *Weyl Inequalities:* These inequalities are a prominent special case of Fact 3. Let  $A, B \in \mathcal{H}_n$  and assume that the eigenvalues of  $A, B$  and  $A+B$  are arranged in decreasing order. Then for each  $j \in \{1, 2, \dots, n\}$ ,

$$\lambda_j(A) + \lambda_n(B) \leq \lambda_j(A+B) \leq \lambda_j(A) + \lambda_1(B).$$

5. *Interlacing Inequalities:* Let  $A \in \mathcal{H}_n$ , let  $\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_n$  be the eigenvalues of  $A$ , and for any  $i \in \{1, 2, \dots, n\}$ , let  $\mu_1 \geq \mu_2 \geq \dots \geq \mu_{n-1}$  be the eigenvalues of  $A(i)$ , where  $A(i)$  is the principal

submatrix of  $A$  obtained by deleting its  $i^{\text{th}}$  row and column. Then

$$\lambda_1 \geq \mu_1 \geq \lambda_2 \geq \mu_2 \geq \lambda_3 \geq \dots \geq \lambda_{n-1} \geq \mu_{n-1} \geq \lambda_n.$$

6. Let  $A \in \mathcal{H}_n$  and let  $B$  be any principal submatrix of  $A$ . If  $\lambda_k$  is the  $k^{\text{th}}$  largest eigenvalue of  $A$  and  $\mu_k$  is the  $k^{\text{th}}$  largest eigenvalue of  $B$ , then  $\lambda_k \geq \mu_k$ .
7. Let  $A \in \mathcal{H}_n$  with eigenvalues  $\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_n$ . Let  $S$  be a  $k$ -dimensional subspace of  $\mathbb{C}^n$  with  $k \in \{1, 2, \dots, n\}$ . Then
  - (a) If there is a constant  $c$  such that  $\mathbf{x}^* A \mathbf{x} \geq c \mathbf{x}^* \mathbf{x}$  for all  $\mathbf{x} \in S$ , then  $\lambda_k \geq c$ .
  - (b) If there is a constant  $c$  such that  $\mathbf{x}^* A \mathbf{x} \leq c \mathbf{x}^* \mathbf{x}$  for all  $\mathbf{x} \in S$ , then  $\lambda_{n-k+1} \leq c$ .
8. Let  $A \in \mathcal{H}_n$ .
  - (a) If  $\mathbf{x}^* A \mathbf{x} \geq 0$  for all  $\mathbf{x}$  in a  $k$ -dimensional subspace of  $\mathbb{C}^n$ , then  $A$  has at least  $k$  nonnegative eigenvalues.
  - (b) If  $\mathbf{x}^* A \mathbf{x} > 0$  for all nonzero  $\mathbf{x}$  in a  $k$ -dimensional subspace of  $\mathbb{C}^n$ , then  $A$  has at least  $k$  positive eigenvalues.
9. Let  $A \in \mathcal{H}_n$ , let  $\lambda = (\lambda_1, \lambda_2, \dots, \lambda_n)$  be the vector of eigenvalues of  $A$  arranged in decreasing order, and let  $\alpha = (a_1, a_2, \dots, a_n)$  be the vector consisting of the diagonal entries of  $A$  arranged in decreasing order. Then  $\lambda \succeq \alpha$ . (See Preliminaries for the definition of  $\succeq$ .)
10. Let  $\alpha = (a_1, a_2, \dots, a_n)$ ,  $\beta = (b_1, b_2, \dots, b_n)$  be decreasing sequences of real numbers such that  $\alpha \succeq \beta$ . Then there exists an  $A \in \mathcal{H}_n$  such that the eigenvalues of  $A$  are  $a_1, a_2, \dots, a_n$ , and the diagonal entries of  $A$  are  $b_1, b_2, \dots, b_n$ .
11. [Lax96, pp. 133–6] or [Bha01, p. 291] (See also Chapter 15.) Let  $A, B \in \mathcal{H}_n$  with eigenvalues  $\lambda_1(A) \geq \lambda_2(A) \geq \dots \geq \lambda_n(A)$  and  $\lambda_1(B) \geq \lambda_2(B) \geq \dots \geq \lambda_n(B)$ . Then
  - (a)  $|\lambda_i(A) - \lambda_i(B)| \leq \|A - B\|_2$ ,  $i = 1, \dots, n$ .
  - (b)  $\sum_{i=1}^n [\lambda_i(A) - \lambda_i(B)]^2 \leq \|A - B\|_F^2$ .

### Examples:

1. Setting  $\mathbf{x} = \mathbf{e}_i$  in the Rayleigh-Ritz theorem, we obtain  $\lambda_n \leq a_{ii} \leq \lambda_1$ . Thus, for any  $A \in \mathcal{H}_n$ , we have  $\lambda_1 \geq \max\{a_{ii} \mid i \in \{1, 2, \dots, n\}\}$  and  $\lambda_n \leq \min\{a_{ii} \mid i \in \{1, 2, \dots, n\}\}$ .
2. Setting  $\mathbf{x} = [1, 1, \dots, 1]^T$  in the Rayleigh-Ritz theorem, we find that  $\lambda_n \leq \frac{1}{n} \sum_{i,j=1}^n a_{ij} \leq \lambda_1$ . If we take  $A$  to be the adjacency matrix of a graph, then this inequality implies that the largest eigenvalue of the graph is greater than or equal to its average degree.
3. The Weyl inequalities in Fact 3 above are a special case of the following general class of inequalities:

$$\sum_{k \in K} \lambda_k(A + B) \leq \sum_{i \in I} \lambda_i(A) + \sum_{j \in J} \lambda_j(B),$$

where  $I, J, K$  are certain subsets of  $\{1, 2, \dots, n\}$ . In 1962, A. Horn conjectured which inequalities of this form are valid for all Hermitian  $A, B$ , and this conjecture was proved correct in papers by A. Klyachko in 1998 and by A. Knutson and T. Tao in 1999. Two detailed accounts of the problem and its solution are given in [Bha01] and [Ful00].

4. Let  $A = \begin{bmatrix} 1 & 1 & 1 & 0 \\ 1 & 1 & 1 & 0 \\ 1 & 1 & 1 & 1 \\ 0 & 0 & 1 & 1 \end{bmatrix}$  have eigenvalues  $\lambda_1 \geq \lambda_2 \geq \lambda_3 \geq \lambda_4$ . Since  $A(4) = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}$

has eigenvalues 3, 0, 0, by the interlacing inequalities,  $\lambda_1 \geq 3 \geq \lambda_2 \geq 0 \geq \lambda_3 \geq 0 \geq \lambda_4$ . In particular,  $\lambda_3 = 0$ .

**Applications:**

1. To use the Rayleigh–Ritz theorem effectively to estimate the largest or smallest eigenvalue of a Hermitian matrix, one needs to take into account the relative magnitudes of the entries of the

matrix. For example, let  $A = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 2 & 2 \\ 1 & 2 & 3 \end{bmatrix}$ . In order to estimate  $\lambda_1$ , we should try to maximize the

Rayleigh quotient. A vector  $\mathbf{x} \in \mathbb{R}^3$  is needed for which no component is zero, but such that each component is weighted more than the last. In a few trials, one is led to  $\mathbf{x} = [1, 2, 3]^T$ , which gives a Rayleigh quotient of 5. So  $\lambda_1 \geq 5$ . This is close to the actual value of  $\lambda_1$ , which is  $\frac{1}{4} \csc^2 \frac{\pi}{14} \approx 5.049$ .

This example is only meant to illustrate the method; its primary importance is as a tool for estimating the largest (smallest) eigenvalue of a large Hermitian matrix when it can neither be found exactly nor be computed numerically.

2. The interlacing inequalities can sometimes be used to efficiently find all the eigenvalues of a Hermitian matrix. The Laplacian matrix (from spectral graph theory, see Section 28.4) of a star is

$$L = \begin{bmatrix} n-1 & -1 & -1 & \cdots & -1 & -1 \\ -1 & 1 & 0 & \cdots & 0 & 0 \\ -1 & 0 & 1 & & 0 & 0 \\ \vdots & \vdots & & \ddots & & \vdots \\ -1 & 0 & 0 & & 1 & 0 \\ -1 & 0 & 0 & \cdots & 0 & 1 \end{bmatrix}.$$

Since  $L(1)$  is an identity matrix, the interlacing inequalities relative to  $L(1)$  are:  $\lambda_1 \geq 1 \geq \lambda_2 \geq 1 \geq \dots \geq \lambda_{n-1} \geq 1 \geq \lambda_n$ . Therefore,  $n - 2$  of the eigenvalues of  $L$  are equal to 1. Since the columns sum to 0, another eigenvalue is 0. Finally, since  $\text{tr } L = 2n - 2$ , the remaining eigenvalue is  $n$ .

3. The sixth fact above is applied in spectral graph theory to establish the useful fact that the  $k^{\text{th}}$  largest eigenvalue of a graph is greater than or equal to the  $k^{\text{th}}$  largest eigenvalue of any induced subgraph.

### 8.3 Congruence

---

**Definitions:**

Two matrices  $A, B \in \mathcal{H}_n$  are **\*congruent** if there is an invertible matrix  $C \in \mathbb{C}^{n \times n}$  such that  $B = C^*AC$ , denoted  $A \stackrel{\sim}{\sim} B$ . If  $C$  is real, then  $A$  and  $B$  are also called **congruent**.

Let  $A \in \mathcal{H}_n$ . The **inertia** of  $A$  is the ordered triple  $\text{in}(A) = (\pi(A), \nu(A), \delta(A))$ , where  $\pi(A)$  is the number of positive eigenvalues of  $A$ ,  $\nu(A)$  is the number of negative eigenvalues of  $A$ , and  $\delta(A)$  is the number of zero eigenvalues of  $A$ .

In the event that  $A \in \mathbb{C}^{n \times n}$  has all real eigenvalues, we adopt the same definition for  $\text{in}(A)$ .

**Facts:**

The following can be found in [HJ85, pp. 221–223] and a variation of the last in [Lax96, pp. 77–78].

1. Unitary similarity is a special case of \*congruence.
2. \*Congruence is an equivalence relation.
3. For  $A \in \mathcal{H}_n$ ,  $\pi(A) + \nu(A) + \delta(A) = n$ .
4. For  $A \in \mathcal{H}_n$ ,  $\text{rank } A = \pi(A) + \nu(A)$ .
5. Let  $A \in \mathcal{H}_n$  with inertia  $(r, s, t)$ . Then  $A$  is \*congruent to  $I_r \oplus (-I_s) \oplus 0_t$ . A matrix  $C$  that implements this \*congruence is found as follows. Let  $U$  be a unitary matrix for which  $U^*AU = D$

is a diagonal matrix with  $d_{11}, \dots, d_{rr}$  the positive eigenvalues,  $d_{r+1,r+1}, \dots, d_{r+s,r+s}$  the negative eigenvalues, and  $d_{ii} = 0$ ,  $k > r + s$ . Let

$$s_i = \begin{cases} 1/\sqrt{d_{ii}}, & i = 1, \dots, r \\ 1/\sqrt{-d_{ii}}, & i = r + 1, \dots, s \\ 1, & i > r + s \end{cases}$$

and let  $S = \text{diag}(s_1, s_2, \dots, s_n)$ . Then  $C = US$ .

6. *Sylvester's Law of Inertia*: Two matrices  $A, B \in \mathcal{H}_n$  are \*congruent if and only if they have the same inertia.

### Examples:

1. Let  $A = \begin{bmatrix} 0 & 0 & 3 \\ 0 & 0 & 4 \\ 3 & 4 & 0 \end{bmatrix}$ . Since  $\text{rank } A = 2$ ,  $\pi(A) + \nu(A) = 2$ , so  $\delta(A) = 1$ . Since  $\text{tr } A = 0$ , we have  $\pi(A) = \nu(A) = 1$ , and  $\text{in}(A) = (1, 1, 1)$ . Letting

$$C = \begin{bmatrix} \frac{3}{5\sqrt{10}} & \frac{3}{5\sqrt{10}} & \frac{4}{5} \\ \frac{4}{5\sqrt{10}} & \frac{4}{5\sqrt{10}} & -\frac{3}{5} \\ \frac{1}{\sqrt{10}} & -\frac{1}{\sqrt{10}} & 0 \end{bmatrix}$$

we have

$$C^*AC = \begin{bmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

Now suppose

$$B = \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}.$$

Clearly  $\text{in}(B) = (1, 1, 1)$  also. By Sylvester's law of inertia,  $B$  must be \*congruent to  $A$ .

## 8.4 Positive Definite Matrices

### Definitions:

A matrix  $A \in \mathcal{H}_n$  is **positive definite** if  $\mathbf{x}^*A\mathbf{x} > 0$  for all nonzero  $\mathbf{x} \in \mathbb{C}^n$ . It is **positive semidefinite** if  $\mathbf{x}^*A\mathbf{x} \geq 0$  for all  $\mathbf{x} \in \mathbb{C}^n$ . It is **indefinite** if neither  $A$  nor  $-A$  is positive semidefinite. The set of positive definite matrices of order  $n$  is denoted by  $\text{PD}_n$ , and the set of positive semidefinite matrices of order  $n$  by  $\text{PSD}_n$ . If the dependence on  $n$  is not significant, these can be abbreviated as PD and PSD. Finally, PD (PSD) are also used to abbreviate "positive definite" ("positive semidefinite").

Let  $k$  be a positive integer. If  $A, B$  are PSD and  $B^k = A$ , then  $B$  is called a **PSD  $k^{\text{th}}$  root** of  $A$  and is denoted  $A^{1/k}$ .

A **correlation matrix** is a PSD matrix in which every main diagonal entry is 1.

**Facts:**

For facts without a specific reference, see [HJ85, Sections 7.1 and 7.2] and [Fie86, pp. 51–57].

1.  $A \in \mathcal{S}_n$  is PD if  $\mathbf{x}^T A \mathbf{x} > 0$  for all nonzero  $\mathbf{x} \in \mathbb{R}^n$ , and is PSD if  $\mathbf{x}^T A \mathbf{x} \geq 0$  for all  $\mathbf{x} \in \mathbb{R}^n$ .
2. Let  $A, B \in \text{PSD}_n$ .
  - (a) Then  $A + B \in \text{PSD}_n$ .
  - (b) If, in addition,  $A \in \text{PD}_n$ , then  $A + B \in \text{PD}_n$ .
  - (c) If  $c \geq 0$ , then  $cA \in \text{PSD}_n$ .
  - (d) If, in addition,  $A \in \text{PD}_n$  and  $c > 0$ , then  $cA \in \text{PD}_n$ .
3. If  $A_1, A_2, \dots, A_k \in \text{PSD}_n$ , then so is  $A_1 + A_2 + \dots + A_k$ . If, in addition, there is an  $i \in \{1, 2, \dots, k\}$  such that  $A_i \in \text{PD}_n$ , then  $A_1 + A_2 + \dots + A_k \in \text{PD}_n$ .
4. Let  $A \in \mathcal{H}_n$ . Then  $A$  is PD if and only if every eigenvalue of  $A$  is positive, and  $A$  is PSD if and only if every eigenvalue of  $A$  is nonnegative.
5. If  $A$  is PD, then  $\text{tr } A > 0$  and  $\det A > 0$ . If  $A$  is PSD, then  $\text{tr } A \geq 0$  and  $\det A \geq 0$ .
6. A PSD matrix is PD if and only if it is invertible.
7. *Inheritance Principle:* Any principal submatrix of a PD (PSD) matrix is PD (PSD).
8. All principal minors of a PD (PSD) matrix are positive (nonnegative).
9. Each diagonal entry of a PD (PSD) matrix is positive (nonnegative). If a diagonal entry of a PSD matrix is 0, then every entry in the row and column containing it is also 0.
10. Let  $A \in \mathcal{H}_n$ . Then  $A$  is PD if and only if every leading principal minor of  $A$  is positive.  $A$  is PSD if and only if every principal minor of  $A$  is nonnegative. (The matrix  $\begin{bmatrix} 0 & 0 \\ 0 & -1 \end{bmatrix}$  shows that it is not sufficient that every leading principal minor be nonnegative in order for  $A$  to be PSD.)
11. Let  $A$  be PD (PSD). Then  $A^k$  is PD (PSD) for all  $k \in \mathbb{N}$ .
12. Let  $A \in \text{PSD}_n$  and express  $A$  as  $A = UDU^*$ , where  $U$  is unitary and  $D$  is the diagonal matrix of eigenvalues. Given any positive integer  $k$ , there exists a unique **PSD**  $k^{\text{th}}$  **root** of  $A$  given by  $A^{1/k} = UD^{1/k}U^*$ . If  $A$  is real so is  $A^{1/k}$ . (See also Chapter 11.2.)
13. If  $A$  is PD, then  $A^{-1}$  is PD.
14. Let  $A \in \text{PSD}_n$  and let  $C \in \mathbb{C}^{n \times m}$ . Then  $C^*AC$  is PSD.
15. Let  $A \in \text{PD}_n$  and let  $C \in \mathbb{C}^{n \times m}$ ,  $n \geq m$ . Then  $C^*AC$  is PD if and only if  $\text{rank } C = m$ ; i.e., if and only if  $C$  has linearly independent columns.
16. Let  $A \in \text{PD}_n$  and  $C \in \mathbb{C}^{n \times n}$ . Then  $C^*AC$  is PD if and only if  $C$  is invertible.
17. Let  $A \in \mathcal{H}_n$ . Then  $A$  is PD if and only if there is an invertible  $B \in \mathbb{C}^{n \times n}$  such that  $A = B^*B$ .
18. *Cholesky Factorization:* Let  $A \in \mathcal{H}_n$ . Then  $A$  is PD if and only if there is an invertible lower triangular matrix  $L$  with positive diagonal entries such that  $A = LL^*$ . (See Chapter 38 for information on the computation of the Cholesky factorization.)
19. Let  $A \in \text{PSD}_n$  with  $\text{rank } A = r < n$ . Then  $A$  can be factored as  $A = B^*B$  with  $B \in \mathbb{C}^{r \times n}$ . If  $A$  is a real matrix, then  $B$  can be taken to be real and  $A = B^T B$ . Equivalently, there exist vectors  $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_n \in \mathbb{C}^r$  (or  $\mathbb{R}^r$ ) such that  $a_{ij} = \mathbf{v}_i^* \mathbf{v}_j$  (or  $\mathbf{v}_i^T \mathbf{v}_j$ ). Note that  $A$  is the Gram matrix (see section 8.1) of the vectors  $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_n$ . In particular, any rank 1 PSD matrix has the form  $\mathbf{xx}^*$  for some nonzero vector  $\mathbf{x} \in \mathbb{C}^n$ .
20. [Lax96, p. 123]; see also [HJ85, p. 407] The Gram matrix  $G$  of a set of vectors  $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_n$  is PSD. If  $\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_n$  are linearly independent, then  $G$  is PD.
21. [HJ85, p. 412] *Polar Form:* Let  $A \in \mathbb{C}^{m \times n}$ ,  $m \geq n$ . Then  $A$  can be factored  $A = UP$ , where  $P \in \text{PSD}_n$ ,  $\text{rank } P = \text{rank } A$ , and  $U \in \mathbb{C}^{m \times n}$  has orthonormal columns. Moreover,  $P$  is uniquely determined by  $A$  and equals  $(A^*A)^{1/2}$ . If  $A$  is real, then  $P$  and  $U$  are real. (See also Section 17.1.)
22. [HJ85, p. 400] Any matrix  $A \in \text{PD}_n$  is diagonally congruent to a correlation matrix via the diagonal matrix  $D = (1/\sqrt{a_{11}}, \dots, 1/\sqrt{a_{nn}})$ .

23. [BJT93] *Parameterization of Correlation Matrices in  $S_3$* : Let  $0 \leq \alpha, \beta, \gamma \leq \pi$ . Then the matrix

$$C = \begin{bmatrix} 1 & \cos \alpha & \cos \gamma \\ \cos \alpha & 1 & \cos \beta \\ \cos \gamma & \cos \beta & 1 \end{bmatrix}$$

is PSD if and only if  $\alpha \leq \beta + \gamma$ ,  $\beta \leq \alpha + \gamma$ ,  $\gamma \leq \alpha + \beta$ ,  $\alpha + \beta + \gamma \leq 2\pi$ . Furthermore,  $C$  is PD if and only if all of these inequalities are strict.

24. [HJ85, p. 472] and [Fie86, p. 55] Let  $A = \begin{bmatrix} B & C \\ C^* & D \end{bmatrix} \in \mathcal{H}_n$ , and assume that  $B$  is invertible. Then

$A$  is PD if and only if the matrices  $B$  and its Schur complement  $S = D - C^*B^{-1}C$  are PD.

25. [Joh92] and [LB96, pp. 93–94] Let  $A = \begin{bmatrix} B & C \\ C^* & D \end{bmatrix}$  be PSD. Then any column of  $C$  lies in the span of the columns of  $B$ .

26. [HJ85, p. 465] Let  $A \in \text{PD}_n$  and  $B \in \mathcal{H}_n$ . Then

- $AB$  is diagonalizable.
- All eigenvalues of  $AB$  are real.
- $\text{in}(AB) = \text{in}(B)$ .

27. Any diagonalizable matrix  $A$  with real eigenvalues can be factored as  $A = BC$ , where  $B$  is PSD and  $C$  is Hermitian.

28. If  $A, B \in \text{PD}_n$ , then every eigenvalue of  $AB$  is positive.

29. [Lax96, p. 120] Let  $A, B \in \mathcal{H}_n$ . If  $A$  is PD and  $AB + BA$  is PD, then  $B$  is PD. It is not true that if

$A, B$  are both PD, then  $AB + BA$  is PD as can be seen by the example  $A = \begin{bmatrix} 1 & 2 \\ 2 & 5 \end{bmatrix}$ ,  $B = \begin{bmatrix} 5 & 2 \\ 2 & 1 \end{bmatrix}$ .

30. [HJ85, pp. 466–467] and [Lax96, pp. 125–126] The real valued function  $f(X) = \log(\det X)$  is concave on the set  $\text{PD}_n$ ; i.e.,  $f((1-t)X + tY) \geq (1-t)f(X) + tf(Y)$  for all  $t \in [0, 1]$  and all  $X, Y \in \text{PD}_n$ .

31. [Lax96, p. 129] If  $A \in \text{PD}_n$  is real,  $\int_{\mathbb{R}^n} e^{-\mathbf{x}^T A \mathbf{x}} d\mathbf{x} = \frac{\pi^{n/2}}{\sqrt{\det A}}$ .

32. [Fie60] Let  $A = [a_{ij}]$ ,  $B = [b_{ij}] \in \text{PD}_n$ , with  $A^{-1} = [\alpha_{ij}]$ ,  $B^{-1} = [\beta_{ij}]$ . Then

$$\sum_{i,j=1}^n (a_{ij} - b_{ij})(\alpha_{ij} - \beta_{ij}) \leq 0,$$

with equality if and only if  $A = B$ .

33. [Ber73, p. 55] Consider  $\text{PD}_n$  to be a subset of  $\mathbb{C}^{n^2}$  (or for real matrices of  $\mathbb{R}^{n^2}$ ). Then the (topological) boundary of  $\text{PD}_n$  is  $\text{PSD}_n$ .

### Examples:

- If  $A = [a]$  is  $1 \times 1$ , then  $A$  is PD if and only if  $a > 0$ , and is PSD if and only if  $a \geq 0$ ; so PD and PSD matrices are a generalization of positive numbers and nonnegative numbers.
- If one attempts to define PD (or PSD) for nonsymmetric real matrices according to the usual definition, many of the facts above for (Hermitian) PD matrices no longer hold. For example,

suppose  $A = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}$ . Then  $\mathbf{x}^T A \mathbf{x} = 0$  for all  $\mathbf{x} \in \mathbb{R}^2$ . But  $\sigma(A) = \{i, -i\}$ , which does not agree

with Fact 4 above.

3. The matrix  $A = \begin{bmatrix} 17 & 8 \\ 8 & 17 \end{bmatrix}$  factors as  $\frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} 25 & 0 \\ 0 & 9 \end{bmatrix} \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$ , so  $A^{1/2} = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} 5 & 0 \\ 0 & 3 \end{bmatrix} \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} = \begin{bmatrix} 4 & 1 \\ 1 & 4 \end{bmatrix}$ .
4. A self-adjoint linear operator on a complex inner product space  $V$  (see Section 5.3) is called **positive** if  $\langle A\mathbf{x}, \mathbf{x} \rangle > 0$  for all nonzero  $\mathbf{x} \in V$ . For the usual inner product in  $\mathbb{C}^n$  we have  $\langle A\mathbf{x}, \mathbf{x} \rangle = \mathbf{x}^* A\mathbf{x}$ , in which case the definition of positive operator and positive definite matrix coincide.
5. Let  $X_1, X_2, \dots, X_n$  be real-valued random variables on a probability space, each with mean zero and finite second moment. Define the matrix

$$a_{ij} = E(X_i X_j), \quad i, j \in \{1, 2, \dots, n\}.$$

The real symmetric matrix  $A$  is called the **covariance matrix** of  $X_1, X_2, \dots, X_n$ , and is necessarily PSD. If we let  $X = (X_1, X_2, \dots, X_n)^T$ , then we may abbreviate the definition to  $A = E(XX^T)$ .

**Applications:**

1. [HFKLMO95, p. 181] or [MT88, p. 253] *Test for Maxima and Minima in Several Variables*: Let  $D$  be an open set in  $\mathbb{R}^n$  containing the point  $\mathbf{x}_0$ , let  $f : D \rightarrow \mathbb{R}$  be a twice continuously differentiable function on  $D$ , and assume that all first derivatives of  $f$  vanish at  $\mathbf{x}_0$ . Let  $H$  be the Hessian matrix of  $f$  (Example 2 of Section 8.1). Then
- (a)  $f$  has a relative minimum at  $\mathbf{x}_0$  if  $H(\mathbf{x}_0)$  is PD.
  - (b)  $f$  has a relative maximum at  $\mathbf{x}_0$  if  $-H(\mathbf{x}_0)$  is PD.
  - (c)  $f$  has a saddle point at  $\mathbf{x}_0$  if  $H(\mathbf{x}_0)$  is indefinite.

Otherwise, the test is inconclusive.

2. Section 1.3 of the textbook [Str86] is an elementary introduction to real PD matrices emphasizing the significance of the Cholesky-like factorization  $LDL^T$  of a PD matrix. This representation is then used as a framework for many applications throughout the first three chapters of this text.
3. Let  $A$  be a real matrix in  $\text{PD}_n$ . A **multivariate normal distribution** is one whose probability density function in  $\mathbb{R}^n$  is given by

$$f(\mathbf{x}) = \frac{1}{\sqrt{(2\pi)^n \det A}} e^{-\frac{1}{2} \mathbf{x}^T A^{-1} \mathbf{x}}.$$

It follows from Fact 31 above that  $\int_{\mathbb{R}^n} f(\mathbf{x}) d\mathbf{x} = 1$ . A **Gaussian family**  $X_1, X_2, \dots, X_n$ , where each  $X_i$  has mean zero, is a set of random variables that have a multivariate normal distribution. The entries of the matrix  $A$  satisfy the identity  $a_{ij} = E(X_i X_j)$ , so the distribution is completely determined by its covariance matrix.

## 8.5 Further Topics in Positive Definite Matrices

---

**Definitions:**

Let  $A, B \in F^{n \times n}$ , where  $F$  is a field. The **Hadamard product** or **Schur product** of  $A$  and  $B$ , denoted  $A \circ B$ , is the matrix in  $F^{n \times n}$  whose  $(i, j)^{\text{th}}$  entry is  $a_{ij} b_{ij}$ .

A function  $f : \mathbb{R} \rightarrow \mathbb{C}$  is called **positive semidefinite** if for each  $n \in \mathbb{N}$  and all  $x_1, x_2, \dots, x_n \in \mathbb{R}$ , the  $n \times n$  matrix  $[f(x_i - x_j)]$  is PSD.

Let  $A, B \in \mathcal{H}_n$ . We write  $A \succ B$  if  $A - B$  is PD, and  $A \succeq B$  if  $A - B$  is PSD. The partial ordering on  $\mathcal{H}_n$  induced by  $\succeq$  is called the **partial semidefinite ordering** or the **Loewner ordering**.

Let  $V$  be an  $n$ -dimensional inner product space over  $\mathbb{C}$  or  $\mathbb{R}$ . A set  $K \subseteq V$  is called a **cone** if

- (a) For each  $\mathbf{x}, \mathbf{y} \in K$ ,  $\mathbf{x} + \mathbf{y} \in K$ .
- (b) If  $\mathbf{x} \in K$  and  $c \geq 0$ , then  $c\mathbf{x} \in K$ .

A cone is frequently referred to as a convex cone. A cone  $K$  is **closed** if  $K$  is a closed subset of  $V$ , is **pointed** if  $K \cap -K = \{0\}$ , and is **full** if it has a nonempty interior. The set

$$K^* = \{\mathbf{y} \in V \mid \langle \mathbf{x}, \mathbf{y} \rangle \geq 0 \quad \forall \mathbf{x} \in K\}$$

is called the **dual space**.

### Facts:

1. [HJ91, pp. 308–309]; also see [HJ85, p. 458] or [Lax96, pp. 124, 234] *Schur Product Theorem*: If  $A, B \in \text{PSD}_n$ , then so is  $A \circ B$ . If  $A \in \text{PSD}_n$ ,  $a_{ii} > 0$ ,  $i = 1, \dots, n$ , and  $B \in \text{PD}_n$ , then  $A \circ B \in \text{PD}_n$ . In particular, if  $A$  and  $B$  are both PD, then so is  $A \circ B$ .
2. [HJ85, p. 459] *Fejer's Theorem*: Let  $A = [a_{ij}] \in \mathcal{H}_n$ . Then  $A$  is PSD if and only if

$$\sum_{i,j=1}^n a_{ij} b_{ij} \geq 0$$

for all matrices  $B \in \text{PSD}_n$ .

3. [HJ91, pp. 245–246] If  $A \in \text{PD}_m$  and  $B \in \text{PD}_n$ , then the Kronecker (tensor) product (see Section 10.4)  $A \otimes B \in \text{PD}_{mn}$ . If  $A \in \text{PSD}_m$  and  $B \in \text{PSD}_n$ , then  $A \otimes B \in \text{PSD}_{mn}$ .
  4. [HJ85, p. 477] or [Lax96, pp. 126–127, 131–132] *Hadamard's Determinantal Inequality*: If  $A \in \text{PD}_n$ , then  $\det A \leq \prod_{i=1}^n a_{ii}$ . Equality holds if and only if  $A$  is a diagonal matrix.
  5. [FJ00, pp. 199–200] or [HJ85, p. 478] *Fischer's Determinantal Inequality*: If  $A \in \text{PD}_n$  and  $\alpha$  is any subset of  $\{1, 2, \dots, n\}$ , then  $\det A \leq \det A[\alpha] \det A[\alpha^c]$  (where  $\det A[\emptyset] = 1$ ). Equality occurs if and only if  $A[\alpha, \alpha^c]$  is a zero matrix. (See Chapter 1.2 for the definition of  $A[\alpha]$  and  $A[\alpha, \beta]$ .)
  6. [FJ00, pp. 199–200] or [HJ85, p. 485] *Koteljanskii's Determinantal Inequality*: Let  $A \in \text{PD}_n$  and let  $\alpha, \beta$  be any subsets of  $\{1, 2, \dots, n\}$ . Then  $\det A[\alpha \cup \beta] \det A[\alpha \cap \beta] \leq \det A[\alpha] \det A[\beta]$ . Note that if  $\alpha \cap \beta = \emptyset$ , Koteljanskii's inequality reduces to Fischer's inequality. Koteljanskii's inequality is also called the Hadamard–Fischer inequality.
- For other determinantal inequalities for PD matrices, see [FJ00] and [HJ85, §7.8].
7. [Fel71, pp. 620–623] and [Rud62, pp. 19–21] *Bochner's Theorem*: A continuous function from  $\mathbb{R}$  into  $\mathbb{C}$  is positive semidefinite if and only if it is the Fourier transform of a finite positive measure.
  8. [Lax96, p. 118] and [HJ85, p. 475, 470] Let  $A, B, C, D \in \mathcal{H}_n$ .

- (a) If  $A \prec B$  and  $C \prec D$ , then  $A + C \prec B + D$ .
- (b) If  $A \prec B$  and  $B \prec C$ , then  $A \prec C$ .
- (c) If  $A \prec B$  and  $S \in \mathbb{C}^{n \times n}$  is invertible, then  $S^*AS \prec S^*BS$ .

The three statements obtained by replacing each occurrence of  $\prec$  by  $\preceq$  are also valid.

9. [Lax96, pp. 118–119, 121–122] and [HJ85, pp. 471–472] Let  $A, B \in \text{PD}_n$  with  $A \prec B$ . Then
  - (a)  $A^{-1} \succ B^{-1}$ .
  - (b)  $A^{1/2} \prec B^{1/2}$ .
  - (c)  $\det A < \det B$ .
  - (d)  $\text{tr } A < \text{tr } B$ .

If  $A \preceq B$ , then statement (a) holds with  $\succ$  replaced by  $\succeq$ , statement (b) holds with  $\prec$  replaced by  $\preceq$ , and statements (c) and (d) hold with  $<$  replaced by  $\leq$ .

10. [HJ85, pp. 182, 471–472] Let  $A, B \in \mathcal{H}_n$  with eigenvalues  $\lambda_1(A) \geq \lambda_2(A) \geq \dots \geq \lambda_n(A)$  and  $\lambda_1(B) \geq \lambda_2(B) \geq \dots \geq \lambda_n(B)$ . If  $A < B$ , then  $\lambda_k(A) < \lambda_k(B)$ ,  $k = 1, \dots, n$ . If  $A \leq B$ , then  $\lambda_k(A) \leq \lambda_k(B)$ ,  $k = 1, \dots, n$ .
11. [HJ85, p. 474] Let  $A$  be PD and let  $\alpha \subseteq \{1, 2, \dots, n\}$ . Then  $A^{-1}[\alpha] \geq (A[\alpha])^{-1}$ .
12. [HJ85, p. 475] If  $A$  is PD, then  $A^{-1} \circ A \geq I \geq (A^{-1} \circ A)^{-1}$ .
13. [Hal83, p. 89] If  $K$  is a cone in an inner product space  $V$ , its dual space is a closed cone and is called the **dual cone** of  $K$ . If  $K$  is a closed cone, then  $(K^*)^* = K$ .
14. [Ber73, pp. 49–50, 55] and [HW87, p. 82] For each pair  $A, B \in \mathcal{H}_n$ , define  $\langle A, B \rangle = \text{tr}(AB)$ .
  - (a)  $\mathcal{H}_n$  is an inner product space over the real numbers with respect to  $\langle \cdot, \cdot \rangle$ .
  - (b)  $\text{PSD}_n$  is a closed, pointed, full cone in  $\mathcal{H}_n$ .
  - (c)  $(\text{PSD}_n)^* = \text{PSD}_n$ .

**Examples:**

1. The matrix  $C = [\cos|i - j|] \in \mathcal{S}_n$  is PSD, as can be verified with Fact 19 of section 8.4 and the addition formula for the cosine. But a quick way to see it is to consider the measure  $\mu(x) = \frac{1}{2}[\delta(x + 1) + \delta(x - 1)]$ ; i.e.,  $\mu(E) = 0$  if  $-1, 1 \notin E$ ,  $\mu(E) = 1$  if  $-1, 1 \in E$ , and  $\mu(E) = 1/2$  if exactly one of  $-1, 1 \in E$ . Since the Fourier transform of  $\mu$  is  $\cos t$ , if we let  $x_1, x_2, \dots, x_n$  be  $1, 2, \dots, n$  in the definition of positive definite function, we see immediately by Bochner’s Theorem that the matrix  $[\cos(i - j)] = [\cos|i - j|] = C$  is PSD. By Hadamard’s determinantal inequality  $\det C \leq \prod_{i=1}^n c_{ii} = 1$ .
2. Since  $\begin{bmatrix} 1 & 1 \\ 1 & 2 \end{bmatrix} < \begin{bmatrix} 2 & 2 \\ 2 & 7 \end{bmatrix}$ , taking inverses we have  $\begin{bmatrix} .7 & -.2 \\ -.2 & .2 \end{bmatrix} < \begin{bmatrix} 2 & -1 \\ -1 & 1 \end{bmatrix}$ .
3. The matrix  $A = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 2 & 2 \\ 1 & 2 & 3 \end{bmatrix}$  is PD with inverse  $A^{-1} = \begin{bmatrix} 2 & -1 & 0 \\ -1 & 2 & -1 \\ 0 & -1 & 1 \end{bmatrix}$ . Then  $(A[\{1, 3\}])^{-1} = \begin{bmatrix} 1.5 & -.5 \\ -.5 & .5 \end{bmatrix} \leq \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix} = A^{-1}[\{1, 3\}]$ . Also,  $A^{-1} \circ A = \begin{bmatrix} 2 & -1 & 0 \\ -1 & 4 & -2 \\ 0 & -2 & 3 \end{bmatrix} \geq \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \geq \frac{1}{13} \begin{bmatrix} 8 & 3 & 2 \\ 3 & 6 & 4 \\ 2 & 4 & 7 \end{bmatrix} = (A^{-1} \circ A)^{-1}$ .
4. If  $A \geq B \geq 0$ , it does not follow that  $A^2 \geq B^2$ . For example, if  $A = \begin{bmatrix} 2 & 1 \\ 1 & 1 \end{bmatrix}$  and  $B = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}$ , then  $B$  and  $A - B$  are PSD, but  $A^2 - B^2$  is not.

**Applications:**

1. Hadamard’s determinantal inequality can be used to obtain a sharp bound on the determinant of a matrix in  $\mathbb{C}^{n \times n}$  if only the magnitudes of the entries are known. [HJ85, pp. 477–478] or [Lax96, p. 127].
 

*Hadamard’s Determinantal Inequality for Matrices in  $\mathbb{C}^{n \times n}$ :* Let  $B \in \mathbb{C}^{n \times n}$ . Then  $|\det B| \leq \prod_{i=1}^n (\sum_{j=1}^n |b_{ij}|^2)^{1/2}$  with equality holding if and only if the rows of  $B$  are orthogonal.

In the case that  $B$  is invertible, the inequality follows from Hadamard’s determinantal inequality for positive definite matrices by using  $A = BB^*$ ; if  $B$  is singular, the inequality is obvious.

The inequality can be alternatively expressed as  $|\det B| \leq \prod_{i=1}^n \|\mathbf{b}_i\|_2$ , where  $\mathbf{b}_i$  are the rows of  $B$ . If  $B$  is a real matrix, it has the geometric meaning that among all parallelepipeds with given side lengths  $\|\mathbf{b}_i\|_2$ ,  $i = 1, \dots, n$ , the one with the largest volume is rectangular.

There is a corresponding inequality in which the right-hand side is the product of the lengths of the columns of  $B$ .

2. [Fel71, pp. 620–623] A special case of Bochner’s theorem, important in probability theory, is: A continuous function  $\phi$  is the characteristic function of a probability distribution if and only if it is positive semidefinite and  $\phi(0) = 1$ .
3. Understanding the cone  $\text{PSD}_n$  is important in semidefinite programming. (See Chapter 51.)

Nonnegativity is a natural property of many measured quantities (physical and virtual). Consequently, nonnegative matrices arise in modelling transformations in numerous branches of science and engineering — these include probability theory (Markov chains), population models, iterative methods in numerical analysis, economics (input–output models), epidemiology, statistical mechanics, stability analysis, and physics. This section is concerned with properties of such matrices. The theory of the subject was originated in the pioneering work of Perron and Frobenius in [Per07a, Per07b, Fro08, Fro09, and Fro12]. There have been books, chapters in books, and hundreds of papers on the subject (e.g., [BNS89], [BP94], [Gan59, Chap. XIII], [Har02] [HJ85, Chap. 8], [LT85, Chap. 15], [Min88], [Sen81], [Var62, Chap. 1]). A brief outline of proofs of the classic result of Perron and a description of several applications of the theory can be found in the survey paper [Mac00]. Generalizations of many facts reported herein to cone-invariant matrices can be found in Chapter 26.

### 9.1 Notation, Terminology, and Preliminaries

---

#### Definitions:

For a positive integer  $n$ ,  $\langle n \rangle = \{1, \dots, n\}$ .

For a matrix  $A \in \mathbb{C}^{m \times n}$ :

$A$  is **nonnegative (positive)**, written  $A \geq 0$  ( $A > 0$ ), if all of  $A$ 's elements are nonnegative (positive).

$A$  is **semipositive**, written  $A \succeq 0$  if  $A \geq 0$  and  $A \neq 0$ .

$|A|$  will denote the nonnegative matrix obtained by taking element-wise absolute values of  $A$ 's coordinates.

For a square matrix  $A = [a_{ij}] \in \mathbb{C}^{n \times n}$ :

The  $k$ -**eigenspace** of  $A$  at a complex number  $\lambda$ , denoted  $N_\lambda^k(A)$ , is  $\ker(A - \lambda I)^k$ ; a **generalized eigenvector** of  $P$  at  $\lambda$  is a vector in  $\cup_{k=0}^\infty N_\lambda^k(A)$ .

The **index** of  $A$  at  $\lambda$ , denoted  $v_A(\lambda)$ , is the smallest integer  $k$  with  $N_\lambda^k(A) = N_\lambda^{k+1}(A)$ .

The **ergodicity coefficient** of  $A$ , denoted  $\tau(A)$ , is  $\max\{|\lambda| : \lambda \in \sigma(A) \text{ and } |\lambda| \neq \rho(A)\}$  (with the maximum over the empty set defined to be 0 and  $\rho(A)$  being the spectral radius of  $A$ ).

A **group inverse** of a square matrix  $A$ , denoted  $A^\#$ , is a matrix  $X$  satisfying  $AXA = A$ ,  $XAX = X$ , and  $AX = XA$  (whenever there exists such an  $X$ , it is unique).

The **digraph** of  $A$ , denoted  $\Gamma(A)$ , is the graph with vertex-set  $V(A) = \langle n \rangle$  and arc-set  $E(A) = \{(i, j) : i, j \in \langle n \rangle \text{ and } a_{ij} \neq 0\}$ ; in particular,  $i = 1, \dots, n$  are called **vertices**.

Vertex  $i \in \langle n \rangle$  **has access** to vertex  $j \in \langle n \rangle$ , written  $i \mapsto j$ , if either  $i = j$  or  $\Gamma(A)$  contains a simple walk (path) from  $i$  to  $j$ ; we say that  $i$  and  $j$  **communicate**, written  $i \sim j$ , if each has access to the other.

A subset  $C$  of  $\langle n \rangle$  is **final** if no vertex in  $C$  has access to a vertex not in  $C$ .

Vertex-communication is an equivalence relation. It partitions  $\langle n \rangle$  into equivalence classes, called the **access equivalence classes** of  $A$ .

$\Gamma(A)$  is **strongly connected** if there is only one access equivalence class.

An access equivalence class  $C$  **has access** to an access equivalence class  $C'$ , written  $C \mapsto C'$  if some, or equivalently every, vertex in  $C$  has access to some, or equivalently every, vertex in  $C'$ ; in this case we also write  $i \mapsto C'$  and  $C \mapsto i'$  when  $i \in C$  and  $i' \in C'$ .

An access equivalence class  $C$  of  $A$  is **final** if its final as a subset of  $\langle n \rangle$ , that is, it does not have access to any access equivalence class but itself.

The **reduced digraph** of  $\Gamma(A)$ , denoted  $R[\Gamma(A)]$ , is the digraph whose vertex-set is the set of access equivalence classes of  $A$  and whose arcs are the pairs  $(C, C')$  with  $C$  and  $C'$  as distinct classes satisfying  $C \mapsto C'$ .

For a sequence  $\{a_m\}_{m=0,1,\dots}$  of complex numbers and a complex number  $a$ :

$a$  is a  $(C, 0)$ -**limit** of  $\{a_m\}_{m=0,1,\dots}$ , written  $\lim_{m \rightarrow \infty} a_m = a (C, 0)$ , if  $\lim_{m \rightarrow \infty} a_m = a$  (in the sense of a regular limit).

$a$  is the  $(C, 1)$ -**limit** of  $\{a_m\}_{m=0,1,\dots}$ , written  $\lim_{m \rightarrow \infty} a_m = a (C, 1)$ , if  $\lim_{m \rightarrow \infty} m^{-1} \sum_{s=0}^{m-1} a_s = a$ .

Inductively for  $k = 2, 3, \dots$ ,  $a$  is a  $(C, k)$ -**limit** of  $\{a_m\}_{m=0,1,\dots}$ , written  $\lim_{m \rightarrow \infty} a_m = a (C, k)$ , if  $\lim_{m \rightarrow \infty} m^{-1} \sum_{s=0}^{m-1} a_s = a (C, k-1)$ .

For  $0 \leq \beta < 1$ ,  $\{a_m\}_{m=0,1,\dots}$  **converges geometrically to  $a$  with (geometric) rate  $\beta$**  if for each  $\beta < \gamma < 1$ , the set of real numbers  $\{\frac{a_m - a}{\gamma^m} : m = 0, 1, \dots\}$  is bounded. (For simplicity, we avoid the reference of geometric convergence for  $(C, k)$ -limits.)

For a square nonnegative matrix  $P$ :

$\rho(P)$  (the spectral radius of  $P$ ) is called the **Perron value** of  $P$  (see Facts 9.2–1(b) and 9.2–5(a) and 9.3–2(a)).

A **distinguished eigenvalue** of  $P$  is a (necessarily nonnegative) eigenvalue of  $P$  that is associated with a semipositive (right) eigenvector.

For more information about generalized eigenvectors, see Chapter 6.1. An example illustrating the digraph definitions is given in Figure 9.1; additional information about digraphs can be found in Chapter 29.

## 9.2 Irreducible Matrices

(See Chapter 27.3, Chapter 29.5, and Chapter 29.6 for additional information.)

**Definitions:**

A nonnegative square matrix  $P$  is **irreducible** if it is not permutation similar to any matrix having the (nontrivial) block-partition

$$\begin{bmatrix} A & B \\ 0 & C \end{bmatrix}$$

with  $A$  and  $C$  square.

The **period** of an irreducible nonnegative square matrix  $P$  (also known as the **index of imprimitivity** of  $P$ ) is the greatest common divisor of lengths of the cycles of  $\Gamma(P)$ , the digraph of  $P$ .

An irreducible nonnegative square matrix  $P$  is **aperiodic** if its period is 1.

*Note:* We exclude from further consideration the (irreducible) trivial 0 matrix of dimension  $1 \times 1$ .

**Facts:**

Facts requiring proofs for which no specific reference is given can be found in [BP94, Chap. 2].

1. (*Positive Matrices — Perron’s Theorem*) [Per07a, Per07b] Let  $P$  be a positive square matrix with spectral radius  $\rho$  and ergodicity coefficient  $\tau$ .
  - (a)  $P$  is irreducible and aperiodic.
  - (b)  $\rho$  is positive and is a simple eigenvalue of  $P$ ; in particular, the index of  $P$  at  $\rho$  is 1.
  - (c) There exist positive right and left eigenvectors of  $P$  corresponding to  $\rho$ , in particular,  $\rho$  is a distinguished eigenvalue of both  $P$  and  $P^T$ .
  - (d)  $\rho$  is the only distinguished eigenvalue of  $P$ .
  - (e)  $\rho$  is the only eigenvalue  $\lambda$  of  $P$  with  $|\lambda| = \rho$ .
  - (f) If  $\mathbf{x} \in \mathbb{R}^n$  satisfies  $\mathbf{x} \geq 0$  and either  $(\rho I - P)\mathbf{x} \geq 0$  or  $(\rho I - P)\mathbf{x} \leq 0$ , then  $(\rho I - P)\mathbf{x} = 0$ .
  - (g) If  $\mathbf{v}$  and  $\mathbf{w}$  are positive right and left eigenvectors of  $P$  corresponding to  $\rho$  (note that  $\mathbf{w}$  is a row vector), then  $\lim_{m \rightarrow \infty} (\frac{P}{\rho})^m = \frac{\mathbf{v}\mathbf{w}}{\mathbf{w}\mathbf{v}}$  and the convergence is geometric with rate  $\frac{\tau}{\rho}$ .
  - (h)  $Q \equiv \rho I - P$  has a group inverse; further, if  $\mathbf{v}$  and  $\mathbf{w}$  are positive right and left eigenvectors of  $P$  corresponding to  $\rho$ , then  $Q + \frac{\mathbf{v}\mathbf{w}}{\mathbf{w}\mathbf{v}}$  is nonsingular,  $Q^\# = (Q + \frac{\mathbf{v}\mathbf{w}}{\mathbf{w}\mathbf{v}})^{-1}(I - \frac{\mathbf{v}\mathbf{w}}{\mathbf{w}\mathbf{v}})$ , and  $\frac{\mathbf{v}\mathbf{w}}{\mathbf{w}\mathbf{v}} = I - QQ^\#$ .
  - (i)  $\lim_{m \rightarrow \infty} \sum_{t=0}^{m-1} (\frac{P}{\rho})^t - m \frac{\mathbf{v}\mathbf{w}}{\mathbf{w}\mathbf{v}} = (\rho I - P)^\#$  and the convergence is geometric with rate  $\frac{\tau}{\rho}$ .
2. (*Characterizing Irreducibility*) Let  $P$  be a nonnegative  $n \times n$  matrix with spectral radius  $\rho$ . The following are equivalent:
  - (a)  $P$  is irreducible.
  - (b)  $\sum_{s=0}^{n-1} P^s > 0$ .
  - (c)  $(I + P)^{n-1} > 0$ .
  - (d) The digraph of  $P$  is strongly connected, i.e.,  $P$  has a single access equivalence class.
  - (e) Every eigenvector of  $P$  corresponding to  $\rho$  is a scalar multiple of a positive vector.
  - (f) For some  $\mu > \rho$ ,  $\mu I - P$  is nonsingular and  $(\mu I - P)^{-1} > 0$ .
  - (g) For every  $\mu > \rho$ ,  $\mu I - P$  is nonsingular and  $(\mu I - P)^{-1} > 0$ .
3. (*Characterizing Aperiodicity*) Let  $P$  be an irreducible nonnegative  $n \times n$  matrix. The following are equivalent:
  - (a)  $P$  is aperiodic.
  - (b)  $P^m > 0$  for some  $m$ . (See Section 29.6.)
  - (c)  $P^m > 0$  for all  $m \geq n$ .
4. (*The Period*) Let  $P$  be an irreducible nonnegative  $n \times n$  matrix with period  $q$ .
  - (a)  $q$  is the greatest common divisor of  $\{m : m \text{ is a positive integer and } (P^m)_{ii} > 0\}$  for any one, or equivalently all,  $i \in \{1, \dots, n\}$ .

(b) There exists a partition  $C_1, \dots, C_q$  of  $\{1, \dots, n\}$  such that:

- i. For  $s, t = 1, \dots, q$ ,  $P[C_s, C_t] \neq 0$  if and only if  $t = s + 1$  (with  $q + 1$  identified with 1); in particular,  $P$  is permutation similar to a block rectangular matrix having a representation

$$\begin{bmatrix} 0 & P[C_1, C_2] & 0 & \dots & 0 \\ 0 & 0 & P[C_2, C_3] & \dots & 0 \\ \vdots & \vdots & \vdots & \dots & \vdots \\ 0 & 0 & 0 & \dots & P[C_{q-1}, C_q] \\ P[C_q, C_1] & 0 & 0 & \dots & 0 \end{bmatrix}.$$

- ii.  $P^q[C_s]$  is irreducible for  $s = 1, \dots, q$  and  $P^q[C_s, C_t] = 0$  for  $s, t = 1, \dots, n$  with  $s \neq t$ ; in particular,  $P^q$  is permutation similar to a block diagonal matrix having irreducible blocks on the diagonal.

5. (*Spectral Properties — The Perron–Frobenius Theorem*) [Fro12] Let  $P$  be an irreducible nonnegative square matrix with spectral radius  $\rho$  and period  $q$ .

- (a)  $\rho$  is positive and is a simple eigenvalue of  $P$ ; in particular, the index of  $P$  at  $\rho$  is 1.  
 (b) There exist positive right and left eigenvectors of  $P$  corresponding to  $\rho$ ; in particular,  $\rho$  is a distinguished eigenvalue of both  $P$  and  $P^T$ .  
 (c)  $\rho$  is the only distinguished eigenvalue of  $P$  and of  $P^T$ .  
 (d) If  $\mathbf{x} \in \mathbb{R}^n$  satisfies  $\mathbf{x} \geq 0$  and either  $(\rho I - P)\mathbf{x} \geq 0$  or  $(\rho I - P)\mathbf{x} \leq 0$ , then  $(\rho I - P)\mathbf{x} = 0$ .  
 (e) The eigenvalues of  $P$  with modulus  $\rho$  are  $\{\rho e^{(2\pi i)k/q} : k = 0, \dots, q - 1\}$  (here,  $i$  is the complex root of  $-1$ ) and each of these eigenvalues is simple. In particular, if  $P$  is aperiodic ( $q = 1$ ), then every eigenvalue  $\lambda \neq \rho$  of  $P$  satisfies  $|\lambda| < \rho$ .  
 (f)  $Q \equiv \rho I - P$  has a group inverse; further, if  $\mathbf{v}$  and  $\mathbf{w}$  are positive right and left eigenvectors of  $P$  corresponding to  $\rho$ , then  $Q + \frac{\mathbf{v}\mathbf{w}}{\mathbf{w}\mathbf{v}}$  is nonsingular,  $Q^\# = (Q + \frac{\mathbf{v}\mathbf{w}}{\mathbf{w}\mathbf{v}})^{-1}(I - \frac{\mathbf{v}\mathbf{w}}{\mathbf{w}\mathbf{v}})$ , and  $\frac{\mathbf{v}\mathbf{w}}{\mathbf{w}\mathbf{v}} = I - QQ^\#$ .

6. (*Convergence Properties of Powers*) Let  $P$  be an irreducible nonnegative square matrix with spectral radius  $\rho$ , index  $v$ , period  $q$ , and ergodicity coefficient  $\tau$ . Also, let  $\mathbf{v}$  and  $\mathbf{w}$  be positive right and left eigenvectors of  $P$  corresponding to  $\rho$  and let  $P^* \equiv \frac{\mathbf{v}\mathbf{w}}{\mathbf{w}\mathbf{v}}$ .

- (a)  $\lim_{m \rightarrow \infty} (\frac{P}{\rho})^m = P^*(C, 1)$ .  
 (b)  $\lim_{m \rightarrow \infty} \frac{1}{q} \sum_{t=m}^{m+q-1} (\frac{P}{\rho})^t = P^*$  and the convergence is geometric with rate  $\frac{\tau}{\rho} < 1$ . In particular, if  $P$  is aperiodic ( $q = 1$ ), then  $\lim_{m \rightarrow \infty} (\frac{P}{\rho})^m = P^*$  and the convergence is geometric with rate  $\frac{\tau}{\rho} < 1$ .  
 (c) For each  $k = 0, \dots, q - 1$ ,  $\lim_{m \rightarrow \infty} (\frac{P}{\rho})^{mq+k}$  exists and the convergence of these sequences to their limit is geometric with rate  $(\frac{\tau}{\rho})^q < 1$ .  
 (d)  $\lim_{m \rightarrow \infty} \sum_{t=0}^{m-1} (\frac{P}{\rho})^t - mP^* = (I - \rho^{-1}P)^\#(C, 1)$ ; further, if  $P$  is aperiodic, this limit holds as a regular limit and the convergence is geometric with rate  $\frac{\tau}{\rho} < 1$ .

7. (*Bounds on the Perron Value*) Let  $P$  be an irreducible nonnegative  $n \times n$  matrix with spectral radius  $\rho$ , let  $\mu$  be a nonnegative scalar, and let  $\diamond \in \{<, \leq, =, \geq, >\}$ . The following are equivalent:

- (a)  $\rho \diamond \mu$ .  
 (b) There exists a vector  $\mathbf{u} \geq 0$  in  $\mathbb{R}^n$  with  $P\mathbf{u} \diamond \mu\mathbf{u}$ .  
 (c) There exists a vector  $\mathbf{u} > 0$  in  $\mathbb{R}^n$  with  $P\mathbf{u} \diamond \mu\mathbf{u}$ .

In particular,

$$\begin{aligned} \rho &= \max_{\mathbf{x} \geq 0} \min_{\{i: x_i > 0\}} \frac{(P\mathbf{x})_i}{x_i} = \min_{\mathbf{x} \geq 0} \max_{\{i: x_i > 0\}} \frac{(P\mathbf{x})_i}{x_i} \\ &= \max_{\mathbf{x} > 0} \min_i \frac{(P\mathbf{x})_i}{x_i} = \min_{\mathbf{x} > 0} \max_i \frac{(P\mathbf{x})_i}{x_i}. \end{aligned}$$

Since  $\rho(P^T) = \rho(P)$ , the above properties (and characterizations) of  $\rho$  can be expressed by applying the above conditions to  $P^T$ .

Consider the sets  $\Omega(P) \equiv \{\mu \geq 0 : \exists \mathbf{x} \geq 0, P\mathbf{x} \geq \mu\mathbf{x}\}$ ,  $\Omega_1(P) \equiv \{\mu \geq 0 : \exists \mathbf{x} > 0, P\mathbf{x} \geq \mu\mathbf{x}\}$ ,  $\Sigma(P) \equiv \{\mu \geq 0 : \exists \mathbf{x} \geq 0, P\mathbf{x} \leq \mu\mathbf{x}\}$ ,  $\Sigma_1(P) \equiv \{\mu \geq 0 : \exists \mathbf{x} > 0, P\mathbf{x} \leq \mu\mathbf{x}\}$ ; these sets were named the Collatz–Wielandt sets in [BS75], giving credit to ideas used in [Col42], [Wie50]. The above properties (and characterizations) of  $\rho$  can be expressed through maximal/minimal elements of the Collatz–Wielandt sets of  $P$  and  $P^T$ . (For further details see Chapter 26.)

8. (*Bounds on the Spectral Radius*) Let  $A$  be a complex  $n \times n$  matrix and let  $P$  be an irreducible nonnegative  $n \times n$  matrix such that  $|A| \leq P$ .

- (a)  $\rho(A) \leq \rho(P)$ .
- (b) [Wie50], [Sch96]  $\rho(A) = \rho(P)$  if and only if there exist a complex number  $\mu$  with  $|\mu| = 1$  and a complex diagonal matrix  $D$  with  $|D| = I$  such that  $A = \mu D^{-1} P D$ ; in particular, in this case  $|A| = P$ .
- (c) If  $A$  is real and  $\mu$  and  $\diamond \in \{<, \leq\}$  satisfy the condition stated in 7b or 7c, then  $\rho(A) < \mu$ .
- (d) If  $A$  is real and  $\mu$  and  $\diamond \in \{\leq, =\}$  satisfy the condition stated in 7b or 7c, then  $\rho(A) \leq \mu$ .

9. (*Functional Inequalities*) Consider the function  $\rho(\cdot)$  mapping irreducible, nonnegative  $n \times n$  matrices to their spectral radius.

- (a)  $\rho(\cdot)$  is strictly increasing in each element (of the domain matrices), i.e., if  $A$  and  $B$  are irreducible, nonnegative  $n \times n$  matrices with  $A \geq B \geq 0$ , then  $\rho(A) > \rho(B)$ .
- (b) [Coh78]  $\rho(\cdot)$  is (jointly) convex in the diagonal elements, i.e., if  $A$  and  $D$  are  $n \times n$  matrices, with  $D$  diagonal,  $A$  and  $A + D$  nonnegative and irreducible and if  $0 < \alpha < 1$ , then  $\rho[\alpha A + (1 - \alpha)(A + D)] \leq \alpha\rho(A) + (1 - \alpha)\rho(A + D)$ .

For further functional inequalities that concern the spectral radius see Fact 8 of Section 9.3.

10. (*Taylor Expansion of the Perron Value*) [HRR92] The function  $\rho(\cdot)$  mapping irreducible nonnegative  $n \times n$  matrices  $X = [x_{ij}]$  to their spectral radius is differentiable of all orders and has a converging Taylor expansion. In particular, if  $P$  is an irreducible nonnegative  $n \times n$  matrix with spectral radius  $\rho$  and corresponding positive right and left eigenvectors  $\mathbf{v} = [v_i]$  and  $\mathbf{w} = [w_j]$ , normalized so that  $\mathbf{w}\mathbf{v} = 1$ , and if  $F$  is an  $n \times n$  matrix with  $P + \epsilon F \geq 0$  for all sufficiently small positive  $\epsilon$ , then  $\rho(P + \epsilon F) = \sum_{k=0}^{\infty} \rho_k \epsilon^k$  with  $\rho_0 = \rho$ ,  $\rho_1 = \mathbf{w}F\mathbf{v}$ ,  $\rho_2 = \mathbf{w}F(\rho I - P)^{\#}F\mathbf{v}$ ,  $\rho_3 = \mathbf{w}F(\rho I - P)^{\#}(\mathbf{w}F\mathbf{v}I - F)(\rho I - P)^{\#}F\mathbf{v}$ ; in particular,  $\frac{\partial \rho(X)}{\partial x_{ij}}|_{X=P} = w_i v_j$ .

An algorithm that iteratively generates all coefficients of the above Taylor expansion is available; see [HRR92].

11. (*Bounds on the Ergodicity Coefficient*) [RT85] Let  $P$  be an irreducible nonnegative  $n \times n$  matrix with spectral radius  $\rho$ , corresponding positive right eigenvector  $\mathbf{v}$ , and ergodicity coefficient  $\tau$ ; let  $D$  be a diagonal  $n \times n$  matrix with positive diagonal elements; and let  $\|\cdot\|$  be a norm on  $\mathbb{R}^n$ . Then

$$\tau \leq \max_{\mathbf{x} \in \mathbb{R}^n, \|\mathbf{x}\| \leq 1, \mathbf{x}^T D^{-1} P D \mathbf{v} = 0} \|\mathbf{x}^T D^{-1} P D\|.$$

**Examples:**

1. We illustrate Fact 1 using the matrix

$$P = \begin{bmatrix} \frac{1}{2} & \frac{1}{6} & \frac{1}{3} \\ \frac{1}{4} & \frac{1}{4} & \frac{1}{2} \\ \frac{3}{4} & \frac{1}{8} & \frac{1}{8} \end{bmatrix}.$$

The eigenvalues of  $P$  are  $1, \frac{1}{48}(-3 - \sqrt{33}), \frac{1}{48}(-3 + \sqrt{33})$ , so  $\rho(A) = 1$ . Also,  $\mathbf{v} = [1, 1, 1]^T$  and  $\mathbf{w} = [57, 18, 32]$  are positive right and left eigenvectors, respectively, corresponding to eigenvalue

1 and

$$\frac{\mathbf{v}\mathbf{w}}{\mathbf{w}\mathbf{v}} = \begin{bmatrix} \frac{57}{107} & \frac{18}{107} & \frac{32}{107} \\ \frac{57}{107} & \frac{18}{107} & \frac{32}{107} \\ \frac{57}{107} & \frac{18}{107} & \frac{32}{107} \end{bmatrix}.$$

2. We illustrate parts of Facts 5 and 6 using the matrix

$$P \equiv \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

The spectral radius of  $P$  is 1 with corresponding right and left eigenvectors  $\mathbf{v} = (1, 1)^T$  and  $\mathbf{w} = (1, 1)$ , respectively, the period of  $P$  is 2, and  $(I - P)^\# = \frac{I-P}{4}$ . Evidently,

$$P^m = \begin{cases} I & \text{if } m \text{ is even} \\ P & \text{if } m \text{ is odd.} \end{cases}$$

In particular,

$$\lim_{m \rightarrow \infty} P^{2m} = I \quad \text{and} \quad \lim_{m \rightarrow \infty} P^{2m+1} = P$$

and

$$\frac{1}{2}[P^m + P^{m+1}] = \frac{I + P}{2} = \begin{bmatrix} .5 & .5 \\ .5 & .5 \end{bmatrix} = \mathbf{v}(\mathbf{w}\mathbf{v})^{-1}\mathbf{w} \quad \text{for each } m = 0, 1, \dots,$$

assuring that, trivially,

$$\lim_{m \rightarrow \infty} \frac{1}{2} \sum_{t=m}^{m+1} P^t = \begin{bmatrix} .5 & .5 \\ .5 & .5 \end{bmatrix} = \mathbf{v}(\mathbf{w}\mathbf{v})^{-1}\mathbf{w}.$$

In this example,  $\tau(P)$  is 0 (as the maximum over the empty set) and the convergence of the above sequences is geometric with rate 0. Finally,

$$\sum_{t=0}^{m-1} P^t = \begin{cases} \frac{m(I+P)}{2} & \text{if } m \text{ is even} \\ \frac{m(I+P)}{2} + \frac{I-P}{2} & \text{if } m \text{ is odd,} \end{cases}$$

implying that

$$\lim_{m \rightarrow \infty} P^m = \frac{(I + P)}{2} = \mathbf{v}(\mathbf{w}\mathbf{v})^{-1}\mathbf{w} \quad (\text{C},1)$$

and

$$\lim_{m \rightarrow \infty} \sum_{t=0}^{m-1} P^t - m \left( \frac{I + P}{2} \right) = \frac{I - P}{4} \quad (\text{C},1).$$

3. We illustrate parts of Fact 10 using the matrix  $P$  of Example 2 and  $F \equiv \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}$ . Then  $\rho(P + \epsilon F) =$

$$\sqrt{1 + \epsilon} = 1 + \frac{1}{2}\epsilon + \sum_{k=2}^{\infty} \epsilon^k \frac{(-1)^{k+1}}{k2^{k-2}} \binom{2k-3}{k-2}.$$

4. [RT85, Theorem 4.1] and [Hof67] With  $\|\cdot\|$  as the 1-norm on  $\mathbb{R}^n$  and  $d_1, \dots, d_n$  as the (positive) diagonal elements of  $D$ , the bound in Fact 11 on the coefficient of ergodicity  $\tau(P)$  of  $P$  becomes

$$\max_{r,s=1,\dots,n,r \neq s} \frac{1}{d_s v_r + d_r v_s} \left( \sum_{k=1}^n d_k |v_s P_{rk} - v_r P_{sk}| \right).$$

With  $D = I$ , a relaxation of this bound on  $\tau(P)$  yields the expression

$$\leq \min \left\{ \rho - \sum_{j=1}^n \min_i \left( \frac{P_{ij} v_j}{v_i} \right), \sum_{j=1}^n \max_i \left( \frac{P_{ij} v_j}{v_i} \right) - \rho \right\}.$$

5. [RT85, Theorem 4.3] For a positive vector  $\mathbf{u} \in \mathbb{R}^n$ , consider the function  $M^{\mathbf{u}}: \mathbb{R}^n \rightarrow \mathbb{R}$  defined for  $\mathbf{a} \in \mathbb{R}^n$  by

$$M^{\mathbf{u}}(\mathbf{a}) = \max\{\mathbf{x}^T \mathbf{a} : \mathbf{x} \in \mathbb{R}^n, \|\mathbf{x}\| \leq 1, \mathbf{x}^T \mathbf{u} = 0\}.$$

This function has a simple explicit representation obtained by sorting the ratios  $\frac{a_i}{u_j}$ , i.e., identifying a permutation  $j(1), \dots, j(n)$  of  $1, \dots, n$  such that

$$\frac{a_{j(1)}}{u_{j(1)}} \leq \frac{a_{j(2)}}{u_{j(2)}} \leq \dots \leq \frac{a_{j(n)}}{u_{j(n)}}.$$

With  $k^*$  as the smallest integer in  $\{1, \dots, n\}$  such that  $2 \sum_{p=1}^{k^*} u_{j(p)} > \sum_{t=1}^n u_t$  and

$$\mu \equiv 1 + \left( \sum_{t=1}^n u_t - 2 \sum_{p=1}^{k^*} u_{j(p)} \right),$$

we have that

$$M^{\mathbf{u}}(\mathbf{a}) = \sum_{p=1}^{k^*-1} a_{j(p)} + \mu a_{j(k^*)} - \sum_{p=k^*+1}^n a_{j(p)}.$$

With  $\|\cdot\|$  as the  $\infty$ -norm on  $\mathbb{R}^n$  and  $(D^{-1}PD)_1, \dots, (D^{-1}PD)_n$  as the columns of  $D^{-1}PD$ , the bound in Fact 11 on the coefficient of ergodicity  $\tau(P)$  of  $P$  becomes

$$\max_{r=1, \dots, n} M^{D^{-1}\mathbf{w}}[(D^{-1}PD)_r].$$

### 9.3 Reducible Matrices

#### Definitions:

For a nonnegative  $n \times n$  matrix  $P$  with spectral radius  $\rho$ :

A **basic class** of  $P$  is an access equivalence class  $B$  of  $P$  with  $\rho(P[B]) = \rho$ .

The **period** of an access equivalence class  $C$  of  $P$  (also known as the **index of imprimitivity** of  $C$ ) is the period of the (irreducible) matrix  $P[C]$ .

The **period** of  $P$  (also known as the **index of imprimitivity** of  $P$ ) is the least common multiple of the periods of its basic classes.

$P$  is **aperiodic** if its period is 1.

The **index** of  $P$ , denoted  $v_P$ , is  $v_P(\rho)$ .

The **co-index** of  $P$ , denoted  $\bar{v}_P$ , is  $\max\{v_P(\lambda) : \lambda \in \sigma(P), |\lambda| = \rho \text{ and } \lambda \neq \rho\}$  (with the maximum over the empty set defined as 0).

The **basic reduced digraph** of  $P$ , denoted  $R^*(P)$ , is the digraph whose vertex-set is the set of basic classes of  $P$  and whose arcs are the pairs  $(B, B')$  of distinct basic classes of  $P$  for which there exists a simple walk in  $R[\Gamma(P)]$  from  $B$  to  $B'$ .

The **height** of a basic class is the largest number of vertices on a simple walk in  $R^*(P)$  which ends at  $B$ .

The **principal submatrix** of  $P$  at a distinguished eigenvalue  $\lambda$ , denoted  $P[\lambda]$ , is the principal submatrix of  $P$  corresponding to a set of vertices of  $\Gamma(P)$  having no access to a vertex of an access equivalence class  $C$  that satisfies  $\rho(P[C]) > \lambda$ .

$P$  is **convergent** or **transient** if  $\lim_{m \rightarrow \infty} P^m = 0$ .

$P$  is **semiconvergent** if  $\lim_{m \rightarrow \infty} P^m$  exists.

$P$  is **weakly expanding** if  $P\mathbf{u} \geq \mathbf{u}$  for some  $\mathbf{u} > 0$ .

$P$  is **expanding** if for some  $P\mathbf{u} > \mathbf{u}$  for some  $\mathbf{u} > 0$ .

An  $n \times n$  **matrix polynomial of degree  $d$**  in the (integer) variable  $m$  is a polynomial in  $m$  with coefficients that are  $n \times n$  matrices (expressible as  $S(m) = \sum_{t=0}^d m^t B_t$  with  $B_1, \dots, B_d$  as  $n \times n$  matrices and  $B_d \neq 0$ ).

### Facts:

Facts requiring proofs for which no specific reference is given can be found in [BP94, Chap. 2].

1. The set of basic classes of a nonnegative matrix is always nonempty.
2. (*Spectral Properties of the Perron Value*) Let  $P$  be a nonnegative  $n \times n$  matrix with spectral radius  $\rho$  and index  $\nu$ .
  - (a) [Fro12]  $\rho$  is an eigenvalue of  $P$ .
  - (b) [Fro12] There exist semipositive right and left eigenvectors of  $P$  corresponding to  $\rho$ , i.e.,  $\rho$  is a distinguished eigenvalue of both  $P$  and  $P^T$ .
  - (c) [Rot75]  $\nu$  is the largest number of vertices on a simple walk in  $R^*(P)$ .
  - (d) [Rot75] For each basic class  $B$  having height  $h$ , there exists a generalized eigenvector  $\mathbf{v}^B$  in  $N_\rho^h(P)$ , with  $(\mathbf{v}^B)_i > 0$  if  $i \mapsto B$  and  $(\mathbf{v}^B)_i = 0$  otherwise.
  - (e) [Rot75] The dimension of  $N_\rho^\nu(P)$  is the number of basic classes of  $P$ . Further, if  $B_1, \dots, B_p$  are the basic classes of  $P$  and  $\mathbf{v}^{B_1}, \dots, \mathbf{v}^{B_p}$  are generalized eigenvectors of  $P$  at  $\rho$  that satisfy the conclusions of Fact 2(d) with respect to  $B_1, \dots, B_p$ , respectively, then  $\mathbf{v}^{B_1}, \dots, \mathbf{v}^{B_p}$  form a basis of  $N_\rho^\nu(P)$ .
  - (f) [RiSc78, Sch86] If  $B_1, \dots, B_p$  is an enumeration of the basic classes of  $P$  with nondecreasing heights (in particular,  $s < t$  assures that we do not have  $B_t \mapsto B_s$ ), then there exist generalized eigenvectors  $\mathbf{v}^{B_1}, \dots, \mathbf{v}^{B_p}$  of  $P$  at  $\rho$  that satisfy the assumptions and conclusions of Fact 2(e) and a nonnegative  $p \times p$  upper triangular matrix  $M$  with all diagonal elements equal to  $\rho$ , such that

$$P[\mathbf{v}^{B_1}, \dots, \mathbf{v}^{B_p}] = [\mathbf{v}^{B_1}, \dots, \mathbf{v}^{B_p}]M$$

(in particular,  $\mathbf{v}^{B_1}, \dots, \mathbf{v}^{B_p}$  is a basis of  $N_\rho^\nu(P)$ ). Relationships between the matrix  $M$  and the Jordan Canonical Form of  $P$  are beyond the scope of the current review; see [Sch56], [Sch86], [HS89], [HS91a], [HS91b], [HRS89], and [NS94].

- (g) [Vic85], [Sch86], [Tam04] If  $B_1, \dots, B_r$  are the basic classes of  $P$  having height 1 and  $\mathbf{v}^{B_1}, \dots, \mathbf{v}^{B_r}$  are generalized eigenvectors of  $P$  at  $\rho$  that satisfy the conclusions of Fact 2(d) with respect to  $B_1, \dots, B_r$ , respectively, then  $\mathbf{v}^{B_1}, \dots, \mathbf{v}^{B_r}$  are linearly independent, nonnegative eigenvectors of  $P$  at  $\rho$  that span the cone  $(\mathbb{R}_0^+)^n \cap N_\rho^1(P)$ ; that is, each vector in the cone  $(\mathbb{R}_0^+)^n \cap N_\rho^1(P)$  is a linear combination with nonnegative coefficients of  $\mathbf{v}^{B_1}, \dots, \mathbf{v}^{B_r}$  (in fact, the sets  $\{\alpha \mathbf{v}^{B_s} : \alpha \geq 0\}$  for  $s = 1, \dots, r$  are the extreme rays of the cone  $(\mathbb{R}_0^+)^n \cap N_\rho^1(P)$ ).
3. (*Spectral Properties of Eigenvalues  $\lambda \neq \rho(P)$  with  $|\lambda| = \rho(P)$* ) Let  $P$  be a nonnegative  $n \times n$  matrix with spectral radius  $\rho$ , index  $\nu$ , co-index  $\bar{\nu}$ , period  $q$ , and coefficient of ergodicity  $\tau$ .
  - (a) [Rot81a] The following are equivalent:
    - i.  $\{\lambda \in \sigma(P) \setminus \{\rho\} : |\lambda| = \rho\} = \emptyset$ .
    - ii.  $\bar{\nu} = 0$ .
    - iii.  $P$  is aperiodic ( $q = 1$ ).

- (b) [Rot81a] If  $\lambda \in \sigma(P) \setminus \{\rho\}$  and  $|\lambda| = \rho$ , then  $(\frac{\lambda}{\rho})^h = 1$  for some  $h \in \{2, \dots, n\}$ ; further,  $q = \min\{h = 2, \dots, n : (\frac{\lambda}{\rho})^h = 1 \text{ for each } \lambda \in \sigma(P) \setminus \{\rho\} \text{ with } |\lambda| = \rho\} \leq n$  (here the minimum over the empty set is taken to be 1).
- (c) [Rot80] If  $\lambda \in \sigma(P) \setminus \{\rho\}$  and  $|\lambda| = \rho$ , then  $v_P(\lambda)$  is bounded by the largest number of vertices on a simple walk in  $R^*(P)$  with each vertex corresponding to a (basic) access equivalence class  $C$  that has  $\lambda \in \sigma(P[C])$ ; in particular,  $\bar{v} \leq v$ .

4. (*Distinguished Eigenvalues*) Let  $P$  be a nonnegative  $n \times n$  matrix.

- (a) [Vic85]  $\lambda$  is a distinguished eigenvalue of  $P$  if and only if there is a final set  $C$  with  $\rho(P[C]) = \lambda$ .  
It is noted that the set of distinguished eigenvalues of  $P$  and  $P^T$  need not coincide (and the above characterization of distinguished eigenvalues is not invariant of the application of the transpose operator). (See Example 1 below.)
- (b) [HS88b] If  $\lambda$  is a distinguished eigenvalue,  $v_P(\lambda)$  is the largest number of vertices on a simple walk in  $R^*(P[\lambda])$ .
- (c) [HS88b] If  $\mu > 0$ , then  $\mu \leq \min\{\lambda : \lambda \text{ is a distinguished eigenvalue of } P\}$  if and only if there exists a vector  $\mathbf{u} > 0$  with  $P\mathbf{u} \geq \mu\mathbf{u}$ .

(For additional characterizations of the minimal distinguished eigenvalue, see the concluding remarks of Facts 12(h) and 12(i).)

Additional properties of distinguished eigenvalues  $\lambda$  of  $P$  that depend on  $P[\lambda]$  can be found in [HS88b] and [Tam04].

5. (*Convergence Properties of Powers*) Let  $P$  be a nonnegative  $n \times n$  matrix with positive spectral radius  $\rho$ , index  $\nu$ , co-index  $\bar{\nu}$ , period  $q$ , and coefficient of ergodicity  $\tau$  (for the case where  $\rho = 0$ , see Fact 12(j) below).

- (a) [Rot81a] There exists an  $n \times n$  matrix polynomial  $S(m)$  of degree  $\nu - 1$  in the (integer) variable  $m$  such that  $\lim_{m \rightarrow \infty} [(\frac{P}{\rho})^m - S(m)] = 0$  ( $C, p$ ) for every  $p \geq \bar{\nu}$ ; further, if  $P$  is aperiodic, this limit holds as a regular limit and the convergence is geometric with rate  $\frac{\tau}{\rho} < 1$ .
- (b) [Rot81a] There exist matrix polynomials  $S^0(m), \dots, S^{q-1}(m)$  of degree  $\nu - 1$  in the (integer) variable  $m$ , such that for each  $k = 0, \dots, q - 1$ ,  $\lim_{m \rightarrow \infty} [(\frac{P}{\rho})^{mq+k} - S^k(m)] = 0$  and the convergence of these sequences to their limit is geometric with rate  $(\frac{\tau}{\rho})^q < 1$ .
- (c) [Rot81a] There exists a matrix polynomial  $T(m)$  of degree  $\nu$  in the (integer) variable  $m$  with  $\lim_{m \rightarrow \infty} [\sum_{s=0}^{m-1} (\frac{P}{\rho})^s - T(m)] = 0$  ( $C, p$ ) for every  $p \geq \bar{\nu}$ ; further, if  $P$  is aperiodic, this limit holds as a regular limit and the convergence is geometric with rate  $\frac{\tau}{\rho} < 1$ .
- (d) [FrSc80] The limit of  $\frac{P^m}{\rho^m m^{\nu-1}} [I + \frac{P}{\rho} + \dots + (\frac{P}{\rho})^{q-1}]$  exists and is semipositive.
- (e) [Rot81b] Let  $\mathbf{x} = [x_i]$  be a nonnegative vector in  $\mathbb{R}^n$  and let  $i \in \langle n \rangle$ . With  $K(i, \mathbf{x}) \equiv \{j \in \langle n \rangle : j \mapsto i\} \cap \{j \in \langle n \rangle : u \mapsto j \text{ for some } u \in \langle n \rangle \text{ with } x_u > 0\}$ ,

$$r(i|\mathbf{x}, P) \equiv \inf\{\alpha > 0 : \lim_{m \rightarrow \infty} \alpha^{-m} (P^m \mathbf{x})_i = 0\} = \rho(P[K(i, \mathbf{x})])$$

and if  $r \equiv r(i|\mathbf{x}, P) > 0$ ,

$$k(i|\mathbf{x}, P) \equiv \inf\{k = 0, 1, \dots : \lim_{m \rightarrow \infty} m^{-k} r^{-m} (P^m \mathbf{x})_i = 0\} = v_{P[K(i, \mathbf{x})]}(r).$$

Explicit expressions for the polynomials mentioned in Facts 5(a) to 5(d) in terms of characteristics of the underlying matrix  $P$  are available in Fact 12(a)ii for the case where  $\nu = 1$  and in [Rot81a] for the general case. In fact, [Rot81a] provides (explicit) polynomial approximations of additional high-order partial sums of normalized powers of nonnegative matrices.

6. (*Bounds on the Perron Value*) Let  $P$  be a nonnegative  $n \times n$  matrix with spectral radius  $\rho$  and let  $\mu$  be a nonnegative scalar.

- (a) For  $\diamond \in \{<, \leq, =, \geq, >\}$ ,

$$[P\mathbf{u} \diamond \mu\mathbf{u} \text{ for some vector } \mathbf{u} > 0] \Rightarrow [\rho \diamond \mu];$$

further, the inverse implication holds for  $\diamond$  as  $<$ , implying that

$$\rho = \max_{\mathbf{x} \geq 0} \min_{\{i: x_i > 0\}} \frac{(A\mathbf{x})_i}{x_i}.$$

- (b) For  $\diamond \in \{\leq, \leq, =, \geq, \geq\}$ ,

$$[\rho \diamond \mu] \Rightarrow [P\mathbf{u} \diamond \mu\mathbf{u} \text{ for some vector } \mathbf{u} \geq 0];$$

further, the inverse implication holds for  $\diamond$  as  $\geq$ .

- (c)  $\rho < \mu$  if and only if  $P\mathbf{u} < \rho\mathbf{u}$  for some vector  $\mathbf{u} \geq 0$ .

Since  $\rho(P^T) = \rho(P)$ , the above properties (and characterizations) of  $\rho$  can be expressed by applying the above conditions to  $P^T$ . (See Example 3 below.)

Some of the above results can be expressed in terms of the Collatz–Wielandt sets. (See Fact 7 of Section 9.2 and Chapter 26.)

7. (*Bounds on the Spectral Radius*) Let  $P$  be a nonnegative  $n \times n$  matrix and let  $A$  be a complex  $n \times n$  matrix such that  $|A| \leq P$ . Then  $\rho(A) \leq \rho(P)$ .
8. (*Functional Inequalities*) Consider the function  $\rho(\cdot)$  mapping nonnegative  $n \times n$  matrices to their spectral radius.
  - (a)  $\rho(\cdot)$  is nondecreasing in each element (of the domain matrices); that is, if  $A$  and  $B$  are nonnegative  $n \times n$  matrices with  $A \geq B \geq 0$ , then  $\rho(A) \geq \rho(B)$ .
  - (b) [Coh78]  $\rho(\cdot)$  is (jointly) convex in the diagonal elements; that is, if  $A$  and  $D$  are  $n \times n$  matrices, with  $D$  diagonal,  $A$  and  $A + D$  nonnegative, and if  $0 < \alpha < 1$ , then  $\rho[\alpha A + (1 - \alpha)(A + D)] \leq \alpha\rho(A) + (1 - \alpha)\rho(A + D)$ .
  - (c) [EJD88] If  $A = [a_{ij}]$  and  $B = [b_{ij}]$  are nonnegative  $n \times n$  matrices,  $0 < \alpha < 1$  and  $C = [c_{ij}]$  with  $c_{ij} = a_{ij}^\alpha b_{ij}^{1-\alpha}$  for each  $i, j = 1, \dots, n$ , then  $\rho(C) \leq \rho(A)^\alpha \rho(B)^{1-\alpha}$ .

Further functional inequalities about  $\rho(\cdot)$  can be found in [EJD88] and [EHP90].

9. (*Resolvent Expansions*) Let  $P$  be a nonnegative square matrix with spectral radius  $\rho$  and let  $\mu > \rho$ . Then  $\mu I - P$  is invertible and

$$(\mu I - P)^{-1} = \sum_{t=0}^{\infty} \frac{P^t}{\mu^{t+1}} \geq \frac{I}{\mu} + \frac{P}{\mu^2} \geq \frac{I}{\mu} \geq 0$$

(the invertibility of  $\mu I - P$  and the power series expansion of its inverse do not require nonnegativity of  $P$ ).

For explicit expansions of the resolvent about the spectral radius, that is, for explicit power series representations of  $[(z + \rho)I - P]^{-1}$  with  $|z|$  positive and sufficiently small, see [Rot81c], and [HNR90] (the latter uses such expansions to prove Perron–Frobenius-type spectral results for nonnegative matrices).

10. (*Puiseux Expansions of the Perron Value*) [ERS95] The function  $\rho(\cdot)$  mapping irreducible nonnegative  $n \times n$  matrices  $X = [x_{ij}]$  to their spectral radius has a converging Puiseux (fractional power series) expansion at each point; i.e., if  $P$  is a nonnegative  $n \times n$  matrix and if  $F$  is an  $n \times n$  matrix with  $P + \epsilon F \geq 0$  for all sufficiently small positive  $\epsilon$ , then  $\rho(P + \epsilon F)$  has a representation  $\sum_{k=0}^{\infty} \rho_k \epsilon^{k/q}$  with  $\rho_0 = \rho(P)$  and  $q$  as a positive integer.
11. (*Bounds on the Ergodicity Coefficient*) [RT85, extension of Theorem 3.1] Let  $P$  be a nonnegative  $n \times n$  matrix with spectral radius  $\rho$ , corresponding semipositive right eigenvector  $\mathbf{v}$ , and ergodicity

coefficient  $\tau$ , let  $D$  be a diagonal  $n \times n$  matrix with positive diagonal elements, and let  $\|\cdot\|$  be a norm on  $\mathbb{R}^n$ . Then

$$\tau \leq \max_{\mathbf{x} \in \mathbb{R}^n, \|\mathbf{x}\| \leq 1, \mathbf{x}^T D^{-1} \mathbf{v} = 0} \|\mathbf{x}^T D^{-1} P D\|.$$

12. (*Special Cases*) Let  $P$  be a nonnegative  $n \times n$  matrix with spectral radius  $\rho$ , index  $\nu$ , and period  $q$ .

(a) (Index 1) Suppose  $\nu = 1$ .

- i.  $\rho I - P$  has a group inverse.
- ii. [Rot81a] With  $P^* \equiv I - (\rho I - P)(\rho I - P)^\#$ , all of the convergence properties stated in Fact 6 of Section 9.2 apply.
- iii. If  $\rho > 0$ , then  $\frac{P^m}{\rho^m}$  is bounded in  $m$  (element-wise).
- iv.  $\rho = 0$  if and only if  $P = 0$ .

(b) (*Positive eigenvector*) The following are equivalent:

- i.  $P$  has a positive right eigenvector corresponding to  $\rho$ .
- ii. The final classes of  $P$  are precisely its basic classes.
- iii. There is no vector  $\mathbf{w}$  satisfying  $\mathbf{w}^T P \leq \rho \mathbf{w}^T$ .

Further, when the above conditions hold:

- i.  $\nu = 1$  and the conclusions of Fact 12(a) hold.
- ii. If  $P$  satisfies the above conditions and  $P \neq 0$ , then  $\rho > 0$  and there exists a diagonal matrix  $D$  having positive diagonal elements such that  $S \equiv \frac{1}{\rho} D^{-1} P D$  is stochastic (that is,  $S \geq 0$  and  $S\mathbf{1} = \mathbf{1}$ ; see Chapter 4).

(c) [Sch53] There exists a vector  $\mathbf{x} > 0$  with  $P\mathbf{x} \leq \rho\mathbf{x}$  if and only if every basic class of  $P$  is final.

(d) (*Positive generalized eigenvector*) [Rot75], [Sch86], [HS88a] The following are equivalent:

- i.  $P$  has a positive right generalized eigenvector at  $\rho$ .
- ii. Each final class of  $P$  is basic.
- iii.  $P\mathbf{u} \geq \rho\mathbf{u}$  for some  $\mathbf{u} > 0$ .
- iv. Every vector  $\mathbf{w} \geq 0$  with  $\mathbf{w}^T P \leq \rho \mathbf{w}^T$  must satisfy  $\mathbf{w}^T P = \rho \mathbf{w}^T$ .
- v.  $\rho$  is the only distinguished eigenvalue of  $P$ .

(e) (*Convergent/Transient*) The following are equivalent:

- i.  $P$  is convergent.
- ii.  $\rho < 1$ .
- iii.  $I - P$  is invertible and  $(I - P)^{-1} \geq 0$ .
- iv. There exists a positive vector  $\mathbf{u} \in R^n$  with  $P\mathbf{u} < \mathbf{u}$ .

Further, when the above conditions hold,  $(I - P)^{-1} = \sum_{t=0}^{\infty} P^t \geq I$ .

(f) (*Semiconvergent*) The following are equivalent:

- i.  $P$  is semiconvergent.
- ii. Either  $\rho < 1$  or  $\rho = \nu = 1$  and 1 is the only eigenvalue  $\lambda$  of  $P$  with  $|\lambda| = 1$ .

(g) (*Bounded*)  $P^m$  is bounded in  $m$  (element-wise) if and only if either  $\rho < 1$  or  $\rho = 1$  and  $\nu = 1$ .

(h) (*Weakly Expanding*) [HS88a], [TW89] [DR05] The following are equivalent:

- i.  $P$  is weakly expanding.
- ii. There is no vector  $\mathbf{w} \in R^n$  with  $\mathbf{w} \geq 0$  and  $\mathbf{w}^T P \leq \mathbf{w}^T$ .
- iii. Every distinguished eigenvalue  $\lambda$  of  $P$  satisfies  $\lambda \geq 1$ .

- iv. Every final class  $C$  of  $P$  has  $\rho(P[C]) \geq 1$ .
- v. If  $C$  is a final set of  $P$ , then  $\rho(P[C]) \geq 1$ .

Given  $\mu > 0$ , the application of the above equivalence to  $\frac{P}{\mu}$  yields characterizations of instances where each distinguished eigenvalue of  $P$  is bigger than or equal to  $\mu$ .

- (i) (*Expanding*) [HS88a], [TW89] [DR05] The following are equivalent:
  - i.  $P$  is expanding.
  - ii. There exists a vector  $\mathbf{u} \in R^n$  with  $\mathbf{u} \geq 0$  and  $P\mathbf{u} > \mathbf{u}$ .
  - iii. There is no vector  $\mathbf{w} \in R^n$  with  $\mathbf{w} \succeq 0$  and  $w^T P \leq w^T$ .
  - iv. Every distinguished eigenvalue  $\lambda$  of  $P$  satisfies  $\lambda > 1$ .
  - v. Every final class  $C$  of  $P$  has  $\rho(P[C]) > 1$ .
  - vi. If  $C$  is a final set of  $P$ , then  $\rho(P[C]) > 1$ .

Given  $\mu > 0$ , the application of the above equivalence to  $\frac{P}{\mu}$  yields characterizations of instances where each distinguished eigenvalue of  $P$  is bigger than  $\mu$ .

- (j) (*Nilpotent*) The following are equivalent conditions:
  - i.  $P$  is nilpotent; that is,  $P^m = 0$  for some positive integer  $m$ .
  - ii.  $P$  is permutation similar to an upper triangular matrix all of whose diagonal elements are 0.
  - iii.  $\rho = 0$ .
  - iv.  $P^n = 0$ .
  - v.  $P^v = 0$ .
- (k) (*Symmetric*) Suppose  $P$  is symmetric.
  - i.  $\rho = \max_{\mathbf{u} \succeq 0} \frac{\mathbf{u}^T P \mathbf{u}}{\mathbf{u}^T \mathbf{u}}$ .
  - ii.  $\rho = \frac{\mathbf{u}^T P \mathbf{u}}{\mathbf{u}^T \mathbf{u}}$  for  $\mathbf{u} \succeq 0$  if and only if  $\mathbf{u}$  is an eigenvector of  $P$  corresponding to  $\rho$ .
  - iii. [CHR97, Theorem 1] For  $\mathbf{u}, \mathbf{w} \succeq 0$  with  $w_i = \sqrt{u_i(Pu)_i}$  for  $i = 1, \dots, n$ ,  $\frac{\mathbf{u}^T P \mathbf{u}}{\mathbf{u}^T \mathbf{u}} \leq \frac{\mathbf{w}^T P \mathbf{w}}{\mathbf{w}^T \mathbf{w}}$  and equality holds if and only if  $\mathbf{u}[\mathcal{S}]$  is an eigenvector of  $P[\mathcal{S}]$  corresponding to  $\rho$ , where  $\mathcal{S} \equiv \{i : u_i > 0\}$ .

### Examples:

1. We illustrate parts of Fact 2 using the matrix

$$P = \begin{bmatrix} 2 & 2 & 2 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 2 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}.$$

The eigenvalues of  $P$  are 2, 1, and 0; so,  $\rho(P) = 2 \in \sigma(P)$  as is implied by Fact 2(a). The vectors  $\mathbf{v} = [1, 0, 0, 0, 0, 0]^T$  and  $\mathbf{w} = [0, 0, 0, 1, 1, 1]$  are semipositive right and left eigenvectors corresponding to the eigenvalue 2; their existence is implied by Fact 2(b).

The basic classes are  $B_1 = \{1\}$ ,  $B_2 = \{2\}$  and  $B_3 = \{4, 5\}$ . The digraph corresponding to  $P$ , its reduced digraph, and the basic reduced digraph of  $P$  are illustrated in Figure 9.1. From Figure 9.1(c), the largest number of vertices in a simple walk in the basic reduced digraph of  $P$  is 2 (going from  $B_1$  to either  $B_2$  or  $B_3$ ); hence, Fact 2(c) implies that  $\nu_P(2) = 2$ . The height of basic class  $B_1$  is 1 and the height of basic classes  $B_2$  and  $B_3$  is 2. Semipositive generalized eigenvectors of  $P$  at (the eigenvalue)

**FIGURE 9.1** (a) The digraph  $\Gamma(P)$ , (b) reduced digraph  $R[\Gamma(P)]$ , and (c) basic reduced digraph  $R^*(P)$ .

2 that satisfy the assumptions of Fact 2(f) are  $\mathbf{u}^{B_1} = [1, 0, 0, 0, 0, 0]^T$ ,  $\mathbf{u}^{B_2} = [1, 1, 0, 0, 0, 0]^T$ , and  $\mathbf{u}^{B_3} = [1, 0, 2, 1, 1, 0]^T$ . The implied equality

$$P[\mathbf{u}^{B_1}, \dots, \mathbf{u}^{B_p}] = [\mathbf{u}^{B_1}, \dots, \mathbf{u}^{B_p}]M$$

of Fact 2(f) holds as

$$\begin{bmatrix} 2 & 2 & 2 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 2 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 1 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & 2 \\ 0 & 0 & 1 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix} = \begin{bmatrix} 2 & 4 & 6 \\ 0 & 2 & 0 \\ 0 & 0 & 4 \\ 0 & 0 & 2 \\ 0 & 0 & 2 \\ 0 & 0 & 0 \end{bmatrix} = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & 2 \\ 0 & 0 & 1 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 2 & 2 & 4 \\ 0 & 2 & 0 \\ 0 & 0 & 2 \end{bmatrix}.$$

In particular, Fact 2(e) implies that  $\mathbf{u}^{B_1}, \mathbf{u}^{B_2}, \mathbf{u}^{B_3}$  form a basis of  $N_{\rho(P)}^{v(P)} = N_2^2$ . We note that while there is only a single basic class of height 1,  $\dim[N_{\rho}^1(P)] = 2$  and  $\mathbf{u}^{B_1}, 2\mathbf{u}^{B_2} - \mathbf{u}^{B_3} = [-1, 2, -2, -1, -1, 0]^T$  form a basis of  $N_{\rho}^1(P)$ . Still, Fact 2(g) assures that  $(\mathbb{R}_0^+)^n \cap N_{\rho}^1(P)$  is the cone  $\{\alpha\mathbf{u}^{B_1} : \alpha \geq 0\}$  (consisting of its single ray).

Fact 4(a) and Figure 9.1 imply that the distinguished eigenvalues of  $P$  are 1 and 2, while 2 is the only distinguished eigenvalue of  $P^T$ .

- Let  $H = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$ ; properties of  $H$  were demonstrated in Example 2 of section 9.2. We will demonstrate Facts 2(c), 5(b), and 5(a) on the matrix

$$P \equiv \begin{bmatrix} H & I \\ 0 & H \end{bmatrix}.$$

The spectral radius of  $P$  is 1 and its basic classes of  $P$  are  $B_1 = \{1, 2\}$  and  $B_2 = \{3, 4\}$  with  $B_1$  having access to  $B_2$ . Thus, the index of 1 with respect to  $P$ , as the largest number of vertices on a walk of the marked reduced graph of  $P$ , is 2 (Fact 2(c)). Also, as the period of each of the two basic

classes of  $P$  is 2, the period of  $P$  is 2. To verify the convergence properties of  $P$ , note that

$$P^m = \begin{cases} \begin{bmatrix} I & mH \\ 0 & I \end{bmatrix} & \text{if } m \text{ is even} \\ \begin{bmatrix} H & mI \\ 0 & H \end{bmatrix} & \text{if } m \text{ is odd,} \end{cases}$$

immediately providing matrix-polynomials  $S^0(m)$  and  $S^1(m)$  of degree 1 such that  $\lim_{m \rightarrow \infty} P^{2m} - S^0(m) = 0$  and  $\lim_{m \rightarrow \infty} P^{2m+1} - S^1(m) = 0$ . In this example,  $\tau(P)$  is 0 (as the maximum over the empty set) and the convergence of the above sequences is geometric with rate 0. The above representation of  $P^m$  shows that

$$P^m = \begin{bmatrix} H^m & mH^{m+1} \\ 0 & H^m \end{bmatrix}$$

and Example 2 of section 9.2 shows that

$$\lim_{m \rightarrow \infty} H^m = \frac{I + H}{2} = \begin{bmatrix} .5 & .5 \\ .5 & .5 \end{bmatrix} \quad (C,1).$$

We next consider the upper-right blocks of  $P^m$ . We observe that

$$\begin{aligned} \frac{1}{m} \sum_{t=0}^{m-1} P^t[B_1, B_2] &= \begin{cases} \frac{mI}{4} + \frac{(m-2)H}{4} & \text{if } m \text{ is even} \\ \frac{(m-1)^2 I}{4m} + \frac{(m^2-1)H}{4m} & \text{if } m \text{ is odd,} \end{cases} \\ &= \begin{cases} \frac{m(I+H)}{4} - \frac{H}{2} & \text{if } m \text{ is even} \\ \frac{m(I+H)}{4} - \frac{I}{2} + \frac{I-H}{4m} & \text{if } m \text{ is odd,} \end{cases} \end{aligned}$$

implying that

$$\lim_{m \rightarrow \infty} \frac{1}{m} \sum_{t=0}^{m-1} P^t[B_1, B_2] - m \left( \frac{I + H}{4} \right) + \frac{I + H}{4} = 0 \quad (C,1).$$

As  $m - 1 = \frac{1}{m} \sum_{t=0}^{m-1} t$  for each  $m = 1, 2, \dots$ , the above shows that

$$\lim_{m \rightarrow \infty} \frac{1}{m} \sum_{t=0}^{m-1} \left\{ P^t[B_1, B_2] - t \left( \frac{I + H}{4} \right) \right\} = 0 \quad (C,1),$$

and, therefore (recalling that (C,1)-convergence implies (C,2)-convergence),

$$\lim_{m \rightarrow \infty} \left\{ P^m - \begin{bmatrix} .5 & .5 & -.25m & -.25m \\ .5 & .5 & -.25m & -.25m \\ 0 & 0 & .5 & .5 \\ 0 & 0 & .5 & .5 \end{bmatrix} \right\} = 0 \quad (C,2).$$

3. Fact 6 implies many equivalencies, in particular, as the spectral radius of a matrix equals that of its transpose. For example, for a nonnegative  $n \times n$  matrix  $P$  with spectral radius  $\rho$  and nonnegative scalar  $\mu$ , the following are equivalent:

- (a)  $\rho < \mu$ .
- (b)  $P\mathbf{u} < \mu\mathbf{u}$  for some vector  $\mathbf{u} > 0$ .
- (c)  $\mathbf{w}^T P < \mu\mathbf{w}^T$  for some vector  $\mathbf{w} > 0$ .

- (d)  $P\mathbf{u} < \rho\mathbf{u}$  for some vector  $\mathbf{u} \geq 0$ .
- (e)  $\mathbf{w}^T P < \rho\mathbf{w}^T$  for some vector  $\mathbf{w} \geq 0$ .
- (f) There is no vector  $\mathbf{u} \geq 0$  satisfying  $P\mathbf{u} \geq \mu\mathbf{u}$ .
- (g) There is no vector  $\mathbf{w} \geq 0$  satisfying  $\mathbf{w}^T P \geq \mu\mathbf{w}^T$ .

## 9.4 Stochastic and Substochastic Matrices

---

(For more information about stochastic matrices see Chapter 54 (including examples).)

### Definitions:

A square  $n \times n$  matrix  $P = [p_{ij}]$  is **stochastic** if it is nonnegative and  $P\mathbf{1} = \mathbf{1}$  where  $\mathbf{1} = [1, \dots, 1]^T \in R^n$ . (Stochastic matrices are sometimes referred to as **row-stochastic**, while **column-stochastic** matrices are matrices whose transpose is (row-)stochastic.)

A square  $n \times n$  matrix  $P$  is **doubly stochastic** if both  $P$  and its transpose are stochastic. The set of doubly stochastic matrices of order  $n$  is denoted  $\Omega_n$ .

A square  $n \times n$  matrix  $P$  is **substochastic** if it is nonnegative and  $P\mathbf{1} \leq \mathbf{1}$ .

A transient substochastic matrix is also called **stopping**.

An **ergodic class** of a stochastic matrix  $P$  is a basic class of  $P$ .

A **transient class** of a stochastic matrix  $P$  is an access equivalence class of  $P$  which is not ergodic.

A **state** of an  $n \times n$  stochastic matrix  $P$  is an index  $i \in \{1, \dots, n\}$ . Such a state is **ergodic** or **transient** depending on whether it belongs to an ergodic class or to a transient class.

A **stationary distribution** of a stochastic matrix  $P$  is a nonnegative vector  $\pi$  that satisfies  $\pi^T \mathbf{1} = 1$  and  $\pi^T P = \pi^T$ .

### Facts:

Facts requiring proofs for which no specific reference is given follow directly from facts in Sections 9.2 and 9.3 and/or can be found in [BP94, Chap. 8].

1. Let  $P = [p_{ij}]$  be an  $n \times n$  stochastic matrix.
  - (a)  $\rho(P) = 1, \mathbf{1} \in R^n$  is a right eigenvector of  $P$  corresponding to 1 and the stationary distributions of  $P$  are nonnegative eigenvectors of  $P$  corresponding to 1.
  - (b)  $\nu_P(\mathbf{1}) = 1$ .
  - (c)  $I - P$  has a group inverse.
  - (d) The height of every ergodic class is 1.
  - (e) The final classes of  $P$  are precisely its ergodic classes.
  - (f)
    - i. For every ergodic class  $C$ ,  $P$  has a unique stationary distribution  $\pi^C$  of  $P$  with  $(\pi^C)_i > 0$  if  $i \in C$  and  $(\pi^C)_i = 0$  otherwise.
    - ii. If  $C^1, \dots, C^p$  are the ergodic classes of  $P$ , then the corresponding stationary distributions  $\pi^{C^1}, \dots, \pi^{C^p}$  (according to Fact 1(f)i above) form a basis of the set of left eigenvectors of  $P$  corresponding to the eigenvalue 1; further, every stationary distribution of  $P$  is a convex combination of these vectors.

(g)

- i. Let  $T$  and  $R$  be the sets of transient and ergodic states of  $P$ , respectively. The matrix  $I - P[T]$  is nonsingular and for each ergodic class  $C$  of  $P$ , the vector  $\mathbf{u}^C$  given by

$$(\mathbf{u}^C)[K] = \begin{cases} e & \text{if } K = C \\ 0 & \text{if } K = R \setminus C \\ (I - P[T])^{-1}P[T, C]e & \text{if } K = T \end{cases}$$

is a right eigenvector of  $P$  corresponding to the eigenvalue 1; in particular,  $(\mathbf{u}^C)_i > 0$  if  $i$  has access to  $C$  and  $(\mathbf{u}^C)_i = 0$  if  $i$  does not have access to  $C$ .

- ii. If  $C^1, \dots, C^p$  are the ergodic classes of  $P$ , then the corresponding vectors  $\mathbf{u}^{C^1}, \dots, \mathbf{u}^{C^p}$  (referred to in Fact 1(g)i above) form a basis of the set of right eigenvectors of  $P$  corresponding to the eigenvalue 1; further,  $\sum_{i=1}^p \mathbf{u}^{C^i} = e$ .
- (h) Let  $C^1, \dots, C^p$  be the ergodic classes of  $P$ ,  $\pi^{C^1}, \dots, \pi^{C^p}$  the corresponding stationary distributions (referred to in Fact 1(f)i above), and  $\mathbf{u}^{C^1}, \dots, \mathbf{u}^{C^p}$  the corresponding eigenvectors referred to in Fact 1(g)i above. Then the matrix

$$P^* = \begin{bmatrix} \mathbf{u}^{C^1}, \dots, \mathbf{u}^{C^p} \end{bmatrix} \begin{bmatrix} \pi^{C^1} \\ \vdots \\ \pi^{C^p} \end{bmatrix}$$

is stochastic and satisfies  $P^*[\langle n \rangle, C] = 0$  if  $C$  is a transient class of  $P$ ,  $P^*[i, C] \neq 0$  if  $C$  is an ergodic class and  $i$  has access to  $C$ , and  $P^*[i, C] = 0$  if  $C$  is an ergodic class and  $i$  does not have access to  $C$ .

- (i) The matrix  $P^*$  from Fact 1(h) above has the representation  $I - (I - P)^\#(I - P)$ ; further,  $I - P + P^*$  is nonsingular and  $(I - P)^\# = (I - P + P^*)^{-1}(I - P)$ .
- (j) With  $P^*$  as the matrix from Fact 1(h) above,  $\lim_{m \rightarrow \infty} P^m = P^*(C, 1)$ ; further, when  $P$  is aperiodic, this limit holds as a regular limit and the convergence is geometric with rate  $\tau(P) < 1$ .
- (k) With  $P^*$  as the matrix from Fact 1(h) above,  $\lim_{m \rightarrow \infty} \sum_{t=0}^{m-1} P^t - mP^* = (I - P)^\#(C, 1)$ ; further, when  $P$  is aperiodic, this limit holds as a regular limit and the convergence is geometric with rate  $\tau(P) < 1$ .
- (l) With  $D$  a diagonal  $n \times n$  matrix with positive diagonal elements and  $\|\cdot\|$  a norm on  $\mathbb{R}^n$ ,

$$\tau(P) \leq \max_{\mathbf{x} \in \mathbb{R}^n, \|\mathbf{x}\| \leq 1, \mathbf{x}^T D^{-1} P D = 0} \|\mathbf{x}^T D^{-1} P D\|.$$

In particular, with  $\|\cdot\|$  as the 1-norm on  $\mathbb{R}^n$  and  $D = I$ , the above bound specializes to

$$\tau(P) \leq \max_{r, s=1, \dots, n, r \neq s} \sum_{k=1}^n \frac{|p_{rk} - p_{sk}|}{2} \leq \min \left\{ 1 - \sum_{k=1}^n \min_r p_{rk}, \sum_{k=1}^n \max_r p_{rk} - 1 \right\}$$

(cf. Fact 11 of section 9.3 and Example 4 of section 9.2).

- (m) For every  $0 < \alpha < 1$ ,  $P_\alpha \equiv (1 - \alpha)I + \alpha P$  is an aperiodic stochastic matrix whose ergodic classes, transient classes, stationary distributions, and the vectors of Fact 1(g)i coincide with those of  $P$ . In particular, with  $P^*$  and  $P_\alpha^*$  as the matrices from Fact 1(h) corresponding to  $P$  and  $P_\alpha$ , respectively,  $\lim_{m \rightarrow \infty} (P_\alpha)^m = P_\alpha^* = P^*$ .

2. Let  $P$  be an irreducible stochastic matrix with coefficient of ergodicity  $\tau$ .
  - (a)  $P$  has a unique stationary distribution, say  $\pi$ . Also, up to scalar multiple,  $\mathbf{1}$  is a unique right eigenvector of  $P$  corresponding to the eigenvalue 1.
  - (b) With  $\pi$  as the unique stationary distribution of  $P$ , the matrix  $P^*$  from Fact 1(h) above equals  $\mathbf{1}\pi$ .
3. A doubly stochastic matrix is a convex combination of permutation matrices (in fact, the  $n \times n$  permutation matrices are the extreme points of the set  $\Omega_n$  of  $n \times n$  doubly stochastic matrices).
4. Let  $P$  be an  $n \times n$  substochastic matrix.
  - (a)  $\rho(P) \leq 1$ .
  - (b)  $\nu_P(\mathbf{1}) \leq 1$ .
  - (c)  $I - P$  has a group inverse.
  - (d) The matrix  $P^* \equiv I - (I - P)^\#(I - P)$  is substochastic; further,  $I - P + P^*$  is nonsingular and  $(I - P)^\# = (I - P + P^*)^{-1}(I - P^*)$ .
  - (e) With  $P^*$  as in Fact 4(d),  $\lim_{m \rightarrow \infty} P^m = P^*(C, 1)$ ; further, when every access equivalence class  $C$  with  $\rho(P[C]) = 1$  is aperiodic, this limit holds as a regular limit and the convergence is geometric with rate  $\max\{|\lambda| : \lambda \in \sigma(P) \text{ and } |\lambda| \neq 1\} < 1$ .
  - (f) With  $P^*$  as the matrix from Fact 4(d) above,  $\lim_{m \rightarrow \infty} \sum_{t=0}^{m-1} P^t - mP^* = (I - P)^\#(C, 1)$ ; further, when every access equivalence class  $C$  with  $\rho(P[C]) = 1$  is aperiodic, this limit holds as a regular limit and the convergence is geometric with rate  $\max\{|\lambda| : \lambda \in \sigma(P) \text{ and } |\lambda| \neq 1\} < 1$ .
  - (g) The following are equivalent:
    - i.  $P$  is stopping.
    - ii.  $\rho(P) < 1$ .
    - iii.  $I - P$  is invertible.
    - iv. There exists a positive vector  $\mathbf{u} \in R^n$  with  $P\mathbf{u} < \mathbf{u}$ .

Further, when the above conditions hold,  $(I - P)^{-1} = \sum_{t=0}^{\infty} P^t \geq 0$ .

## 9.5 M-Matrices

---

### Definitions:

An  $n \times n$  real matrix  $A = [a_{ij}]$  is a **Z-matrix** if its off-diagonal elements are nonpositive, i.e., if  $a_{ij} \leq 0$  for all  $i, j = 1, \dots, n$  with  $i \neq j$ .

An  **$M_0$ -matrix** is a Z-matrix  $A$  that can be written as  $A = sI - P$  with  $P$  as a nonnegative matrix and with  $s$  as a scalar satisfying  $s \geq \rho(P)$ .

An **M-matrix**  $A$  is a Z-matrix  $A$  that can be written as  $A = sI - P$  with  $P$  as a nonnegative matrix and with  $s$  as a scalar satisfying  $s > \rho(P)$ .

A square real matrix  $A$  is an **inverse M-matrix** if it is nonsingular and its inverse is an M-matrix.

A square real matrix  $A$  is **inverse-nonnegative** if it is nonsingular and  $A^{-1} \geq 0$  (the property is sometimes referred to as **inverse-positivity**).

A square real matrix  $A$  has a **convergent regular splitting** if  $A$  has a representation  $A = M - N$  such that  $N \geq 0$ ,  $M$  invertible with  $M^{-1} \geq 0$  and  $M^{-1}N$  is convergent.

A square complex matrix  $A$  is **positive stable** if the real part of each eigenvalue of  $A$  is positive;  $A$  is **nonnegative stable** if the real part of each eigenvalue of  $A$  is nonnegative.

An  $n \times n$  complex matrix  $A = [a_{ij}]$  is **strictly diagonally dominant (diagonally dominant)** if  $|a_{ii}| > \sum_{j=1, j \neq i}^n |a_{ij}|$  ( $|a_{ii}| \geq \sum_{j=1, j \neq i}^n |a_{ij}|$ ) for  $i = 1, \dots, n$ .

An  $n \times n$  M-matrix  $A$  **satisfies property C** if there exists a representation of  $A$  of the form  $A = sI - P$  with  $s > 0$ ,  $P \geq 0$  and  $\frac{P}{s}$  semiconvergent.

**Facts:**

Facts requiring proofs for which no specific reference is given follow directly from results about nonnegative matrices stated in Sections 9.2 and 9.3 and/or can be found in [BP94, Chap. 6].

1. Let  $A$  be an  $n \times n$  real matrix with  $n \geq 2$ . The following are equivalent:
  - (a)  $A$  is an  $M$ -matrix; that is,  $A$  is a  $Z$ -matrix that can be written as  $sI - P$  with  $P$  nonnegative and  $s > \rho(P)$ .
  - (b)  $A$  is a nonsingular  $M_0$ -matrix.
  - (c) For each nonnegative diagonal matrix  $D$ ,  $A + D$  is inverse-nonnegative.
  - (d) For each  $\mu \geq 0$ ,  $A + \mu I$  is inverse-nonnegative.
  - (e) Each principal submatrix of  $A$  is inverse-nonnegative.
  - (f) Each principal submatrix of  $A$  of orders  $1, \dots, n$  is inverse-nonnegative.
2. Let  $A = [a_{ij}]$  be an  $n \times n$   $Z$ -matrix. The following are equivalent:\*
  - (a)  $A$  is an  $M$ -matrix.
  - (b) Every real eigenvalue of  $A$  is positive.
  - (c)  $A + D$  is nonsingular for each nonnegative diagonal matrix  $D$ .
  - (d) All of the principal minors of  $A$  are positive.
  - (e) For each  $k = 1, \dots, n$ , the sum of all the  $k \times k$  principal minors of  $A$  is positive.
  - (f) There exist lower and upper triangular matrices  $L$  and  $U$ , respectively, with positive diagonal elements such that  $A = LU$ .
  - (g)  $A$  is permutation similar to a matrix satisfying condition 2(f).
  - (h)  $A$  is positive stable.
  - (i) There exists a diagonal matrix  $D$  with positive diagonal elements such that  $AD + DA^T$  is positive definite.
  - (j) There exists a vector  $\mathbf{x} > 0$  with  $A\mathbf{x} > 0$ .
  - (k) There exists a vector  $\mathbf{x} > 0$  with  $A\mathbf{x} \succeq 0$  and  $\sum_{j=1}^i a_{ij}x_j > 0$  for  $i = 1, \dots, n$ .
  - (l)  $A$  is permutation similar to a matrix satisfying condition 2(k).
  - (m) There exists a vector  $\mathbf{x} > 0$  such that  $A\mathbf{x} \succeq 0$  and the matrix  $\hat{A} = [\hat{a}_{ij}]$  defined by

$$\hat{a}_{ij} = \begin{cases} 1 & \text{if either } a_{ij} \neq 0 \text{ or } (A\mathbf{x})_i \neq 0 \\ 0 & \text{otherwise} \end{cases}$$

is irreducible.

- (n) All the diagonal elements of  $A$  are positive and there exists a diagonal matrix  $D$  such that  $AD$  is strictly diagonally dominant.
- (o)  $A$  is inverse-nonnegative.
- (p) Every representation of  $A$  of the form  $A = M - N$  with  $N \geq 0$  and  $M$  inverse-positive must have  $M^{-1}N$  convergent (i.e.,  $\rho(M^{-1}N) < 1$ ).
- (q) For each vector  $\mathbf{y} \geq 0$ , the set  $\{\mathbf{x} \geq 0 : A^T \mathbf{x} \leq \mathbf{y}\}$  is bounded and  $A$  is nonsingular.

---

\*Each of the 17 conditions that are listed in Fact 2 is a representative of a set of conditions that are known to be equivalent for all matrices (not just  $Z$ -matrices); see [BP94, Theorem 6.2.3]. For additional characterizations of  $M$ -matrices, see [FiSc83].

3. Let  $A$  be an irreducible  $n \times n$   $Z$ -matrix with  $n \geq 2$ . The following are equivalent:
  - (a)  $A$  is an  $M$ -matrix.
  - (b)  $A$  is a nonsingular and  $A^{-1} > 0$ .
  - (c)  $A\mathbf{x} \geq 0$  for some  $\mathbf{x} > 0$ .
4. Let  $A = [a_{ij}]$  be an  $n \times n$   $M$ -matrix and let  $B = [b_{ij}]$  be an  $n \times n$   $Z$ -matrix with  $B \geq A$ . Then:
  - (a)  $B$  is an  $M$ -matrix.
  - (b)  $\det B \geq \det A$ .
  - (c)  $A^{-1} \geq B^{-1}$ .
  - (d)  $\det A \leq a_{11} \dots a_{nn}$ .
5. If  $P$  is an inverse  $M$ -matrix, then  $P \geq 0$  and  $\Gamma(P)$  is transitive; that is, if  $(v, u)$  and  $(u, w)$  are arcs of  $\Gamma(P)$ , then so is  $(v, w)$ .
6. Let  $A$  be an  $n \times n$  real matrix with  $n \geq 2$ . The following are equivalent:
  - (a)  $A$  is a nonsingular  $M_0$ -matrix.
  - (b) For each diagonal matrix  $D$  with positive diagonal elements,  $A + D$  is inverse-nonnegative.
  - (c) For each  $\mu > 0$ ,  $A + \mu I$  is inverse-nonnegative.
7. Let  $A$  be an  $n \times n$   $Z$ -matrix. The following are equivalent:\*
  - (a)  $A$  is an  $M_0$ -matrix.
  - (b) Every real eigenvalue of  $A$  is nonnegative.
  - (c)  $A + D$  is nonsingular for each diagonal matrix  $D$  having positive diagonal elements.
  - (d) For each  $k = 1, \dots, n$ , the sum of all the  $k \times k$  principal minors of  $A$  is nonnegative.
  - (e)  $A$  is permutation similar to a matrix having a representation  $LU$  with  $L$  and  $U$  as lower and upper triangular matrices having positive diagonal elements.
  - (f)  $A$  is nonnegative stable.
  - (g) There exists a nonnegative matrix  $Y$  satisfying  $YA^{k+1} = A^k$  for some  $k \geq 1$ .
  - (h)  $A$  has a representation of the form  $A = M - N$  with  $M$  inverse-nonnegative,  $N \geq 0$  and  $B \equiv M^{-1}N$  satisfying  $\bigcap_{k=0}^{\infty} \text{range}(B^k) = \bigcap_{k=0}^{\infty} \text{range}(A^k)$  and  $\rho(B) \leq 1$ .
  - (i)  $A$  has a representation of the form  $A = M - N$  with  $M$  inverse-nonnegative,  $M^{-1}N \geq 0$  and  $B \equiv M^{-1}N$  satisfying  $\bigcap_{k=0}^{\infty} \text{range}(B^k) = \bigcap_{k=0}^{\infty} \text{range}(A^k)$  and  $\rho(B) \leq 1$ .
8. Let  $A$  be an  $M_0$ -matrix.
  - (a)  $A$  satisfies property C if and only if  $v_A(0) \leq 1$ .
  - (b)  $A$  is permutation similar to a matrix having a representation  $LU$  with  $L$  as a lower triangular  $M$ -matrix and  $U$  as an upper triangular  $M_0$  matrix.
9. [BP94, Theorem 8.4.2] If  $P$  is substochastic (see Section 9.4), then  $I - P$  is an  $M_0$ -matrix satisfying property C.
10. Let  $A$  be an irreducible  $n \times n$  singular  $M_0$ -matrix.
  - (a)  $A$  has rank  $n - 1$ .
  - (b) There exists a vector  $\mathbf{x} > 0$  such that  $A\mathbf{x} = 0$ .

---

\*Each of the 9 conditions that are listed in Fact 7 is a representative of a set of conditions that are known to be equivalent for all matrices (not just  $Z$ -matrices); see [BP94, Theorem 6.4.6]. For additional characterizations of  $M$ -matrices, see [FiSc83].

- (c)  $A$  has property  $C$ .
- (d) Each principal submatrix of  $A$  other than  $A$  itself is an  $M$ -matrix.
- (e)  $[Ax \geq 0] \Rightarrow [Ax = 0]$ .

## 9.6 Scaling of Nonnegative Matrices

---

A scaling of a (usually nonnegative) matrix is the outcome of its pre- and post-multiplication by diagonal matrices having positive diagonal elements. Scaling problems concern the search for scalings of given matrices such that specified properties are satisfied. Such problems are characterized by:

- (a) The class of matrices to be scaled.
- (b) Restrictions on the pre- and post-multiplying diagonal matrices to be used.
- (c) The target property.

Classes of matrices under (a) may refer to arbitrary rectangular matrices, square matrices, symmetric matrices, positive semidefinite matrices, etc. For possible properties of pre- and post-multiplying diagonal matrices under (b) see the following Definition subsection. Finally, examples for target properties under (c) include:

- i. The specification of the row- and/or column-sums; for example, being stochastic or being doubly stochastic. See the following Facts subsection.
- ii. The specification of the row- and/or column-maxima.
- iii. (For a square matrix) being line-symmetric, that is, having each row-sum equal to the corresponding column-sum.
- iv. Being optimal within a prescribed class of scalings under some objective function. One example of such optimality is to minimize the maximal element of a scalings of the form  $XAX^{-1}$ . Also, in numerical analysis, preconditioning a matrix may involve its replacement with a scaling that has a low ratio of largest to smallest element; so, a potential target property is to be a minimizer of this ratio among all scalings of the underlying matrix.

Typical questions that are considered when addressing scaling problems include:

- (a) Characterizing existence of a scaling that satisfies the target property (precisely or approximately).
- (b) Computing a scaling of a given matrix that satisfies the target property (precisely or approximately) or verifying that none exists.
- (c) Determining complexity bounds for corresponding computation.

Early references that address scaling problems include [Kru37], which describes a heuristic for finding a doubly stochastic scaling of a positive square matrix, and Sinkhorn's [Sin64] pioneering paper, which provides a formal analysis of that problem. The subject has been intensively studied and an aspiration to provide a comprehensive survey of the rich literature is beyond the scope of the current review; consequently, we address only scaling problems where the target is to achieve, precisely or approximately, prescribed row- and column-sums.

### Definitions:

Let  $A = [a_{ij}]$  be an  $m \times n$  matrix.

A **scaling** (sometimes referred to as an **equivalence-scaling** or a **DAE-scaling**) of  $A$  is any matrix of the form  $DAE$  where  $D$  and  $E$  are square diagonal matrices having positive diagonal elements; such a scaling is a **row-scaling** of  $A$  if  $E = I$  and it is a **normalized-scaling** if  $\det(D) = \det(E) = 1$ .

If  $m = n$ , a scaling  $DAE$  of  $A$  is a **similarity-scaling** (sometimes referred to as a  $DAD^{-1}$  **scaling**) of  $A$  if  $E = D^{-1}$ , and  $DAE$  is a **symmetric-scaling** (sometimes referred to as a  $DAD$  **scaling**) of  $A$  if  $E = D$ .

The **support** (or **sparsity pattern**) of  $A$ , denoted  $\text{Struct}(A)$ , is the set of indices  $ij$  with  $a_{ij} \neq 0$ ; naturally, this definition applies to vectors.

**Facts:**

1. (*Prescribed-Line-Sum Scalings*) [RoSc89] Let  $A = [a_{ij}] \in \mathbb{R}^{m \times n}$  be a nonnegative matrix, and let  $\mathbf{r} = [r_i] \in \mathbb{R}^m$  and  $\mathbf{c} = [c_j] \in \mathbb{R}^n$  be positive vectors.

(a) The following are equivalent:

- i. There exists a scaling  $B$  of  $A$  with  $B\mathbf{1} = \mathbf{r}$  and  $\mathbf{1}^T B = \mathbf{c}^T$ .
- ii. There exists nonnegative  $m \times n$  matrix  $B$  having the same support as  $A$  with  $B\mathbf{1} = \mathbf{r}$  and  $\mathbf{1}^T B = \mathbf{c}^T$ .
- iii. For every  $I \subseteq \{1, \dots, m\}$  and  $J \subseteq \{1, \dots, n\}$  for which  $A[I^c, J] = 0$ ,

$$\sum_{i \in I} r_i \geq \sum_{j \in J} c_j$$

and equality holds if and only if  $A[I, J^c] = 0$ .

- iv.  $\mathbf{1}^T \mathbf{r} = \mathbf{1}^T \mathbf{c}$  and the following (geometric) optimization problem has an optimal solution:

$$\min \mathbf{x}^T \mathbf{A} \mathbf{y}$$

$$\text{subject to : } \mathbf{x} = [x_i] \in \mathbb{R}^m, \mathbf{y} = [y_j] \in \mathbb{R}^n$$

$$\mathbf{x} \geq 0, \mathbf{y} \geq 0$$

$$\prod_{i=1}^m (x_i)^{r_i} = \prod_{j=1}^n (y_j)^{c_j} = 1.$$

A standard algorithm for approximating a scaling of a matrix to one that has prescribed row- and column-sums (when one exists) is to iteratively scale rows and columns separately so as to achieve corresponding line-sums.

- (b) Suppose  $\mathbf{1}^T \mathbf{r} = \mathbf{1}^T \mathbf{c}$  and  $\bar{\mathbf{x}} = [\bar{x}_i]$  and  $\bar{\mathbf{y}} = [\bar{y}_j]$  form an optimal solution of the optimization problem of Fact 1(d). Let  $\bar{\lambda} \equiv \frac{\bar{\mathbf{x}}^T \mathbf{A} \bar{\mathbf{y}}}{\mathbf{1}^T \mathbf{r}}$  and let  $\bar{X} \in \mathbb{R}^{m \times m}$  and  $\bar{Y} \in \mathbb{R}^{n \times n}$  be the diagonal matrices having diagonal elements  $\bar{X}_{ii} = \frac{\bar{x}_i}{\bar{\lambda}}$  and  $\bar{Y}_{jj} = \bar{y}_j$ . Then  $B \equiv \bar{X} \mathbf{A} \bar{Y}$  is a scaling of  $A$  satisfying  $B\mathbf{1} = \mathbf{r}$  and  $\mathbf{1}^T B = \mathbf{c}^T$ .

- (c) Suppose  $\bar{X} \in \mathbb{R}^{m \times m}$  and  $\bar{Y} \in \mathbb{R}^{n \times n}$  are diagonal matrices such that  $B \equiv \bar{X} \mathbf{A} \bar{Y}$  is a scaling of  $A$  satisfying  $B\mathbf{1} = \mathbf{r}$  and  $\mathbf{1}^T B = \mathbf{c}^T$ . Then  $\mathbf{1}^T \mathbf{r} = \mathbf{1}^T \mathbf{c}$  and with

$$\bar{\lambda} \equiv \prod_{i=1}^m (\bar{X}_{ii})^{-r_i / \mathbf{1}^T \mathbf{r}}$$

and

$$\bar{\mu} \equiv \prod_{j=1}^n (\bar{Y}_{jj})^{-c_j / \mathbf{1}^T \mathbf{c}},$$

the vectors  $\bar{\mathbf{x}} = [\bar{x}_i] \in \mathbb{R}^m$  and  $\bar{\mathbf{y}} = [\bar{y}_j] \in \mathbb{R}^n$  with  $\bar{x}_i = \bar{\lambda} X_{ii}$  for  $i = 1, \dots, m$  and  $\bar{y}_j = \bar{\mu} Y_{jj}$  for  $j = 1, \dots, n$  are optimal for the optimization problem of Fact 1(d).

2. (*Approximate Prescribed-Line-Sum Scalings*) [RoSc89] Let  $A = [a_{ij}] \in \mathbb{R}^{m \times n}$  be a nonnegative matrix, and let  $\mathbf{r} = [r_i] \in \mathbb{R}^m$  and  $\mathbf{c} = [c_j] \in \mathbb{R}^n$  be positive vectors.

(a) The following are equivalent:

- i. For every  $\epsilon > 0$  there exists a scaling  $B$  of  $A$  with  $\|B\mathbf{1} - \mathbf{r}\|_1 \leq \epsilon$  and  $\|\mathbf{1}^T B - \mathbf{c}^T\|_1 \leq \epsilon$ .

- ii. There exists nonnegative  $m \times n$  matrix  $A' = [a'_{ij}]$  with  $\text{Struct}(A') \subseteq \text{Struct}(A)$  and  $a'_{ij} = a_{ij}$  for each  $ij \in \text{Struct}(A')$  such that  $A'$  has a scaling  $B$  satisfying  $B\mathbf{1} = \mathbf{r}$  and  $\mathbf{1}^T B = \mathbf{c}^T$ .
- iii. For every  $\epsilon > 0$  there exists a matrix  $B$  having the same support as  $A$  and satisfying  $\|B\mathbf{1} - \mathbf{r}\|_1 \leq \epsilon$  and  $\|\mathbf{1}^T B - \mathbf{c}^T\|_1 \leq \epsilon$ .
- iv. There exists a matrix  $B$  satisfying  $\text{Struct}(B) \subseteq \text{Struct}(A)$ ,  $B\mathbf{1} = \mathbf{r}$  and  $\mathbf{1}^T B = \mathbf{c}^T$ .
- v. For every  $I \subseteq \{1, \dots, m\}$  and  $J \subseteq \{1, \dots, n\}$  for which  $A[I^c, J] = 0$ ,

$$\sum_{i \in I} r_i \geq \sum_{j \in J} c_j.$$

- vi.  $\mathbf{1}^T \mathbf{r} = \mathbf{1}^T \mathbf{c}$  and the objective of the optimization problem of Fact 2(a)iii is bounded away from zero.

See [NR99] for a reduction of the problem of finding a scaling of  $A$  that satisfies  $\|B\mathbf{1} - \mathbf{r}\|_1 \leq \epsilon$  and  $\|\mathbf{1}^T B - \mathbf{c}^T\|_1 \leq \epsilon$  for a given  $\epsilon > 0$  to the approximate solution of geometric program that is similar to the one in Fact 1(a)iv and for the description of an (ellipsoid) algorithm that solves the latter with complexity bound of  $O(1)(m+n)^4 \ln[2 + \frac{mn\sqrt{m^3+n^3} \ln(mn\beta)}{\epsilon^3}]$ , where  $\beta$  is the ratio between the largest and smallest positive entries of  $A$ .

## 9.7 Miscellaneous Topics

---

In this subsection, we mention several important topics about nonnegative matrices that are not covered in detail in the current section due to size constraint; some relevant material appears in other sections.

### 9.7.1 Nonnegative Factorization and Completely Positive Matrices

A *nonnegative factorization* of a nonnegative matrix  $A \in R^{m \times n}$  is a representation  $A = LR$  of  $A$  with  $L$  and  $R$  as nonnegative matrices. The *nonnegative rank* of  $A$  is the smallest number of columns of  $L$  (rows of  $R$ ) in such a factorization.

A square matrix  $A$  is *doubly nonnegative* if it is nonnegative and positive semidefinite. Such a matrix  $A$  is *completely positive* if it has a nonnegative factorization  $A = BB^T$ ; the *CP-rank* of  $A$  is then the smallest number of columns of a matrix  $B$  in such a factorization.

Facts about nonnegative factorizations and completely positive matrices can be found in [CR93], [BSM03], and [CP05].

### 9.7.2 The Inverse Eigenvalue Problem

The *inverse eigenvalue problem* concerns the identification of necessary conditions and sufficient conditions for a finite set of complex numbers to be the spectrum of a nonnegative matrix.

Facts about the inverse eigenvalue problem can be found in [BP94, Sections 4.2 and 11.2] and Chapter 20.

### 9.7.3 Nonhomogenous Products of Matrices

A *nonhomogenous product* of nonnegative matrices is the finite matrix product of nonnegative matrices  $P_1 P_2 \dots P_m$ , generalizing powers of matrices where the multiplicands are equal (i.e.,  $P_1 = P_2 = \dots = P_m$ ); the study of such products focuses on the case where the multiplicands are taken from a prescribed set.

Facts about Perron–Frobenius type properties of nonhomogenous products of matrices can be found in [Sen81], and [Har02].

### 9.7.4 Operators Determined by Sets of Nonnegative Matrices in Product Form

A finite set of nonnegative  $n \times n$  matrices  $\{P_\delta : \delta \in \Delta\}$  is said to be in *product form* if there exists finite sets of row vectors  $\Delta_1, \dots, \Delta_n$  such that  $\Delta = \prod_{i=1}^n \Delta_i$  and for each  $\delta = (\delta_1, \dots, \delta_n) \in \Delta$ ,  $P_\delta$  is the matrix whose rows are, respectively,  $\delta_1, \dots, \delta_n$ . Such a family determines the operators  $P_\Delta^{\max}$  and  $P_\Delta^{\min}$  on  $\mathbb{R}^n$  with  $P_\Delta^{\max}x = \max_{\delta \in \Delta} P_\delta x$  and  $P_\Delta^{\min}x = \min_{\delta \in \Delta} P_\delta x$  for each  $x \in \mathbb{R}^n$ .

Facts about Perron–Frobenius-type properties of the operators corresponding to families of matrices in product form can be found in [Zij82], [Zij84], and [RW82].

### 9.7.5 Max Algebra over Nonnegative Matrices

Matrix operations under the max algebra are executed with the max operator replacing (real) addition and (real) addition replacing (real) multiplication.

Perron–Frobenius-type results and scaling results are available for nonnegative matrices when considered as operators under the max algebra; see [RSS94], [Bap98], [But03], [BS05], and Chapter 25.

### 10.1 Submatrices and Block Matrices

---

#### Definitions:

Let  $A \in F^{m \times n}$ . Then the row indices of  $A$  are  $\{1, \dots, m\}$ , and the column indices of  $A$  are  $\{1, \dots, n\}$ . Let  $\alpha, \beta$  be nonempty sets of indices with  $\alpha \subseteq \{1, \dots, m\}$  and  $\beta \subseteq \{1, \dots, n\}$ .

A **submatrix**  $A[\alpha, \beta]$  is a matrix whose rows have indices  $\alpha$  among the row indices of  $A$ , and whose columns have indices  $\beta$  among the column indices of  $A$ .  $A(\alpha, \beta) = A[\alpha^c, \beta^c]$ , where  $\alpha^c$  is the complement of  $\alpha$ .

A **principal submatrix** is a submatrix  $A[\alpha, \alpha]$ , denoted more compactly as  $A[\alpha]$ .

Let the set  $\{1, \dots, m\}$  be partitioned into the subsets  $\alpha_1, \dots, \alpha_r$  in the usual sense of partitioning a set (so that  $\alpha_i \cap \alpha_j = \emptyset$ , for all  $i \neq j$ ,  $1 \leq i, j \leq r$ , and  $\alpha_1 \cup \dots \cup \alpha_r = \{1, \dots, m\}$ ), and let  $\{1, \dots, n\}$  be partitioned into the subsets  $\beta_1, \dots, \beta_s$ .

The matrix  $A \in F^{m \times n}$  is said to be **partitioned** into the submatrices  $A[\alpha_i, \beta_j]$ ,  $1 \leq i \leq r$ ,  $1 \leq j \leq s$ .

A **block matrix** is a matrix that is partitioned into submatrices  $A[\alpha_i, \beta_j]$  with the row indices  $\{1, \dots, m\}$  and column indices  $\{1, \dots, n\}$  partitioned into subsets sequentially, i.e.,  $\alpha_1 = \{1, \dots, i_1\}$ ,  $\alpha_2 = \{i_1 + 1, \dots, i_2\}$ , etc.

Each entry of a block matrix, which is a submatrix  $A[\alpha_i, \beta_j]$ , is called a **block**, and we will sometimes write  $A = [A_{ij}]$  to label the blocks, where  $A_{ij} = A[\alpha_i, \beta_j]$ .

If the block matrix  $A \in F^{m \times p}$  is partitioned with  $\alpha_i$ s and  $\beta_j$ s,  $1 \leq i \leq r$ ,  $1 \leq j \leq s$ , and the block matrix  $B \in F^{p \times n}$  is partitioned with  $\beta_j$ s and  $\gamma_k$ s,  $1 \leq j \leq s$ ,  $1 \leq k \leq t$ , then the partitions of  $A$  and  $B$  are said to be **conformal** (or sometimes **conformable**).

#### Facts:

The following facts can be found in [HJ85]. This information is also available in many other standard references such as [LT85] or [Mey00].

1. Two block matrices  $A = [A_{ij}]$  and  $B = [B_{ij}]$  in  $F^{m \times n}$ , which are both partitioned with the same  $\alpha_i$ s and  $\beta_j$ s,  $1 \leq i \leq r$ ,  $1 \leq j \leq s$ , may be added block-wise, as with the usual matrix addition, so that the  $(i, j)$  block entry of  $A + B$  is  $(A + B)_{ij} = A_{ij} + B_{ij}$ .

- If the block matrix  $A \in F^{m \times p}$  and the block matrix  $B \in F^{p \times n}$  have conformal partitions, then we can think of  $A$  and  $B$  as having entries, which are blocks, so that we can then multiply  $A$  and  $B$  block-wise to form the  $m \times n$  block matrix  $C = AB$ . Then  $C_{ik} = \sum_{j=1}^s A_{ij}B_{jk}$ , and the matrix  $C$  will be partitioned with the  $\alpha_i$ 's and  $\gamma_k$ 's,  $1 \leq i \leq r$ ,  $1 \leq k \leq t$ , where  $A$  is partitioned with  $\alpha_i$ 's and  $\beta_j$ 's,  $1 \leq i \leq r$ ,  $1 \leq j \leq s$ , and  $B$  is partitioned with  $\beta_j$ 's and  $\gamma_k$ 's,  $1 \leq j \leq s$ ,  $1 \leq k \leq t$ .
- With addition and multiplication of block matrices described as in Facts 1 and 2 the usual properties of associativity of addition and multiplication of block matrices hold, as does distributivity, and commutativity of addition. The additive identity  $\mathbf{0}$  and multiplicative identity  $I$  are the same under block addition and multiplication, as with the usual matrix addition and multiplication. The additive identity  $\mathbf{0}$  has zero matrices as blocks; the multiplicative identity  $I$  has multiplicative identity submatrices as diagonal blocks and zero matrices as off-diagonal blocks.
- If the partitions of  $A$  and  $B$  are conformal, the partitions of  $B$  and  $A$  are not necessarily conformal, even if  $BA$  is defined.
- Let  $A \in F^{n \times n}$  be a block matrix of the form  $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & \mathbf{0} \end{bmatrix}$ , where  $A_{12}$  is  $k \times k$ , and  $A_{21}$  is  $(n-k) \times (n-k)$ . Then  $\det(A) = (-1)^{(n+1)k} \det(A_{12}) \det(A_{21})$ .

### Examples:

- Let the block matrix  $A \in \mathbb{C}^{n \times n}$  given by  $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$  be Hermitian. Then  $A_{11}$  and  $A_{22}$  are Hermitian, and  $A_{21} = A_{12}^*$ .
- If  $A = [a_{ij}]$ , then  $A[\{i\}, \{j\}]$  is the  $1 \times 1$  matrix whose entry is  $a_{ij}$ . The submatrix  $A(\{i\}, \{j\})$  is the submatrix of  $A$  obtained by deleting row  $i$  and column  $j$  of  $A$ .

$$\text{Let } A = \begin{bmatrix} 1 & -2 & 5 & 3 & -1 \\ -3 & 0 & 1 & 6 & 1 \\ 2 & 7 & 4 & 5 & -7 \end{bmatrix}.$$

- Then  $A[\{2\}, \{3\}] = [a_{23}] = [1]$  and  $A(\{2\}, \{3\}) = \begin{bmatrix} 1 & -2 & 3 & -1 \\ 2 & 7 & 5 & -7 \end{bmatrix}$ .
- Let  $\alpha = \{1, 3\}$  and  $\beta = \{1, 2, 4\}$ . Then the submatrix  $A[\alpha, \beta] = \begin{bmatrix} 1 & -2 & 3 \\ 2 & 7 & 5 \end{bmatrix}$ , and the principal submatrix  $A[\alpha] = \begin{bmatrix} 1 & 5 \\ 2 & 4 \end{bmatrix}$ .
- Let  $\alpha_1 = \{1\}$ ,  $\alpha_2 = \{2, 3\}$  and let  $\beta_1 = \{1, 2\}$ ,  $\beta_2 = \{3\}$ ,  $\beta_3 = \{4, 5\}$ . Then the block matrix, with  $(i, j)$  block entry  $A_{ij} = A[\alpha_i, \beta_j]$ ,  $1 \leq i \leq 2$ ,  $1 \leq j \leq 3$ , is

$$A = \begin{bmatrix} A_{11} & A_{12} & A_{13} \\ A_{21} & A_{22} & A_{23} \end{bmatrix} = \begin{bmatrix} 1 & -2 & | & 5 & | & 3 & -1 \\ - & - & - & - & | & - & - & - & - \\ -3 & 0 & | & 1 & | & 6 & 1 \\ 2 & 7 & | & 4 & | & 5 & -7 \end{bmatrix}.$$

- Let  $B = \begin{bmatrix} B_{11} & B_{12} & B_{13} \\ B_{21} & B_{22} & B_{23} \end{bmatrix} = \begin{bmatrix} 2 & -1 & | & 0 & | & 6 & -2 \\ - & - & - & - & | & - & - & - & - \\ -4 & 0 & | & 5 & | & 3 & 7 \\ 1 & 1 & | & -2 & | & 2 & 6 \end{bmatrix}$ . Then the matrices  $A$  (of this example) and  $B$  are partitioned with the same  $\alpha_i$ 's and  $\beta_j$ 's, so they can be added block-wise

$$\begin{aligned} \text{as } & \begin{bmatrix} A_{11} & A_{12} & A_{13} \\ A_{21} & A_{22} & A_{23} \end{bmatrix} + \begin{bmatrix} B_{11} & B_{12} & B_{13} \\ B_{21} & B_{22} & B_{23} \end{bmatrix} \\ &= \begin{bmatrix} A_{11} + B_{11} & A_{12} + B_{12} & A_{13} + B_{13} \\ A_{21} + B_{21} & A_{22} + B_{22} & A_{23} + B_{23} \end{bmatrix} \\ &= \left[ \begin{array}{cc|c|cc} 3 & -3 & 5 & 9 & -3 \\ \hline -7 & 0 & 6 & 9 & 8 \\ 3 & 8 & 2 & 7 & -1 \end{array} \right]. \end{aligned}$$

7. The block matrices  $A = \begin{bmatrix} A_{11} & A_{12} & A_{13} \\ A_{21} & A_{22} & A_{13} \end{bmatrix}$  and  $B = \begin{bmatrix} B_{11} \\ B_{21} \\ B_{31} \end{bmatrix}$  have conformal partitions if the  $\beta_j$  index sets, which form the submatrices  $A_{ij} = A[\alpha_i, \beta_j]$  of  $A$ , are the same as the  $\beta_j$  index sets, which form the submatrices  $B_{jk} = B[\beta_j, \gamma_k]$  of  $B$ . For instance, the matrix

$$A = \begin{bmatrix} A_{11} & A_{12} & A_{13} \\ A_{21} & A_{22} & A_{23} \end{bmatrix} = \left[ \begin{array}{cc|c|cc} 1 & -2 & 5 & 3 & -1 \\ \hline -3 & 0 & 1 & 6 & 1 \\ 2 & 7 & 4 & 5 & -7 \end{array} \right]$$

and the matrix  $B = \begin{bmatrix} B_{11} \\ B_{21} \\ B_{31} \end{bmatrix} = \left[ \begin{array}{c|c} 4 & -1 \\ 3 & 9 \\ \hline 5 & 2 \\ \hline 2 & -8 \\ 7 & -1 \end{array} \right]$  have conformal partitions, so  $A$  and  $B$  can be

multiplied block-wise to form the  $3 \times 2$  matrix

$$\begin{aligned} AB &= \begin{bmatrix} A_{11}B_{11} + A_{12}B_{21} + A_{13}B_{31} \\ A_{21}B_{11} + A_{22}B_{21} + A_{23}B_{31} \end{bmatrix} \\ &= \left[ \begin{array}{c} [1 \ -2] \begin{bmatrix} 4 & -1 \\ 3 & 9 \end{bmatrix} + 5[5 \ 2] + [3 \ -1] \begin{bmatrix} 2 & -8 \\ 7 & -1 \end{bmatrix} \\ \begin{bmatrix} -3 & 0 \\ 2 & 7 \end{bmatrix} \begin{bmatrix} 4 & -1 \\ 3 & 9 \end{bmatrix} + \begin{bmatrix} 1 \\ 4 \end{bmatrix} [5 \ 2] + \begin{bmatrix} 6 & 1 \\ 5 & -7 \end{bmatrix} \begin{bmatrix} 2 & -8 \\ 7 & -1 \end{bmatrix} \end{array} \right] \\ &= \left[ \begin{array}{c} [-2 \ -19] + [25 \ 10] + [-1 \ -23] \\ [-12 \ 3] + [5 \ 2] + [19 \ -49] \\ [29 \ 61] + [20 \ 8] + [-39 \ -33] \end{array} \right] = \begin{bmatrix} 22 & -32 \\ 12 & -44 \\ 10 & 36 \end{bmatrix}. \end{aligned}$$

8. Let  $A = \left[ \begin{array}{cc|c} 1 & 2 & 3 \\ 4 & 5 & 6 \end{array} \right]$  and  $B = \left[ \begin{array}{c|c} 7 & 8 \\ 9 & 0 \\ \hline 1 & 2 \end{array} \right]$ . Then  $A$  and  $B$  have conformal partitions.  $BA$  is defined, but  $B$  and  $A$  do not have conformal partitions.

## 10.2 Block Diagonal and Block Triangular Matrices

### Definitions:

A matrix  $A = [a_{ij}] \in F^{n \times n}$  is **diagonal** if  $a_{ij} = 0$ , for all  $i \neq j$ ,  $1 \leq i, j \leq n$ .

A diagonal matrix  $A = [a_{ij}] \in F^{n \times n}$  is said to be **scalar** if  $a_{ii} = a$ , for all  $i$ ,  $1 \leq i \leq n$ , and some scalar  $a \in F$ , i.e.,  $A = aI_n$ .

A matrix  $A \in F^{n \times n}$  is **block diagonal** if  $A$  as a block matrix is partitioned into submatrices  $A_{ij} \in F^{n_i \times n_j}$ , so that  $A = [A_{ij}]$ ,  $\sum_{i=1}^k n_i = n$ , and  $A_{ij} = \mathbf{0}$ , for all  $i \neq j$ ,  $1 \leq i, j \leq k$ . Thus,  $A =$

$$\begin{bmatrix} A_{11} & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & A_{22} & \cdots & \mathbf{0} \\ \vdots & & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \cdots & A_{kk} \end{bmatrix}.$$
 This block diagonal matrix  $A$  is denoted  $A = \text{diag}(A_{11}, \dots, A_{kk})$ , where  $A_{ii}$  is  $n_i \times n_i$ , (or sometimes denoted  $A = A_{11} \oplus \cdots \oplus A_{kk}$ , and called the **direct sum** of  $A_{11}, \dots, A_{kk}$ ).

A matrix  $A = [a_{ij}] \in F^{n \times n}$  is **upper triangular** if  $a_{ij} = 0$ , for all  $i > j$ ,  $1 \leq i, j \leq n$ .

An upper triangular matrix  $A = [a_{ij}] \in F^{n \times n}$  is **strictly upper triangular** if  $a_{ij} = 0$  for all  $i \geq j$ ,  $1 \leq i, j \leq n$ .

A matrix  $A \in F^{n \times n}$  is **lower triangular** if  $a_{ij} = 0$  for all  $i < j$ ,  $1 \leq i, j \leq n$ , i.e., if  $A^T$  is upper triangular.

A matrix  $A \in F^{n \times n}$  is **strictly lower triangular** if  $A^T$  is strictly upper triangular.

A matrix is **triangular** if it is upper or lower triangular.

A matrix  $A \in F^{n \times n}$  is **block upper triangular**, if  $A$  as a block matrix is partitioned into the submatrices  $A_{ij} \in F^{n_i \times n_j}$ , so that  $A = [A_{ij}]$ ,  $\sum_{i=1}^k n_i = n$ , and  $A_{ij} = \mathbf{0}$ , for all  $i > j$ ,  $1 \leq i, j \leq k$ , i.e., considering

the  $A_{ij}$  blocks as the entries of  $A$ ,  $A$  is upper triangular. Thus,  $A =$

$$\begin{bmatrix} A_{11} & A_{12} & \cdots & A_{1k} \\ \mathbf{0} & A_{22} & \cdots & A_{2k} \\ \vdots & & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \cdots & A_{kk} \end{bmatrix},$$

where each

$A_{ij}$  is  $n_i \times n_j$ , and  $\sum_{i=1}^k n_i = n$ . The matrix  $A$  is **strictly block upper triangular** if  $A_{ij} = \mathbf{0}$ , for all  $i \geq j$ ,  $1 \leq i, j \leq k$ .

A matrix  $A \in F^{n \times n}$  is **block lower triangular** if  $A^T$  is block upper triangular.

A matrix  $A \in F^{n \times n}$  is **strictly block lower triangular** if  $A^T$  is strictly block upper triangular.

A matrix  $A = [a_{ij}] \in F^{n \times n}$  is **upper Hessenberg** if  $a_{ij} = 0$ , for all  $i - 2 \geq j$ ,  $1 \leq i, j \leq n$ , i.e.,  $A$  has

the form  $A =$

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} & \cdots & a_{1n-1} & a_{1n} \\ a_{21} & a_{22} & a_{23} & \cdots & a_{2n-1} & a_{2n} \\ 0 & a_{32} & a_{33} & \cdots & a_{3n-1} & a_{3n} \\ \vdots & \vdots & \ddots & \ddots & & \vdots \\ 0 & 0 & \cdots & a_{n-1n-2} & a_{n-1n-1} & a_{n-1n} \\ 0 & 0 & \cdots & 0 & a_{nn-1} & a_{nn} \end{bmatrix}.$$

A matrix  $A = [a_{ij}] \in F^{n \times n}$  is **lower Hessenberg** if  $A^T$  is upper Hessenberg.

### Facts:

The following facts can be found in [HJ85]. This information is also available in many other standard references such as [LT85] or [Mey00].

1. Let  $D, D' \in F^{n \times n}$  be any diagonal matrices. Then  $D + D'$  and  $DD'$  are diagonal, and  $DD' = D'D$ . If  $D = \text{diag}(d_1, \dots, d_n)$  is nonsingular, then  $D^{-1} = \text{diag}(1/d_1, \dots, 1/d_n)$ .
2. Let  $D \in F^{n \times n}$  be a matrix such that  $DA = AD$  for all  $A \in F^{n \times n}$ . Then  $D$  is a scalar matrix.
3. If  $A \in F^{n \times n}$  is a block diagonal matrix, so that  $A = \text{diag}(A_{11}, \dots, A_{kk})$ , then  $\text{tr}(A) = \sum_{i=1}^k \text{tr}(A_{ii})$ ,  $\det(A) = \prod_{i=1}^k \det(A_{ii})$ ,  $\text{rank}(A) = \sum_{i=1}^k \text{rank}(A_{ii})$ , and  $\sigma(A) = \sigma(A_{11}) \cup \dots \cup \sigma(A_{kk})$ .
4. Let  $A \in F^{n \times n}$  be a block diagonal matrix, so that  $A = \text{diag}(A_{11}, A_{22}, \dots, A_{kk})$ . Then  $A$  is nonsingular if and only if  $A_{ii}$  is nonsingular for each  $i$ ,  $1 \leq i \leq k$ . Moreover,  $A^{-1} = \text{diag}(A_{11}^{-1}, A_{22}^{-1}, \dots, A_{kk}^{-1})$ .
5. See Chapter 4.3 for information on diagonalizability of matrices.
6. Let  $A \in F^{n \times n}$  be a block diagonal matrix, so that  $A = \text{diag}(A_{11}, \dots, A_{kk})$ . Then  $A$  is diagonalizable if and only if  $A_{ii}$  is diagonalizable for each  $i$ ,  $1 \leq i \leq k$ .
7. If  $A, B \in F^{n \times n}$  are upper (lower) triangular matrices, then  $A + B$  and  $AB$  are upper (lower) triangular. If the upper (lower) triangular matrix  $A = [a_{ij}]$  is nonsingular, then  $A^{-1}$  is upper (lower) triangular with diagonal entries  $1/a_{11}, \dots, 1/a_{nn}$ .

8. Let  $A \in F^{n \times n}$  be block upper triangular, so that  $A = \begin{bmatrix} A_{11} & A_{12} & \cdots & A_{1k} \\ \mathbf{0} & A_{22} & \cdots & A_{2k} \\ \vdots & & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \cdots & A_{kk} \end{bmatrix}$ . Then  $\text{tr}(A) = \sum_{i=1}^k \text{tr}(A_{ii})$ ,  $\det(A) = \prod_{i=1}^k \det(A_{ii})$ ,  $\text{rank}(A) \geq \sum_{i=1}^k \text{rank}(A_{ii})$ , and  $\sigma(A) = \sigma(A_{11}) \cup \dots \cup \sigma(A_{kk})$ .

9. Let  $A = (A_{ij}) \in F^{n \times n}$  be a block triangular matrix (either upper or lower triangular). Then  $A$  is nonsingular if and only if  $A_{ii}$  is nonsingular for each  $i$ ,  $1 \leq i \leq k$ . Moreover, the  $n_i \times n_i$  diagonal block entries of  $A^{-1}$  are  $A_{ii}^{-1}$ , for each  $i$ ,  $1 \leq i \leq k$ .
10. *Schur's Triangularization Theorem:* Let  $A \in \mathbb{C}^{n \times n}$ . Then there is a unitary matrix  $U \in \mathbb{C}^{n \times n}$  so that  $U^*AU$  is upper triangular. The diagonal entries of  $U^*AU$  are the eigenvalues of  $A$ .
11. Let  $A \in \mathbb{R}^{n \times n}$ . Then there is an orthogonal matrix  $V \in \mathbb{R}^{n \times n}$  so that  $V^TAV$  is of upper Hessenberg

form  $\begin{bmatrix} A_{11} & A_{12} & \cdots & A_{1k} \\ \mathbf{0} & A_{22} & \cdots & A_{2k} \\ \vdots & & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \cdots & A_{kk} \end{bmatrix}$ , where each  $A_{ii}$ ,  $1 \leq i \leq k$ , is  $1 \times 1$  or  $2 \times 2$ . Moreover, when  $A_{ii}$  is

$1 \times 1$ , the entry of  $A_{ii}$  is an eigenvalue of  $A$ , whereas when  $A_{ii}$  is  $2 \times 2$ , then  $A_{ii}$  has two eigenvalues which are nonreal complex conjugates of each other, and are eigenvalues of  $A$ .

12. (For more information on unitary triangularization, see Chapter 7.2.)
13. Let  $A = [A_{ij}] \in F^{n \times n}$  with  $|\sigma(A)| = n$ , where  $\lambda_1, \dots, \lambda_k \in \sigma(A)$  are the distinct eigenvalues of  $A$ . Then there is a nonsingular matrix  $T \in F^{n \times n}$  so that  $T^{-1}AT = \text{diag}(A_{11}, \dots, A_{kk})$ , where each  $A_{ii} \in F^{n_i \times n_i}$  is upper triangular with all diagonal entries of  $A_{ii}$  equal to  $\lambda_i$ , for  $1 \leq i \leq k$  (and  $\sum_{i=1}^k n_i = n$ ).

14. Let  $A \in F^{n \times n}$  be a block upper triangular matrix, of the form  $A = \begin{bmatrix} A_{11} & A_{12} \\ \mathbf{0} & A_{22} \end{bmatrix}$ , where  $A_{ij}$  is

$n_i \times n_j$ ,  $1 \leq i, j \leq 2$ , and  $\sum_{i=1}^2 n_i = n$ . (Note that any block upper triangular matrix can be said to have this form.) Let  $\mathbf{x}$  be an eigenvector of  $A_{11}$ , with corresponding eigenvalue  $\lambda$ , so that  $A_{11}\mathbf{x} = \lambda\mathbf{x}$ , where  $\mathbf{x}$  is a (column) vector with  $n_1$  components. Then the (column) vector with  $n$

components  $\begin{bmatrix} \mathbf{x} \\ \mathbf{0} \end{bmatrix}$  is an eigenvector of  $A$  with eigenvalue  $\lambda$ . Let  $\mathbf{y}$  be a left eigenvector of  $A_{22}$ , with corresponding eigenvalue  $\mu$ , so that  $\mathbf{y}A_{22} = \mathbf{y}\mu$ , where  $\mathbf{y}$  is a row vector with  $n_2$  components. Then the (row) vector with  $n$  components  $[\mathbf{0} \ \mathbf{y}]$  is a left eigenvector of  $A$  with eigenvalue  $\mu$ .

**Examples:**

1. The matrix  $A = \begin{bmatrix} 1 & 3 & 0 & 0 & 0 \\ 2 & 4 & 0 & 0 & 0 \\ 0 & 0 & 5 & 0 & 0 \\ 0 & 0 & 0 & 6 & 8 \\ 0 & 0 & 0 & 7 & 9 \end{bmatrix}$  is a block diagonal matrix, and the trace, determinant, and

rank can be calculated block-wise, where  $A_{11} = \begin{bmatrix} 1 & 3 \\ 2 & 4 \end{bmatrix}$ ,  $A_{22} = 5$ , and  $A_{33} = \begin{bmatrix} 6 & 8 \\ 7 & 9 \end{bmatrix}$ , as  $\text{tr}(A) =$

$25 = \sum_{i=1}^3 \text{tr}(A_{ii})$ ,  $\det(A) = (-2)(5)(-2) = \prod_{i=1}^3 \det(A_{ii})$ , and  $\text{rank}(A) = 5 = \sum_{i=1}^3 \text{rank}(A_{ii})$ .

2. Let  $A = \begin{bmatrix} a & b & c \\ 0 & d & e \\ 0 & 0 & f \end{bmatrix} \in F^{3 \times 3}$ , an upper triangular matrix. If  $a, d, f$  are nonzero, then  $A^{-1} =$

$$\begin{bmatrix} \frac{1}{a} & -\frac{b}{ad} & \frac{be-cd}{adf} \\ 0 & \frac{1}{d} & -\frac{e}{df} \\ 0 & 0 & \frac{1}{f} \end{bmatrix}.$$

3. The matrix  $B = \begin{bmatrix} 1 & 3 & 0 & 0 & 0 \\ 2 & 4 & 5 & 0 & 0 \\ 0 & 0 & 0 & 6 & 0 \\ 0 & 0 & 0 & 0 & 7 \\ 0 & 0 & 0 & 0 & 8 \end{bmatrix}$  is not block diagonal. However,  $B$  is block upper triangular,

with  $B_{11} = \begin{bmatrix} 1 & 3 \\ 2 & 4 \end{bmatrix}$ ,  $B_{22} = 0$ ,  $B_{33} = \begin{bmatrix} 0 & 7 \\ 0 & 8 \end{bmatrix}$ ,  $B_{12} = \begin{bmatrix} 0 \\ 5 \end{bmatrix}$ ,  $B_{13} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$ , and  $B_{23} = [6 \ 0]$ .

Notice that  $4 = \text{rank}(B) \geq \sum_{i=1}^3 \text{rank}(B_{ii}) = 2 + 0 + 1 = 3$ .

4. The  $4 \times 4$  matrix  $\begin{bmatrix} 1 & 2 & 0 & 0 \\ 3 & 4 & 5 & 0 \\ 6 & 7 & 8 & 9 \\ 10 & 11 & 12 & 13 \end{bmatrix}$  is not lower triangular, but is lower Hessenberg.

### 10.3 Schur Complements

In this subsection, the square matrix  $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$  is partitioned as a block matrix, where  $A_{11}$  is nonsingular.

**Definitions:**

The **Schur complement** of  $A_{11}$  in  $A$  is the matrix  $A_{22} - A_{21}A_{11}^{-1}A_{12}$ , sometimes denoted  $A/A_{11}$ .

**Facts:**

$$1. [\text{Zha99}] \begin{bmatrix} I & \mathbf{0} \\ -A_{21}A_{11}^{-1} & I \end{bmatrix} \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \begin{bmatrix} I & -A_{11}^{-1}A_{12} \\ \mathbf{0} & I \end{bmatrix} = \begin{bmatrix} A_{11} & \mathbf{0} \\ \mathbf{0} & A/A_{11} \end{bmatrix}.$$

$$2. [\text{Zha99}] \text{ Let } A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}, \text{ where } A_{11} \text{ is nonsingular. Then } \det(A) = \det(A_{11})\det(A/A_{11}).$$

Also,  $\text{rank}(A) = \text{rank}(A_{11}) + \text{rank}(A/A_{11})$ .

3. [Zha99] Let  $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$ . Then  $A$  is nonsingular if and only if both  $A_{11}$  and the Schur complement of  $A_{11}$  in  $A$  are nonsingular.
4. [HJ85] Let  $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$ , where  $A_{11}$ ,  $A_{22}$ ,  $A/A_{11}$ ,  $A/A_{22}$ , and  $A$  are nonsingular. Then  $A^{-1} = \begin{bmatrix} (A/A_{22})^{-1} & -A_{11}^{-1}A_{12}(A/A_{11})^{-1} \\ -A_{22}^{-1}A_{21}(A/A_{22})^{-1} & (A/A_{11})^{-1} \end{bmatrix}$ .
5. [Zha99] Let  $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$ , where  $A_{11}$ ,  $A_{22}$ ,  $A/A_{11}$ , and  $A/A_{22}$  are nonsingular. An equation relating the Schur complements of  $A_{11}$  in  $A$  and  $A_{22}$  in  $A$  is  $(A/A_{22})^{-1} = A_{11}^{-1} + A_{11}^{-1}A_{12}(A/A_{11})^{-1}A_{21}A_{11}^{-1}$ .
6. [LT85] Let  $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$ , where the  $k \times k$  matrix  $A_{11}$  is nonsingular. Then  $\text{rank}(A) = k$  if and only if  $A/A_{11} = \mathbf{0}$ .
7. [Hay68] Let  $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{12}^* & A_{22} \end{bmatrix}$  be Hermitian, where  $A_{11}$  is nonsingular. Then the inertia of  $A$  is  $\text{in}(A) = \text{in}(A_{11}) + \text{in}(A/A_{11})$ .
8. [Hay68] Let  $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{12}^* & A_{22} \end{bmatrix}$  be Hermitian, where  $A_{11}$  is nonsingular. Then  $A$  is positive (semi)definite if and only if both  $A_{11}$  and  $A/A_{11}$  are positive (semi)definite.

**Examples:**

1. Let  $A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 10 \end{bmatrix}$ . Then with  $A_{11} = 1$ , we have

$$\begin{aligned} \begin{bmatrix} 1 & \mathbf{0} \\ -\begin{bmatrix} 4 \\ 7 \end{bmatrix} & I_2 \end{bmatrix} \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 10 \end{bmatrix} \begin{bmatrix} 1 & -[2 \ 3] \\ \mathbf{0} & I_2 \end{bmatrix} &= \begin{bmatrix} 1 & \mathbf{0} \\ \mathbf{0} & \begin{bmatrix} 5 & 6 \\ 8 & 10 \end{bmatrix} \end{bmatrix} - \begin{bmatrix} 4 \\ 7 \end{bmatrix} I^{-1} [2 \ 3] \\ &= \begin{bmatrix} 1 & \mathbf{0} \\ \mathbf{0} & \begin{bmatrix} -3 & -6 \\ -6 & -11 \end{bmatrix} \end{bmatrix}. \end{aligned}$$

2. Let  $A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 10 \end{bmatrix}$ . With  $A_{11} = 1$ , and  $A_{22} = \begin{bmatrix} 5 & 6 \\ 8 & 10 \end{bmatrix}$ , then  $A/A_{11} = \begin{bmatrix} -3 & -6 \\ -6 & -11 \end{bmatrix}$ ,  $A/A_{22} =$

$$1 - [2 \ 3] \begin{bmatrix} 5 & 6 \\ 8 & 10 \end{bmatrix}^{-1} \begin{bmatrix} 4 \\ 7 \end{bmatrix} = -\frac{3}{2}, \text{ and}$$

$$\begin{aligned} A^{-1} &= \begin{bmatrix} (-\frac{3}{2})^{-1} & -[2 \ 3] \begin{bmatrix} -3 & -6 \\ -6 & -11 \end{bmatrix}^{-1} \\ -\begin{bmatrix} 5 & 6 \\ 8 & 10 \end{bmatrix}^{-1} \begin{bmatrix} 4 \\ 7 \end{bmatrix} (-\frac{3}{2})^{-1} & \begin{bmatrix} -3 & -6 \\ -6 & -11 \end{bmatrix}^{-1} \end{bmatrix} \\ &= \begin{bmatrix} -\frac{2}{3} & \frac{1}{3}[-4 \ 3] \\ \begin{bmatrix} -\frac{2}{3} \\ 1 \end{bmatrix} & -\frac{1}{3} \begin{bmatrix} -11 & 6 \\ 6 & -3 \end{bmatrix} \end{bmatrix} = \begin{bmatrix} -\frac{2}{3} & -\frac{4}{3} & 1 \\ -\frac{2}{3} & \frac{11}{3} & -2 \\ 1 & -2 & 1 \end{bmatrix}. \end{aligned}$$

3. Let  $A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 10 \end{bmatrix}$ .

Then, from Fact 5,

$$\begin{aligned} (A/A_{22})^{-1} &= \left(-\frac{3}{2}\right)^{-1} = 1^{-1} + 1^{-1} \begin{bmatrix} 2 & 3 \end{bmatrix} \begin{bmatrix} -3 & -6 \\ -6 & -11 \end{bmatrix}^{-1} \begin{bmatrix} 4 \\ 7 \end{bmatrix} 1^{-1}, \\ &= A_{11}^{-1} + A_{11}^{-1} A_{12} (A/A_{11})^{-1} A_{21} A_{11}^{-1}. \end{aligned}$$

## 10.4 Kronecker Products

### Definitions:

Let  $A \in F^{m \times n}$  and  $B \in F^{p \times q}$ . Then the **Kronecker product** (sometimes called the **tensor product**) of  $A$

and  $B$ , denoted  $A \otimes B$ , is the  $mp \times nq$  partitioned matrix  $A \otimes B = \begin{bmatrix} a_{11}B & a_{12}B & \cdots & a_{1n}B \\ a_{21}B & a_{22}B & \cdots & a_{2n}B \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1}B & a_{m2}B & \cdots & a_{mn}B \end{bmatrix}$ .

Let  $A \in F^{m \times n}$  and let the  $j$ th column of  $A$ , namely,  $A[\{1, \dots, m\}, \{j\}]$  be denoted  $a_j$ , for  $1 \leq j \leq n$ .

The column vector with  $mn$  components, denoted  $\text{vec}(A)$ , defined by  $\text{vec}(A) = \begin{bmatrix} a_1 \\ a_2 \\ \vdots \\ a_n \end{bmatrix} \in F^{mn}$ , is the

**vec-function** of  $A$ , i.e.,  $\text{vec}(A)$  is formed by stacking the columns of  $A$  on top of each other in their natural order.

### Facts:

All of the following facts except those for which a specific reference is given can be found in [LT85].

1. Let  $A \in F^{m \times n}$  and  $B \in F^{p \times q}$ . If  $a \in F$ , then  $a(A \otimes B) = (aA) \otimes B = A \otimes (aB)$ .
2. Let  $A, B \in F^{m \times n}$  and  $C \in F^{p \times q}$ . Then  $(A + B) \otimes C = A \otimes C + B \otimes C$ .
3. Let  $A \in F^{m \times n}$  and  $B, C \in F^{p \times q}$ . Then  $A \otimes (B + C) = A \otimes B + A \otimes C$ .
4. Let  $A \in F^{m \times n}$ ,  $B \in F^{p \times q}$ , and  $C \in F^{r \times s}$ . Then  $A \otimes (B \otimes C) = (A \otimes B) \otimes C$ .
5. Let  $A \in F^{m \times n}$  and  $B \in F^{p \times q}$ . Then  $(A \otimes B)^T = A^T \otimes B^T$ .
6. [MM64] Let  $A \in \mathbb{C}^{m \times n}$  and  $B \in \mathbb{C}^{p \times q}$ . Then  $\overline{(A \otimes B)} = \overline{A} \otimes \overline{B}$ .
7. [MM64] Let  $A \in \mathbb{C}^{m \times n}$  and  $B \in \mathbb{C}^{p \times q}$ . Then  $(A \otimes B)^* = A^* \otimes B^*$ .
8. Let  $A \in F^{m \times n}$ ,  $B \in F^{p \times q}$ ,  $C \in F^{n \times r}$ , and  $D \in F^{q \times s}$ . Then  $(A \otimes B)(C \otimes D) = AC \otimes BD$ .
9. Let  $A \in F^{m \times n}$  and  $B \in F^{p \times q}$ . Then  $A \otimes B = (A \otimes I_p)(I_n \otimes B) = (I_m \otimes B)(A \otimes I_q)$ .
10. If  $A \in F^{m \times m}$  and  $B \in F^{n \times n}$  are nonsingular, then  $A \otimes B$  is nonsingular and  $(A \otimes B)^{-1} = A^{-1} \otimes B^{-1}$ .
11. Let  $A_1, A_2, \dots, A_k \in F^{m \times m}$ , and  $B_1, B_2, \dots, B_k \in F^{n \times n}$ . Then  $(A_1 \otimes B_1)(A_2 \otimes B_2) \cdots (A_k \otimes B_k) = (A_1 A_2 \cdots A_k) \otimes (B_1 B_2 \cdots B_k)$ .
12. Let  $A \in F^{m \times m}$  and  $B \in F^{n \times n}$ . Then  $(A \otimes B)^k = A^k \otimes B^k$ .

13. If  $A \in F^{m \times m}$  and  $B \in F^{n \times n}$ , then there is an  $mn \times mn$  permutation matrix  $P$  so that  $P^T(A \otimes B)P = B \otimes A$ .
14. Let  $A, B \in F^{m \times n}$ . Then  $\text{vec}(aA + bB) = a \text{vec}(A) + b \text{vec}(B)$ , for any  $a, b \in F$ .
15. If  $A \in F^{m \times n}$ ,  $B \in F^{p \times q}$ , and  $X \in F^{n \times p}$ , then  $\text{vec}(AXB) = (B^T \otimes A)\text{vec}(X)$ .
16. If  $A \in F^{m \times m}$  and  $B \in F^{n \times n}$ , then  $\det(A \otimes B) = (\det(A))^n (\det(B))^m$ ,  $\text{tr}(A \otimes B) = (\text{tr}(A))(\text{tr}(B))$ , and  $\text{rank}(A \otimes B) = (\text{rank}(A))(\text{rank}(B))$ .
17. Let  $A \in F^{m \times m}$  and  $B \in F^{n \times n}$ , with  $\sigma(A) = \{\lambda_1, \dots, \lambda_m\}$  and  $\sigma(B) = \{\mu_1, \dots, \mu_n\}$ . Then  $A \otimes B \in F^{mn \times mn}$  has eigenvalues  $\{\lambda_s \mu_t | 1 \leq s \leq m, 1 \leq t \leq n\}$ . Moreover, if the right eigenvectors of  $A$  are denoted  $\mathbf{x}_i$ , and the right eigenvectors of  $B$  are denoted  $\mathbf{y}_j$ , so that  $A\mathbf{x}_i = \lambda_i \mathbf{x}_i$  and  $B\mathbf{y}_j = \mu_j \mathbf{y}_j$ , then  $(A \otimes B)(\mathbf{x}_i \otimes \mathbf{y}_j) = \lambda_i \mu_j (\mathbf{x}_i \otimes \mathbf{y}_j)$ .
18. Let  $A \in F^{m \times m}$  and  $B \in F^{n \times n}$ , with  $\sigma(A) = \{\lambda_1, \dots, \lambda_m\}$  and  $\sigma(B) = \{\mu_1, \dots, \mu_n\}$ . Then  $(I_n \otimes A) + (B \otimes I_m)$  has eigenvalues  $\{\lambda_s + \mu_t | 1 \leq s \leq m, 1 \leq t \leq n\}$ .
19. Let  $p(x, y) \in F[x, y]$  so that  $p(x, y) = \sum_{i,j=1}^k a_{ij} x^i y^j$ , where  $a_{ij} \in F$ ,  $1 \leq i \leq k$ ,  $1 \leq j \leq k$ . Let  $A \in F^{m \times m}$  and  $B \in F^{n \times n}$ . Define  $p(A; B)$  to be the  $mn \times mn$  matrix  $p(A; B) = \sum_{i,j=1}^k a_{ij}(A^i \otimes B^j)$ . If  $\sigma(A) = \{\lambda_1, \dots, \lambda_m\}$  and  $\sigma(B) = \{\mu_1, \dots, \mu_n\}$ , then  $\sigma(p(A; B)) = \{p(\lambda_s, \mu_t) | 1 \leq s \leq m, 1 \leq t \leq n\}$ .
20. Let  $A_1, A_2 \in F^{m \times m}$ ,  $B_1, B_2 \in F^{n \times n}$ . If  $A_1$  and  $A_2$  are similar, and  $B_1$  and  $B_2$  are similar, then  $A_1 \otimes B_1$  is similar to  $A_2 \otimes B_2$ .
21. If  $A \in F^{m \times n}$ ,  $B \in F^{p \times q}$ , and  $X \in F^{n \times p}$ , then  $\text{vec}(AX) = (I_p \otimes A)\text{vec}(X)$ ,  $\text{vec}(XB) = (B^T \otimes I_n)\text{vec}(X)$ , and  $\text{vec}(AX + XB) = [(I_p \otimes A) + (B^T \otimes I_n)]\text{vec}(X)$ .
22. If  $A \in F^{m \times n}$ ,  $B \in F^{p \times q}$ ,  $C \in F^{m \times q}$ , and  $X \in F^{n \times p}$ , then the equation  $AXB = C$  can be written in the form  $(B^T \otimes A)\text{vec}(X) = \text{vec}(C)$ .
23. Let  $A \in F^{m \times m}$ ,  $B \in F^{n \times n}$ ,  $C \in F^{m \times n}$ , and  $X \in F^{m \times n}$ . Then the equation  $AX + XB = C$  can be written in the form  $[(I_n \otimes A) + (B^T \otimes I_m)]\text{vec}(X) = \text{vec}(C)$ .
24. Let  $A \in \mathbb{C}^{m \times m}$  and  $B \in \mathbb{C}^{n \times n}$  be Hermitian. Then  $A \otimes B$  is Hermitian.
25. Let  $A \in \mathbb{C}^{m \times m}$  and  $B \in \mathbb{C}^{n \times n}$  be positive definite. Then  $A \otimes B$  is positive definite.

**Examples:**

1. Let  $A = \begin{bmatrix} 1 & -1 \\ 0 & 2 \end{bmatrix}$  and  $B = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{bmatrix}$ . Then  $A \otimes B = \begin{bmatrix} 1 & 2 & 3 & -1 & -2 & -3 \\ 4 & 5 & 6 & -4 & -5 & -6 \\ 7 & 8 & 9 & -7 & -8 & -9 \\ 0 & 0 & 0 & 2 & 4 & 6 \\ 0 & 0 & 0 & 8 & 10 & 12 \\ 0 & 0 & 0 & 14 & 16 & 18 \end{bmatrix}$ .

2. Let  $A = \begin{bmatrix} 1 & -1 \\ 0 & 2 \end{bmatrix}$ . Then  $\text{vec}(A) = \begin{bmatrix} 1 \\ 0 \\ -1 \\ 2 \end{bmatrix}$ .

3. Let  $A \in F^{m \times m}$  and  $B \in F^{n \times n}$ . If  $A$  is upper (lower) triangular, then  $A \otimes B$  is block upper (lower) triangular. If  $A$  is diagonal then  $A \otimes B$  is block diagonal. If both  $A$  and  $B$  are upper (lower) triangular, then  $A \otimes B$  is (upper) triangular. If both  $A$  and  $B$  are diagonal, then  $A \otimes B$  is diagonal.
4. Let  $A \in F^{m \times n}$  and  $B \in F^{p \times q}$ . If  $A \otimes B = \mathbf{0}$ , then  $A = \mathbf{0}$  or  $B = \mathbf{0}$ .

5. Let  $A \in F^{m \times n}$ . Then  $A \otimes I_n = \begin{bmatrix} a_{11}I_n & a_{12}I_n & \cdots & a_{1n}I_n \\ a_{21}I_n & a_{22}I_n & \cdots & a_{2n}I_n \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1}I_n & a_{m2}I_n & \cdots & a_{mn}I_n \end{bmatrix} \in F^{mn \times n^2}$ . Let  $B \in F^{p \times p}$ . Then

$$I_n \otimes B = \text{diag}(B, B, \dots, B) \in F^{np \times np}, \text{ and } I_m \otimes I_n = I_{mn}.$$

Nicholas J. Higham  
*University of Manchester*

Matrix functions are used in many areas of linear algebra and arise in numerous applications in science and engineering. The most common matrix function is the matrix inverse; it is not treated specifically in this chapter, but is covered in Section 1.1 and Section 38.2. This chapter is concerned with general matrix functions as well as specific cases such as matrix square roots, trigonometric functions, and the exponential and logarithmic functions.

The specific functions just mentioned can all be defined via power series or as the solution of nonlinear systems. For example,  $\cos(A) = I - A^2/2! + A^4/4! - \dots$ . However, a general theory exists from which a number of properties possessed by all matrix functions can be deduced and which suggests computational methods. This chapter treats general theory, then specific functions, and finally outlines computational methods.

### 11.1 General Theory

---

#### Definitions:

A function of a matrix can be defined in several ways, of which the following three are the most generally useful.

- *Jordan canonical form definition.* Let  $A \in \mathbb{C}^{n \times n}$  have the Jordan canonical form  $Z^{-1}AZ = J_A = \text{diag}(J_1(\lambda_1), J_2(\lambda_2), \dots, J_p(\lambda_p))$ , where  $Z$  is nonsingular,

$$J_k(\lambda_k) = \begin{bmatrix} \lambda_k & 1 & & \\ & \lambda_k & \ddots & \\ & & \ddots & 1 \\ & & & \lambda_k \end{bmatrix} \in \mathbb{C}^{m_k \times m_k}, \quad (11.1)$$

and  $m_1 + m_2 + \cdots + m_p = n$ . Then

$$f(A) := Zf(J_A)Z^{-1} = Z \operatorname{diag}(f(J_k(\lambda_k)))Z^{-1}, \quad (11.2)$$

where

$$f(J_k(\lambda_k)) := \begin{bmatrix} f(\lambda_k) & f'(\lambda_k) & \cdots & \frac{f^{(m_k-1)}(\lambda_k)}{(m_k-1)!} \\ & f(\lambda_k) & \ddots & \vdots \\ & & \ddots & f'(\lambda_k) \\ & & & f(\lambda_k) \end{bmatrix}. \quad (11.3)$$

- *Polynomial interpolation definition.* Denote by  $\lambda_1, \dots, \lambda_s$  the distinct eigenvalues of  $A$  and let  $n_i$  be the **index** of  $\lambda_i$ , that is, the order of the largest Jordan block in which  $\lambda_i$  appears. Then  $f(A) := r(A)$ , where  $r$  is the unique Hermite interpolating polynomial of degree less than  $\sum_{i=1}^s n_i$  that satisfies the interpolation conditions

$$r^{(j)}(\lambda_i) = f^{(j)}(\lambda_i), \quad j = 0: n_i - 1, \quad i = 1: s. \quad (11.4)$$

Note that in both these definitions the derivatives in (11.4) must exist in order for  $f(A)$  to be defined. The function  $f$  is said to be **defined on the spectrum of  $A$**  if all the derivatives in (11.4) exist.

- *Cauchy integral definition.*

$$f(A) := \frac{1}{2\pi i} \int_{\Gamma} f(z)(zI - A)^{-1} dz, \quad (11.5)$$

where  $f$  is analytic inside a closed contour  $\Gamma$  that encloses  $\sigma(A)$ .

When the function  $f$  is multivalued and  $A$  has a repeated eigenvalue occurring in more than one Jordan block (i.e.,  $A$  is derogatory), the Jordan canonical form definition has more than one interpretation. Usually, for each occurrence of an eigenvalue in different Jordan blocks the same branch is taken for  $f$  and its derivatives. This gives a **primary matrix function**. If different branches are taken for the same eigenvalue in two different Jordan blocks, then a **nonprimary matrix function** is obtained. A nonprimary matrix function is not expressible as a polynomial in the matrix, and if such a function is obtained from the Jordan canonical form definition (11.2) then it depends on the matrix  $Z$ . In most applications it is primary matrix functions that are of interest. For the rest of this section  $f(A)$  is assumed to be a primary matrix function, unless otherwise stated.

### Facts:

Proofs of the facts in this section can be found in one or more of [Hig], [HJ91], or [LT85], unless otherwise stated.

1. The Jordan canonical form and polynomial interpolation definitions are equivalent. Both definitions are equivalent to the Cauchy integral definition when  $f$  is analytic.
2.  $f(A)$  is a polynomial in  $A$  and the coefficients of the polynomial depend on  $A$ .
3.  $f(A)$  commutes with  $A$ .
4.  $f(A^T) = f(A)^T$ .
5. For any nonsingular  $X$ ,  $f(XAX^{-1}) = Xf(A)X^{-1}$ .
6. If  $A$  is diagonalizable, with  $Z^{-1}AZ = D = \operatorname{diag}(d_1, d_2, \dots, d_n)$ , then  $f(A) = Zf(D)Z^{-1} = Z \operatorname{diag}(f(d_1), f(d_2), \dots, f(d_n))Z^{-1}$ .
7.  $f(\operatorname{diag}(A_1, A_2, \dots, A_m)) = \operatorname{diag}(f(A_1), f(A_2), \dots, f(A_m))$ .

8. Let  $f$  and  $g$  be functions defined on the spectrum of  $A$ .
  - (a) If  $h(t) = f(t) + g(t)$ , then  $h(A) = f(A) + g(A)$ .
  - (b) If  $h(t) = f(t)g(t)$ , then  $h(A) = f(A)g(A)$ .
9. Let  $G(u_1, \dots, u_t)$  be a polynomial in  $u_1, \dots, u_t$  and let  $f_1, \dots, f_t$  be functions defined on the spectrum of  $A$ . If  $g(\lambda) = G(f_1(\lambda), \dots, f_t(\lambda))$  takes zero values on the spectrum of  $A$ , then  $g(A) = G(f_1(A), \dots, f_t(A)) = 0$ . For example,  $\sin^2(A) + \cos^2(A) = I$ ,  $(A^{1/p})^p = A$ , and  $e^{iA} = \cos A + i \sin A$ .
10. Suppose  $f$  has a Taylor series expansion

$$f(z) = \sum_{k=0}^{\infty} a_k(z - \alpha)^k \quad \left( a_k = \frac{f^{(k)}(\alpha)}{k!} \right)$$

with radius of convergence  $r$ . If  $A \in \mathbb{C}^{n \times n}$ , then  $f(A)$  is defined and is given by

$$f(A) = \sum_{k=0}^{\infty} a_k(A - \alpha I)^k$$

if and only if each of the distinct eigenvalues  $\lambda_1, \dots, \lambda_s$  of  $A$  satisfies one of the conditions:

- (a)  $|\lambda_i - \alpha| < r$ .
  - (b)  $|\lambda_i - \alpha| = r$  and the series for  $f^{n_i-1}(\lambda)$ , where  $n_i$  is the index of  $\lambda_i$ , is convergent at the point  $\lambda = \lambda_i, i = 1:s$ .
11. [Dav73], [Des63], [GVL96, Theorem 11.1.3]. Let  $T \in \mathbb{C}^{n \times n}$  be upper triangular and suppose that  $f$  is defined on the spectrum of  $T$ . Then  $F = f(T)$  is upper triangular with  $f_{ii} = f(t_{ii})$  and

$$f_{ij} = \sum_{(s_0, \dots, s_k) \in S_{ij}} t_{s_0, s_1} t_{s_1, s_2} \dots t_{s_{k-1}, s_k} f[\lambda_{s_0}, \dots, \lambda_{s_k}],$$

where  $\lambda_i = t_{ii}$ ,  $S_{ij}$  is the set of all strictly increasing sequences of integers that start at  $i$  and end at  $j$ , and  $f[\lambda_{s_0}, \dots, \lambda_{s_k}]$  is the  $k$ th order divided difference of  $f$  at  $\lambda_{s_0}, \dots, \lambda_{s_k}$ .

**Examples:**

1. For  $\lambda_1 \neq \lambda_2$ ,

$$f\left(\begin{bmatrix} \lambda_1 & \alpha \\ 0 & \lambda_2 \end{bmatrix}\right) = \begin{bmatrix} f(\lambda_1) & \alpha \frac{f(\lambda_2) - f(\lambda_1)}{\lambda_2 - \lambda_1} \\ 0 & f(\lambda_2) \end{bmatrix}.$$

For  $\lambda_1 = \lambda_2 = \lambda$ ,

$$f\left(\begin{bmatrix} \lambda & \alpha \\ 0 & \lambda \end{bmatrix}\right) = \begin{bmatrix} f(\lambda) & \alpha f'(\lambda) \\ 0 & f(\lambda) \end{bmatrix}.$$

2. Compute  $e^A$  for the matrix

$$A = \begin{bmatrix} -7 & -4 & -3 \\ 10 & 6 & 4 \\ 6 & 3 & 3 \end{bmatrix}.$$

We have  $A = XJ_A X^{-1}$ , where  $J_A = [0] \oplus \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$  and

$$X = \begin{bmatrix} 1 & -1 & -1 \\ -1 & 2 & 0 \\ -1 & 0 & 3 \end{bmatrix}.$$

Hence, using the Jordan canonical form definition, we have

$$\begin{aligned} e^A &= X e_A^J X^{-1} = X \left( [1] \oplus \begin{bmatrix} e & e \\ 0 & e \end{bmatrix} \right) X^{-1} \\ &= \begin{bmatrix} 1 & -1 & -1 \\ -1 & 2 & 0 \\ -1 & 0 & 3 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & e & e \\ 0 & 0 & e \end{bmatrix} \begin{bmatrix} 6 & 3 & 2 \\ 2 & 2 & 1 \\ 2 & 1 & 1 \end{bmatrix} \\ &= \begin{bmatrix} 6 - 7e & 3 - 4e & 2 - 3e \\ -6 + 10e & -3 + 6e & -2 + 4e \\ -6 + 6e & -3 + 3e & -2 + 3e \end{bmatrix}. \end{aligned}$$

3. Compute  $\sqrt{A}$  for the matrix in Example 2. To obtain the square root, we use the polynomial interpolation definition. The eigenvalues of  $A$  are 0 and 1, with indices 1 and 2, respectively. The unique polynomial  $r$  of degree at most 2 satisfying the interpolation conditions  $r(0) = f(0)$ ,  $r(1) = f(1)$ ,  $r'(1) = f'(1)$  is

$$r(t) = f(0)(t-1)^2 + t(2-t)f(1) + t(t-1)f'(1).$$

With  $f(t) = t^{1/2}$ , taking the positive square root, we have  $r(t) = t(2-t) + t(t-1)/2$  and, therefore,

$$A^{1/2} = A(2I - A) + A(A - I)/2 = \begin{bmatrix} -6 & -3.5 & -2.5 \\ 8 & 5 & 3 \\ 6 & 3 & 3 \end{bmatrix}.$$

4. Consider the  $m_k \times m_k$  Jordan block  $J_k(\lambda_k)$  in (11.1). The polynomial satisfying the interpolation conditions (11.4) is

$$r(t) = f(\lambda_k) + (t - \lambda_k)f'(\lambda_k) + \frac{(t - \lambda_k)^2}{2!}f''(\lambda_k) + \cdots + \frac{(t - \lambda_k)^{m_k-1}}{(m_k - 1)!}f^{(m_k-1)}(\lambda_k),$$

which, of course, is the first  $m_k$  terms of the Taylor series of  $f$  about  $\lambda_k$ . Hence, from the polynomial interpolation definition,

$$\begin{aligned} f(J_k(\lambda_k)) &= r(J_k(\lambda_k)) \\ &= f(\lambda_k)I + (J_k(\lambda_k) - \lambda_k I)f'(\lambda_k) + \frac{(J_k(\lambda_k) - \lambda_k I)^2}{2!}f''(\lambda_k) + \cdots \\ &\quad + \frac{(J_k(\lambda_k) - \lambda_k I)^{m_k-1}}{(m_k - 1)!}f^{(m_k-1)}(\lambda_k). \end{aligned}$$

The matrix  $(J_k(\lambda_k) - \lambda_k I)^j$  is zero except for 1s on the  $j$ th superdiagonal. This expression for  $f(J_k(\lambda_k))$  is, therefore, equal to that in (11.3), confirming the consistency of the first two definitions of  $f(A)$ .

## 11.2 Matrix Square Root

---

### Definitions:

Let  $A \in \mathbb{C}^{n \times n}$ . Any  $X$  such that  $X^2 = A$  is a **square root** of  $A$ .

**Facts:**

Proofs of the facts in this section can be found in one or more of [Hig], [HJ91], or [LT85], unless otherwise stated.

1. If  $A \in \mathbb{C}^{n \times n}$  has no eigenvalues on  $\mathbb{R}_0^-$  (the closed negative real axis) then there is a unique square root  $X$  of  $A$  each of whose eigenvalues is 0 or lies in the open right half-plane, and it is a primary matrix function of  $A$ . This is the **principal square root** of  $A$  and is written  $X = A^{1/2}$ . If  $A$  is real then  $A^{1/2}$  is real. An integral representation is

$$A^{1/2} = \frac{2}{\pi} A \int_0^\infty (t^2 I + A)^{-1} dt.$$

2. A positive (semi)definite matrix  $A \in \mathbb{C}^{n \times n}$  has a unique positive (semi)definite square root. (See also Section 8.3.)
3. [CL74] A singular matrix  $A \in \mathbb{C}^{n \times n}$  may or may not have a square root. A necessary and sufficient condition for  $A$  to have a square root is that in the “ascent sequence” of integers  $d_1, d_2, \dots$  defined by

$$d_i = \dim(\ker(A^i)) - \dim(\ker(A^{i-1})),$$

no two terms are the same odd integer.

4.  $A \in \mathbb{R}^{n \times n}$  has a real square root if and only if  $A$  satisfies the condition in the previous fact and  $A$  has an even number of Jordan blocks of each size for every negative eigenvalue.
5. The  $n \times n$  identity matrix  $I_n$  has  $2^n$  diagonal square roots  $\text{diag}(\pm 1)$ . Only two of these are primary matrix functions, namely  $I$  and  $-I$ . Nondiagonal but symmetric nonprimary square roots of  $I_n$  include any Householder matrix  $I - 2\mathbf{v}\mathbf{v}^T / (\mathbf{v}^T \mathbf{v})$  ( $\mathbf{v} \neq 0$ ) and the identity matrix with its columns in reverse order. Nonsymmetric square roots of  $I_n$  are easily constructed in the form  $XD X^{-1}$ , where  $X$  is nonsingular but nonorthogonal and  $D = \text{diag}(\pm 1) \neq \pm I$ .

**Examples:**

1. The Jordan block  $\begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}$  has no square root. The matrix

$$\begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

has ascent sequence 2, 1, 0, ... and so does have a square root — for example, the matrix

$$\begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}.$$

## 11.3 Matrix Exponential

---

**Definitions:**

The exponential of  $A \in \mathbb{C}^{n \times n}$ , written  $e^A$  or  $\exp(A)$ , is defined by

$$e^A = I + A + \frac{A^2}{2!} + \dots + \frac{A^k}{k!} + \dots.$$

**Facts:**

Proofs of the facts in this section can be found in one or more of [Hig], [HJ91], or [LT85], unless otherwise stated.

1.  $e^{(A+B)t} = e^{At}e^{Bt}$  holds for all  $t$  if and only if  $AB = BA$ .
2. The differential equation in  $n \times n$  matrices

$$\frac{dY}{dt} = AY, \quad Y(0) = C, \quad A, Y \in \mathbb{C}^{n \times n},$$

has solution  $Y(t) = e^{At}C$ .

3. The differential equation in  $n \times n$  matrices

$$\frac{dY}{dt} = AY + YB, \quad Y(0) = C, \quad A, B, Y \in \mathbb{C}^{n \times n},$$

has solution  $Y(t) = e^{At}Ce^{Bt}$ .

4.  $A \in \mathbb{C}^{n \times n}$  is unitary if and only if it can be written  $A = e^{iH}$ , where  $H$  is Hermitian. In this representation  $H$  can be taken to be Hermitian positive definite.
5.  $A \in \mathbb{R}^{n \times n}$  is orthogonal with  $\det(A) = 1$  if and only if  $A = e^S$  with  $S \in \mathbb{R}^{n \times n}$  skew-symmetric.

**Examples:**

1. Fact 5 is illustrated by the matrix

$$A = \begin{bmatrix} 0 & \alpha \\ -\alpha & 0 \end{bmatrix},$$

for which

$$e^A = \begin{bmatrix} \cos \alpha & \sin \alpha \\ -\sin \alpha & \cos \alpha \end{bmatrix}.$$

## 11.4 Matrix Logarithm

---

**Definitions:**

Let  $A \in \mathbb{C}^{n \times n}$ . Any  $X$  such that  $e^X = A$  is a **logarithm** of  $A$ .

**Facts:**

Proofs of the facts in this section can be found in one or more of [Hig], [HJ91], or [LT85], unless otherwise stated.

1. If  $A$  has no eigenvalues on  $\mathbb{R}^-$ , then there is a unique logarithm  $X$  of  $A$  all of whose eigenvalues lie in the strip  $\{z : -\pi < \text{Im}(z) < \pi\}$ . This is the **principal logarithm** of  $A$  and is written  $X = \log A$ . If  $A$  is real, then  $\log A$  is real.
2. If  $\rho(A) < 1$ ,

$$\log(I + A) = A - \frac{A^2}{2} + \frac{A^3}{3} - \frac{A^4}{4} + \dots$$

3.  $A \in \mathbb{R}^{n \times n}$  has a real logarithm if and only if  $A$  is nonsingular and  $A$  has an even number of Jordan blocks of each size for every negative eigenvalue.
4.  $\exp(\log A) = A$  holds when  $\log$  is defined on the spectrum of  $A \in \mathbb{C}^{n \times n}$ . But  $\log(\exp(A)) = A$  does not generally hold unless the spectrum of  $A$  is restricted.
5. If  $A \in \mathbb{C}^{n \times n}$  is nonsingular then  $\det(A) = \exp(\text{tr}(\log A))$ , where  $\log A$  is any logarithm of  $A$ .

**Examples:**

For the matrix

$$A = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 0 & 1 & 2 & 3 \\ 0 & 0 & 1 & 3 \\ 0 & 0 & 0 & 1 \end{bmatrix},$$

we have

$$\log(A) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 3 \\ 0 & 0 & 0 & 0 \end{bmatrix}.$$

## 11.5 Matrix Sine and Cosine

---

**Definitions:**

The sine and cosine of  $A \in \mathbb{C}^{n \times n}$  are defined by

$$\begin{aligned} \cos(A) &= I - \frac{A^2}{2!} + \dots + \frac{(-1)^k}{(2k)!} A^{2k} + \dots, \\ \sin(A) &= A - \frac{A^3}{3!} + \dots + \frac{(-1)^k}{(2k+1)!} A^{2k+1} + \dots. \end{aligned}$$

**Facts:**

Proofs of the facts in this subsection can be found in one or more of [Hig], [HJ91], or [LT85], unless otherwise stated.

1.  $\cos(2A) = 2 \cos^2(A) - I$ .
2.  $\sin(2A) = 2 \sin(A) \cos(A)$ .
3.  $\cos^2(A) + \sin^2(A) = I$ .
4. The differential equation

$$\frac{d^2 y}{dt^2} + Ay = 0, \quad y(0) = y_0, \quad y'(0) = y'_0$$

has solution

$$y(t) = \cos(\sqrt{A}t)y_0 + (\sqrt{A})^{-1} \sin(\sqrt{A}t)y'_0,$$

where  $\sqrt{A}$  denotes any square root of  $A$ .

**Examples:**

1. For

$$A = \begin{bmatrix} 0 & i\alpha \\ i\alpha & 0 \end{bmatrix},$$

we have

$$e^A = \begin{bmatrix} \cos \alpha & i \sin \alpha \\ i \sin \alpha & \cos \alpha \end{bmatrix}.$$

2. For

$$A = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 0 & -1 & -2 & -3 \\ 0 & 0 & 1 & 3 \\ 0 & 0 & 0 & -1 \end{bmatrix},$$

we have

$$\cos(A) = \cos(1)I, \quad \sin(A) = \begin{bmatrix} \sin(1) & \sin(1) & \sin(1) & \sin(1) \\ 0 & -\sin(1) & -2\sin(1) & -3\sin(1) \\ 0 & 0 & \sin(1) & 3\sin(1) \\ 0 & 0 & 0 & -\sin(1) \end{bmatrix},$$

and  $\sin^2(A) = \sin(1)^2 I$ , so  $\cos(A)^2 + \sin(A)^2 = I$ .

## 11.6 Matrix Sign Function

---

### Definitions:

If  $A = ZJ_A Z^{-1} \in \mathbb{C}^{n \times n}$  is a Jordan canonical form arranged so that

$$J_A = \begin{bmatrix} J_A^{(1)} & 0 \\ 0 & J_A^{(2)} \end{bmatrix},$$

where the eigenvalues of  $J_A^{(1)} \in \mathbb{C}^{p \times p}$  lie in the open left half-plane and those of  $J_A^{(2)} \in \mathbb{C}^{q \times q}$  lie in the open right half-plane, with  $p + q = n$ , then

$$\text{sign}(A) = Z \begin{bmatrix} -I_p & 0 \\ 0 & I_q \end{bmatrix} Z^{-1}.$$

Alternative formulas are

$$\begin{aligned} \text{sign}(A) &= A(A^2)^{-1/2}, \\ \text{sign}(A) &= \frac{2}{\pi} A \int_0^\infty (t^2 I + A^2)^{-1} dt. \end{aligned} \tag{11.6}$$

If  $A$  has any pure imaginary eigenvalues, then  $\text{sign}(A)$  is not defined.

### Facts:

Proofs of the facts in this section can be found in [Hig].

Let  $S = \text{sign}(A)$  be defined. Then

1.  $S^2 = I$  ( $S$  is involutory).
2.  $S$  is diagonalizable with eigenvalues  $\pm 1$ .
3.  $SA = AS$ .
4. If  $A$  is real, then  $S$  is real.
5. If  $A$  is symmetric positive definite, then  $\text{sign}(A) = I$ .

### Examples:

1. For the matrix  $A$  in Example 2 of the previous subsection we have  $\text{sign}(A) = A$ , which follows from (11.6) and the fact that  $A$  is involutory.

## 11.7 Computational Methods for General Functions

---

Many methods have been proposed for evaluating matrix functions. Three general approaches of wide applicability are outlined here. They have in common that they do not require knowledge of Jordan structure and are suitable for computer implementation. References for this subsection are [GVL96], [Hig].

### 1. Polynomial and Rational Approximations:

Polynomial approximations

$$p_m(X) = \sum_{k=0}^m b_k X^k, \quad b_k \in \mathbb{C}, \quad X \in \mathbb{C}^{n \times n},$$

to matrix functions can be obtained by truncating or economizing a power series representation, or by constructing a best approximation (in some norm) of a given degree. How to most efficiently evaluate a polynomial at a matrix argument is a nontrivial question. Possibilities include Horner's method, explicit computation of the powers of the matrix, and a method of Paterson and Stockmeyer [GVL96, Sec. 11.2.4], [PS73], which is a combination of these two methods that requires fewer matrix multiplications.

Rational approximations  $r_{mk}(X) = p_m(X)q_k(X)^{-1}$  are also widely used, particularly those arising from Padé approximation, which produces rationals matching as many terms of the Taylor series of the function at the origin as possible. The evaluation of rationals at matrix arguments needs careful consideration in order to find the best compromise between speed and accuracy. The main possibilities are

- Evaluating the numerator and denominator polynomials and then solving a multiple right-hand side linear system.
- Evaluating a continued fraction representation (in either top-down or bottom-up order).
- Evaluating a partial fraction representation.

Since polynomials and rationals are typically accurate over a limited range of matrices, practical methods involve a reduction stage prior to evaluating the polynomial or rational.

### 2. Factorization Methods:

Many methods are based on the property  $f(XAX^{-1}) = Xf(A)X^{-1}$ . If  $X$  can be found such that  $B = XAX^{-1}$  has the property that  $f(B)$  is easily evaluated, then an obvious method results. When  $A$  is diagonalizable,  $B$  can be taken to be diagonal, and evaluation of  $f(B)$  is trivial. In finite precision arithmetic, though, this approach is reliable only if  $X$  is well conditioned, that is, if the condition number  $\kappa(X) = \|X\|\|X^{-1}\|$  is not too large. Ideally,  $X$  will be unitary, so that in the 2-norm  $\kappa_2(X) = 1$ . For Hermitian  $A$ , or more generally normal  $A$ , the spectral decomposition  $A = QDQ^*$  with  $Q$  unitary and  $D$  diagonal is always possible, and if this decomposition can be computed then the formula  $f(A) = Qf(D)Q^*$  provides an excellent way of computing  $f(A)$ .

For general  $A$ , if  $X$  is restricted to be unitary, then the furthest that  $A$  can be reduced is to Schur form:  $A = QTQ^*$ , where  $Q$  is unitary and  $T$  upper triangular. This decomposition is computed by the QR algorithm. Computing a function of a triangular matrix is an interesting problem. While Fact 11 of section 11.1 gives an explicit formula for  $F = f(T)$ , the formula is not practically viable due to its exponential cost in  $n$ . Much more efficient is a recurrence of Parlett [Par76]. This is derived by starting with the observation that since  $F$  is representable as a polynomial in  $T$ ,  $F$  is upper triangular, with diagonal elements  $f(t_{ii})$ . The elements in the strict upper triangle are determined by solving the equation  $FT = TF$ . Parlett's recurrence is:

**Algorithm 1.** Parlett's recurrence.

```

 $f_{ii} = f(t_i), i = 1:n$ 
for  $j = 2:n$ 
  for  $i = j - 1:-1:1$ 
     $f_{ij} = t_{ij} \frac{f_{ii} - f_{jj}}{t_{ii} - t_{jj}} + \left( \sum_{k=i+1}^{j-1} f_{ik}t_{kj} - t_{ik}f_{kj} \right) / (t_{ii} - t_{jj})$ 
  end
end

```

This recurrence can be evaluated in  $2n^3/3$  operations. The recurrence breaks down when  $t_{ii} = t_{jj}$  for some  $i \neq j$ . In this case,  $T$  can be regarded as a block matrix  $T = (T_{ij})$ , with square diagonal blocks, possibly of different sizes.  $T$  can be reordered so that no two diagonal blocks have an eigenvalue in common; reordering means applying a unitary similarity transformation to permute the diagonal elements whilst preserving triangularity. Then a block form of the recurrence can be employed. This requires the evaluation of the diagonal blocks  $F_{ii} = f(T_{ii})$ , where  $T_{ii}$  will typically be of small dimension. A general way to obtain  $F_{ii}$  is via a Taylor series. The use of the block Parlett recurrence in combination with a Schur decomposition represents the state of the art in evaluation of  $f(A)$  for general functions [DH03].

### 3. Iteration Methods:

Several matrix functions  $f$  can be computed by iteration:

$$X_{k+1} = g(X_k), \quad X_0 = A, \quad (11.7)$$

where, for reasons of computational cost,  $g$  is usually a polynomial or a rational function. Such an iteration might converge for all  $A$  for which  $f$  is defined, or just for a subset of such  $A$ . A standard means of deriving matrix iterations is to apply Newton's method to an algebraic equation satisfied by  $f(A)$ . The iterations most used in practice are quadratically convergent, but iterations with higher orders of convergence are known.

### 4. Contour Integration:

The Cauchy integral definition (11.5) provides a way to compute or approximate  $f(A)$  via contour integration. While not suitable as a practical method for all functions or all matrices, this approach can be effective when numerical integration is done over a suitable contour using the repeated trapezium rule, whose high accuracy properties for periodic functions integrated over a whole period are beneficial [DH05], [TW05].

## 11.8 Computational Methods for Specific Functions

Some methods specialized to particular functions are now outlined. References for this section are [GVL96], [Hig].

### 1. Matrix Exponential:

A large number of methods have been proposed for the matrix exponential, many of them of pedagogic interest only or of dubious numerical stability. Some of the more computationally useful methods are surveyed in [MVL03]. Probably the best general-purpose method is the scaling and squaring method. In this method an integral power of 2,  $\sigma = 2^s$  say, is chosen so that  $A/\sigma$  has norm not too far from 1. The exponential of the scaled matrix is approximated by an  $[m/m]$  Padé approximant,  $e^{A/2^s} \approx r_{mm}(A/2^s)$ , and then  $s$  repeated squarings recover an approximation to  $e^A$ :  $e^A \approx r_{mm}(A/2^s)^{2^s}$ . Symmetries in the Padé

approximant permit an efficient evaluation of  $r_{mm}(A)$ . The scaling and squaring method was originally developed in [MVL78] and [War77], and it is the method employed by MATLAB's `xpm` function. How best to choose  $\sigma$  and  $m$  is described in [Hig05].

2. *Matrix Logarithm:*

The (principal) matrix logarithm can be computed using an inverse scaling and squaring method based on the identity  $\log A = 2^k \log A^{1/2^k}$ , where  $A$  is assumed to have no eigenvalues on  $\mathbb{R}^-$ . Square roots are taken to make  $\|A^{1/2^k} - I\|$  small enough that an  $[m/m]$  Padé approximant approximates  $\log A^{1/2^k}$  sufficiently accurately, for some suitable  $m$ . Then  $\log A$  is recovered by multiplying by  $2^k$ . To reduce the cost of computing the square roots and evaluating the Padé approximant, a Schur decomposition can be computed initially so that the method works with a triangular matrix. For details, see [CHKL01], [Hig01], or [KL89, App. A].

3. *Matrix Cosine and Sine:*

A method analogous to the scaling and squaring method for the exponential is the standard method for computing the matrix cosine. The idea is again to scale  $A$  to have norm not too far from 1 and then compute a Padé approximant. The difference is that the scaling is undone by repeated use of the double-angle formula  $\cos(2A) = 2 \cos^2 A - I$ , rather than by repeated squaring. The sine function can be obtained as  $\sin(A) = \cos(A - \frac{\pi}{2}I)$ . (See [SB80], [HS03], [HH05].)

4. *Matrix Square Root:*

The most numerically reliable way to compute matrix square roots is via the Schur decomposition,  $A = QTQ^*$  [BH83]. Rather than use the Parlett recurrence, a square root  $U$  of the upper triangular factor  $T$  can be computed by directly solving the equation  $U^2 = T$ . The choices of sign in the diagonal of  $U$ ,  $u_{ii} = \sqrt{t_{ii}}$ , determine which square root is obtained. When  $A$  is real, the real Schur decomposition can be used to compute real square roots entirely in real arithmetic [Hig87].

Various iterations exist for computing the principal square root when  $A$  has no eigenvalues on  $\mathbb{R}^-$ . The basic Newton iteration,

$$X_{k+1} = \frac{1}{2}(X_k + X_k^{-1}A), \quad X_0 = A, \tag{11.8}$$

is quadratically convergent, but is numerically unstable unless  $A$  is extremely well conditioned and its use is not recommended [Hig86]. Stable alternatives include the Denman–Beavers iteration [DB76]

$$\begin{aligned} X_{k+1} &= \frac{1}{2}(X_k + Y_k^{-1}), & X_0 &= A, \\ Y_{k+1} &= \frac{1}{2}(Y_k + X_k^{-1}), & Y_0 &= I, \end{aligned}$$

for which  $\lim_{k \rightarrow \infty} X_k = A^{1/2}$  and  $\lim_{k \rightarrow \infty} Y_k = A^{-1/2}$ , and the Meini iteration [Mei04]

$$\begin{aligned} Y_{k+1} &= -Y_k Z_k^{-1} Y_k, & Y_0 &= I - A, \\ Z_{k+1} &= Z_k + 2Y_{k+1}, & Z_0 &= 2(I + A), \end{aligned}$$

for which  $Y_k \rightarrow 0$  and  $Z_k \rightarrow 4A^{1/2}$ . Both of these iterations are mathematically equivalent to (11.8) and, hence, are quadratically convergent.

An iteration not involving matrix inverses is the Schulz iteration

$$\begin{aligned} Y_{k+1} &= \frac{1}{2}Y_k(3I - Z_k Y_k), & Y_0 &= A, \\ Z_{k+1} &= \frac{1}{2}(3I - Z_k Y_k)Z_k, & Z_0 &= I, \end{aligned}$$

for which  $Y_k \rightarrow A^{1/2}$  and  $Z_k \rightarrow A^{-1/2}$  quadratically provided that  $\|\text{diag}(A - I, A - I)\| < 1$ , where the norm is any consistent matrix norm [Hig97].

### 5. Matrix Sign Function:

The standard method for computing the matrix sign function is the Newton iteration

$$X_{k+1} = \frac{1}{2}(X_k + X_k^{-1}), \quad X_0 = A,$$

which converges quadratically to  $\text{sign}(A)$ , provided  $A$  has no pure imaginary eigenvalues. In practice, a scaled iteration

$$X_{k+1} = \frac{1}{2}(\mu_k X_k + \mu_k^{-1} X_k^{-1}), \quad X_0 = A$$

is used, where the scale parameters  $\mu_k$  are chosen to reduce the number of iterations needed to enter the regime where asymptotic quadratic convergence sets in. (See [Bye87], [KL92].)

The Newton–Schulz iteration

$$X_{k+1} = \frac{1}{2}X_k(3I - X_k^2), \quad X_0 = A,$$

involves no matrix inverses, but convergence is guaranteed only for  $\|I - A^2\| < 1$ .

A Padé family of iterations

$$X_{k+1} = X_k p_{\ell m} (1 - X_k^2) q_{\ell m} (1 - X_k^2)^{-1}, \quad X_0 = A$$

is obtained in [KL91], where  $p_{\ell m}(\xi)/q_{\ell m}(\xi)$  is the  $[\ell/m]$  Padé approximant to  $(1 - \xi)^{-1/2}$ . The iteration is globally convergent to  $\text{sign}(A)$  for  $\ell = m - 1$  and  $\ell = m$ , and for  $\ell \geq m - 1$  is convergent when  $\|I - A^2\| < 1$ , with order of convergence  $\ell + m + 1$  in all cases.

	References .....	12-9

Bilinear forms are maps defined on  $V \times V$ , where  $V$  is a vector space, and are linear with respect to each of their variables. There are some similarities between bilinear forms and inner products that are discussed in Chapter 5. Basic properties of bilinear forms, symmetric bilinear forms, and alternating bilinear forms are discussed. The latter two types of forms satisfy additional symmetry conditions.

Quadratic forms are obtained from symmetric bilinear forms by equating the two variables. They are widely used in many areas. A canonical representation of a quadratic form is given when the underlying field is  $\mathbb{R}$  or  $\mathbb{C}$ .

When the field is the complex numbers, it is standard to expect the form to be conjugate linear rather than linear in the second variable; such a form is called sesquilinear. The role of a symmetric bilinear form is played by a Hermitian sesquilinear form. The idea of a sesquilinear form can be generalized to an arbitrary automorphism, encompassing both bilinear and sesquilinear forms as  $\varphi$ -sesquilinear forms, where  $\varphi$  is an automorphism of the field.

Quadratic, bilinear, and  $\varphi$ -sesquilinear forms have applications to classical matrix groups. (See Chapter 67 for more information.)

### 12.1 Bilinear Forms

---

It is assumed throughout this section that  $V$  is a finite dimensional vector space over a field  $F$ .

#### Definitions:

A **bilinear form** on  $V$  is a map  $f$  from  $V \times V$  into  $F$  which satisfies

$$f(a\mathbf{u}_1 + b\mathbf{u}_2, \mathbf{v}) = af(\mathbf{u}_1, \mathbf{v}) + bf(\mathbf{u}_2, \mathbf{v}), \quad \mathbf{u}_1, \mathbf{u}_2, \mathbf{v} \in V, \quad a, b \in F,$$

and

$$f(\mathbf{u}, a\mathbf{v}_1 + b\mathbf{v}_2) = af(\mathbf{u}, \mathbf{v}_1) + bf(\mathbf{u}, \mathbf{v}_2), \quad \mathbf{u}, \mathbf{v}_1, \mathbf{v}_2 \in V, \quad a, b \in F.$$

The space of all bilinear forms on  $V$  is denoted  $B(V, V, F)$ .

Let  $\mathcal{B} = (\mathbf{w}_1, \mathbf{w}_2, \dots, \mathbf{w}_n)$  be an ordered basis of  $V$  and let  $f \in B(V, V, F)$ . **The matrix representing  $f$  relative to  $\mathcal{B}$**  is the matrix  $A = [a_{ij}] \in F^{n \times n}$  such that  $a_{ij} = f(\mathbf{w}_i, \mathbf{w}_j)$ .

The **rank** of  $f \in B(V, V, F)$ ,  $\text{rank}(f)$ , is  $\text{rank}(A)$ , where  $A$  is a matrix representing  $f$  relative to an arbitrary ordered basis of  $V$ .

$f \in B(V, V, F)$  is **nondegenerate** if its rank is equal to  $\dim V$ , and **degenerate** if it is not nondegenerate.

Let  $A, B \in F^{n \times n}$ .  $B$  is **congruent** to  $A$  if there exists an invertible  $P \in F^{n \times n}$  such that  $B = P^T A P$ .

Let  $f, g \in B(V, V, F)$ .  $g$  is **equivalent** to  $f$  if there exists an ordered basis  $\mathcal{B}$  of  $V$  such that the matrix of  $g$  relative to  $\mathcal{B}$  is congruent to the matrix of  $f$  relative to  $\mathcal{B}$ .

Let  $T$  be a linear operator on  $V$  and let  $f \in B(V, V, F)$ .  $T$  **preserves**  $f$  if  $f(T\mathbf{u}, T\mathbf{v}) = f(\mathbf{u}, \mathbf{v})$  for all  $\mathbf{u}, \mathbf{v} \in V$ .

### Facts:

Let  $f \in B(V, V, F)$ . The following facts can be found in [HK71, Chap. 10].

1.  $f$  is a linear functional in each of its variables when the other variable is held fixed.
2. Let  $\mathcal{B} = (\mathbf{w}_1, \mathbf{w}_2, \dots, \mathbf{w}_n)$  be an ordered basis of  $V$  and let

$$\mathbf{u} = \sum_{i=1}^n a_i \mathbf{w}_i, \quad \mathbf{v} = \sum_{i=1}^n b_i \mathbf{w}_i.$$

Then,

$$f(\mathbf{u}, \mathbf{v}) = \sum_{i=1}^n \sum_{j=1}^n a_i b_j f(\mathbf{w}_i, \mathbf{w}_j).$$

3. Let  $A$  denote the matrix representing  $f$  relative to  $\mathcal{B}$ , and let  $[\mathbf{u}]_{\mathcal{B}}$  and  $[\mathbf{v}]_{\mathcal{B}}$  be the vectors in  $F^n$  that are the coordinate vectors of  $\mathbf{u}$  and  $\mathbf{v}$ , respectively, with respect to  $\mathcal{B}$ . Then  $f(\mathbf{u}, \mathbf{v}) = [\mathbf{u}]_{\mathcal{B}}^T A [\mathbf{v}]_{\mathcal{B}}$ .
4. Let  $\mathcal{B}$  and  $\mathcal{B}'$  be ordered bases of  $V$ , and  $P$  be the matrix whose columns are the  $\mathcal{B}$ -coordinates of vectors in  $\mathcal{B}'$ . Let  $f \in B(V, V, F)$ . Let  $A$  and  $B$  denote the matrices representing  $f$  relative to  $\mathcal{B}$  and  $\mathcal{B}'$ . Then

$$B = P^T A P.$$

5. The concept of rank of  $f$ , as given, is well defined.
6. The set  $L = \{\mathbf{v} \in V : f(\mathbf{u}, \mathbf{v}) = 0 \text{ for all } \mathbf{u} \in V\}$  is a subspace of  $V$  and  $\text{rank}(f) = \dim V - \dim L$ . In particular,  $f$  is nondegenerate if and only if  $L = \{0\}$ .
7. Suppose that  $\dim V = n$ . The space  $B(V, V, F)$  is a vector space over  $F$  under the obvious addition of two bilinear forms and multiplication of a bilinear form by a scalar. Moreover,  $B(V, V, F)$  is isomorphic to  $F^{n \times n}$ .
8. Congruence is an equivalence relation on  $F^{n \times n}$ .
9. Let  $f \in B(V, V, F)$  be nondegenerate. Then the set of all linear operators on  $V$ , which preserve  $f$ , is a group under the operation of composition.

### Examples:

1. Let  $A \in F^{n \times n}$ . The map  $f : F^n \times F^n \rightarrow F$  defined by

$$f(\mathbf{u}, \mathbf{v}) = \mathbf{u}^T A \mathbf{v} = \sum_{i=1}^n \sum_{j=1}^n a_{ij} u_i v_j, \quad \mathbf{u}, \mathbf{v} \in F^n,$$

is a bilinear form. Since  $f(\mathbf{e}_i, \mathbf{e}_j) = a_{ij}$ ,  $i, j = 1, 2, \dots, n$ ,  $f$  is represented in the standard basis of  $F^n$  by  $A$ . It follows that  $\text{rank}(f) = \text{rank}(A)$ , and  $f$  is nondegenerate if and only if  $A$  is invertible.

2. Let  $C \in F^{m \times m}$  and  $\text{rank}(C) = k$ . The map  $f : F^{m \times n} \times F^{m \times n} \rightarrow F$  defined by  $f(A, B) = \text{tr}(A^T C B)$  is a bilinear form. This follows immediately from the basic properties of the trace function. To compute  $\text{rank}(f)$ , let  $L$  be defined as in Fact 6, that is,  $L = \{B \in F^{m \times n} : \text{tr}(A^T C B) = 0 \text{ for all } A \in F^{m \times n}\}$ . It follows that  $L = \{B \in F^{m \times n} : C B = 0\}$ , which implies that  $\dim L = n(m - k)$ . Hence,  $\text{rank}(f) = mn - n(m - k) = kn$ . In particular,  $f$  is nondegenerate if and only if  $C$  is invertible.
3. Let  $\mathbb{R}[x; n]$  denote the space of all real polynomials of the form  $\sum_{i=0}^n a_i x^i$ . Then  $f(p(x), q(x)) = p(0)q(0) + p(1)q(1) + p(2)q(2)$  is a bilinear form on  $\mathbb{R}[x; n]$ . It is nondegenerate if  $n = 2$  and degenerate if  $n \geq 3$ .

## 12.2 Symmetric Bilinear Forms

It is assumed throughout this section that  $V$  is a finite dimensional vector space over a field  $F$ .

### Definitions:

Let  $f \in B(V, V, F)$ . Then  $f$  is **symmetric** if  $f(\mathbf{u}, \mathbf{v}) = f(\mathbf{v}, \mathbf{u})$  for all  $\mathbf{u}, \mathbf{v} \in V$ .

Let  $f$  be a symmetric bilinear form on  $V$ , and let  $\mathbf{u}, \mathbf{v} \in V$ ;  $\mathbf{u}$  and  $\mathbf{v}$  are **orthogonal with respect to  $f$**  if  $f(\mathbf{u}, \mathbf{v}) = 0$ .

Let  $f$  be a symmetric bilinear form on  $V$ . The **quadratic form corresponding to  $f$**  is the map  $g : V \rightarrow F$  defined by  $g(\mathbf{v}) = f(\mathbf{v}, \mathbf{v})$ ,  $\mathbf{v} \in V$ .

A symmetric bilinear form  $f$  on a real vector space  $V$  is **positive semidefinite (positive definite)** if  $f(\mathbf{v}, \mathbf{v}) \geq 0$  for all  $\mathbf{v} \in V$  ( $f(\mathbf{v}, \mathbf{v}) > 0$  for all  $0 \neq \mathbf{v} \in V$ ).

$f$  is **negative semidefinite (negative definite)** if  $-f$  is positive semidefinite (positive definite).

The **signature** of a real symmetric matrix  $A$  is the integer  $\pi - \nu$ , where  $(\pi, \nu, \delta)$  is the inertia of  $A$ . (See Section 8.3.)

The **signature** of a real symmetric bilinear form is the signature of a matrix representing the form relative to some basis.

### Facts:

Additional facts about real symmetric matrices can be found in Chapter 8. Except where another reference is provided, the following facts can be found in [Coh89, Chap. 8], [HJ85, Chap. 4], or [HK71, Chap. 10].

1. A positive definite bilinear form is nondegenerate.
2. An inner product on a real vector space is a positive definite symmetric bilinear form. Conversely, a positive definite symmetric bilinear form on a real vector space is an inner product.
3. Let  $\mathcal{B}$  be an ordered basis of  $V$  and let  $f \in B(V, V, F)$ . Let  $A$  be the matrix representing  $f$  relative to  $\mathcal{B}$ . Then  $f$  is symmetric if and only if  $A$  is a symmetric matrix, that is,  $A = A^T$ .
4. Let  $f$  be a symmetric bilinear form on  $V$  and let  $g$  be the quadratic form corresponding to  $f$ . Suppose that the characteristic of  $F$  is not 2. Then  $f$  can be recovered from  $g$ :

$$f(\mathbf{u}, \mathbf{v}) = \frac{1}{2}[g(\mathbf{u} + \mathbf{v}) - g(\mathbf{u}) - g(\mathbf{v})] \quad \text{for all } \mathbf{u}, \mathbf{v} \in V.$$

5. Let  $f$  be a symmetric bilinear form on  $V$  and suppose that the characteristic of  $F$  is not 2. Then there exists an ordered basis  $\mathcal{B}$  of  $V$  such that the matrix representing  $f$  relative to it is diagonal; i.e., if  $A \in F^{n \times n}$  is a symmetric matrix, then  $A$  is congruent to a diagonal matrix.
6. Suppose that  $V$  is a complex vector space and  $f$  is a symmetric bilinear form on  $V$ . Let  $r = \text{rank}(f)$ . Then there is an ordered basis  $\mathcal{B}$  of  $V$  such that the matrix representing  $f$  relative to  $\mathcal{B}$  is  $I_r \oplus \mathbf{0}$ . In matrix language, this fact states that if  $A \in \mathbb{C}^{n \times n}$  is symmetric with  $\text{rank}(A) = r$ , then it is congruent to  $I_r \oplus \mathbf{0}$ .
7. The only invariant of  $n \times n$  complex symmetric matrices under congruence is the rank.
8. Two complex  $n \times n$  symmetric matrices are congruent if and only if they have the same rank.

9. (*Sylvester's law of inertia for symmetric bilinear forms*) Suppose that  $V$  is a real vector space and  $f$  is a symmetric bilinear form on  $V$ . Then there is an ordered basis  $\mathcal{B}$  of  $V$  such that the matrix representing  $f$  relative to it has the form  $I_\pi \oplus -I_\nu \oplus \mathbf{0}_\delta$ . Moreover,  $\pi, \nu$ , and  $\delta$  do not depend on the choice of  $\mathcal{B}$ , but only on  $f$ .
10. (*Sylvester's law of inertia for matrices*) If  $A \in \mathbb{R}^{n \times n}$  is symmetric, then  $A$  is congruent to the diagonal matrix  $D = I_\pi \oplus -I_\nu \oplus \mathbf{0}_\delta$ , where  $(\pi, \nu, \delta) = \text{in}(A)$ .
11. There are exactly two invariants of  $n \times n$  real symmetric matrices under congruence, namely the rank and the signature.
12. Two real  $n \times n$  symmetric matrices are congruent if and only if they have the same rank and the same signature.
13. The signature of a real symmetric bilinear form is well defined.
14. Two real symmetric bilinear forms are equivalent if and only if they have the same rank and the same signature.
15. [Hes68] Let  $n \geq 3$  and let  $A, B \in \mathbb{R}^{n \times n}$  be symmetric. Suppose that  $\mathbf{x} \in \mathbb{R}^n$ ,  $\mathbf{x}^T A \mathbf{x} = \mathbf{x}^T B \mathbf{x} = 0 \Rightarrow \mathbf{x} = \mathbf{0}$ . Then  $\exists \mathbf{a}, \mathbf{b} \in \mathbb{R}$  such that  $\mathbf{a}A + \mathbf{b}B$  is positive definite.
16. The group of linear operators preserving the form  $f(\mathbf{u}, \mathbf{v}) = \sum_{i=1}^n u_i v_i$  on  $\mathbb{R}^n$  is the real  $n$ -dimensional orthogonal group, while the group preserving the same form on  $\mathbb{C}^n$  is the complex  $n$ -dimensional orthogonal group.

### Examples:

1. Consider Example 1 in section 12.1. The map  $f$  is a symmetric bilinear form if and only if  $A = A^T$ . The quadratic form  $g$  corresponding to  $f$  is given by

$$g(\mathbf{u}) = \sum_{i=1}^n \sum_{j=1}^n a_{ij} u_i u_j, \quad \mathbf{u} \in F^n.$$

2. Consider Example 2 in section 12.1. The map  $f$  is a symmetric bilinear form if and only if  $C = C^T$ .
3. The symmetric bilinear form  $f_a$  on  $\mathbb{R}^2$  given by

$$f_a(\mathbf{u}, \mathbf{v}) = u_1 v_1 - 2u_1 v_2 - 2u_2 v_1 + a u_2 v_2, \quad \mathbf{u}, \mathbf{v} \in \mathbb{R}^2, \quad a \in \mathbb{R} \text{ is a parameter,}$$

is an inner product on  $\mathbb{R}^2$  if and only if  $a > 4$ .

4. Since we consider in this article only finite dimensional vector spaces, let  $V$  be any finite dimensional subspace of  $C[0, 1]$ , the space of all real valued, continuous functions on  $[0, 1]$ . Then the map  $f : V \times V \rightarrow \mathbb{R}$  defined by

$$f(\mathbf{u}, \mathbf{v}) = \int_0^1 t^3 u(t)v(t)dt, \quad \mathbf{u}, \mathbf{v} \in V,$$

is a symmetric bilinear form on  $V$ .

### Applications:

1. Conic sections: Consider the set of points  $(x_1, x_2)$  in  $\mathbb{R}^2$ , which satisfy the equation

$$ax_1^2 + bx_1x_2 + cx_2^2 + dx_1 + ex_2 + f = 0,$$

where  $a, b, c, d, e, f \in \mathbb{R}$ . The solution set is a conic section, namely an ellipse, hyperbola, parabola, or a degenerate form of those. The analysis of this equation depends heavily on the quadratic form

$ax_1^2 + bx_1x_2 + cx_2^2$ , which is represented in the standard basis of  $\mathbb{R}^2$  by  $A = \begin{bmatrix} a & b/2 \\ b/2 & c \end{bmatrix}$ . If the

solution of the quadratic equation above represents a nondegenerate conic section, then its type is determined by the sign of  $4ac - b^2$ . More precisely, the conic is an ellipse, hyperbola, or parabola if  $4ac - b^2$  is positive, negative, or zero, respectively.

2. Theory of small oscillations: Suppose a mechanical system undergoes small oscillations about an equilibrium position. Let  $x_1, x_2, \dots, x_n$  denote the coordinates of the system, and let  $\mathbf{x} = (x_1, x_2, \dots, x_n)^T$ . Then the kinetic energy of the system is given by a quadratic form (in the velocities  $\dot{x}_1, \dot{x}_2, \dots, \dot{x}_n$ )  $\frac{1}{2}\dot{\mathbf{x}}^T A \dot{\mathbf{x}}$ , where  $A$  is a positive definite matrix. If  $\mathbf{x} = \mathbf{0}$  is the equilibrium position, then the potential energy of the system is given by another quadratic form  $\frac{1}{2}\mathbf{x}^T B \mathbf{x}$ , where  $B = B^T$ . The equations of motion are  $A\ddot{\mathbf{x}} + B\dot{\mathbf{x}} = \mathbf{0}$ . It is known that  $A$  and  $B$  can be simultaneously diagonalized, that is, there exists an invertible  $P \in \mathbb{R}^{n \times n}$  such that  $P^T A P$  and  $P^T B P$  are diagonal matrices. This can be used to obtain the solution of the system.

### 12.3 Alternating Bilinear Forms

It is assumed throughout this section that  $V$  is a finite dimensional vector space over a field  $F$ .

**Definitions:**

Let  $f \in B(V, V, F)$ . Then  $f$  is **alternating** if  $f(\mathbf{v}, \mathbf{v}) = 0$  for all  $\mathbf{v} \in V$ .  $f$  is **antisymmetric** if  $f(\mathbf{u}, \mathbf{v}) = -f(\mathbf{v}, \mathbf{u})$  for all  $\mathbf{u}, \mathbf{v} \in V$ .

Let  $A \in F^{n \times n}$ . Then  $A$  is **alternating** if  $a_{ii} = 0, i = 1, 2, \dots, n$  and  $a_{ji} = -a_{ij}, 1 \leq i < j \leq n$ .

**Facts:**

The following facts can be found in [Coh89, Chap. 8], [HK71, Chap. 10], or [Lan99, Chap. 15].

1. Let  $f \in B(V, V, F)$  be alternating. Then  $f$  is antisymmetric because for all  $\mathbf{u}, \mathbf{v} \in V$ ,

$$f(\mathbf{u}, \mathbf{v}) + f(\mathbf{v}, \mathbf{u}) = f(\mathbf{u} + \mathbf{v}, \mathbf{u} + \mathbf{v}) - f(\mathbf{u}, \mathbf{u}) - f(\mathbf{v}, \mathbf{v}) = 0.$$

The converse is true if the characteristic of  $F$  is not 2.

2. Let  $A \in F^{n \times n}$  be an alternating matrix. Then  $A^T = -A$ . The converse is true if the characteristic of  $F$  is not 2.
3. Let  $\mathcal{B}$  be an ordered basis of  $V$  and let  $f \in B(V, V, F)$ . Let  $A$  be the matrix representing  $f$  relative to  $\mathcal{B}$ . Then  $f$  is alternating if and only if  $A$  is an alternating matrix.
4. Let  $f$  be an alternating bilinear form on  $V$  and let  $r = \text{rank}(f)$ . Then  $r$  is even and there exists an ordered basis  $\mathcal{B}$  of  $V$  such that the matrix representing  $f$  relative to it has the form

$$\underbrace{\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \oplus \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \oplus \cdots \oplus \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}}_{r/2 \text{ - times}} \oplus \mathbf{0}.$$

There is an ordered basis  $\mathcal{B}_1$  where  $f$  is represented by the matrix  $\begin{bmatrix} \mathbf{0} & I_{r/2} \\ -I_{r/2} & \mathbf{0} \end{bmatrix} \oplus \mathbf{0}$ .

5. Let  $f \in B(V, V, F)$  and suppose that the characteristic of  $F$  is not 2. Define:
 
$$f_1 : V \times V \rightarrow F \text{ by } f_1(\mathbf{u}, \mathbf{v}) = \frac{1}{2} [f(\mathbf{u}, \mathbf{v}) + f(\mathbf{v}, \mathbf{u})], \mathbf{u}, \mathbf{v} \in V,$$

$$f_2 : V \times V \rightarrow F \text{ by } f_2(\mathbf{u}, \mathbf{v}) = \frac{1}{2} [f(\mathbf{u}, \mathbf{v}) - f(\mathbf{v}, \mathbf{u})], \mathbf{u}, \mathbf{v} \in V.$$
 Then  $f_1$  ( $f_2$ ) is a symmetric (alternating) bilinear form on  $V$ , and  $f = f_1 + f_2$ . Moreover, this representation of  $f$  as a sum of a symmetric and an alternating bilinear form is unique.
6. Let  $A \in F^{n \times n}$  be an alternating matrix and suppose that  $A$  is invertible. Then  $n$  is even and  $A$  is congruent to the matrix  $\begin{bmatrix} \mathbf{0} & I_{n/2} \\ -I_{n/2} & \mathbf{0} \end{bmatrix}$ , so  $\det(A)$  is a square in  $F$ . There exists a polynomial in  $n(n-1)/2$  variables, called the **Pfaffian**, such that  $\det(A) = a^2$ , where  $a \in F$  is obtained by substituting into the Pfaffian the entries of  $A$  above the main diagonal for the indeterminates.

7. Let  $f$  be an alternating nondegenerate bilinear form on  $V$ . Then  $\dim V = 2m$  for some positive integer  $m$ . The group of all linear operators on  $V$  that preserve  $f$  is the symplectic group.

**Examples:**

1. Consider Example 1 in section 12.1. The map  $f$  is alternating if and only if the matrix  $A$  is an alternating matrix.
2. Consider Example 2 in section 12.1. The map  $f$  is alternating if and only if  $C$  is an alternating matrix.
3. Let  $C \in F^{n \times n}$ . Define  $f : F^{n \times n} \rightarrow F^{n \times n}$  by  $f(A, B) = \text{tr}(ACB - BCA)$ . Then  $f$  is alternating.

## 12.4 $\varphi$ -Sesquilinear Forms

This section generalizes Section 12.1, and is consequently very similar. This generalization is required by applications to matrix groups (see Chapter 67), but for most purposes such generality is not required, and the simpler discussion of bilinear forms in Section 12.1 is preferred. It is assumed throughout this section that  $V$  is a finite dimensional vector space over a field  $F$  and  $\varphi$  is an automorphism of  $F$ .

**Definitions:**

A  $\varphi$ -**sesquilinear form** on  $V$  is a map  $f : V \times V \rightarrow F$ , which is linear as a function in the first variable and  $\varphi$ -semilinear in the second, i.e.,

$$f(a\mathbf{u}_1 + b\mathbf{u}_2, \mathbf{v}) = af(\mathbf{u}_1, \mathbf{v}) + bf(\mathbf{u}_2, \mathbf{v}), \quad \mathbf{u}_1, \mathbf{u}_2, \mathbf{v} \in V, \quad a, b \in F,$$

and

$$f(\mathbf{u}, a\mathbf{v}_1 + b\mathbf{v}_2) = \varphi(a)f(\mathbf{u}, \mathbf{v}_1) + \varphi(b)f(\mathbf{u}, \mathbf{v}_2), \quad \mathbf{u}, \mathbf{v}_1, \mathbf{v}_2 \in V, \quad a, b \in F.$$

In the case  $F = \mathbb{C}$  and  $\varphi$  is complex conjugation, a  $\varphi$ -sesquilinear form is called a **sesquilinear form**. The space of all  $\varphi$ -sesquilinear forms on  $V$  is denoted  $B(V, V, F, \varphi)$ .

Let  $\mathcal{B} = (\mathbf{w}_1, \mathbf{w}_2, \dots, \mathbf{w}_n)$  be an ordered basis of  $V$  and let  $f \in B(V, V, F, \varphi)$ . The **matrix representing  $f$  relative to  $\mathcal{B}$**  is the matrix  $A = [a_{ij}] \in F^{n \times n}$  such that  $a_{ij} = f(\mathbf{w}_i, \mathbf{w}_j)$ .

The **rank** of  $f \in B(V, V, F, \varphi)$ ,  $\text{rank}(f)$ , is  $\text{rank}(A)$ , where  $A$  is a matrix representing  $f$  relative to an arbitrary ordered basis of  $V$ .

$f \in B(V, V, F, \varphi)$  is **nondegenerate** if its rank is equal to  $\dim V$ , and **degenerate** if it is not nondegenerate.

Let  $A = [a_{ij}] \in F^{n \times n}$ .  $\varphi(A)$  is the  $n \times n$  matrix whose  $i, j$ -entry is  $\varphi(a_{ij})$ .

Let  $A, B \in F^{n \times n}$ .  $B$  is  $\varphi$ -**congruent** to  $A$  if there exists an invertible  $P \in F^{n \times n}$  such that  $B = P^T A \varphi(P)$ .

Let  $f, g \in B(V, V, F, \varphi)$ .  $g$  is  $\varphi$ -**equivalent** to  $f$  if there exists an ordered basis  $\mathcal{B}$  of  $V$  such that the matrix of  $g$  relative to  $\mathcal{B}$  is  $\varphi$ -congruent to the matrix of  $f$  relative to  $\mathcal{B}$ .

Let  $T$  be a linear operator on  $V$  and let  $f \in B(V, V, F, \varphi)$ .  $T$  **preserves**  $f$  if  $f(T\mathbf{u}, T\mathbf{v}) = f(\mathbf{u}, \mathbf{v})$  for all  $\mathbf{u}, \mathbf{v} \in V$ .

**Facts:**

Let  $f \in B(V, V, F, \varphi)$ . The following facts can be obtained by obvious generalizations of the proofs of the corresponding facts in section 12.1; see that section for references.

1. A bilinear form is a  $\varphi$ -sesquilinear form with the automorphism being the identity map.
2. Let  $\mathcal{B} = (\mathbf{w}_1, \mathbf{w}_2, \dots, \mathbf{w}_n)$  be an ordered basis of  $V$  and let

$$\mathbf{u} = \sum_{i=1}^n a_i \mathbf{w}_i, \quad \mathbf{v} = \sum_{i=1}^n b_i \mathbf{w}_i.$$

Then,

$$f(\mathbf{u}, \mathbf{v}) = \sum_{i=1}^n \sum_{j=1}^n a_i \varphi(b_j) f(\mathbf{w}_i, \mathbf{w}_j).$$

3. Let  $A$  denote the matrix representing the  $\varphi$ -sesquilinear  $f$  relative to  $\mathcal{B}$ , and let  $[\mathbf{u}]_{\mathcal{B}}$  and  $[\mathbf{v}]_{\mathcal{B}}$  be the vectors in  $F^n$ , which are the coordinate vectors of  $\mathbf{u}$  and  $\mathbf{v}$ , respectively, with respect to  $\mathcal{B}$ . Then  $f(\mathbf{u}, \mathbf{v}) = [\mathbf{u}]_{\mathcal{B}}^T A \varphi([\mathbf{v}]_{\mathcal{B}})$ .
4. Let  $\mathcal{B}$  and  $\mathcal{B}'$  be ordered bases of  $V$ , and  $P$  be the matrix whose columns are the  $\mathcal{B}$ -coordinates of vectors in  $\mathcal{B}'$ . Let  $f \in B(V, V, F, \varphi)$ . Let  $A$  and  $B$  denote the matrices representing  $f$  relative to  $\mathcal{B}$  and  $\mathcal{B}'$ . Then

$$B = P^T A \varphi(P).$$

5. The concept of rank of  $f$ , as given, is well defined.
6. The set  $L = \{\mathbf{v} \in V : f(\mathbf{u}, \mathbf{v}) = 0 \text{ for all } \mathbf{u} \in V\}$  is a subspace of  $V$  and  $\text{rank}(f) = \dim V - \dim L$ . In particular,  $f$  is nondegenerate if and only if  $L = \{0\}$ .
7. Suppose that  $\dim V = n$ . The space  $B(V, V, F, \varphi)$  is a vector space over  $F$  under the obvious addition of two  $\varphi$ -sesquilinear forms and multiplication of a  $\varphi$ -sesquilinear form by a scalar. Moreover,  $B(V, V, F, \varphi)$  is isomorphic to  $F^{n \times n}$ .
8.  $\varphi$ -Congruence is an equivalence relation on  $F^{n \times n}$ .
9. Let  $f \in B(V, V, F, \varphi)$  be nondegenerate. Then the set of all linear operators on  $V$  which preserve  $f$  is a group under the operation of composition.

**Examples:**

1. Let  $F = \mathbb{Q}(\sqrt{5}) = \{a + b\sqrt{5} : a, b \in \mathbb{Q}\}$  and  $\varphi(a + b\sqrt{5}) = a - b\sqrt{5}$ . Define the  $\varphi$ -sesquilinear form  $f$  on  $F^2$  by  $f(\mathbf{u}, \mathbf{v}) = \mathbf{u}^T \varphi(\mathbf{v})$ .  $f([1 + \sqrt{5}, 3]^T, [-2\sqrt{5}, -1 + \sqrt{5}]^T) = (1 + \sqrt{5})(2\sqrt{5}) + 3(-1 - \sqrt{5}) = 7 - \sqrt{5}$ .

The matrix of  $f$  with respect to the standard basis is the identity matrix,  $\text{rank } f = 2$ , and  $f$  is nondegenerate.

2. Let  $A \in F^{n \times n}$ . The map  $f : F^n \times F^n \rightarrow F$  defined by

$$f(\mathbf{u}, \mathbf{v}) = \mathbf{u}^T A \varphi(\mathbf{v}) = \sum_{i=1}^n \sum_{j=1}^n a_{ij} u_i \varphi(v_j), \quad \mathbf{u}, \mathbf{v} \in F^n,$$

is a  $\varphi$ -sesquilinear form. Since  $f(\mathbf{e}_i, \mathbf{e}_j) = a_{ij}$ ,  $i, j = 1, 2, \dots, n$ ,  $f$  is represented in the standard basis of  $F^n$  by  $A$ . It follows that  $\text{rank}(f) = \text{rank}(A)$ , and  $f$  is nondegenerate if and only if  $A$  is invertible.

## 12.5 Hermitian Forms

---

This section closely resembles the results related to symmetric bilinear forms on real vector spaces. We assume here that  $V$  is a finite dimensional complex vector space.

**Definitions:**

A **Hermitian form** on  $V$  is a map  $f : V \times V \rightarrow \mathbb{C}$ , which satisfies

$$f(a\mathbf{u}_1 + b\mathbf{u}_2, \mathbf{v}) = af(\mathbf{u}_1, \mathbf{v}) + bf(\mathbf{u}_2, \mathbf{v}), \quad \mathbf{u}, \mathbf{v} \in V, \quad a, b \in \mathbb{C},$$

and

$$f(\mathbf{v}, \mathbf{u}) = \overline{f(\mathbf{u}, \mathbf{v})}, \quad \mathbf{u}, \mathbf{v} \in V.$$

A Hermitian form  $f$  on  $V$  is **positive semidefinite** (**positive definite**) if  $f(\mathbf{v}, \mathbf{v}) \geq 0$  for all  $\mathbf{v} \in V$  ( $f(\mathbf{v}, \mathbf{v}) > 0$  for all  $0 \neq \mathbf{v} \in V$ ).

$f$  is **negative semidefinite** (**negative definite**) if  $-f$  is positive semidefinite (positive definite).

The **signature** of a Hermitian matrix  $A$  is the integer  $\pi - \nu$ , where  $(\pi, \nu, \delta)$  is the inertia of  $A$ . (See Section 8.3.)

The **signature** of a Hermitian form is the signature of a matrix representing the form.

Let  $A, B \in \mathbb{C}^{n \times n}$ .  $B$  is **\*congruent** to  $A$  if there exists an invertible  $S \in \mathbb{C}^{n \times n}$  such that  $B = S^*AS$  (where  $S^*$  denotes the Hermitian adjoint of  $S$ ).

Let  $f, g$  be Hermitian forms on a finite dimensional complex vector space  $V$ .  $g$  is **\*equivalent** to  $f$  if there exists an ordered basis  $\mathcal{B}$  of  $V$  such that the matrix of  $g$  relative to  $\mathcal{B}$  is \*congruent to the matrix of  $f$  relative to  $\mathcal{B}$ .

### Facts:

Except where another reference is provided, the following facts can be found in [Coh89, Chap. 8], [HJ85, Chap. 4], or [Lan99, Chap. 15]. Let  $f$  be a Hermitian form on  $V$ .

1. A Hermitian form is sesquilinear.
2. A positive definite Hermitian form is nondegenerate.
3.  $f$  is a linear functional in the first variable and conjugate linear in the second variable, that is,

$$f(\mathbf{u}, a\mathbf{v}_1 + b\mathbf{v}_2) = \bar{a}f(\mathbf{u}, \mathbf{v}_1) + \bar{b}f(\mathbf{u}, \mathbf{v}_2).$$

4.  $f(\mathbf{v}, \mathbf{v}) \in \mathbb{R}$  for all  $\mathbf{v} \in V$ .
5. An inner product on a complex vector space is a positive definite Hermitian form. Conversely, a positive definite Hermitian form on a complex vector space is an inner product.
6. (*Polarization formula*)

$$4f(\mathbf{u}, \mathbf{v}) = f(\mathbf{u} + \mathbf{v}, \mathbf{u} + \mathbf{v}) - f(\mathbf{u} - \mathbf{v}, \mathbf{u} - \mathbf{v}) + if(\mathbf{u} + i\mathbf{v}, \mathbf{u} + i\mathbf{v}) - if(\mathbf{u} - i\mathbf{v}, \mathbf{u} - i\mathbf{v}).$$

7. Let  $\mathcal{B} = (\mathbf{w}_1, \mathbf{w}_2, \dots, \mathbf{w}_n)$  be an ordered basis of  $V$  and let

$$\mathbf{u} = \sum_{i=1}^n a_i \mathbf{w}_i, \quad \mathbf{v} = \sum_{i=1}^n b_i \mathbf{w}_i.$$

Then

$$f(\mathbf{u}, \mathbf{v}) = \sum_{i=1}^n \sum_{j=1}^n a_i \bar{b}_j f(\mathbf{w}_i, \mathbf{w}_j).$$

8. Let  $A$  denote the matrix representing  $f$  relative to the basis  $\mathcal{B}$ . Then

$$f(\mathbf{u}, \mathbf{v}) = [\mathbf{u}]_{\mathcal{B}}^T A [\bar{\mathbf{v}}]_{\mathcal{B}}.$$

9. The matrix representing a Hermitian form  $f$  relative to any basis of  $V$  is a Hermitian matrix.
10. Let  $A, B$  be matrices that represent  $f$  relative to bases  $\mathcal{B}$  and  $\mathcal{B}'$  of  $V$ , respectively. Then  $B$  is \*congruent to  $A$ .
11. (*Sylvester's law of inertia for Hermitian forms*, cf. 12.2) There exists an ordered basis  $\mathcal{B}$  of  $V$  such that the matrix representing  $f$  relative to it has the form

$$I_{\pi} \oplus -I_{\nu} \oplus \mathbf{0}_{\delta}.$$

Moreover,  $\pi$ ,  $\nu$ , and  $\delta$  depend only on  $f$  and not on the choice of  $\mathcal{B}$ .

12. (*Sylvester's law of inertia for Hermitian matrices*, cf. 12.2) If  $A \in \mathbb{C}^{n \times n}$  is a Hermitian matrix, then  $A$  is \*congruent to the diagonal matrix  $D = I_{\pi} \oplus -I_{\nu} \oplus \mathbf{0}_{\delta}$ , where  $(\pi, \nu, \delta) = \text{in}(A)$ .

13. There are exactly two invariants of  $n \times n$  Hermitian matrices under  $*$ -congruence, namely the rank and the signature.
14. Two Hermitian  $n \times n$  matrices are  $*$ -congruent if and only if they have the same rank and the same signature.
15. The signature of a Hermitian form is well-defined.
16. Two Hermitian forms are  $*$ -equivalent if and only if they have the same rank and the same signature.
17. [HJ91, Theorem 1.3.5] Let  $A, B \in \mathbb{C}^{n \times n}$  be Hermitian matrices. Suppose that  $\mathbf{x} \in \mathbb{C}^n$ ,  $\mathbf{x}^* A \mathbf{x} = \mathbf{x}^* B \mathbf{x} = 0 \Rightarrow \mathbf{x} = 0$ . Then  $\exists \mathbf{a}, \mathbf{b} \in \mathbb{R}$  such that  $\mathbf{a}A + \mathbf{b}B$  is positive definite. This fact can be obtained from [HJ91], where it is stated in a slightly different form, using the decomposition of every square, complex matrix as a sum of a Hermitian matrix and a skew-Hermitian matrix.
18. The group of linear operators preserving the Hermitian form  $f(u, v) = \sum_{i=1}^n u_i \bar{v}_i$  on  $\mathbb{C}^n$  is the  $n$ -dimensional unitary group.

**Examples:**

1. Let  $A \in \mathbb{C}^{n \times n}$  be a Hermitian matrix. The map  $f: \mathbb{C}^n \times \mathbb{C}^n \rightarrow \mathbb{C}$  defined by  $f(\mathbf{u}, \mathbf{v}) = \sum_{i=1}^n \sum_{j=1}^n a_{ij} u_i \bar{v}_j$  is a Hermitian form on  $\mathbb{C}^n$ .
2. Let  $\psi_1, \psi_2, \dots, \psi_k$  be linear functionals on  $V$ , and let  $a_1, a_2, \dots, a_k \in \mathbb{R}$ . Then the map  $f: V \times V \rightarrow \mathbb{C}$  defined by  $f(\mathbf{u}, \mathbf{v}) = \sum_{i=1}^k a_i \psi_i(\mathbf{u}) \overline{\psi_i(\mathbf{v})}$  is a Hermitian form on  $V$ .
3. Let  $H \in \mathbb{C}^{n \times n}$  be a Hermitian matrix.  
The map  $f: \mathbb{C}^{n \times n} \times \mathbb{C}^{n \times n} \rightarrow \mathbb{C}$  defined by  $f(A, B) = \text{tr}(AHB^*)$  is a Hermitian form.

### 13.1 Multilinear Maps

---

Unless otherwise stated, within this section  $V$ ,  $U$ , and  $W$  as well as these letters with subscripts, superscripts, or accents, are finite dimensional vector spaces over a field  $F$  of characteristic zero.

#### Definitions:

A map  $\varphi$  from  $V_1 \times \cdots \times V_m$  into  $U$  is a **multilinear map** ( **$m$ -linear map**) if it is linear on each coordinate, i.e., for every  $\mathbf{v}_i, \mathbf{v}'_i \in V_i$ ,  $i = 1, \dots, m$  and for every  $a \in F$  the following conditions hold:

- (a)  $\varphi(\mathbf{v}_1, \dots, \mathbf{v}_i + \mathbf{v}'_i, \dots, \mathbf{v}_m) = \varphi(\mathbf{v}_1, \dots, \mathbf{v}_i, \dots, \mathbf{v}_m) + \varphi(\mathbf{v}_1, \dots, \mathbf{v}'_i, \dots, \mathbf{v}_m)$ ;
- (b)  $\varphi(\mathbf{v}_1, \dots, a\mathbf{v}_i, \dots, \mathbf{v}_m) = a\varphi(\mathbf{v}_1, \dots, \mathbf{v}_i, \dots, \mathbf{v}_m)$ .

The 2-linear maps and 3-linear maps are also called **bilinear** and **trilinear** maps, respectively.

If  $U = F$  then a multilinear map into  $U$  is called a **multilinear form**.

The set of multilinear maps from  $V_1 \times \cdots \times V_m$  into  $U$ , together with the operations defined as follows, is denoted  $L(V_1, \dots, V_m; U)$ . For  $m$ -linear maps  $\varphi, \psi$ , and  $a \in F$ ,

$$\begin{aligned}(\psi + \varphi)(\mathbf{v}_1, \dots, \mathbf{v}_m) &= \psi(\mathbf{v}_1, \dots, \mathbf{v}_m) + \varphi(\mathbf{v}_1, \dots, \mathbf{v}_m), \\ (a\varphi)(\mathbf{v}_1, \dots, \mathbf{v}_m) &= a\varphi(\mathbf{v}_1, \dots, \mathbf{v}_m).\end{aligned}$$

Let  $(\mathbf{b}_{i_1}, \dots, \mathbf{b}_{i_m})$  be an ordered basis of  $V_i$ ,  $i = 1, \dots, m$ . The set of sequences  $(j_1, \dots, j_m)$ ,  $1 \leq j_i \leq n_i$ ,  $i = 1, \dots, m$ , will be identified with the set  $\Gamma(n_1, \dots, n_m)$  of maps  $\alpha$  from  $\{1, \dots, m\}$  into  $\mathbb{N}$  satisfying  $1 \leq \alpha(i) \leq n_i$ ,  $i = 1, \dots, m$ .

For  $\alpha \in \Gamma(n_1, \dots, n_m)$ , the  $m$ -tuple of basis vectors  $(\mathbf{b}_{1\alpha(1)}, \dots, \mathbf{b}_{m\alpha(m)})$  is denoted by  $\mathbf{b}_\alpha$ .

Unless otherwise stated  $\Gamma(n_1, \dots, n_m)$  is considered ordered by the lexicographic order. When there is no risk of confusion,  $\Gamma$  is used instead of  $\Gamma(n_1, \dots, n_m)$ .

Let  $p, q$  be positive integers. If  $\varphi$  is an  $(p + q)$ -linear map from  $W_1 \times \dots \times W_p \times V_1 \times \dots \times V_q$  into  $U$ , then for each choice of  $\mathbf{w}_i$  in  $W_i$ ,  $i = 1, \dots, p$ , the map

$$(\mathbf{v}_1, \dots, \mathbf{v}_q) \mapsto \varphi(\mathbf{w}_1, \dots, \mathbf{w}_p, \mathbf{v}_1, \dots, \mathbf{v}_q),$$

from  $V_1 \times \dots \times V_q$  into  $U$ , is denoted  $\varphi_{\mathbf{w}_1, \dots, \mathbf{w}_p}$ , i.e.

$$\varphi_{\mathbf{w}_1, \dots, \mathbf{w}_p}(\mathbf{v}_1, \dots, \mathbf{v}_q) = \varphi(\mathbf{w}_1, \dots, \mathbf{w}_p, \mathbf{v}_1, \dots, \mathbf{v}_q).$$

Let  $\eta$  be a linear map from  $U$  into  $U'$  and  $\theta_i$  a linear map from  $V'_i$  into  $V_i$ ,  $i = 1, \dots, m$ . If  $(\mathbf{v}_1, \dots, \mathbf{v}_m) \mapsto \varphi(\mathbf{v}_1, \dots, \mathbf{v}_m)$  is a multilinear map from  $V_1 \times \dots \times V_m$  into  $U$ ,  $L(\theta_1, \dots, \theta_m; \eta)(\varphi)$  denotes the map from  $V'_1 \times \dots \times V'_m$  into  $U'$ , defined by

$$(\mathbf{v}'_1, \dots, \mathbf{v}'_m) \mapsto \eta(\varphi(\theta_1(\mathbf{v}'_1), \dots, \theta_m(\mathbf{v}'_m))).$$

### Facts:

The following facts can be found in [Mar73, Chap. 1] and in [Mer97, Chap. 5].

1. If  $\varphi$  is a multilinear map, then  $\varphi(\mathbf{v}_1, \dots, \mathbf{0}, \dots, \mathbf{v}_m) = 0$ .
2. The set  $L(V_1, \dots, V_m; U)$  is a vector space over  $F$ .
3. If  $\varphi$  is an  $m$ -linear map from  $V_1 \times \dots \times V_m$  into  $U$ , then for every integer  $p$ ,  $1 \leq p < m$ , and  $\mathbf{v}_i \in V_i$ ,  $1 \leq i \leq p$ , the map  $\varphi_{\mathbf{v}_1, \dots, \mathbf{v}_p}$  is an  $(m - p)$ -linear map.
4. Under the same assumptions than in (3.) the map  $(\mathbf{v}_1, \dots, \mathbf{v}_p) \mapsto \varphi_{\mathbf{v}_1, \dots, \mathbf{v}_p}$  from  $V_1 \times \dots \times V_p$  into  $L(V_{p+1}, \dots, V_m; U)$ , is  $p$ -linear. A linear isomorphism from  $L(V_1, \dots, V_p, V_{p+1}, \dots, V_m; U)$  into  $L(V_1, \dots, V_p; L(V_{p+1}, \dots, V_m; U))$  arises through this construction.
5. Let  $\eta$  be a linear map from  $U$  into  $U'$  and  $\theta_i$  a linear map from  $V'_i$  into  $V_i$ ,  $i = 1, \dots, m$ . The map  $L(\theta_1, \dots, \theta_m; \eta)$  from  $L(V_1, \dots, V_m; U)$  into  $L(V'_1, \dots, V'_m; U')$  is a linear map. When  $m = 1$ , and  $U = U' = F$ , then  $L(\theta_1, I)$  is the dual or adjoint linear map  $\theta_1^*$  from  $V_1^*$  into  $V_1'^*$ .
6.  $|\Gamma(n_1, \dots, n_m)| = \prod_{i=1}^m n_i$  where  $|\cdot|$  denotes cardinality.
7. Let  $(\mathbf{y}_\alpha)_{\alpha \in \Gamma}$  be a family of vectors of  $U$ . Then, there exists a unique  $m$ -linear map  $\varphi$  from  $V_1 \times \dots \times V_m$  into  $U$  satisfying  $\varphi(\mathbf{b}_\alpha) = \mathbf{y}_\alpha$ , for every  $\alpha \in \Gamma$ .
8. If  $(\mathbf{u}_1, \dots, \mathbf{u}_n)$  is a basis of  $U$ , then  $(\varphi_{i,\alpha} : \alpha \in \Gamma, i = 1, \dots, m)$  is a basis of  $L(V_1, \dots, V_m; U)$ , where  $\varphi_{i,\alpha}$  is characterized by the conditions  $\varphi_{i,\alpha}(\mathbf{b}_\beta) = \delta_{\alpha,\beta} \mathbf{u}_i$ . Moreover, if  $\varphi$  is an  $m$ -linear map from  $V_1 \times \dots \times V_m$  into  $U$  such that for each  $\alpha \in \Gamma$ ,

$$\varphi(\mathbf{b}_\alpha) = \sum_{i=1}^n a_{i,\alpha} \mathbf{u}_i,$$

then

$$\varphi = \sum_{\alpha, i} a_{i,\alpha} \varphi_{i,\alpha}.$$

### Examples:

1. The map from  $F^m$  into  $F$ ,  $(a_1, \dots, a_m) \mapsto \prod_{i=1}^m a_i$ , is an  $m$ -linear map.
2. Let  $V$  be a vector space over  $F$ . The map  $(a, \mathbf{v}) \mapsto a\mathbf{v}$  from  $F \times V$  into  $V$  is a bilinear map.
3. The map from  $F^m \times F^m$  into  $F$ ,  $((a_1, \dots, a_m), (b_1, \dots, b_m)) \mapsto \sum a_i b_i$ , is bilinear.
4. Let  $U, V$ , and  $W$  be vector spaces over  $F$ . The map  $(\theta, \eta) \mapsto \theta\eta$  from  $L(V, W) \times L(U, V)$  into  $L(U, W)$ , given by composition, is bilinear.
5. The multiplication of matrices,  $(A, B) \mapsto AB$ , from  $F^{m \times n} \times F^{n \times p}$  into  $F^{m \times p}$ , is bilinear. Observe that this example is the matrix counterpart of the previous one.

6. Let  $V$  and  $W$  be vector spaces over  $F$ . The evaluation map, from  $L(V, W) \times V$  into  $W$ ,

$$(\theta, \mathbf{v}) \mapsto \theta(\mathbf{v}),$$

is bilinear.

7. The map

$$((a_{11}, a_{21}, \dots, a_{m1}), \dots, (a_{1m}, a_{2m}, \dots, a_{mm})) \rightarrow \det([a_{ij}])$$

from the Cartesian product of  $m$  copies of  $F^m$  into  $F$  is  $m$ -linear.

## 13.2 Tensor Products

---

### Definitions:

Let  $V_1, \dots, V_m, P$  be vector spaces over  $F$ . Let  $\nu : V_1 \times \dots \times V_m \mapsto P$  be a multilinear map. The pair  $(\nu, P)$  is called a **tensor product** of  $V_1, \dots, V_m$ , or  $P$  is said to be a **tensor product of  $V_1, \dots, V_m$  with tensor multiplication  $\nu$** , if the following condition is satisfied:

#### Universal factorization property

If  $\varphi$  is a multilinear map from  $V_1 \times \dots \times V_m$  into the vector space  $U$ , then there exists a unique linear map,  $h$ , from  $P$  into  $U$ , that makes the following diagram commutative:

i.e.,  $h\nu = \varphi$ .

If  $P$  is a tensor product of  $V_1, \dots, V_m$ , with tensor multiplication  $\nu$ , then  $P$  is denoted by  $V_1 \otimes \dots \otimes V_m$  and  $\nu(\mathbf{v}_1, \dots, \mathbf{v}_m)$  is denoted by  $\mathbf{v}_1 \otimes \dots \otimes \mathbf{v}_m$  and is called the **tensor product of the vectors  $\mathbf{v}_1, \dots, \mathbf{v}_m$** .

The elements of  $V_1 \otimes \dots \otimes V_m$  are called **tensors**. The tensors that are the tensor product of  $m$  vectors are called **decomposable tensors**.

When  $V_1 = \dots = V_m = V$ , the vector space  $V_1 \otimes \dots \otimes V_m$  is called the  $m$ th **tensor power** of  $V$  and is denoted by  $\otimes^m V$ . It is convenient to define  $\otimes^0 V = F$  and assume that 1 is the unique decomposable tensor of  $\otimes^0 V$ . When we consider simultaneously different models of tensor product, sometimes we use alternative forms to denote the tensor multiplication like  $\otimes'$ ,  $\tilde{\otimes}$ , or  $\hat{\otimes}$  to emphasize these different choices.

Within this section,  $V_1, \dots, V_m$  are finite dimensional vector spaces over  $F$  and  $(\mathbf{b}_{i1}, \dots, \mathbf{b}_{im_i})$  denotes a basis of  $V_i, i = 1, \dots, m$ . When  $V$  is a vector space and  $\mathbf{x}_1, \dots, \mathbf{x}_k \in V$ ,  $\text{Span}(\{\mathbf{x}_1, \dots, \mathbf{x}_k\})$  denotes the subspace of  $V$  spanned by these vectors.

### Facts:

The following facts can be found in [Mar73, Chap. 1] and in [Mer97, Chap. 5].

1. If  $V_1 \otimes \dots \otimes V_m$  and  $V_1 \otimes' \dots \otimes' V_m$  are two tensor products of  $V_1, \dots, V_m$ , then the unique linear map  $h$  from  $V_1 \otimes \dots \otimes V_m$  into  $V_1 \otimes' \dots \otimes' V_m$  satisfying

$$h(\mathbf{v}_1 \otimes \dots \otimes \mathbf{v}_m) = \mathbf{v}_1 \otimes' \dots \otimes' \mathbf{v}_m$$

is an isomorphism.

2. If  $(\mathbf{v}_\alpha)_{\alpha \in \Gamma(n_1, \dots, n_m)}$  is a basis of  $P$ , then the pair  $(\nu, P)$  is a tensor product of  $V_1, \dots, V_m$ . This is often the most effective way to identify a model for the tensor product of vector spaces. It also implies the existence of a tensor product.
3. If  $P$  is the tensor product of  $V_1, \dots, V_m$  with tensor multiplication  $\nu$ , and  $h : P \rightarrow Q$  is a linear isomorphism, then  $(h\nu, Q)$  is a tensor product of  $V_1, \dots, V_m$ .
4. When  $m = 1$ , it makes sense to speak of a tensor product of one vector space  $V$  and  $V$  itself is used as a model for that tensor product with the identity as tensor multiplication, i.e.,  $\otimes^1 V = V$ .
5. **Bilinear version of the universal property**— Given a multilinear map from  $V_1 \times \dots \times V_k \times U_1 \times \dots \times U_m$  into  $W$ ,

$$(\mathbf{v}_1, \dots, \mathbf{v}_k, \mathbf{u}_1, \dots, \mathbf{u}_m) \mapsto \varphi(\mathbf{v}_1, \dots, \mathbf{v}_k, \mathbf{u}_1, \dots, \mathbf{u}_m),$$

there exists a unique bilinear map  $\chi$  from  $(V_1 \otimes \dots \otimes V_k) \times (U_1 \otimes \dots \otimes U_m)$  into  $W$  satisfying

$$\begin{aligned} \chi(\mathbf{v}_1 \otimes \dots \otimes \mathbf{v}_k, \mathbf{u}_1 \otimes \dots \otimes \mathbf{u}_m) &= \varphi(\mathbf{v}_1, \dots, \mathbf{v}_k, \mathbf{u}_1, \dots, \mathbf{u}_m), \\ \mathbf{v}_i &\in V_i \quad \mathbf{u}_j \in U_j, \quad i = 1, \dots, k, \quad j = 1, \dots, m. \end{aligned}$$

6. Let  $a \in F$  and  $\mathbf{v}_i, \mathbf{v}'_i \in V_i$ ,  $i = 1, \dots, m$ . As the consequence of the multilinearity of  $\otimes$ , the following equalities hold:
  - (a)  $\mathbf{v}_1 \otimes \dots \otimes (\mathbf{v}_i + \mathbf{v}'_i) \otimes \dots \otimes \mathbf{v}_m$   
 $= \mathbf{v}_1 \otimes \dots \otimes \mathbf{v}_i \otimes \dots \otimes \mathbf{v}_m + \mathbf{v}_1 \otimes \dots \otimes \mathbf{v}'_i \otimes \dots \otimes \mathbf{v}_m$ ,
  - (b)  $a(\mathbf{v}_1 \otimes \dots \otimes \mathbf{v}_m) = (a\mathbf{v}_1) \otimes \dots \otimes \mathbf{v}_m = \dots = \mathbf{v}_1 \otimes \dots \otimes (a\mathbf{v}_m)$ ,
  - (c)  $\mathbf{v}_1 \otimes \dots \otimes 0 \otimes \dots \otimes \mathbf{v}_m = 0$ .
7. If one of the vector spaces  $V_i$  is zero, then  $V_1 \otimes \dots \otimes V_m = \{0\}$ .
8. Write  $\mathbf{b}_\alpha^\otimes$  to mean

$$\mathbf{b}_\alpha^\otimes := \mathbf{b}_{1\alpha(1)} \otimes \dots \otimes \mathbf{b}_{m\alpha(m)}.$$

Then

$$(\mathbf{b}_\alpha^\otimes)_{\alpha \in \Gamma}$$

is a basis of  $V_1 \otimes \dots \otimes V_m$ . This basis is said to be induced by the bases  $(\mathbf{b}_{i1}, \dots, \mathbf{b}_{im_i})$ ,  $i = 1, \dots, m$ .

9. The decomposable tensors span the tensor product  $V_1 \otimes \dots \otimes V_m$ . Furthermore, if the set  $C_i$  spans  $V_i$ ,  $i = 1, \dots, m$ , then the set  $\{\mathbf{v}_1 \otimes \dots \otimes \mathbf{v}_m : \mathbf{v}_i \in C_i, i = 1, \dots, m\}$  spans  $V_1 \otimes \dots \otimes V_m$ .
10.  $\dim(V_1 \otimes \dots \otimes V_m) = \prod_{i=1}^m \dim(V_i)$ .
11. The tensor product is commutative,

$$V_1 \otimes V_2 = V_2 \otimes V_1,$$

meaning that if  $V_1 \otimes V_2$  is a tensor product of  $V_1$  and  $V_2$ , then  $V_1 \otimes V_2$  is also a tensor product of  $V_2$  and  $V_1$  with tensor multiplication  $(\mathbf{v}_2, \mathbf{v}_1) \mapsto \mathbf{v}_1 \otimes \mathbf{v}_2$ .

In general, with a similar meaning, for any  $\sigma \in S_m$ ,

$$V_1 \otimes \dots \otimes V_m = V_{\sigma(1)} \otimes \dots \otimes V_{\sigma(m)}.$$

12. The tensor product is associative,

$$(V_1 \otimes V_2) \otimes V_3 = V_1 \otimes (V_2 \otimes V_3) = V_1 \otimes V_2 \otimes V_3,$$

meaning that:

- (a) A tensor product  $V_1 \otimes V_2 \otimes V_3$  is also a tensor product of  $V_1 \otimes V_2$  and  $V_3$  (respectively of  $V_1$  and  $V_2 \otimes V_3$ ) with tensor multiplication defined (uniquely by Fact 5 above) for  $\mathbf{v}_i \in V_i, i = 1, 2, 3$ , by  $(\mathbf{v}_1 \otimes \mathbf{v}_2) \otimes \mathbf{v}_3 = \mathbf{v}_1 \otimes \mathbf{v}_2 \otimes \mathbf{v}_3$  (respectively by  $\mathbf{v}_1 \otimes (\mathbf{v}_2 \otimes \mathbf{v}_3) = \mathbf{v}_1 \otimes \mathbf{v}_2 \otimes \mathbf{v}_3$ ).
- (b) And,  $V_1 \otimes (V_2 \otimes V_3)$  (respectively  $V_1 \otimes (V_2 \otimes V_3)$ ) is a tensor product of  $V_1, V_2, V_3$  with tensor multiplication defined by  $\mathbf{v}_1 \otimes \mathbf{v}_2 \otimes \mathbf{v}_3 = (\mathbf{v}_1 \otimes \mathbf{v}_2) \otimes \mathbf{v}_3, \mathbf{v}_i \in V_i, i = 1, 2, 3$  (respectively  $\mathbf{v}_1 \otimes \mathbf{v}_2 \otimes \mathbf{v}_3 = \mathbf{v}_1 \otimes (\mathbf{v}_2 \otimes \mathbf{v}_3), \mathbf{v}_i \in V_i, i = 1, 2, 3$ ).

In general, with an analogous meaning,

$$(V_1 \otimes \cdots \otimes V_k) \otimes (V_{k+1} \otimes \cdots \otimes V_m) = V_1 \otimes \cdots \otimes V_m,$$

for any  $k, 1 \leq k < m$ .

- 13. Let  $W_i$  be a subspace of  $V_i, i = 1, \dots, m$ . Then  $W_1 \otimes \cdots \otimes W_m$  is a subspace of  $V_1 \otimes \cdots \otimes V_m$ , meaning that the subspace of  $V_1 \otimes \cdots \otimes V_m$  spanned by the set of decomposable tensors of the form

$$\mathbf{w}_1 \otimes \cdots \otimes \mathbf{w}_m, \quad \mathbf{w}_i \in W_i, \quad i = 1, \dots, m$$

is a tensor product of  $W_1, \dots, W_m$  with tensor multiplication equal to the restriction of  $\otimes$  to  $W_1 \times \cdots \times W_m$ .

From now on, the model for the tensor product described above is assumed when dealing with the tensor product of subspaces of  $V_i$ .

- 14. Let  $W_1, W'_1$  be subspaces of  $V_1$  and  $W_2$  and  $W'_2$  be subspaces of  $V_2$ . Then

- (a)  $(W_1 \otimes W_2) \cap (W'_1 \otimes W'_2) = (W_1 \cap W'_1) \otimes (W_2 \cap W'_2)$ .

- (b)  $W_1 \otimes (W_2 + W'_2) = (W_1 \otimes W_2) + (W_1 \otimes W'_2)$ ,

- (c)  $(W_1 + W'_1) \otimes W_2 = (W_1 \otimes W_2) + (W'_1 \otimes W_2)$ .

- (c) Assuming  $W_1 \cap W'_1 = \{0\}$ ,

$$(W_1 \oplus W'_1) \otimes W_2 = (W_1 \otimes W_2) \oplus (W'_1 \otimes W_2).$$

Assuming  $W_2 \cap W'_2 = \{0\}$ ,

$$W_1 \otimes (W_2 \oplus W'_2) = (W_1 \otimes W_2) \oplus (W_1 \otimes W'_2).$$

- 15. In a more general setting, if  $W_{ij}, j = 1, \dots, p_i$  are subspaces of  $V_i, i \in \{1, \dots, m\}$ , then

$$\left( \sum_{j=1}^{p_1} W_{1j} \right) \otimes \cdots \otimes \left( \sum_{j=1}^{p_m} W_{mj} \right) = \sum_{\gamma \in \Gamma(p_1, \dots, p_m)} W_{1\gamma(1)} \otimes \cdots \otimes W_{m\gamma(m)}.$$

If the sums of subspaces in the left-hand side are direct, then

$$\left( \bigoplus_{j=1}^{p_1} W_{1j} \right) \otimes \cdots \otimes \left( \bigoplus_{j=1}^{p_m} W_{mj} \right) = \bigoplus_{\gamma \in \Gamma(p_1, \dots, p_m)} W_{1\gamma(1)} \otimes \cdots \otimes W_{m\gamma(m)}.$$

**Examples:**

1. The vector space  $F^{m \times n}$  of the  $m \times n$  matrices over  $F$  is a tensor product of  $F^m$  and  $F^n$  with tensor multiplication (the usual tensor multiplication for  $F^{m \times n}$ ) defined, for  $(a_1, \dots, a_m) \in F^m$  and  $(b_1, \dots, b_n) \in F^n$ , by

$$(a_1, \dots, a_m) \otimes (b_1, \dots, b_n) = \begin{bmatrix} a_1 \\ \vdots \\ a_m \end{bmatrix} \begin{bmatrix} b_1 & \cdots & b_n \end{bmatrix}.$$

With this definition,  $\mathbf{e}_i \otimes \mathbf{e}'_j = E_{ij}$  where  $\mathbf{e}_i$ ,  $\mathbf{e}'_j$ , and  $E_{ij}$  are standard basis vectors of  $F^m$ ,  $F^n$ , and  $F^{m \times n}$ .

2. The field  $F$ , viewed as a vector space over  $F$ , is an  $m$ th tensor power of  $F$  with tensor multiplication defined by

$$a_1 \otimes \cdots \otimes a_m = \prod_{i=1}^m a_i, \quad a_i \in F, \quad i = 1, \dots, m.$$

3. The vector space  $V$  is a tensor product of  $F$  and  $V$  with tensor multiplication defined by

$$a \otimes \mathbf{v} = a\mathbf{v}, \quad a \in F, \quad \mathbf{v} \in V.$$

4. Let  $U$  and  $V$  be vector spaces over  $F$ . Then  $L(V; U)$  is a tensor product  $U \otimes V^*$  with tensor multiplication (the usual tensor multiplication for  $L(V; U)$ ) defined by the equality  $(\mathbf{u} \otimes f)(\mathbf{v}) = f(\mathbf{v})\mathbf{u}$ ,  $\mathbf{u} \in U, \mathbf{v} \in V$ .
5. Let  $V_1, \dots, V_m$  be vector spaces over  $F$ . The vector space  $L(V_1, \dots, V_m; U)$  is a tensor product  $L(V_1, \dots, V_m; F) \otimes U$  with tensor multiplication

$$(\varphi \otimes \mathbf{u})(\mathbf{v}_1, \dots, \mathbf{v}_m) = \varphi(\mathbf{v}_1, \dots, \mathbf{v}_m)\mathbf{u}.$$

6. Denote by  $F^{n_1 \times \cdots \times n_m}$  the set of all families with elements indexed in  $\{1, \dots, n_1\} \times \cdots \times \{1, \dots, n_m\} = \Gamma(n_1, \dots, n_m)$ . The set  $F^{n_1 \times \cdots \times n_m}$  equipped with the sum and scalar product defined, for every  $(j_1, \dots, j_m) \in \Gamma(n_1, \dots, n_m)$ , by the equalities

$$(a_{j_1, \dots, j_m}) + (b_{j_1, \dots, j_m}) = (a_{j_1, \dots, j_m} + b_{j_1, \dots, j_m}),$$

$$\alpha(a_{j_1, \dots, j_m}) = (\alpha a_{j_1, \dots, j_m}), \quad \alpha \in F,$$

is a vector space over  $F$ . This vector space is a tensor product of  $F^{n_1}, \dots, F^{n_m}$  with tensor multiplication defined by

$$(a_{11}, \dots, a_{1n_1}) \otimes \cdots \otimes (a_{m1}, \dots, a_{mn_m}) = \left( \prod_{i=1}^m a_{ij_i} \right)_{(j_1, \dots, j_m) \in \Gamma}.$$

7. The vector space  $L(V_1, \dots, V_m; F)$  is a tensor product of  $V_1^* = L(V_1; F), \dots, V_m^* = L(V_m; F)$  with tensor multiplication defined by

$$g_1 \otimes \cdots \otimes g_m(\mathbf{v}_1, \dots, \mathbf{v}_m) = \prod_{t=1}^m g_t(\mathbf{v}_t).$$

Very often, for example in the context of geometry, the factors of the tensor product are vector space duals. In those situations, this is the model of tensor product implicitly assumed.

8. The vector space

$$L(V_1, \dots, V_m; F)^*$$

is a tensor product of  $V_1, \dots, V_m$  with tensor multiplication defined by

$$\mathbf{v}_1 \otimes \dots \otimes \mathbf{v}_m(\psi) = \psi(\mathbf{v}_1, \dots, \mathbf{v}_m).$$

9. The vector space  $L(V_1, \dots, V_m; F)$  is a tensor product  $L(V_1, \dots, V_k; F) \otimes L(V_{k+1}, \dots, V_m; F)$  with tensor multiplication defined, for every  $\mathbf{v}_i \in V_i, i = 1, \dots, m$ , by the equalities

$$(\varphi \otimes \psi)(\mathbf{v}_1, \dots, \mathbf{v}_m) = \varphi(\mathbf{v}_1, \dots, \mathbf{v}_k)\psi(\mathbf{v}_{k+1}, \dots, \mathbf{v}_m).$$

### 13.3 Rank of a Tensor: Decomposable Tensors

---

**Definitions:**

Let  $z \in V_1 \otimes \dots \otimes V_m$ . The tensor  $z$  has **rank**  $k$  if  $z$  is the sum of  $k$  decomposable tensors but it cannot be written as sum of  $l$  decomposable tensors, for any  $l$  less than  $k$ .

**Facts:**

The following facts can be found in [Bou89, Chap. II, §7.8]and [Mar73, Chap. 1].

1. The tensor  $z = \mathbf{v}_1 \otimes \mathbf{w}_1 + \dots + \mathbf{v}_t \otimes \mathbf{w}_t \in V \otimes W$  has rank  $t$  if and only if  $(\mathbf{v}_1, \dots, \mathbf{v}_t)$  and  $(\mathbf{w}_1, \dots, \mathbf{w}_t)$  are linearly independent.
2. If the model for the tensor product of  $F^m$  and  $F^n$  is the vector space of  $m \times n$  matrices over  $F$  with the usual tensor multiplication, then the rank of a tensor is equal to the rank of the corresponding matrix.
3. If the model for the tensor product  $U \otimes V^*$  is the vector space  $L(V; U)$  with the usual tensor multiplication, then the rank of a tensor is equal to the rank of the corresponding linear map.
4.  $\mathbf{x}_1 \otimes \dots \otimes \mathbf{x}_m = 0$  if and only if  $\mathbf{x}_i = 0$  for some  $i \in \{1, \dots, m\}$ .
5. If  $\mathbf{x}_i, \mathbf{y}_i$  are nonzero vectors of  $V_i, i = 1, \dots, m$ , then

$$\text{Span}(\{\mathbf{x}_1 \otimes \dots \otimes \mathbf{x}_m\}) = \text{Span}(\{\mathbf{y}_1 \otimes \dots \otimes \mathbf{y}_m\})$$

if and only if  $\text{Span}(\{\mathbf{x}_i\}) = \text{Span}(\{\mathbf{y}_i\}), i = 1, \dots, m$ .

**Examples:**

1. Consider as a model of  $F^m \otimes F^n$ , the vector space of the  $m \times n$  matrices over  $F$  with the usual tensor multiplication. Let  $A$  be a tensor of  $F^m \otimes F^n$ . If  $\text{rank } A = k$  (using the matrix definition of rank), then

$$A = M \begin{bmatrix} I_k & 0 \\ 0 & 0 \end{bmatrix} N,$$

where  $M = [\mathbf{x}_1 \dots \mathbf{x}_m]$  is an invertible matrix with columns  $\mathbf{x}_1, \dots, \mathbf{x}_m$  and

$$N = \begin{bmatrix} \mathbf{y}_1 \\ \mathbf{y}_2 \\ \vdots \\ \mathbf{y}_n \end{bmatrix}$$

is an invertible matrix with rows  $\mathbf{y}_1, \dots, \mathbf{y}_n$ . (See Chapter 2.) Then

$$A = \mathbf{x}_1 \otimes \mathbf{y}_1 + \dots + \mathbf{x}_k \otimes \mathbf{y}_k$$

has rank  $k$  as a tensor .

## 13.4 Tensor Product of Linear Maps

### Definitions:

Let  $\theta_i$  be a linear map from  $V_i$  into  $U_i$ ,  $i = 1, \dots, m$ . The unique linear map  $h$  from  $V_1 \otimes \dots \otimes V_m$  into  $U_1 \otimes \dots \otimes U_m$  satisfying, for all  $\mathbf{v}_i \in V_i$ ,  $i = 1, \dots, m$ ,

$$h(\mathbf{v}_1 \otimes \dots \otimes \mathbf{v}_m) = \theta_1(\mathbf{v}_1) \otimes \dots \otimes \theta_m(\mathbf{v}_m)$$

is called the **tensor product** of  $\theta_1, \dots, \theta_m$  and is denoted by  $\theta_1 \otimes \dots \otimes \theta_m$ .

Let  $A_t = (a_{ij}^{(t)})$  be an  $r_t \times s_t$  matrix over  $F$ ,  $t = 1, \dots, m$ . The **Kronecker product** of  $A_1, \dots, A_m$ , denoted  $A_1 \otimes \dots \otimes A_m$ , is the  $(\prod_{t=1}^m r_t) \times (\prod_{t=1}^m s_t)$  matrix whose  $(\alpha, \beta)$ -entry ( $\alpha \in \Gamma(r_1, \dots, r_m)$  and  $\beta \in \Gamma(s_1, \dots, s_m)$ ) is  $\prod_{t=1}^m a_{\alpha(t)\beta(t)}^{(t)}$ . (See also Section 10.4.)

### Facts:

The following facts can be found in [Mar73, Chap. 2] and in [Mer97, Chap. 5].

Let  $\theta_i$  be a linear map from  $V_i$  into  $U_i$ ,  $i = 1, \dots, m$ .

1. If  $\eta_i$  is a linear map from  $W_i$  into  $V_i$ ,  $i = 1, \dots, m$ ,

$$(\theta_1 \otimes \dots \otimes \theta_m)(\eta_1 \otimes \dots \otimes \eta_m) = (\theta_1 \eta_1) \otimes \dots \otimes (\theta_m \eta_m).$$

2.  $I_{V_1 \otimes \dots \otimes V_m} = I_{V_1} \otimes \dots \otimes I_{V_m}$ .
3.  $\text{Ker}(\theta_1 \otimes \dots \otimes \theta_m) = \text{Ker}(\theta_1) \otimes V_2 \otimes \dots \otimes V_m + V_1 \otimes \text{Ker}(\theta_2) \otimes \dots \otimes V_m + \dots + V_1 \otimes \dots \otimes V_{m-1} \otimes \text{Ker}(\theta_m)$ .

In particular,  $\theta_1 \otimes \dots \otimes \theta_m$  is one to one if  $\theta_i$  is one to one,  $i = 1, \dots, m$ , [Bou89, Chap. II, §3.5].

4.  $\theta_1 \otimes \dots \otimes \theta_m(V_1 \otimes \dots \otimes V_m) = \theta_1(V_1) \otimes \dots \otimes \theta_m(V_m)$ . In particular  $\theta_1 \otimes \dots \otimes \theta_m$  is onto if  $\theta_i$  is onto,  $i = 1, \dots, m$ .

In the next three facts, assume that  $\theta_i$  is a linear operator on the  $n_i$ -dimensional vector space  $V_i$ ,  $i = 1, \dots, m$ .

5.  $\text{tr}(\theta_1 \otimes \dots \otimes \theta_m) = \prod_{i=1}^m \text{tr}(\theta_i)$ .
6. If  $\sigma(\theta_i) = \{a_{i1}, \dots, a_{in_i}\}$ ,  $i = 1, \dots, m$ , then

$$\sigma(\theta_1 \otimes \dots \otimes \theta_m) = \left\{ \prod_{i=1}^m a_{i, \alpha(i)} \right\}_{\alpha \in \Gamma(n_1, \dots, n_m)}.$$

7.  $\det(\theta_1 \otimes \theta_2 \otimes \dots \otimes \theta_m) = \det(\theta_1)^{n_2 \dots n_m} \det(\theta_2)^{n_1 \dots n_m} \dots \det(\theta_m)^{n_1 \dots n_{m-1}}$ .
8. The map  $\nu : (\theta_1, \dots, \theta_m) \mapsto \theta_1 \otimes \dots \otimes \theta_m$  is a multilinear map from  $L(V_1; U_1) \times \dots \times L(V_m; U_m)$  into  $L(V_1 \otimes \dots \otimes V_m; U_1 \otimes \dots \otimes U_m)$ .
9. The vector space  $L(V_1 \otimes \dots \otimes V_m; U_1 \otimes \dots \otimes U_m)$  is a tensor product of the vector spaces  $L(V_1; U_1), \dots, L(V_m; U_m)$ , with tensor multiplication  $(\theta_1, \dots, \theta_m) \mapsto \theta_1 \otimes \dots \otimes \theta_m$ :

$$L(V_1; U_1) \otimes \dots \otimes L(V_m; U_m) = L(V_1 \otimes \dots \otimes V_m; U_1 \otimes \dots \otimes U_m).$$

10. As a consequence of (9.), choosing  $F$  as the model for  $\otimes^m F$  with the product in  $F$  as tensor multiplication,

$$V_1^* \otimes \dots \otimes V_m^* = (V_1 \otimes \dots \otimes V_m)^*.$$

11. Let  $(\mathbf{v}_{ij})_{j=1,\dots,n_i}$  be an ordered basis of  $V_i$  and  $(\mathbf{u}_{ij})_{j=1,\dots,q_i}$  an ordered basis of  $U_i$ ,  $i = 1, \dots, m$ . Let  $A_i$  be the matrix of  $\theta_i$  on the bases fixed in  $V_i$  and  $U_i$ . Then the matrix of  $\theta_1 \otimes \dots \otimes \theta_m$  on the bases  $(\mathbf{v}_\alpha^\otimes)_{\alpha \in \Gamma(n_1, \dots, n_m)}$  and  $(\mathbf{u}_\alpha^\otimes)_{\alpha \in \Gamma(q_1, \dots, q_r)}$  (induced by the bases  $(\mathbf{v}_{ij})_{j=1,\dots,n_i}$  and  $(\mathbf{u}_{ij})_{j=1,\dots,q_i}$ , respectively) is the Kronecker product of  $A_1, \dots, A_m$ ,

$$A_1 \otimes \dots \otimes A_m.$$

12. Let  $n_1, \dots, n_m, r_1, \dots, r_m, t_1, \dots, t_m$  be positive integers. Let  $A_i$  be an  $n_i \times r_i$  matrix, and  $B_i$  be an  $r_i \times t_i$  matrix,  $i = 1, \dots, m$ . Then the following holds:

(a)  $(A_1 \otimes \dots \otimes A_m)(B_1 \otimes \dots \otimes B_m) = A_1 B_1 \otimes \dots \otimes A_m B_m$ ,

(b)  $(A_1 \otimes \dots \otimes A_k) \otimes (A_{k+1} \otimes \dots \otimes A_m) = A_1 \otimes \dots \otimes A_m$ .

**Examples:**

1. Consider as a model of  $U \otimes V^*$ , the vector space  $L(V; U)$  with tensor multiplication defined by  $(\mathbf{u} \otimes f)(\mathbf{v}) = f(\mathbf{v})\mathbf{u}$ . Use a similar model for the tensor product of  $U'$  and  $V'^*$ . Let  $\eta \in L(U; U')$  and  $\theta \in L(V'; V)$ . Then, for all  $\xi \in U \otimes V^* = L(V; U)$ ,

$$\eta \otimes \theta^*(\xi) = \eta\xi\theta.$$

2. Consider as a model of  $F^m \otimes F^n$ , the vector space of the  $m \times n$  matrices over  $F$  with the usual tensor multiplication. Use a similar model for the tensor product of  $F^r$  and  $F^s$ . Identify the set of column matrices,  $F^{m \times 1}$ , with  $F^m$  and the set of row matrices,  $F^{1 \times n}$ , with  $F^n$ . Let  $A$  be an  $r \times m$  matrix over  $F$ . Let  $\theta_A$  be the linear map from  $F^m$  into  $F^r$  defined by

$$\theta_A(a_1, \dots, a_m) = A \begin{bmatrix} a_1 \\ a_2 \\ \vdots \\ a_m \end{bmatrix}.$$

Let  $B$  be an  $s \times n$  matrix. Then, for all  $C \in F^{m \times n} = F^m \otimes F^n$ ,  $\theta_A \otimes \theta_B(C) = ACB^T$ .

3. For every  $i = 1, \dots, m$  consider the ordered basis  $(\mathbf{b}_{i1}, \dots, \mathbf{b}_{in_i})$  fixed in  $V_i$ , and the basis  $(\mathbf{b}'_{i1}, \dots, \mathbf{b}'_{is_i})$  fixed in  $U_i$ . Let  $\theta_i$  be a linear map from  $V_i$  into  $U_i$  and let  $A_i = (a_{jk}^{(i)})$  be the  $s_i \times n_i$  matrix of  $\theta_i$  with respect to the bases  $(\mathbf{b}_{i1}, \dots, \mathbf{b}_{in_i})$ ,  $(\mathbf{b}'_{i1}, \dots, \mathbf{b}'_{is_i})$ . For every  $z \in V_1 \otimes \dots \otimes V_m$ ,

$$\begin{aligned} z &= \sum_{j_1=1}^{n_1} \sum_{j_2=1}^{n_2} \dots \sum_{j_m=1}^{n_m} c_{j_1, \dots, j_m} \mathbf{b}_{1j_1} \otimes \dots \otimes \mathbf{b}_{mj_m} \\ &= \sum_{\alpha \in \Gamma(n_1, \dots, n_m)} c_\alpha \mathbf{b}_\alpha^\otimes. \end{aligned}$$

Then, for  $\beta = (i_1, \dots, i_m) \in \Gamma(s_1, \dots, s_m)$ , the component  $c'_{i_1, \dots, i_m}$  of  $\theta_1 \otimes \dots \otimes \theta_m(z)$  on the basis element  $\mathbf{b}'_{i_1} \otimes \dots \otimes \mathbf{b}'_{i_m}$  of  $U_1 \otimes \dots \otimes U_m$  is

$$\begin{aligned} c'_\beta &= c'_{i_1, \dots, i_m} = \sum_{j_1=1}^{n_1} \dots \sum_{j_m=1}^{n_m} a_{i_1, j_1}^{(1)} \dots a_{i_m, j_m}^{(m)} c_{j_1, \dots, j_m} \\ &= \sum_{\gamma \in \Gamma(n_1, \dots, n_m)} \left( \prod_{i=1}^m a_{\beta(i)\gamma(i)}^{(i)} \right) c_\gamma. \end{aligned}$$

4. If  $A = [a_{ij}]$  is an  $p \times q$  matrix over  $F$  and  $B$  is an  $r \times s$  matrix over  $F$ , then the Kronecker product of  $A$  and  $B$  is the matrix whose partition in  $r \times s$  blocks is

$$A \otimes B = \begin{bmatrix} a_{11}B & a_{12}B & \cdots & a_{1q}B \\ a_{21}B & a_{22}B & \cdots & a_{2q}B \\ \vdots & \vdots & \ddots & \vdots \\ a_{p1}B & a_{p2}B & \cdots & a_{pq}B \end{bmatrix}.$$

## 13.5 Symmetric and Antisymmetric Maps

Recall that we are assuming  $F$  to be of characteristic zero and that all vector spaces are finite dimensional over  $F$ . In particular,  $V$  and  $U$  denote finite dimensional vector spaces over  $F$ .

### Definitions:

Let  $m$  be a positive integer. When  $V_1 = V_2 = \cdots = V_m = V$   $L^m(V; U)$  denotes the vector space of the multilinear maps  $L(V_1, \dots, V_m; U)$ . By convention  $L^0(V; U) = U$ .

An  $m$ -linear map  $\psi \in L^m(V; U)$  is called **antisymmetric or alternating** if it satisfies

$$\psi(\mathbf{v}_{\sigma(1)}, \dots, \mathbf{v}_{\sigma(m)}) = \text{sgn}(\sigma)\psi(\mathbf{v}_1, \dots, \mathbf{v}_m), \quad \sigma \in S_m,$$

where  $\text{sgn}(\sigma)$  denotes the sign of the permutation  $\sigma$ .

Similarly, an  $m$ -linear map  $\varphi \in L^m(V; U)$  satisfying

$$\varphi(\mathbf{v}_{\sigma(1)}, \dots, \mathbf{v}_{\sigma(m)}) = \varphi(\mathbf{v}_1, \dots, \mathbf{v}_m)$$

for all permutations  $\sigma \in S_m$  and for all  $\mathbf{v}_1, \dots, \mathbf{v}_m$  in  $V$  is called **symmetric**. Let  $S^m(V; U)$  and  $A^m(V; U)$  denote the subsets of  $L^m(V; U)$  whose elements are respectively the symmetric and the antisymmetric  $m$ -linear maps. The elements of  $A^m(V; F)$  are called **antisymmetric forms**. The elements of  $S^m(V; F)$  are called **symmetric forms**.

Let  $\Gamma_{m,n}$  be the set of all maps from  $\{1, \dots, m\}$  into  $\{1, \dots, n\}$ , i.e.,

$$\Gamma_{m,n} = \Gamma(\underbrace{n, \dots, n}_{m \text{ times}}).$$

The subset of  $\Gamma_{m,n}$  of the strictly increasing maps  $\alpha$  ( $\alpha(1) < \cdots < \alpha(m)$ ) is denoted by  $Q_{m,n}$ . The subset of the increasing maps  $\alpha \in \Gamma_{m,n}$  ( $\alpha(1) \leq \cdots \leq \alpha(m)$ ) is denoted by  $G_{m,n}$ .

Let  $A = [a_{ij}]$  be an  $m \times n$  matrix over  $F$ . Let  $\alpha \in \Gamma_{p,m}$  and  $\beta \in \Gamma_{q,n}$ . Then  $A[\alpha|\beta]$  be the  $p \times q$ -matrix over  $F$  whose  $(i, j)$ -entry is  $a_{\alpha(i), \beta(j)}$ , i.e.,

$$A[\alpha|\beta] = [a_{\alpha(i), \beta(j)}].$$

The  $m$ th-tuple  $(1, 2, \dots, m)$  is denoted by  $\iota_m$ . If there is no risk of confusion  $\iota$  is used instead of  $\iota_m$ .

**Facts:**

1. If  $m > n$ , we have  $Q_{m,n} = \emptyset$ . The cardinality of  $\Gamma_{m,n}$  is  $n^m$ , the cardinality of  $Q_{m,n}$  is  $\binom{n}{m}$ , and the cardinality of  $G_{m,n}$  is  $\binom{m+n-1}{m}$ .
2.  $A^m(V; U)$  and  $S^m(V; U)$  are vector subspaces of  $L^m(V; U)$ .
3. Let  $\psi \in L^m(V; U)$ . The following conditions are equivalent:

- (a)  $\psi$  is an antisymmetric multilinear map.
- (b) For  $1 \leq i < j \leq m$  and for all  $\mathbf{v}_1, \dots, \mathbf{v}_m \in V$ ,

$$\begin{aligned} \psi(\mathbf{v}_1, \dots, \mathbf{v}_{i-1}, \mathbf{v}_j, \mathbf{v}_{i+1}, \dots, \mathbf{v}_{j-1}, \mathbf{v}_i, \mathbf{v}_{j+1}, \dots, \mathbf{v}_m) \\ = -\psi(\mathbf{v}_1, \dots, \mathbf{v}_{i-1}, \mathbf{v}_i, \mathbf{v}_{i+1}, \dots, \mathbf{v}_{j-1}, \mathbf{v}_j, \mathbf{v}_{j+1}, \dots, \mathbf{v}_m). \end{aligned}$$

- (c) For  $1 \leq i < m$  and for all  $\mathbf{v}_1, \dots, \mathbf{v}_m \in V$ ,

$$\psi(\mathbf{v}_1, \dots, \mathbf{v}_{i+1}, \mathbf{v}_i, \dots, \mathbf{v}_m) = -\psi(\mathbf{v}_1, \dots, \mathbf{v}_i, \mathbf{v}_{i+1}, \dots, \mathbf{v}_m).$$

4. Let  $\psi \in L^m(V; U)$ . The following conditions are equivalent:

- (a)  $\psi$  is a symmetric multilinear map.
- (b) For  $1 \leq i < j \leq m$  and for all  $\mathbf{v}_1, \dots, \mathbf{v}_m \in V$ ,

$$\begin{aligned} \psi(\mathbf{v}_1, \dots, \mathbf{v}_{i-1}, \mathbf{v}_j, \mathbf{v}_{i+1}, \dots, \mathbf{v}_{j-1}, \mathbf{v}_i, \mathbf{v}_{j+1}, \dots, \mathbf{v}_m) \\ = \psi(\mathbf{v}_1, \dots, \mathbf{v}_{i-1}, \mathbf{v}_i, \mathbf{v}_{i+1}, \dots, \mathbf{v}_{j-1}, \mathbf{v}_j, \mathbf{v}_{j+1}, \dots, \mathbf{v}_m). \end{aligned}$$

- (c) For  $1 \leq i < m$  and for all  $\mathbf{v}_1, \dots, \mathbf{v}_m \in V$ ,

$$\psi(\mathbf{v}_1, \dots, \mathbf{v}_{i+1}, \mathbf{v}_i, \dots, \mathbf{v}_m) = \psi(\mathbf{v}_1, \dots, \mathbf{v}_i, \mathbf{v}_{i+1}, \dots, \mathbf{v}_m).$$

5. When we consider  $L^m(V; U)$  as the tensor product,  $L^m(V; F) \otimes U$ , with the tensor multiplication described in Example 5 in Section 13.2, we have

$$A^m(V; U) = A^m(V; F) \otimes U \quad \text{and} \quad S^m(V; U) = S^m(V; F) \otimes U.$$

6. **Polarization identity** [Dol04] If  $\varphi$  is a symmetric multilinear map, then for every  $m$ -tuple  $(\mathbf{v}_1, \dots, \mathbf{v}_m)$  of vectors of  $V$ , and for any vector  $\mathbf{w} \in V$ , the following identity holds:

$$\begin{aligned} \varphi(\mathbf{v}_1, \dots, \mathbf{v}_m) &= \\ &= \frac{1}{2^m m!} \sum_{\varepsilon_1 \dots \varepsilon_m} \varepsilon_1 \cdots \varepsilon_m \varphi(\mathbf{w} + \varepsilon_1 \mathbf{v}_1 + \cdots + \varepsilon_m \mathbf{v}_m, \dots, \mathbf{w} + \varepsilon_1 \mathbf{v}_1 + \cdots + \varepsilon_m \mathbf{v}_m), \end{aligned}$$

where  $\varepsilon_i \in \{-1, +1\}$ ,  $i = 1, \dots, m$ .

**Examples:**

1. The map

$$((a_{11}, a_{21}, \dots, a_{m1}), \dots, (a_{1m}, a_{2m}, \dots, a_{mm})) \rightarrow \det([a_{ij}])$$

from the Cartesian product of  $m$  copies of  $F^m$  into  $F$  is  $m$ -linear and antisymmetric.

2. The map

$$((a_{11}, a_{21}, \dots, a_{m1}), \dots, (a_{1m}, a_{2m}, \dots, a_{mm})) \rightarrow \text{per}([a_{ij}])$$

from the Cartesian product of  $m$  copies of  $F^m$  into  $F$  is  $m$ -linear and symmetric.

3. The map  $((a_1, \dots, a_n), (b_1, \dots, b_n)) \mapsto (a_i b_j - b_i a_j)$  from  $F^n \times F^n$  into  $F^{n \times n}$  is bilinear anti-symmetric.
4. The map  $((a_1, \dots, a_n), (b_1, \dots, b_n)) \mapsto (a_i b_j + b_i a_j)$  from  $F^n \times F^n$  into  $F^{n \times n}$  is bilinear symmetric.
5. The map  $\chi$  from  $V^m$  into  $A^m(V; F)^*$  defined by

$$\chi(\mathbf{v}_1, \dots, \mathbf{v}_m)(\psi) = \psi(\mathbf{v}_1, \dots, \mathbf{v}_m), \quad \mathbf{v}_1, \dots, \mathbf{v}_m \in V,$$

is an antisymmetric multilinear map.

6. The map  $\chi$  from  $V^m$  into  $S^m(V; F)^*$  defined by

$$\chi(\mathbf{v}_1, \dots, \mathbf{v}_m)(\psi) = \psi(\mathbf{v}_1, \dots, \mathbf{v}_m), \quad \mathbf{v}_1, \dots, \mathbf{v}_m \in V,$$

is a symmetric multilinear map.

## 13.6 Symmetric and Grassmann Tensors

---

### Definitions:

Let  $\sigma \in S_m$  be a permutation of  $\{1, \dots, m\}$ . The unique linear map, from  $\otimes^m V$  into  $\otimes^m V$  satisfying

$$\mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_m \mapsto \mathbf{v}_{\sigma^{-1}(1)} \otimes \cdots \otimes \mathbf{v}_{\sigma^{-1}(m)}, \quad \mathbf{v}_1, \dots, \mathbf{v}_m \in V,$$

is denoted  $P(\sigma)$ .

Let  $\psi$  be a multilinear form of  $L^m(V; F)$  and  $\sigma$  an element of  $S_m$ . The multilinear form  $(\mathbf{v}_1, \dots, \mathbf{v}_m) \mapsto \psi(\mathbf{v}_{\sigma(1)}, \dots, \mathbf{v}_{\sigma(m)})$  is denoted  $\psi_\sigma$ .

The linear operator Alt from  $\otimes^m V$  into  $\otimes^m V$  defined by

$$\text{Alt} := \frac{1}{m!} \sum_{\sigma \in S_m} \text{sgn}(\sigma) P(\sigma)$$

is called the **alternator**. In order to emphasize the degree of the domain of Alt,  $\text{Alt}_m$  is often used for the operator having  $\otimes^m V$ , as domain.

Similarly, the linear operator Sym is defined as the following linear combination of the maps  $P(\sigma)$ :

$$\text{Sym} = \frac{1}{m!} \sum_{\sigma \in S_m} P(\sigma).$$

As before,  $\text{Sym}_m$  is often written to mean the Sym operator having  $\otimes^m V$ , as domain.

The range of Alt is denoted by  $\bigwedge^m V$ , i.e.,  $\bigwedge^m V = \text{Alt}(\otimes^m V)$ , and is called the **Grassmann space of degree  $m$**  associated with  $V$  or the  **$m$ th-exterior power** of  $V$ .

The range of Sym is denoted by  $\bigvee^m V$ , i.e.,  $\bigvee^m V = \text{Sym}(\otimes^m V)$ , and is called the **symmetric space of degree  $m$**  associated with  $V$  or the  **$m$ th symmetric power** of  $V$ .

By convention

$$\otimes^0 V = \bigwedge^0 V = \bigvee^0 V = F.$$

Assume  $m \geq 1$ . The elements of  $\bigwedge^m V$  that are the image under Alt of decomposable tensors of  $\bigotimes^m V$  are called **decomposable elements of  $\bigwedge^m V$** . If  $\mathbf{x}_1, \dots, \mathbf{x}_m \in V$ ,  $\mathbf{x}_1 \wedge \dots \wedge \mathbf{x}_m$  denotes the decomposable element of  $\bigwedge^m V$ ,

$$\mathbf{x}_1 \wedge \dots \wedge \mathbf{x}_m = m! \text{Alt}(\mathbf{x}_1 \otimes \dots \otimes \mathbf{x}_m),$$

and  $\mathbf{x}_1 \wedge \dots \wedge \mathbf{x}_m$  is called the **exterior product** of  $\mathbf{x}_1, \dots, \mathbf{x}_m$ . Similarly, the elements of  $\bigvee^m V$  that are the image under Sym of decomposable tensors of  $\bigotimes^m V$  are called **decomposable elements of  $\bigvee^m V$** . If  $\mathbf{x}_1, \dots, \mathbf{x}_m \in V$ ,  $\mathbf{x}_1 \vee \dots \vee \mathbf{x}_m$  denotes the decomposable element of  $\bigvee^m V$ ,

$$\mathbf{x}_1 \vee \dots \vee \mathbf{x}_m = m! \text{Sym}(\mathbf{x}_1 \otimes \dots \otimes \mathbf{x}_m),$$

and  $\mathbf{x}_1 \vee \dots \vee \mathbf{x}_m$  is called the **symmetric product** of  $\mathbf{x}_1, \dots, \mathbf{x}_m$ .

Let  $(\mathbf{b}_1, \dots, \mathbf{b}_n)$  be a basis of  $V$ . If  $\alpha \in \Gamma_{m,n}$ ,  $\mathbf{b}_\alpha^\otimes$ ,  $\mathbf{b}_\alpha^\wedge$ , and  $\mathbf{b}_\alpha^\vee$  denote respectively the tensors

$$\begin{aligned} \mathbf{b}_\alpha^\otimes &= \mathbf{b}_{\alpha(1)} \otimes \dots \otimes \mathbf{b}_{\alpha(m)}, \\ \mathbf{b}_\alpha^\wedge &= \mathbf{b}_{\alpha(1)} \wedge \dots \wedge \mathbf{b}_{\alpha(m)}, \\ \mathbf{b}_\alpha^\vee &= \mathbf{b}_{\alpha(1)} \vee \dots \vee \mathbf{b}_{\alpha(m)}. \end{aligned}$$

Let  $n$  and  $m$  be positive integers. An  $n$ -**composition** of  $m$  is a sequence

$$\mu = (\mu_1, \dots, \mu_n)$$

of nonnegative integers that sum to  $m$ . Let  $\mathcal{C}_{m,n}$  be the set of  $n$ -compositions of  $m$ .

Let  $\lambda = (\lambda_1, \dots, \lambda_n)$  be an  $n$ -composition of  $m$ . The integer  $\lambda_1! \dots \lambda_n!$  will be denoted by  $\lambda!$ .

Let  $\alpha \in \Gamma_{m,n}$ . The **multiplicity composition** of  $\alpha$  is the  $n$ -tuple of the cardinalities of the fibers of  $\alpha$ ,  $(|\alpha^{-1}(1)|, \dots, |\alpha^{-1}(n)|)$ , and is denoted by  $\lambda_\alpha$ .

**Facts:**

The following facts can be found in [Mar73, Chap. 2], [Mer97, Chap. 5], and [Spi79, Chap. 7].

1.  $\bigwedge^m V$  and  $\bigvee^m V$  are vector subspaces of  $\bigotimes^m V$ .
2. The map  $\sigma \mapsto P(\sigma)$  from the symmetric group of degree  $m$  into  $L(\bigotimes^m V; \bigotimes^m V)$  is an  $F$ -representation of  $S_m$ , i.e.,  $P(\sigma\tau) = P(\sigma)P(\tau)$  for any  $\sigma, \tau \in S_m$  and  $P(I) = I_{\bigotimes^m V}$ .
3. Choosing  $L^m(V; F)$ , with the usual tensor multiplication, as the model for the tensor power,  $\bigotimes^m V^*$ , the linear operator  $P(\sigma)$  acts on  $L^m(V; F)$  by the following transformation

$$(P(\sigma)\psi) = \psi_\sigma.$$

4. The linear operators Alt and Sym are projections, i.e.,  $\text{Alt}^2 = \text{Alt}$  and  $\text{Sym}^2 = \text{Sym}$ .
5. If  $m = 1$ , we have

$$\text{Sym} = \text{Alt} = I_{\bigotimes^1 V} = I_V.$$

6.  $\bigwedge^m V = \{z \in \bigotimes^m V : P(\sigma)(z) = \text{sgn}(\sigma)z, \forall \sigma \in S_m\}$ .
7.  $\bigvee^m V = \{z \in \bigotimes^m V : P(\sigma)(z) = z, \forall \sigma \in S_m\}$ .
8. Choosing  $L^m(V; F)$  as the model for the tensor power  $\bigotimes^m V^*$  with the usual tensor multiplication,

$$\bigwedge^m V^* = A^m(V; F) \quad \text{and} \quad \bigvee^m V^* = S^m(V; F).$$

9.

$$\bigotimes^1 V = \bigwedge^1 V = \bigvee^1 V = V.$$

10.  $\bigotimes^2 V = \bigwedge^2 V \oplus \bigvee^2 V$ . Moreover for  $z \in \bigotimes^2 V$ ,

$$z = \text{Alt}(z) + \text{Sym}(z).$$

The corresponding equality is no more true in  $\bigotimes^m V$  if  $m \neq 2$ .

11.  $\bigwedge^m V = \{0\}$  if  $m > \dim(V)$ .
12. If  $m \geq 1$ , any element of  $\bigwedge^m V$  is a sum of decomposable elements of  $\bigwedge^m V$ .
13. If  $m \geq 1$ , any element of  $\bigvee^m V$  is a sum of decomposable elements of  $\bigvee^m V$ .
14.  $\text{Alt}(P(\sigma)z) = \text{sgn}(\sigma)\text{Alt}(z)$  and  $\text{Sym}(P(\sigma)(z)) = \text{Sym}(z)$ ,  $z \in \bigotimes^m V$ .
15. The map  $\wedge$  from  $V^m$  into  $\bigwedge^m V$  defined for  $\mathbf{v}_1, \dots, \mathbf{v}_m \in V$  by

$$\wedge(\mathbf{v}_1, \dots, \mathbf{v}_m) = \mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_m$$

is an antisymmetric  $m$ -linear map.

16. The map  $\vee$  from  $V^m$  into  $\bigvee^m V$  defined for  $\mathbf{v}_1, \dots, \mathbf{v}_m \in V$  by

$$\vee(\mathbf{v}_1, \dots, \mathbf{v}_m) = \mathbf{v}_1 \vee \cdots \vee \mathbf{v}_m$$

is a symmetric  $m$ -linear map.

17. **(Universal property for  $\bigwedge^m V$ )** Given an antisymmetric  $m$ -linear map  $\psi$  from  $V^m$  into  $U$ , there exists a unique linear map  $h$  from  $\bigwedge^m V$  into  $U$  such that

$$\psi(\mathbf{v}_1, \dots, \mathbf{v}_m) = h(\mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_m), \quad \mathbf{v}_1, \dots, \mathbf{v}_m \in V,$$

i.e., there exists a unique linear map  $h$  that makes the following diagram commutative:

$$\begin{array}{ccc} V^m & \xrightarrow{\wedge} & \bigwedge^m V \\ & \searrow \psi & \downarrow h \\ & & U \end{array}$$

18. **(Universal property for  $\bigvee^m V$ )** Given a symmetric  $m$ -linear map  $\varphi$  from  $V^m$  into  $U$ , there exists a unique linear map  $h$  from  $\bigvee^m V$  into  $U$  such that

$$\varphi(\mathbf{v}_1, \dots, \mathbf{v}_m) = h(\mathbf{v}_1 \vee \cdots \vee \mathbf{v}_m), \quad \mathbf{v}_1, \dots, \mathbf{v}_m \in V,$$

i.e., there exists a unique linear map  $h$  that makes the following diagram commutative:

$$\begin{array}{ccc} V^m & \xrightarrow{\vee} & \bigvee^m V \\ & \searrow \varphi & \downarrow h \\ & & U \end{array}$$

Let  $p$  and  $q$  be positive integers.

19. **(Universal property for  $\otimes^m V$ -bilinear version)** If  $\psi$  is a  $(p + q)$ -linear map from  $V^{p+q}$  into  $U$ , then there exists a unique bilinear map  $\chi$  from  $\otimes^p V \times \otimes^q V$  into  $U$  satisfying (recall Fact 5 in Section 13.2)

$$\chi(\mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_p, \mathbf{v}_{p+1} \otimes \cdots \otimes \mathbf{v}_{p+q}) = \psi(\mathbf{v}_1, \dots, \mathbf{v}_{p+q}).$$

20. **(Universal property for  $\wedge^m V$ -bilinear version)** If  $\psi$  is a  $(p + q)$ -linear map from  $V^{p+q}$  into  $U$  antisymmetric in the first  $p$  variables and antisymmetric in the last  $q$  variables, then there exists a unique bilinear map  $\chi$  from  $\wedge^p V \times \wedge^q V$  into  $U$  satisfying

$$\chi(\mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_p, \mathbf{v}_{p+1} \wedge \cdots \wedge \mathbf{v}_{p+q}) = \psi(\mathbf{v}_1, \dots, \mathbf{v}_{p+q}).$$

21. **(Universal property for  $\vee^m V$ -bilinear version)** If  $\varphi$  is a  $(p + q)$ -linear map from  $V^{p+q}$  into  $U$  symmetric in the first  $p$  variables and symmetric in the last  $q$  variables, then there exists a unique bilinear map  $\chi$  from  $\vee^p V \times \vee^q V$  into  $U$  satisfying

$$\chi(\mathbf{v}_1 \vee \cdots \vee \mathbf{v}_p, \mathbf{v}_{p+1} \vee \cdots \vee \mathbf{v}_{p+q}) = \varphi(\mathbf{v}_1, \dots, \mathbf{v}_{p+q}).$$

22. If  $(\mathbf{b}_1, \dots, \mathbf{b}_n)$  is a basis of  $V$ , then  $(\mathbf{b}_\alpha^\otimes)_{\alpha \in \Gamma_{m,n}}$  is a basis of  $\otimes^m V$ ,  $(\mathbf{b}_\alpha^\wedge)_{\alpha \in Q_{m,n}}$  is a basis of  $\wedge^m V$ , and  $(\mathbf{b}_\alpha^\vee)_{\alpha \in G_{m,n}}$  is a basis of  $\vee^m V$ . These bases are said to be **induced** by the basis  $(\mathbf{b}_1, \dots, \mathbf{b}_n)$ .
23. Assume  $L^m(V; F)$  as the model for the tensor power of  $\otimes^m V^*$ , with the usual tensor multiplication. Let  $(f_1, \dots, f_n)$  be the dual basis of the basis  $(\mathbf{b}_1, \dots, \mathbf{b}_n)$ . Then:

- (a) For every  $\varphi \in L^m(V; F)$ ,

$$\varphi = \sum_{\alpha \in \Gamma_{m,n}} \varphi(\mathbf{b}_\alpha) f_\alpha^\otimes.$$

- (b) For every  $\varphi \in A^m(V, F)$ ,

$$\varphi = \sum_{\alpha \in Q_{m,n}} \varphi(\mathbf{b}_\alpha) f_\alpha^\wedge.$$

- (c) For every  $\varphi \in S^m(V, F)$ ,

$$\varphi = \sum_{\alpha \in G_{m,n}} \frac{1}{\lambda_\alpha!} \varphi(\mathbf{b}_\alpha) f_\alpha^\vee.$$

24.  $\dim \otimes^m V = n^m$ ,  $\dim \wedge^m V = \binom{n}{m}$ , and  $\dim \vee^m V = \binom{n+m-1}{m}$ .

25. The family

$$((\mu_1 \mathbf{b}_1 + \cdots + \mu_n \mathbf{b}_n) \vee \cdots \vee (\mu_1 \mathbf{b}_1 + \cdots + \mu_n \mathbf{b}_n))_{\mu \in C_{m,n}}$$

is a basis of  $\vee^m V$  [Mar73, Chap. 3].

26. Let  $\mathbf{x}_1, \dots, \mathbf{x}_m$  be vectors of  $V$  and  $g_1, \dots, g_m$  forms of  $V^*$ . Let  $a_{ij} = g_i(\mathbf{x}_j)$ ,  $i, j = 1, \dots, m$ . Then, choosing  $(\otimes^m V)^*$  as the model for  $\otimes^m V^*$  with tensor multiplication as described in Fact 10 in Section 13.4,

$$g_1 \otimes \cdots \otimes g_m(\mathbf{x}_1 \wedge \cdots \wedge \mathbf{x}_m) = \det[a_{ij}].$$

27. Under the same conditions of the former fact,

$$g_1 \otimes \cdots \otimes g_m(\mathbf{x}_1 \vee \cdots \vee \mathbf{x}_m) = \text{per}[a_{ij}].$$

28. Let  $(f_1, \dots, f_n)$  be the dual basis of the basis  $(\mathbf{b}_1, \dots, \mathbf{b}_n)$ . Then, choosing  $(\otimes^m V)^*$  as the model for  $\otimes^m V^*$ :

(a)

$$(f_\alpha^\otimes)_{\alpha \in \Gamma_{m,n}}$$

is the dual basis of the basis  $(\mathbf{b}_\alpha^\otimes)_{\alpha \in \Gamma_{m,n}}$  of  $\otimes^m V$ .

(b)

$$\left( (f_\alpha^\otimes) | \wedge^m V \right)_{\alpha \in Q_{m,n}}$$

is the dual basis of the basis  $(\mathbf{b}_\alpha^\wedge)_{\alpha \in Q_{m,n}}$  of  $\wedge^m V$ .

(c)

$$\left( \frac{1}{\lambda_\alpha!} (f_\alpha^\otimes) | \vee^m V \right)_{\alpha \in G_{m,n}}$$

is the dual basis of the basis  $(\mathbf{b}_\alpha^\vee)_{\alpha \in G_{m,n}}$  of  $\vee^m V$ .

Let  $\mathbf{v}_1, \dots, \mathbf{v}_m$  be vectors of  $V$  and  $(\mathbf{b}_1, \dots, \mathbf{b}_n)$  be a basis of  $V$ .

29. Let  $A = [a_{ij}]$  be the  $n \times m$  matrix over  $F$  such that  $\mathbf{v}_j = \sum_{i=1}^n a_{ij} \mathbf{b}_i$ ,  $j = 1, \dots, m$ . Then:

(a)

$$\mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_m = \sum_{\alpha \in \Gamma_{m,n}} \left( \prod_{t=1}^m a_{\alpha(t),t} \right) \mathbf{b}_\alpha^\otimes;$$

(b)

$$\mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_m = \sum_{\alpha \in Q_{m,n}} \det A[\alpha | t] \mathbf{b}_\alpha^\wedge;$$

(c)

$$\mathbf{v}_1 \vee \cdots \vee \mathbf{v}_m = \sum_{\alpha \in G_{m,n}} \frac{1}{\lambda_\alpha!} \text{per} A[\alpha | t] \mathbf{b}_\alpha^\vee.$$

30.  $\mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_m = 0$  if and only if  $(\mathbf{v}_1, \dots, \mathbf{v}_m)$  is linearly dependent.

31.  $\mathbf{v}_1 \vee \cdots \vee \mathbf{v}_m = 0$  if and only if one of the  $\mathbf{v}_i$ s is equal to 0.

32. Let  $\mathbf{u}_1, \dots, \mathbf{u}_m$  be vectors of  $V$ .

(a) If  $(\mathbf{v}_1, \dots, \mathbf{v}_m)$  and  $(\mathbf{u}_1, \dots, \mathbf{u}_m)$  are linearly independent families, then

$$\text{Span}(\{\mathbf{u}_1 \wedge \cdots \wedge \mathbf{u}_m\}) = \text{Span}(\{\mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_m\})$$

if and only if

$$\text{Span}(\{\mathbf{u}_1, \dots, \mathbf{u}_m\}) = \text{Span}(\{\mathbf{v}_1, \dots, \mathbf{v}_m\}).$$

(b) If  $(\mathbf{v}_1, \dots, \mathbf{v}_m)$  and  $(\mathbf{u}_1, \dots, \mathbf{u}_m)$  are families of nonzero vectors of  $V$ , then

$$\text{Span}(\{\mathbf{v}_1 \vee \cdots \vee \mathbf{v}_m\}) = \text{Span}(\{\mathbf{u}_1 \vee \cdots \vee \mathbf{u}_m\})$$

if and only if there exists a permutation  $\sigma$  of  $S_m$  satisfying

$$\text{Span}(\{\mathbf{v}_i\}) = \text{Span}(\{\mathbf{u}_{\sigma(i)}\}), \quad i = 1, \dots, m.$$

**Examples:**

1. If  $m = 1$ , we have

$$\text{Sym} = \text{Alt} = I_{\otimes^1 V} = I_V.$$

2. Consider as a model of  $\otimes^2 F^n$ , the vector space of the  $n \times n$  matrices with the usual tensor multiplication. Then  $\wedge^2 F^n$  is the subspace of the  $n \times n$  antisymmetric matrices over  $F$  and  $\vee^2 F^n$  is the subspace of the  $n \times n$  symmetric matrices over  $F$ . Moreover, for  $(a_1, \dots, a_n), (b_1, \dots, b_n) \in F^n$ :

(a)  $(a_1, \dots, a_n) \wedge (b_1, \dots, b_n) = [a_i b_j - b_i a_j]_{i,j=1,\dots,n}$ .

(b)  $(a_1, \dots, a_n) \vee (b_1, \dots, b_n) = [a_i b_j + b_i a_j]_{i,j=1,\dots,n}$ .

With these definitions,  $\mathbf{e}_i \wedge \mathbf{e}_j = E_{ij} - E_{ji}$  and  $\mathbf{e}_i \vee \mathbf{e}_j = E_{ij} + E_{ji}$ , where  $\mathbf{e}_i, \mathbf{e}_j$ , and  $E_{ij}$  are standard basis vectors of  $F^m, F^n$ , and  $F^{m \times n}$ .

3. For  $\mathbf{x} \in V, \mathbf{x} \vee \dots \vee \mathbf{x} = m! \mathbf{x} \otimes \dots \otimes \mathbf{x}$ .

## 13.7 The Tensor Multiplication, the Alt Multiplication, and the Sym Multiplication

Next we will introduce “external multiplications” for tensor powers, Grassmann spaces, and symmetric spaces, Let  $p, q$  be positive integers.

**Definitions:**

The  $(p, q)$ -**tensor multiplication** is the unique bilinear map,  $(z, z') \mapsto z \otimes z'$  from  $(\otimes^p V) \times (\otimes^q V)$  into  $\otimes^{p+q} V$ , satisfying

$$(\mathbf{v}_1 \otimes \dots \otimes \mathbf{v}_p) \otimes (\mathbf{v}_{p+1} \otimes \dots \otimes \mathbf{v}_{p+q}) = \mathbf{v}_1 \otimes \dots \otimes \mathbf{v}_{p+q}.$$

The  $(p, q)$ -**alt multiplication** (briefly alt multiplication) is the unique bilinear map (recall Fact 20 in section 13.6),  $(z, z') \mapsto z \wedge z'$  from  $(\wedge^p V) \times (\wedge^q V)$  into  $\wedge^{p+q} V$ , satisfying

$$(\mathbf{v}_1 \wedge \dots \wedge \mathbf{v}_p) \wedge (\mathbf{v}_{p+1} \wedge \dots \wedge \mathbf{v}_{p+q}) = \mathbf{v}_1 \wedge \dots \wedge \mathbf{v}_{p+q}.$$

The  $(p, q)$ -**sym multiplication** (briefly sym multiplication) is the unique bilinear map (recall Fact 21 in section 13.6),  $(z, z') \mapsto z \vee z'$  from  $(\vee^p V) \times (\vee^q V)$  into  $\vee^{p+q} V$ , satisfying

$$(\mathbf{v}_1 \vee \dots \vee \mathbf{v}_p) \vee (\mathbf{v}_{p+1} \vee \dots \vee \mathbf{v}_{p+q}) = \mathbf{v}_1 \vee \dots \vee \mathbf{v}_{p+q}.$$

These definitions can be extended to include the cases where either  $p$  or  $q$  is zero, taking as multiplication the scalar product.

Let  $m, n$  be positive integers satisfying  $1 \leq m < n$ . Let  $\alpha \in Q_{m,n}$ . We denote by  $\alpha^c$  the element of  $Q_{n-m,n}$  whose range is the complement in  $\{1, \dots, n\}$  of the range of  $\alpha$  and by  $\tilde{\alpha}$  the permutation of  $S_n$ :

$$\tilde{\alpha} = \begin{pmatrix} 1 & \dots & m & m+1 & \dots & n \\ \alpha(1) & \dots & \alpha(m) & \alpha^c(1) & \dots & \alpha^c(n) \end{pmatrix}.$$

**Facts:**

The following facts can be found in [Mar73, Chap. 2], [Mer97, Chap. 5], and in [Spi79, Chap. 7].

1. The value of the alt multiplication for arbitrary elements  $z \in \bigwedge^p V$  and  $z' \in \bigwedge^q V$  is given by

$$z \wedge z' = \frac{(p+q)!}{p!q!} \text{Alt}_{p+q}(z \otimes z').$$

2. The product of  $z \in \bigvee^p V$  and  $z' \in \bigvee^q V$  by the sym multiplication is given by

$$z \vee z' = \frac{(p+q)!}{p!q!} \text{Sym}_{p+q}(z \otimes z').$$

3. The alt-multiplication  $z \wedge z'$  and the sym-multiplication  $z \vee z'$  are not, in general, decomposable elements of any Grassmann or symmetric space of degree 2.
4. Let  $0 \neq z \in \bigwedge^m V$ . Then  $z$  is decomposable if and only if there exists a linearly independent family of vectors  $\mathbf{v}_1, \dots, \mathbf{v}_m$  satisfying  $z \wedge \mathbf{v}_i = 0, i = 1, \dots, m$ .
5. If  $\dim(V) = n$ , all elements of  $\bigwedge^{n-1} V$  are decomposable.
6. The multiplications defined in this subsection are associative. Therefore,

$$\begin{aligned} z \otimes z' \otimes z'', z \in \bigotimes^p V, \quad z' \in \bigotimes^q V, \quad z'' \in \bigotimes^r V; \\ w \wedge w' \wedge w'', w \in \bigwedge^p V, \quad w' \in \bigwedge^q V, \quad w'' \in \bigwedge^r V; \\ y \vee y' \vee y'', y \in \bigvee^p V, \quad y' \in \bigvee^q V, \quad y'' \in \bigvee^r V \end{aligned}$$

are meaningful as well as similar expressions with more than three factors.

7. If  $w \in \bigwedge^p V, w' \in \bigwedge^q V$ , then

$$w' \wedge w = (-1)^{pq} w \wedge w'.$$

8. If  $y \in \bigvee^p V, y' \in \bigvee^q V$ , then

$$y' \vee y = y \vee y'.$$

**Examples:**

1. When the vector space is the dual  $V^* = L(V; F)$  of a vector space and we choose as the models of tensor powers of  $V^*$  the spaces of multilinear forms (with the usual tensor multiplication), then the image of the tensor multiplication  $\varphi \otimes \psi$  ( $\varphi \in L^p(V; F)$  and  $\psi \in L^q(V; F)$ ) on  $(\mathbf{v}_1, \dots, \mathbf{v}_{p+q})$  is given by the equality

$$(\varphi \otimes \psi)(\mathbf{v}_1, \dots, \mathbf{v}_{p+q}) = \varphi(\mathbf{v}_1, \dots, \mathbf{v}_p) \psi(\mathbf{v}_{p+1}, \dots, \mathbf{v}_{p+q}).$$

2. When the vector space is the dual  $V^* = L(V; F)$  of a vector space and we choose as the models for the tensor powers of  $V^*$  the spaces of multilinear forms (with the usual tensor multiplication), the alt multiplication of  $\varphi \in A^p(V; F)$  and  $\psi \in A^q(V; F)$  takes the form

$$\begin{aligned} (\varphi \wedge \psi)(\mathbf{v}_1, \dots, \mathbf{v}_{p+q}) \\ = \frac{1}{p!q!} \sum_{\sigma \in S_{p+q}} \text{sgn}(\sigma) \varphi(\mathbf{v}_{\sigma(1)}, \dots, \mathbf{v}_{\sigma(p)}) \psi(\mathbf{v}_{\sigma(p+1)}, \dots, \mathbf{v}_{\sigma(p+q)}). \end{aligned}$$

3. The equality in Example 2 has an alternative expression that can be seen as a ‘‘Laplace expansion’’ for antisymmetric forms

$$\begin{aligned}
 & (\varphi \wedge \psi)(\mathbf{v}_1, \dots, \mathbf{v}_{p+q}) \\
 &= \sum_{\alpha \in Q_{p,p+q}} \text{sgn}(\tilde{\alpha}) \varphi(\mathbf{v}_{\alpha(1)}, \dots, \mathbf{v}_{\alpha(p)}) \psi(\mathbf{v}_{\alpha^c(1)}, \dots, \mathbf{v}_{\alpha^c(q)}).
 \end{aligned}$$

4. In the case  $p = 1$ , the equality in Example 3 has the form

$$\begin{aligned}
 & (\varphi \wedge \psi)(\mathbf{v}_1, \dots, \mathbf{v}_{q+1}) \\
 &= \sum_{j=1}^{q+1} (-1)^{j+1} \varphi(\mathbf{v}_j) \psi(\mathbf{v}_1, \dots, \mathbf{v}_{j-1}, \mathbf{v}_{j+1}, \dots, \mathbf{v}_{q+1}).
 \end{aligned}$$

5. When the vector space is the dual  $V^* = L(V; F)$  of a vector space and we choose as the models of tensor powers of  $V^*$  the spaces of multilinear forms (with the usual tensor multiplication), the value of sym multiplication of  $\varphi \in S^p(V; F)$  and  $\psi \in S^q(V; F)$  on  $(\mathbf{v}_1, \dots, \mathbf{v}_{p+q})$  is

$$\begin{aligned}
 & (\varphi \vee \psi)(\mathbf{v}_1, \dots, \mathbf{v}_{p+q}) \\
 &= \frac{1}{p!q!} \sum_{\sigma \in S_{p+q}} \varphi(\mathbf{v}_{\sigma(1)}, \dots, \mathbf{v}_{\sigma(p)}) \psi(\mathbf{v}_{\sigma(p+1)}, \dots, \mathbf{v}_{\sigma(p+q)}).
 \end{aligned}$$

6. The equality in Example 5 has an alternative expression that can be seen as a ‘‘Laplace expansion’’ for symmetric forms

$$\begin{aligned}
 & (\varphi \vee \psi)(\mathbf{v}_1, \dots, \mathbf{v}_{p+q}) \\
 &= \sum_{\alpha \in Q_{p,p+q}} \varphi(\mathbf{v}_{\alpha(1)}, \dots, \mathbf{v}_{\alpha(p)}) \psi(\mathbf{v}_{\alpha^c(1)}, \dots, \mathbf{v}_{\alpha^c(q)}).
 \end{aligned}$$

7. In the case  $p = 1$ , the equality in Example 6 has the form

$$\begin{aligned}
 & (\varphi \vee \psi)(\mathbf{v}_1, \dots, \mathbf{v}_{q+1}) \\
 &= \sum_{j=1}^{q+1} \varphi(\mathbf{v}_j) \psi(\mathbf{v}_1, \dots, \mathbf{v}_{j-1}, \mathbf{v}_{j+1}, \dots, \mathbf{v}_{q+1}).
 \end{aligned}$$

## 13.8 Associated Maps

---

### Definitions:

Let  $\theta \in L(V; U)$ . The linear map  $\theta \otimes \dots \otimes \theta$  from  $\otimes^m V$  into  $\otimes^m U$  (the tensor product of  $m$  copies of  $\theta$ ) will be denoted by  $\otimes^m \theta$ . The subspaces  $\wedge^m V$  and  $\vee^m V$  are mapped by  $\otimes^m \theta$  into  $\wedge^m U$  and  $\vee^m U$ , respectively. The restriction of  $\otimes^m \theta$  to  $\wedge^m V$  and to  $\vee^m V$  will be respectively denoted,  $\wedge^m \theta$  e  $\vee^m \theta$ .

### Facts:

The following facts can be found in [Mar73, Chap. 2].

1. Let  $\mathbf{v}_1, \dots, \mathbf{v}_m \in V$ . The following properties hold:
  - (a)  $\bigwedge^m \theta(\mathbf{v}_1 \wedge \dots \wedge \mathbf{v}_m) = \theta(\mathbf{v}_1) \wedge \dots \wedge \theta(\mathbf{v}_m)$ .
  - (b)  $\bigvee^m \theta(\mathbf{v}_1 \vee \dots \vee \mathbf{v}_m) = \theta(\mathbf{v}_1) \vee \dots \vee \theta(\mathbf{v}_m)$ .
2. Let  $\theta \in L(V; U)$  and  $\eta \in L(W, V)$ . The following equalities hold:
  - (a)  $\bigwedge^m(\theta\eta) = \bigwedge^m(\theta) \bigwedge^m(\eta)$ .
  - (b)  $\bigvee^m(\theta\eta) = \bigvee^m(\theta) \bigvee^m(\eta)$ .
3.  $\bigwedge^m(I_V) = I_{\bigwedge^m V}$ ;  $\bigvee^m(I_V) = I_{\bigvee^m V}$ .
4. Let  $\theta, \eta \in L(V; U)$  and assume that  $\text{rank}(\theta) > m$ . Then

$$\bigwedge^m \theta = \bigwedge^m \eta$$

if and only if  $\theta = a\eta$  and  $a^m = 1$ .

5. Let  $\theta, \eta \in L(V; U)$ . Then  $\bigvee^m \theta = \bigvee^m \eta$  if and only if  $\theta = a\eta$  and  $a^m = 1$ .
6. If  $\theta$  is one-to-one (respectively onto), then  $\bigwedge^m \theta$  and  $\bigvee^m \theta$  are one-to-one (respectively onto).  
From now on  $\theta$  is a linear operator on the  $n$ -dimensional vector space  $V$ .
7. Considering  $\bigwedge^n \theta$  as an operator in the one-dimensional space  $\bigwedge^n V$ ,

$$\left(\bigwedge^n \theta\right)(z) = \det(\theta)z, \text{ for all } z \in \bigwedge^n V.$$

8. If the characteristic polynomial of  $\theta$  is

$$\mathbf{p}_\theta(x) = x^n + \sum_{i=1}^n (-1)^i a_i x^{n-i},$$

then

$$a_i = \text{tr}\left(\bigwedge^i \theta\right), \quad i = 1, \dots, n.$$

9. If  $\theta$  has spectrum  $\sigma(\theta) = \{\lambda_1, \dots, \lambda_n\}$ , then

$$\sigma\left(\bigwedge^m \theta\right) = \left\{ \prod_{i=1}^m \lambda_{\alpha(i)} \right\}_{\alpha \in Q_{m,n}}, \quad \sigma\left(\bigvee^m \theta\right) = \left\{ \prod_{i=1}^m \lambda_{\alpha(i)} \right\}_{\alpha \in G_{m,n}}.$$

10.

$$\det\left(\bigwedge^m \theta\right) = \det(\theta)^{\binom{n-1}{m-1}}, \quad \det\left(\bigvee^m \theta\right) = \det(\theta)^{\binom{m+n-1}{m-1}}.$$

### Examples:

1. Let  $A$  be the matrix of the linear operator  $\theta \in L(V; V)$  in the basis  $(\mathbf{b}_1, \dots, \mathbf{b}_n)$ . The linear operator on  $\bigwedge^m V$  whose matrix in the basis  $(\mathbf{b}_\alpha^\wedge)_{\alpha \in Q_{m,n}}$  is the  $m$ th compound of  $A$  is  $\bigwedge^m \theta$ .

## 13.9 Tensor Algebras

---

### Definitions:

Let  $A$  be an  $F$ -algebra and  $(A_k)_{k \in \mathbb{N}}$  a family of vector subspaces of  $A$ . The algebra  $A$  is **graded** by  $(A_k)_{k \in \mathbb{N}}$  if the following conditions are satisfied:

- (a)  $A = \bigoplus_{k \in \mathbb{N}} A_k$ .
- (b)  $A_i A_j \subseteq A_{i+j}$  for every  $i, j \in \mathbb{N}$ .

The elements of  $A_k$  are known as **homogeneous of degree  $k$** , and the elements of  $\bigcup_{n \in \mathbb{N}} A_k$  are called **homogeneous**.

By condition (a), every element of  $A$  can be written uniquely as a sum of (a finite number of nonzero) homogeneous elements, i.e., given  $u \in A$  there exist uniquely determined  $\mathbf{u}_k \in A_k, k \in \mathbb{N}$  satisfying

$$\mathbf{u} = \sum_{k \in \mathbb{N}} \mathbf{u}_k.$$

These elements are called **homogeneous components of  $\mathbf{u}$** . The summand of degree  $k$  in the former equation is denoted by  $[\mathbf{u}]_k$ .

From now on  $V$  is a finite dimensional vector space over  $F$  of dimension  $n$ . As before  $\otimes^k V$  denotes the  $k$ th-tensor power of  $V$ .

Denote by  $\bigotimes V$  the external direct sum of the vector spaces  $\otimes^k V, k \in \mathbb{N}$ . If  $z_i \in \otimes^i V, z_i$  is identified with the sequence  $z \in \bigotimes V$  whose  $i$ th coordinate is  $z_i$  and the remaining coordinates are 0. Therefore, after this identification,

$$\bigotimes V = \bigoplus_{k \in \mathbb{N}} \otimes^k V.$$

Consider in  $\bigotimes V$  the multiplication  $(x, y) \mapsto x \otimes y$  defined for  $x, y \in \bigotimes V$  by

$$[x \otimes y]_k = \sum_{\substack{r, s \in \mathbb{N} \\ r+s=k}} [x]_r \otimes [y]_s, \quad k \in \mathbb{N},$$

where  $[x]_r \otimes [y]_s$  is the  $(r, s)$ -tensor multiplication of  $[x]_r$  and  $[y]_s$  introduced in the definitions of Section 13.7. The vector space  $\bigotimes V$  equipped with this multiplication is called the **tensor algebra** on  $V$ .

Denote by  $\bigwedge V$  the external direct sum of the vector spaces  $\wedge^k V, k \in \mathbb{N}$ . If  $z_i \in \wedge^i V, z_i$  is identified with the sequence  $z \in \bigwedge V$  whose  $i$ th coordinate is  $z_i$  and the remaining coordinates are 0. Therefore, after this identification,

$$\bigwedge V = \bigoplus_{k \in \mathbb{N}} \wedge^k V.$$

Recall that  $\wedge^k V = \{0\}$  if  $k > n$ . Then

$$\bigwedge V = \bigoplus_{k=0}^n \wedge^k V$$

and the elements of  $\bigwedge V$  can be uniquely written in the form

$$z_0 + z_1 + \cdots + z_n, \quad z_i \in \wedge^i V, \quad i = 0, \dots, n.$$

Consider in  $\bigwedge V$  the multiplication  $(x, y) \mapsto x \wedge y$  defined, for  $x, y \in \bigwedge V$ , by

$$[x \wedge y]_k = \sum_{\substack{r, s \in \{0, \dots, n\} \\ r+s=k}} [x]_r \wedge [y]_s, \quad k \in \{0, \dots, n\},$$

where  $[x]_r \wedge [y]_s$  is the  $(r, s)$ -alt multiplication of  $[x]_r$  and  $[y]_s$  referred in definitions of Section 13.7. The vector space  $\bigwedge V$  equipped with this multiplication is called the **Grassmann algebra** on  $V$ .

Denote by  $\bigvee V$  the external direct sum of the vector spaces  $\vee^k V, k \in \mathbb{N}$ .

If  $z_i \in \vee^i V$ , we identify  $z_i$  with the sequence  $z \in \bigvee V$  whose  $i$ th coordinate is  $z_i$  and the remaining coordinates are 0. Therefore, after this identification

$$\bigvee V = \bigoplus_{k \in \mathbb{N}} \vee^k V.$$

Consider in  $\bigvee V$  the multiplication  $(x, y) \mapsto x \vee y$  defined for  $x, y \in \bigvee V$  by

$$[x \vee y]_k = \sum_{\substack{r,s \in \mathbb{N} \\ r+s=k}} [x]_r \vee [y]_s, \quad k \in \mathbb{N},$$

where  $[x]_r \vee [y]_s$  is the  $(r, s)$ -sym multiplication of  $[x]_r$  and  $[y]_s$  referred in definitions of Section 13.7.

The vector space  $\bigvee V$  equipped with this multiplication is called the **symmetric algebra** on  $V$ .

### Facts:

The following facts can be found in [Mar73, Chap. 3] and [Gre67, Chaps. II and III].

1. The vector space  $\bigotimes V$  with the multiplication  $(x, y) \mapsto x \otimes y$  is an algebra over  $F$  graded by  $(\bigotimes^k V)_{k \in \mathbb{N}}$ , whose identity is the identity of  $F = \bigotimes^0 V$ .
2. The vector space  $\bigwedge V$  with the multiplication  $(x, y) \mapsto x \wedge y$  is an algebra over  $F$  graded by  $(\bigwedge^k V)_{k \in \mathbb{N}}$  whose identity is the identity of  $F = \bigwedge^0 V$ .
3. The vector space  $\bigvee V$  with the multiplication  $(x, y) \mapsto x \vee y$  is an algebra over  $F$  graded by  $(\bigvee^k V)_{k \in \mathbb{N}}$  whose identity is the identity of  $F = \bigvee^0 V$ .
4. The  $F$ -algebra  $\bigotimes V$  does not have zero divisors.
5. Let  $B$  be an  $F$ -algebra and  $\theta$  a linear map from  $V$  into  $B$  satisfying  $\theta(\mathbf{x})\theta(\mathbf{y}) = -\theta(\mathbf{y})\theta(\mathbf{x})$  for all  $\mathbf{x}, \mathbf{y} \in V$ . Then there exists a unique algebra homomorphism  $h$  from  $\bigwedge V$  into  $B$  satisfying  $h|_V = \theta$ .
6. Let  $B$  be an  $F$ -algebra and  $\theta$  a linear map from  $V$  into  $B$  satisfying  $\theta(\mathbf{x})\theta(\mathbf{y}) = \theta(\mathbf{y})\theta(\mathbf{x})$ , for all  $\mathbf{x}, \mathbf{y} \in V$ . Then there exists a unique algebra homomorphism  $h$  from  $\bigvee V$  into  $B$  satisfying  $h|_V = \theta$ .
7. Let  $(\mathbf{b}_1, \dots, \mathbf{b}_n)$  be a basis of  $V$ . The symmetric algebra  $\bigvee^m V$  is isomorphic to the algebra of polynomials in  $n$  indeterminates,  $F[x_1, \dots, x_n]$ , by the algebra isomorphism whose restriction to  $V$  is the linear map that maps  $\mathbf{b}_i$  into  $x_i$ ,  $i = 1, \dots, n$ .

### Examples:

1. Let  $x_1, \dots, x_n$  be  $n$  distinct indeterminates. Let  $V$  be the vector space of the formal linear combinations with coefficients in  $F$  in the indeterminates  $x_1, \dots, x_n$ . The tensor algebra on  $V$  is the algebra of the polynomials in the noncommuting indeterminates  $x_1, \dots, x_n$  ([Coh03], [Jac64]). This algebra is denoted by

$$F \langle x_1, \dots, x_n \rangle.$$

The elements of this algebra are of the form

$$f(x_1, \dots, x_n) = \sum_{m \in \mathbb{N}} \sum_{\alpha \in \Gamma_{m,n}} c_\alpha x_{\alpha(1)} \otimes \cdots \otimes x_{\alpha(m)},$$

with all but a finite number of the coefficients  $c_\alpha$  equal to zero.

## 13.10 Tensor Product of Inner Product Spaces

Unless otherwise stated, within this section  $V, U$ , and  $W$ , as well as these letters subscripts, superscripts, or accents, are finite dimensional vector spaces over  $\mathbb{R}$  or over  $\mathbb{C}$ , equipped with an inner product.

The inner product of  $V$  is denoted by  $\langle \cdot, \cdot \rangle_V$ . When there is no risk of confusion  $\langle \cdot, \cdot \rangle$  is used instead. In this section  $F$  means either the field  $\mathbb{R}$  or the field  $\mathbb{C}$ .

### Definitions:

Let  $\theta$  be a linear map from  $V$  into  $W$ . The notation  $\theta^*$  will be used for the **adjoint** of  $\theta$  (i.e., the linear map from  $W$  into  $V$  satisfying  $\langle \theta(\mathbf{x}), \mathbf{y} \rangle = \langle \mathbf{x}, \theta^*(\mathbf{y}) \rangle$  for all  $\mathbf{x} \in V$  and  $\mathbf{y} \in W$ ).

The unique inner product  $\langle \cdot, \cdot \rangle$  on  $V_1 \otimes \cdots \otimes V_m$  satisfying, for every  $\mathbf{v}_i, \mathbf{u}_i \in V_i, i = 1, \dots, m$ ,

$$\langle \mathbf{v}_1 \otimes \cdots \otimes \mathbf{v}_m, \mathbf{u}_1 \otimes \cdots \otimes \mathbf{u}_m \rangle = \prod_{i=1}^m \langle \mathbf{v}_i, \mathbf{u}_i \rangle_{V_i},$$

is called **induced inner product** associated with the inner products  $\langle \cdot, \cdot \rangle_{V_i}, i = 1, \dots, m$ .

For each  $\mathbf{v} \in V$ , let  $f_{\mathbf{v}} \in V^*$  be defined by  $f_{\mathbf{v}}(\mathbf{u}) = \langle \mathbf{u}, \mathbf{v} \rangle$ . The inverse of the map  $\mathbf{v} \rightarrow f_{\mathbf{v}}$  is denoted by  $\varrho_V$  (briefly  $\varrho$ ). The inner product on  $V^*$ , defined by

$$\langle f, g \rangle = \langle \varrho(g), \varrho(f) \rangle_V,$$

is called the **dual** of  $\langle \cdot, \cdot \rangle_V$ .

Let  $U, V$  be inner product spaces over  $F$ . We consider defined in  $L(V; U)$  the **Hilbert–Schmidt** inner product, i.e., the inner product defined, for  $\theta, \eta \in L(V; U)$ , by  $\langle \theta, \eta \rangle = \text{tr}(\eta^* \theta)$ .

From now on  $V_1 \otimes \cdots \otimes V_m$  is assumed to be equipped with the inner product induced by the inner products  $\langle \cdot, \cdot \rangle_{V_i}, i = 1, \dots, m$ .

**Facts:**

The following facts can be found in [Mar73, Chap. 2].

1. The map  $\mathbf{v} \rightarrow f_{\mathbf{v}}$  is bijective-linear if  $F = \mathbb{R}$  and conjugate-linear (i.e.,  $c\mathbf{v} \mapsto \bar{c}f_{\mathbf{v}}$ ) if  $F = \mathbb{C}$ .
2. If  $(\mathbf{b}_{i1}, \dots, \mathbf{b}_{in_i})$  is an orthonormal basis of  $V_i, i = 1, \dots, m$ , then  $\{\mathbf{b}_{\alpha}^{\otimes} : \alpha \in \Gamma(n_1, \dots, n_m)\}$  is an orthonormal basis of  $V_1 \otimes \cdots \otimes V_m$ .
3. Let  $\theta_i \in L(V_i; W_i), i = 1, \dots, m$ , with adjoint map  $\theta_i^* \in L(W_i, V_i)$ . Then,

$$(\theta_1 \otimes \cdots \otimes \theta_m)^* = \theta_1^* \otimes \cdots \otimes \theta_m^*.$$

4. If  $\theta_i \in L(V_i; V_i)$  is Hermitian (normal, unitary),  $i = 1, \dots, m$ , then  $\theta_1 \otimes \cdots \otimes \theta_m$  is also Hermitian (normal, unitary).
5. Let  $\theta \in L(V; V)$ . If  $\bigotimes^m \theta$  ( $\bigvee^m \theta$ ) is normal, then  $\theta$  is normal.
6. Let  $\theta \in L(V; V)$ . Assume that  $\theta$  is a linear operator on  $V$  with rank greater than  $m$ . If  $\bigwedge^m \theta$  is normal, then  $\theta$  is normal.
7. If  $\mathbf{u}_1, \dots, \mathbf{u}_m, \mathbf{v}_1, \dots, \mathbf{v}_m \in V$ :

$$\langle \mathbf{u}_1 \wedge \cdots \wedge \mathbf{u}_m, \mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_m \rangle = m! \det \langle \mathbf{u}_i, \mathbf{v}_j \rangle,$$

$$\langle \mathbf{u}_1 \vee \cdots \vee \mathbf{u}_m, \mathbf{v}_1 \vee \cdots \vee \mathbf{v}_m \rangle = m! \text{per} \langle \mathbf{u}_i, \mathbf{v}_j \rangle.$$

8. Let  $(\mathbf{b}_1, \dots, \mathbf{b}_n)$  be an orthonormal basis of  $V$ . Then the basis  $(\mathbf{b}_{\alpha}^{\otimes})_{\alpha \in \Gamma_{m,n}}$  is an orthonormal basis of  $\bigotimes^m V$ ,  $(\sqrt{\frac{1}{m!}} \mathbf{b}_{\alpha}^{\wedge})_{\alpha \in Q_{m,n}}$  is an orthonormal basis of  $\bigwedge^m V$ , and  $(\sqrt{\frac{1}{m! \lambda_{\alpha}!}} \mathbf{b}_{\alpha}^{\vee})_{\alpha \in G_{m,n}}$  is an orthonormal basis of  $\bigvee^m V$ .

**Examples:**

The field  $F$  (recall that  $F = \mathbb{R}$  or  $F = \mathbb{C}$ ) has an inner product,  $(a, b) \mapsto \langle a, b \rangle = a\bar{b}$ . This inner product is called the **standard** inner product in  $F$  and it is the one assumed to equip  $F$  from now on.

1. When we choose  $F$  as the  $m$ th tensor power of  $F$  with the field multiplication as the tensor multiplication, then the canonical inner product is the inner product induced in  $\bigotimes^m F$  by the canonical inner product.
2. When we assume  $V$  as the tensor product of  $F$  and  $V$  with the tensor multiplication  $a \otimes \mathbf{v} = a\mathbf{v}$ , the inner product induced by the canonical inner product of  $F$  and the inner product of  $V$  is the inner product of  $V$ .

3. Consider  $L(V; U)$  as the tensor product of  $U$  and  $V^*$  by the tensor multiplication  $(\mathbf{u} \otimes f)(\mathbf{v}) = f(\mathbf{v})\mathbf{u}$ . Assume in  $V^*$  the inner product dual of the inner product of  $V$ . Then, if  $(\mathbf{v}_1, \dots, \mathbf{v}_n)$  is an orthonormal basis of  $V$  and  $\theta, \eta \in L(V; U)$ , we have

$$\langle \theta, \eta \rangle = \sum_{j=1}^m \langle \theta(\mathbf{v}_j), \eta(\mathbf{v}_j) \rangle = \text{tr}(\eta^* \theta),$$

i.e., the associated inner product of  $L(V; U)$  is the Hilbert–Schmidt one.

4. Consider  $F^{m \times n}$  as the tensor product of  $F^m$  and  $F^n$  by the tensor multiplication described in Example 1 in section 13.2. Then if we consider in  $F^m$  and  $F^n$  the usual inner product we get in  $F^{m \times n}$  as the induced inner product, the inner product

$$(A, B) \mapsto \text{tr}(\overline{B}^T A) = \sum_{i,j} a_{ij} \overline{b_{i,j}}.$$

5. Assume that in  $V_i^*$  is defined the inner product dual of  $\langle \cdot, \cdot \rangle_{V_i}$ ,  $i = 1, \dots, m$ . Then choosing  $L(V_1, \dots, V_m; F)$  as the tensor product of  $V_1^*, \dots, V_m^*$ , with the usual tensor multiplication, the inner product of  $L(V_1, \dots, V_m; F)$  induced by the duals of inner products on  $V_i^*$ ,  $i = 1, \dots, m$  is given by the equalities

$$\langle \varphi, \psi \rangle = \sum_{\alpha \in \Gamma} \varphi(\mathbf{b}_{1,\alpha(1)}, \dots, \mathbf{b}_{m,\alpha(m)}) \overline{\psi(\mathbf{b}_{1,\alpha(1)}, \dots, \mathbf{b}_{m,\alpha(m)})}.$$

## 13.11 Orientation and Hodge Star Operator

In this section, we assume that all vector spaces are real finite dimensional inner product spaces.

### Definitions:

Let  $V$  be a one-dimensional vector space. The equivalence classes of the equivalence relation  $\sim$ , defined by the condition  $\mathbf{v} \sim \mathbf{v}'$  if there exists a positive real number  $a > 0$  such that  $\mathbf{v}' = a\mathbf{v}$ , partitions the set of nonzero vectors of  $V$  into two subsets.

Each one of these subsets is known as an open **half-line**.

An **orientation** of  $V$  is a choice of one of these subsets. The fixed open half-line is called the **positive half-line** and its vectors are known as **positive**. The other open half-line of  $V$  is called **negative half-line**, and its vectors are also called **negative**.

The field  $\mathbb{R}$ , regarded as one-dimensional vector space, has a “natural” orientation that corresponds to choose as positive half-line the set of positive numbers.

If  $V$  is an  $n$ -dimensional vector space,  $\wedge^n V$  is a one-dimensional vector space (recall Fact 22 in section 13.6). An **orientation** of  $V$  is an orientation of  $\wedge^n V$ .

A basis  $(\mathbf{b}_1, \dots, \mathbf{b}_n)$  of  $V$  is said to be **positively oriented** if  $\mathbf{b}_1 \wedge \dots \wedge \mathbf{b}_n$  is positive and **negatively oriented** if  $\mathbf{b}_1 \wedge \dots \wedge \mathbf{b}_n$  is negative.

Throughout this section  $\wedge^m V$  will be equipped with the inner product  $\langle \cdot, \cdot \rangle_{\wedge}$ , a positive multiple of the induced the inner product, defined by

$$\langle z, w \rangle_{\wedge} = \frac{1}{m!} \langle z, w \rangle,$$

where the inner product on the right-hand side of the former equality is the inner product of  $\otimes^m V$  induced by the inner product of  $V$ . This is also the inner product that is considered whenever the norm of antisymmetric tensors is referred.

The positive tensor of norm 1 of  $\bigwedge^n V, u_V$ , is called **fundamental tensor of  $V$**  or **element of volume of  $V$** .

Let  $V$  be a real oriented inner product space. Let  $0 \leq m \leq n$ .

The **Hodge star operator** is the linear operator  $\star_m$  (denoted also by  $\star$ ) from  $\bigwedge^m V$  into  $\bigwedge^{n-m} V$  defined by the following condition:

$$\langle \star_m(w), w' \rangle_{\wedge^{n-m} V} = w \wedge w', \text{ for all } w' \in \bigwedge^{n-m} V.$$

Let  $n \geq 1$  and let  $V$  be an  $n$ -dimensional oriented inner product space over  $\mathbb{R}$ . The **external product on  $V$**  is the map

$$(\mathbf{v}_1, \dots, \mathbf{v}_{n-1}) \mapsto \mathbf{v}_1 \times \dots \times \mathbf{v}_{n-1} = \star_{n-1}(\mathbf{v}_1 \wedge \dots \wedge \mathbf{v}_{n-1}),$$

from  $V^{n-1}$  into  $V$ .

**Facts:**

The following facts can be found in [Mar75, Chap. 1] and [Sch75, Chap. 1].

1. If  $(\mathbf{b}_1, \dots, \mathbf{b}_n)$  is a positively oriented orthonormal basis of  $V$ , then  $u_V = \mathbf{b}_1 \wedge \dots \wedge \mathbf{b}_n$ .
2. If  $(\mathbf{b}_1, \dots, \mathbf{b}_n)$  is a positively oriented orthonormal basis of  $V$ , then

$$\star_m \mathbf{b}_\alpha^\wedge = \text{sgn}(\tilde{\alpha}) \mathbf{b}_{\alpha^c}^\wedge, \quad \alpha \in Q_{m,n},$$

where  $\tilde{\alpha}$  and  $\alpha^c$  are defined in Section 13.7.

3. Let  $(\mathbf{v}_1, \dots, \mathbf{v}_n)$  and  $(\mathbf{u}_1, \dots, \mathbf{u}_n)$  be two bases of  $V$  and  $\mathbf{v}_j = \sum a_{ij} \mathbf{u}_i, j = 1, \dots, n$ . Let  $A = [a_{ij}]$ . Since (recall Fact 29 in Section 13.6)

$$\mathbf{v}_1 \wedge \dots \wedge \mathbf{v}_n = \det(A) \mathbf{u}_1 \wedge \dots \wedge \mathbf{u}_n,$$

two bases have the same orientation if and only if their transition matrix has a positive determinant.

4.  $\star$  is an isometric isomorphism.
5.  $\star_0$  is the linear isomorphism that maps  $1 \in \mathbb{R}$  onto the fundamental tensor.
6.  $\star_m \star_{n-m} = (-1)^{m(n-m)} I_{\bigwedge^{n-m} V}$ .

Let  $V$  be an  $n$ -dimensional oriented inner product space over  $\mathbb{R}$ .

7. If  $m \neq 0$  and  $m \neq n$ , the Hodge star operator maps the set of decomposable elements of  $\bigwedge^m V$  onto the set of decomposable elements of  $\bigwedge^{n-m} V$ .
8. Let  $(\mathbf{x}_1, \dots, \mathbf{x}_m)$  be a linearly independent family of vectors of  $V$ . Then

$$\mathbf{y}_1 \wedge \dots \wedge \mathbf{y}_{n-m} = \star_m(\mathbf{x}_1 \wedge \dots \wedge \mathbf{x}_m)$$

if and only if the following three conditions hold:

- (a)  $\mathbf{y}_1, \dots, \mathbf{y}_{n-m} \in \text{Span}(\{\mathbf{x}_1, \dots, \mathbf{x}_m\})^\perp$ ;
- (b)  $\|\mathbf{y}_1 \wedge \dots \wedge \mathbf{y}_{n-m}\| = \|\mathbf{x}_1 \wedge \dots \wedge \mathbf{x}_m\|$ ;
- (c)  $(\mathbf{x}_1, \dots, \mathbf{x}_m, \mathbf{y}_1, \dots, \mathbf{y}_{n-m})$  is a positively oriented basis of  $V$ .

9. If  $(\mathbf{v}_1, \dots, \mathbf{v}_{n-1})$  is linearly independent,  $\mathbf{v}_1 \times \cdots \times \mathbf{v}_{n-1}$  is completely characterized by the following three conditions:

- (a)  $\mathbf{v}_1 \times \cdots \times \mathbf{v}_{n-1} \in \text{Span}(\{\mathbf{v}_1, \dots, \mathbf{v}_{n-1}\})^\perp$ .
- (b)  $\|\mathbf{v}_1 \times \cdots \times \mathbf{v}_{n-1}\| = \|\mathbf{v}_1 \wedge \cdots \wedge \mathbf{v}_{n-1}\|$ .
- (c)  $(\mathbf{v}_1, \dots, \mathbf{v}_{n-1}, \mathbf{v}_1 \times \cdots \times \mathbf{v}_{n-1})$  is a positively oriented basis of  $V$ .

10. Assume  $V^* = L(V; F)$ , with  $\dim(V) \geq 1$ , is equipped with the dual inner product. Consider  $L^m(V; F)$  as a model for the  $m$ th tensor power of  $V^*$  with the usual tensor multiplication. Then  $\bigwedge^m V^* = A^m(V; F)$ . If  $\lambda$  is an antisymmetric form in  $A^m(V; F)$ , then  $\star_m(\lambda)$  is the form whose value in  $(\mathbf{v}_1, \dots, \mathbf{v}_{n-m})$  is the component in the fundamental tensor of  $\lambda \wedge \varrho^{-1}(\mathbf{v}_1) \wedge \cdots \wedge \varrho^{-1}(\mathbf{v}_{n-m})$ , where  $\varrho$  is defined in the definition of section 13.10.

$$\star_m(\lambda)(\mathbf{v}_1, \dots, \mathbf{v}_{n-m})u_{V^*} = \lambda \wedge \varrho^{-1}(\mathbf{v}_1) \wedge \cdots \wedge \varrho^{-1}(\mathbf{v}_{n-m}).$$

11. Assuming the above setting for the Hodge star operator, the external product of  $\mathbf{v}_1, \dots, \mathbf{v}_{n-1}$  is the image by  $\varrho$  of the form  $(u_{V^*})_{\mathbf{v}_1, \dots, \mathbf{v}_{n-1}}$  (recall that  $(u_{V^*})_{\mathbf{v}_1, \dots, \mathbf{v}_{n-1}}(\mathbf{v}_n) = u_{V^*}(\mathbf{v}_1, \dots, \mathbf{v}_{n-1}, \mathbf{v}_n)$ ), i.e.,

$$\mathbf{v}_1 \times \cdots \times \mathbf{v}_{n-1} = \varrho((u_{V^*})_{\mathbf{v}_1, \dots, \mathbf{v}_{n-1}}).$$

The preceding formula can be unfolded by stating that for each  $v \in V$ ,  $\langle \mathbf{v}, \mathbf{v}_1 \times \cdots \times \mathbf{v}_{n-1} \rangle = u_{V^*}(\mathbf{v}_1, \dots, \mathbf{v}_{n-1}, \mathbf{v})$ .

### Examples:

1. If  $V$  has dimension 0, the isomorphism  $\star_0$  from  $\bigwedge^0 V = \mathbb{R}$  into  $\bigwedge^0 V = \mathbb{R}$  is either the identity (in the case we choose the natural orientation of  $V$ ) or  $-I$  (in the case we fix the nonnatural orientation of  $V$ ).
2. When  $V$  has dimension 2, the isomorphism  $\star_1$  is usually denoted by  $J$ . It has the property  $J^2 = -I$  and corresponds to the positively oriented rotation of  $\pi/2$ .
3. Assume that  $V$  has dimension 2. Then the external product is the isomorphism  $J$ .
4. If  $\dim(V) = 3$ , the external product is the well-known cross product.

Michael Tsatsomeros  
*Washington State University*

In this chapter, we have collected classical equalities and inequalities regarding the eigenvalues, the singular values, the determinant, and the dimensions of the fundamental subspaces of a matrix. Also included is a section on identities for matrix inverses. The majority of these results can be found in comprehensive books on linear algebra and matrix theory, although some are of specialized nature. The reader is encouraged to consult, e.g., [HJ85], [HJ91], [MM92], or [Mey00] for details, proofs, and further bibliography.

### 14.1 Eigenvalue Equalities and Inequalities

---

The majority of the facts in this section concern general matrices; however, some classical and frequently used results on eigenvalues of Hermitian and positive definite matrices are also included. For the latter, see also Chapter 8 and [HJ85, Chap. 4]. Many of the definitions and some of the facts in this section are also given in Section 4.3.

#### Facts:

- [HJ85, Chap. 1] Let  $A \in F^{n \times n}$ , where  $F = \mathbb{C}$  or any algebraically closed field. Let  $p_A(x) = \det(xI - A)$  be the characteristic polynomial of  $A$ , and  $\lambda_1, \lambda_2, \dots, \lambda_n$  be the eigenvalues of  $A$ . Denote by  $S_k(\lambda_1, \dots, \lambda_n)$  ( $k = 1, 2, \dots, n$ ) the  $k$ th elementary symmetric function of the eigenvalues (here abbreviated  $S_k(\lambda)$ ), and by  $S_k(A)$  the sum of all  $k \times k$  principal minors of  $A$ . Then

- The characteristic polynomial satisfies

$$\begin{aligned} p_A(x) &= (x - \lambda_1)(x - \lambda_2) \cdots (x - \lambda_n) \\ &= x^n - S_1(\lambda)x^{n-1} + S_2(\lambda)x^{n-2} + \cdots + (-1)^{n-1}S_{n-1}(\lambda)x + (-1)^n S_n(\lambda) \\ &= x^n - S_1(A)x^{n-1} + S_2(A)x^{n-2} + \cdots + (-1)^{n-1}S_{n-1}(A)x + (-1)^n S_n(A). \end{aligned}$$

- $S_k(\lambda) = S_k(\lambda_1, \dots, \lambda_n) = S_k(A)$  ( $k = 1, 2, \dots, n$ ).
  - $\text{tr} A = S_1(A) = \sum_{i=1}^n a_{ii} = \sum_{i=1}^n \lambda_i$  and  $\det A = S_n(A) = \prod_{i=1}^n \lambda_i$ .
2. [HJ85, (1.2.13)] Let  $A(i)$  be obtained from  $A \in \mathbb{C}^{n \times n}$  by deleting row and column  $i$ . Then

$$\frac{d}{dx} p_A(x) = \sum_{i=1}^n p_{A(i)}(x).$$

Facts 3 to 9 are collected, together with historical commentary, proofs, and further references, in [MM92, Chap. III].

3. (Hirsch and Bendixson) Let  $A = [a_{ij}] \in \mathbb{C}^{n \times n}$  and  $\lambda$  be an eigenvalue of  $A$ . Denote  $B = [b_{ij}] = (A + A^*)/2$  and  $C = [c_{ij}] = (A - A^*)/(2i)$ . Then the following inequalities hold:

$$\begin{aligned} |\lambda| &\leq n \max_{i,j} |a_{ij}|, \\ |\text{Re}\lambda| &\leq n \max_{i,j} |b_{ij}|, \\ |\text{Im}\lambda| &\leq n \max_{i,j} |c_{ij}|. \end{aligned}$$

Moreover, if  $A + A^T \in \mathbb{R}^{n \times n}$ , then

$$|\text{Im}\lambda| \leq \max_{i,j} |c_{ij}| \sqrt{\frac{n(n-1)}{2}}.$$

4. (Pick's inequality) Let  $A = [a_{ij}] \in \mathbb{R}^{n \times n}$  and  $\lambda$  be an eigenvalue of  $A$ . Denote  $C = [c_{ij}] = (A - A^T)/2$ . Then

$$|\text{Im}\lambda| \leq \max_{i,j} |c_{ij}| \cot\left(\frac{\pi}{2n}\right).$$

5. Let  $A = [a_{ij}] \in \mathbb{C}^{n \times n}$  and  $\lambda$  be an eigenvalue of  $A$ . Denote  $B = [b_{ij}] = (A + A^*)/2$  and  $C = [c_{ij}] = (A - A^*)/(2i)$ . Then the following inequalities hold:

$$\begin{aligned} \min\{\mu : \mu \in \sigma(B)\} &\leq \text{Re}\lambda \leq \max\{\mu : \mu \in \sigma(B)\}, \\ \min\{v : v \in \sigma(C)\} &\leq \text{Im}\lambda \leq \max\{v : v \in \sigma(C)\}. \end{aligned}$$

6. (Schur's inequality) Let  $A = [a_{ij}] \in \mathbb{C}^{n \times n}$  have eigenvalues  $\lambda_j$  ( $j = 1, 2, \dots, n$ ). Then

$$\sum_{j=1}^n |\lambda_j|^2 \leq \sum_{i,j=1}^n |a_{ij}|^2$$

with equality holding if and only if  $A$  is a normal matrix (i.e.,  $A^*A = AA^*$ ). (See Section 7.2 for more information on normal matrices.)

7. (Browne's Theorem) Let  $A = [a_{ij}] \in \mathbb{C}^{n \times n}$  and  $\lambda_j$  ( $j = 1, 2, \dots, n$ ) be the eigenvalues of  $A$  ordered so that  $|\lambda_1| \geq |\lambda_2| \geq \dots \geq |\lambda_n|$ . Let also  $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_n$  be the singular values of  $A$ , which are real and nonnegative. (See Section 5.6 for the definition.) Then

$$\sigma_n \leq |\lambda_j| \leq \sigma_1 \quad (j = 1, 2, \dots, n).$$

In fact, the following more general statement holds:

$$\prod_{i=1}^k \sigma_{n-i+1} \leq \prod_{j=1}^k |\lambda_{t_j}| \leq \prod_{i=1}^k \sigma_i,$$

for every  $k \in \{1, 2, \dots, n\}$  and every  $k$ -tuple  $(t_1, t_2, \dots, t_k)$  of strictly increasing elements chosen from  $\{1, 2, \dots, n\}$ .

8. Let  $A \in \mathbb{C}^{n \times n}$  and  $R_i, C_i$  ( $i = 1, 2, \dots, n$ ) denote the sums of the absolute values of the entries of  $A$  in row  $i$  and column  $i$ , respectively. Also denote

$$R = \max_i \{R_i\} \quad \text{and} \quad C = \max_i \{C_i\}.$$

Let  $\lambda$  be an eigenvalue of  $A$ . Then the following inequalities hold:

$$\begin{aligned} |\lambda| &\leq \max_i \frac{R_i + C_i}{2} \leq \frac{R + C}{2}, \\ |\lambda| &\leq \max_i \sqrt{R_i C_i} \leq \sqrt{RC}, \\ |\lambda| &\leq \min\{R, C\}. \end{aligned}$$

9. (Schneider's Theorem) Let  $A = [a_{ij}] \in \mathbb{C}^{n \times n}$  and  $\lambda_j$  ( $j = 1, 2, \dots, n$ ) be the eigenvalues of  $A$  ordered so that  $|\lambda_1| \geq |\lambda_2| \geq \dots \geq |\lambda_n|$ . Let  $\mathbf{x} = [x_i]$  be any vector in  $\mathbb{R}^n$  with positive entries and define the quantities

$$r_i = \sum_{j=1}^n \frac{|a_{ij}|x_j}{x_i} \quad (i = 1, 2, \dots, n).$$

Then

$$\prod_{j=1}^k |\lambda_j| \leq \prod_{j=1}^k r_{i_j} \quad (k = 1, 2, \dots, n)$$

for all  $n$ -tuples  $(i_1, i_2, \dots, i_n)$  of elements from  $\{1, 2, \dots, n\}$  such that

$$r_{i_1} \geq r_{i_2} \geq \dots \geq r_{i_n}.$$

10. [HJ85, Theorem 8.1.18] For  $A = [a_{ij}] \in \mathbb{C}^{n \times n}$ , let its entrywise absolute value be denoted by  $|A| = [|a_{ij}|]$ . Let  $B \in \mathbb{C}^{n \times n}$  and assume that  $|A| \leq B$  (entrywise). Then

$$\rho(A) \leq \rho(|A|) \leq \rho(B).$$

11. [HJ85, Chap. 5, Sec. 6] Let  $A \in \mathbb{C}^{n \times n}$  and  $\|\cdot\|$  denote any matrix norm on  $\mathbb{C}^{n \times n}$ . (See Chapter 37). Then

$$\rho(A) \leq \|A\|$$

and

$$\lim_{k \rightarrow \infty} \|A^k\|^{1/k} = \rho(A).$$

12. [HJ91, Corollary 1.5.5] Let  $A = [a_{ij}] \in \mathbb{C}^{n \times n}$ . The numerical range of  $A \in \mathbb{C}^{n \times n}$  is  $W(A) = \{v^* A v \in \mathbb{C} : v \in \mathbb{C}^n \text{ with } v^* v = 1\}$  and the numerical radius of  $A \in \mathbb{C}^{n \times n}$  is  $r(A) = \max\{|z| : z \in W(A)\}$ . (See Chapter 18 for more information about the numerical range and numerical radius.) Then the following inequalities hold:

$$\begin{aligned} r(A^m) &\leq [r(A)]^m \quad (m = 1, 2, \dots), \\ \rho(A) &\leq r(A) \leq \frac{\|A\|_1 + \|A\|_\infty}{2}, \\ \frac{\|A\|_2}{2} &\leq r(A) \leq \|A\|_2, \\ r(A) &\leq r(|A|) = \frac{|A| + |A|^T}{2} \quad (\text{where } |A| = [|a_{ij}|]). \end{aligned}$$

Moreover, the following statements are equivalent:

- (a)  $r(A) = \|A\|_2$ .
- (b)  $\rho(A) = \|A\|_2$ .
- (c)  $\|A^n\|_2 = \|A\|_2^n$ .
- (d)  $\|A^k\|_2 = \|A\|_2^k$  ( $k = 1, 2, \dots$ ).

Facts 13 to 15 below, along with proofs, can be found in [HJ85, Chap. 4].

13. (Rayleigh–Ritz) Let  $A \in \mathbb{C}^{n \times n}$  be Hermitian (i.e.,  $A = A^*$ ) with eigenvalues  $\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_n$ . Then
- (a)  $\lambda_n x^* x \leq x^* A x \leq \lambda_1 x^* x$  for all  $x \in \mathbb{C}^n$ .
  - (b)  $\lambda_1 = \max_{x \neq 0} \frac{x^* A x}{x^* x} = \max_{x^* x = 1} x^* A x$ .
  - (c)  $\lambda_n = \min_{x \neq 0} \frac{x^* A x}{x^* x} = \min_{x^* x = 1} x^* A x$ .
14. (Courant–Fischer) Let  $A \in \mathbb{C}^{n \times n}$  be Hermitian with eigenvalues  $\lambda_1 \geq \lambda_2 \geq \dots \geq \lambda_n$ . Let  $k \in \{1, 2, \dots, n\}$ . Then

$$\begin{aligned} \lambda_k &= \min_{w_1, w_2, \dots, w_{k-1} \in \mathbb{C}^n} \max_{\substack{x \neq 0, x \in \mathbb{C}^n \\ x \perp w_1, w_2, \dots, w_{k-1}}} \frac{x^* A x}{x^* x} \\ &= \max_{w_1, w_2, \dots, w_{n-k} \in \mathbb{C}^n} \min_{\substack{x \neq 0, x \in \mathbb{C}^n \\ x \perp w_1, w_2, \dots, w_{n-k}}} \frac{x^* A x}{x^* x}. \end{aligned}$$

15. (Weyl) Let  $A, B \in \mathbb{C}^{n \times n}$  be Hermitian. Consider the eigenvalues of  $A$ ,  $B$ , and  $A + B$ , denoted by  $\lambda_i(A)$ ,  $\lambda_i(B)$ ,  $\lambda_i(A + B)$ , respectively, arranged in decreasing order. Then the following hold:

- (a) For each  $k \in \{1, 2, \dots, n\}$ ,

$$\lambda_k(A) + \lambda_n(A) \leq \lambda_k(A + B) \leq \lambda_k(A) + \lambda_1(B).$$

- (b) For every pair  $j, k \in \{1, 2, \dots, n\}$  such that  $j + k \geq n + 1$ ,

$$\lambda_{j+k-n}(A + B) \geq \lambda_j(A) + \lambda_k(B).$$

- (c) For every pair  $j, k \in \{1, 2, \dots, n\}$  such that  $j + k \leq n + 1$ ,

$$\lambda_j(A) + \lambda_k(B) \geq \lambda_{j+k-1}(A + B).$$

### Examples:

1. To illustrate several of the facts in this section, consider

$$A = \begin{bmatrix} 1 & -1 & 0 & 2 \\ 3 & 1 & -2 & 1 \\ 1 & 0 & 0 & -1 \\ -1 & 2 & 1 & 0 \end{bmatrix},$$

whose spectrum,  $\sigma(A)$ , consists of

$$\lambda_1 = -0.7112 + 2.6718i, \lambda_2 = -0.7112 - 2.6718i, \lambda_3 = 2.5506, \lambda_4 = 0.8719.$$

Note that the eigenvalues are ordered decreasingly with respect to their moduli (absolute values):

$$|\lambda_1| = |\lambda_2| = 2.7649 > |\lambda_3| = 2.5506 > |\lambda_4| = 0.8719.$$

The maximum and minimum eigenvalues of  $(A + A^*)/2$  are 2.8484 and  $-1.495$ . Note that, as required by Fact 5, for every  $\lambda \in \sigma(A)$ ,

$$-1.495 \leq |\lambda| \leq 2.8484.$$

To illustrate Fact 7, let  $(t_1, t_2) = (1, 3)$  and compute the singular values of  $A$ :

$$\sigma_1 = 4.2418, \sigma_2 = 2.5334, \sigma_3 = 1.9890, \sigma_4 = 0.7954.$$

Then, indeed,

$$\sigma_4\sigma_3 = 1.5821 \leq |\lambda_1||\lambda_3| = 7.0522 \leq \sigma_1\sigma_2 = 10.7462.$$

Referring to the notation in Fact 8, we have  $C = 6$  and  $R = 7$ . The spectral radius of  $A$  is  $\rho(A) = 2.7649$  and, thus, the modulus of every eigenvalue of  $A$  is indeed bounded above by the quantities

$$\frac{R + C}{2} = \frac{13}{2} = 6.5, \quad \sqrt{RC} = 6.4807, \quad \min\{R, C\} = 6.$$

Letting  $B$  denote the entrywise absolute value of  $A$ , Facts 10 and 11 state that

$$\rho(A) = 2.7649 \leq \rho(B) = 4.4005 \quad \text{and} \quad \rho(A) = 2.7649 \leq \|A\|_2 = 4.2418.$$

Examples related to Fact 12 and the numerical range are found in Chapter 18. See also Example 2 that associates the numerical range with the location of the eigenvalues.

2. Consider the matrix

$$A = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix}$$

and note that for every integer  $m \geq 2$ ,  $A^m$  consists of zero entries, except for its  $(1, 1)$  entry that is equal to 1. One may easily verify that

$$\rho(A) = 1, \quad \|A\|_\infty = \|A\|_1 = \|A\|_2 = 1.$$

By Fact 12, it follows that  $r(A) = 1$  and all of the equivalent conditions (a) to (d) in that fact hold, despite  $A$  not being a normal matrix.

## 14.2 Spectrum Localization

---

This section presents results on classical inclusion regions for the eigenvalues of a matrix. The following facts, proofs, and details, as well as additional references, can be found in [MM92, Chap. III, Sec. 2], [HJ85, Chap. 6], and [Bru82].

### Facts:

1. (Geršgorin) Let  $A = [a_{ij}] \in \mathbb{C}^{n \times n}$  and define the quantities

$$R_i = \sum_{\substack{j=1 \\ j \neq i}}^n |a_{ij}| \quad (i = 1, 2, \dots, n).$$

Consider the **Geršgorin discs** (centered at  $a_{ii}$  with radii  $R_i$ ),

$$D_i = \{z \in \mathbb{C} : |z - a_{ii}| \leq R_i\} \quad (i = 1, 2, \dots, n).$$

Then all the eigenvalues of  $A$  lie in the union of the Geršgorin discs; that is,

$$\sigma(A) \subset \bigcup_{i=1}^n D_i.$$

Moreover, if the union of  $k$  Geršgorin discs,  $G$ , forms a connected region disjoint from the remaining  $n - k$  discs, then  $G$  contains exactly  $k$  eigenvalues of  $A$  (counting algebraic multiplicities).

2. (Lévy–Desplanques) Let  $A = [a_{ij}] \in \mathbb{C}^{n \times n}$  be a strictly diagonally dominant matrix, namely,

$$|a_{ii}| > \sum_{\substack{j=1 \\ j \neq i}}^n |a_{ij}| \quad (i = 1, 2, \dots, n).$$

Then  $A$  is an invertible matrix.

3. (Brauer) Let  $A = [a_{ij}] \in \mathbb{C}^{n \times n}$  and define the quantities

$$R_i = \sum_{\substack{j=1 \\ j \neq i}}^n |a_{ij}| \quad (i = 1, 2, \dots, n).$$

Consider the **ovals of Cassini**, which are defined by

$$V_{i,j} = \{z \in \mathbb{C} : |z - a_{ii}||z - a_{jj}| \leq R_i R_j\} \quad (i, j = 1, 2, \dots, n, i \neq j).$$

Then all the eigenvalues of  $A$  lie in the union of the ovals of Cassini; that is,

$$\sigma(A) \subset \bigcup_{\substack{i,j=1 \\ i \neq j}}^n V_{i,j}.$$

4. [VK99, Eq. 3.1] Denoting the union of the Geršgorin discs of  $A \in \mathbb{C}^{n \times n}$  by  $\Gamma(A)$  (see Fact 1) and the union of the ovals of Cassini of  $A$  by  $K(A)$  (see Fact 2), we have that

$$\sigma(A) \subset K(A) \subseteq \Gamma(A).$$

That is, the ovals of Cassini provided at least as good a localization for the eigenvalues of  $A$  as do the Geršgorin discs.

5. Let  $A = [a_{ij}] \in \mathbb{C}^{n \times n}$  such that

$$|a_{ii}||a_{kk}| > \sum_{\substack{j=1 \\ j \neq i}}^n |a_{ij}| \sum_{\substack{j=1 \\ j \neq k}}^n |a_{kj}| \quad (i, k = 1, 2, \dots, n, i \neq k).$$

Then  $A$  is an invertible matrix.

6. Facts 1 to 5 can also be stated in terms of *column sums* instead of row sums.  
7. (Ostrowski) Let  $A = [a_{ij}] \in \mathbb{C}^{n \times n}$  and  $\alpha \in [0, 1]$ . Define the quantities

$$R_i = \sum_{\substack{j=1 \\ j \neq i}}^n |a_{ij}|, \quad C_i = \sum_{\substack{j=1 \\ j \neq i}}^n |a_{ji}| \quad (i = 1, 2, \dots, n).$$

Then all the eigenvalues of  $A$  lie in the union of the discs

$$D_i(\alpha) = \{z \in \mathbb{C} : |z - a_{ii}| \leq R_i^\alpha C_i^{1-\alpha}\} \quad (i = 1, 2, \dots, n);$$

that is,

$$\sigma(A) \subset \bigcup_{i=1}^n D_i(\alpha).$$

8. Let  $A \in \mathbb{C}^{n \times n}$  and consider the spectrum of  $A$ ,  $\sigma(A)$ , as well as its numerical range,  $W(A)$ . Then

$$\sigma(A) \subset W(A).$$

In particular, if  $A$  is a normal matrix (i.e.,  $A^*A = AA^*$ ), then  $W(A)$  is exactly equal to the convex hull of the eigenvalues of  $A$ .

**Examples:**

1. To illustrate Fact 1 (see also Facts 3 and 4) let

$$A = \begin{bmatrix} 3i & 1 & 0.5 & -1 & 0 \\ -1 & 2i & 1.5 & 0 & 0 \\ 1 & 2 & -7 & 0 & 1 \\ 0 & -1 & 0 & 10 & i \\ 1 & 0 & 1 & -1 & 1 \end{bmatrix}$$

and consider the Geršgorin discs of  $A$  displayed in Figure 14.1. Note that there are three connected regions of discs that are disjoint of each other. Each region contains as many eigenvalues (marked with +’s) as the number of discs it comprises. The ovals of Cassini are contained in the union of the Geršgorin discs. In general, although it is easy to verify whether a complex number belongs to an oval of Cassini or not, these ovals are generally difficult to draw. An interactive supplement to [VK99] (accessible at: [www.emis.math.ca/EMIS/journals/ETNA/vol.8.1999/pp15-20.dir/gershini.html](http://www.emis.math.ca/EMIS/journals/ETNA/vol.8.1999/pp15-20.dir/gershini.html)) allows one to draw and compare the Geršgorin discs and ovals of Cassini of  $3 \times 3$  matrices.

2. To illustrate Fact 8, consider the matrices

$$A = \begin{bmatrix} 1 & -1 & 2 \\ 2 & -1 & 0 \\ -1 & 0 & 1 \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} 2 + 2i & -2 - i & -1 - 2i \\ 1 + 2i & -1 - i & -1 - 2i \\ 2 + i & -2 - i & -1 - i \end{bmatrix}.$$

FIGURE 14.1 The Geršgorin disks of  $A$ .

FIGURE 14.2 The numerical range of  $A$  and of the normal matrix  $B$ .

Note that  $B$  is a normal matrix with spectrum  $\{1, i, -1 - i\}$ . As indicated in Figure 14.2, the numerical ranges of  $A$  and  $B$  contain the eigenvalues of  $A$  and  $B$ , respectively, marked with '+'s. The numerical range of  $B$  is indeed the convex hull of the eigenvalues.

### 14.3 Inequalities for the Singular Values and the Eigenvalues

The material in this section is a selection of classical inequalities about the singular values. Extensive details and proofs, as well as a host of additional results on singular values, can be found in [HJ91, Chap. 3]. Definitions of many of the terms in this section are given in Section 5.6, Chapter 17, and Chapter 45; additional facts and examples are also given there.

**Facts:**

- Let  $A \in \mathbb{C}^{m \times n}$  and  $\sigma_1$  be its largest singular value. Then

$$\sigma_1 = \|A\|_2.$$

- Let  $A \in \mathbb{C}^{m \times n}$ ,  $q = \min\{m, n\}$ . Denote the singular values of  $A$  by  $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_q$  and let  $k \in \{1, 2, \dots, q\}$ . Then

$$\begin{aligned} \sigma_k &= \min_{w_1, w_2, \dots, w_{k-1} \in \mathbb{C}^n} \max_{\substack{\|x\|_2=1, x \in \mathbb{C}^n \\ x \perp w_1, w_2, \dots, w_{k-1}}} \|Ax\|_2 \\ &= \max_{w_1, w_2, \dots, w_{n-k} \in \mathbb{C}^n} \min_{\substack{\|x\|_2=1, x \in \mathbb{C}^n \\ x \perp w_1, w_2, \dots, w_{n-k}}} \|Ax\|_2 \\ &= \min_{\substack{W \subseteq \mathbb{C}^n \\ \dim W = n-k+1}} \max_{\substack{x \in W \\ \|x\|_2=1}} \|Ax\|_2 \\ &= \max_{\substack{W \subseteq \mathbb{C}^n \\ \dim W = k}} \min_{\substack{x \in W \\ \|x\|_2=1}} \|Ax\|_2, \end{aligned}$$

where the optimizations take place over all subspaces  $W \subseteq \mathbb{C}^n$  of the indicated dimensions.

- (Weyl) Let  $A \in \mathbb{C}^{n \times n}$  have singular values  $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_n$  and eigenvalues  $\lambda_j$  ( $j = 1, 2, \dots, n$ ) be ordered so that  $|\lambda_1| \geq |\lambda_2| \geq \dots \geq |\lambda_n|$ . Then

$$|\lambda_1 \lambda_2 \dots \lambda_k| \leq \sigma_1 \sigma_2 \dots \sigma_k \quad (k = 1, 2, \dots, n).$$

Equality holds in (3) when  $k = n$ .

4. (A. Horn) Let  $A \in \mathbb{C}^{m \times p}$  and  $B \in \mathbb{C}^{p \times n}$ . Let also  $r = \min\{m, p\}$ ,  $s = \min\{p, n\}$ , and  $q = \min\{r, s\}$ . Denote the singular values of  $A$ ,  $B$ , and  $AB$ , respectively, by  $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_r$ ,  $\tau_1 \geq \tau_2 \geq \dots \geq \tau_s$ , and  $\chi_1 \geq \chi_2 \geq \dots \geq \chi_q$ . Then

$$\prod_{i=1}^k \chi_i \leq \prod_{i=1}^k \sigma_i \tau_i \quad (k = 1, 2, \dots, q).$$

Equality holds if  $k = n = p = m$ . Also for any  $t > 0$ ,

$$\sum_{i=1}^k \chi_i^t \leq \sum_{i=1}^k (\sigma_i \tau_i)^t \quad (k = 1, 2, \dots, q).$$

5. Let  $A \in \mathbb{C}^{n \times n}$  have singular values  $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_n$  and eigenvalues  $\lambda_j$  ( $j = 1, 2, \dots, n$ ) ordered so that  $|\lambda_1| \geq |\lambda_2| \geq \dots \geq |\lambda_n|$ . Then for any  $t > 0$ ,

$$\sum_{i=1}^k |\lambda_i|^t \leq \sum_{i=1}^k \sigma_i^t \quad (k = 1, 2, \dots, n).$$

In particular, for  $t = 1$  and  $k = n$  we obtain from the inequality above that

$$|\operatorname{tr} A| \leq \sum_{i=1}^n \sigma_i.$$

6. Let  $A, B \in \mathbb{C}^{m \times n}$  and  $q = \min\{m, n\}$ . Denote the singular values of  $A$ ,  $B$ , and  $A + B$ , respectively, by  $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_q$ ,  $\tau_1 \geq \tau_2 \geq \dots \geq \tau_q$ , and  $\psi_1 \geq \psi_2 \geq \dots \geq \psi_q$ . Then the following inequalities hold:

(a)  $\psi_{i+j-1} \leq \sigma_i + \tau_j \quad (1 \leq i, j \leq q, \quad i + j \leq q + 1).$

(b)  $|\rho_i - \sigma_i| \leq \tau_1 \quad (i = 1, 2, \dots, q).$

(c)  $\sum_{i=1}^k \psi_i \leq \sum_{i=1}^k \sigma_i + \sum_{i=1}^k \tau_i \quad (k = 1, 2, \dots, q).$

7. Let  $A \in \mathbb{C}^{n \times n}$  have eigenvalues  $\lambda_j$  ( $j = 1, 2, \dots, n$ ) ordered so that  $|\lambda_1| \geq |\lambda_2| \geq \dots \geq |\lambda_n|$ . Denote the singular values of  $A^k$  by  $\sigma_1(A^k) \geq \sigma_2(A^k) \geq \dots \geq \sigma_n(A^k)$ . Then

$$\lim_{k \rightarrow \infty} [\sigma_i(A^k)]^{1/k} = |\lambda_i| \quad (i = 1, 2, \dots, n).$$

**Examples:**

1. To illustrate Facts 1, 3, and 5, as well as gauge the bounds they provide, let

$$A = \begin{bmatrix} i & 2 & -1 & 0 \\ 2 & 1+i & 1 & 0 \\ 2i & 1 & 1 & 0 \\ 0 & 1-i & 1 & 0 \end{bmatrix},$$

whose eigenvalues and singular values ordered as required in Fact 3 are, respectively,

$$\lambda_1 = 2.6775 + 1.0227i, \lambda_2 = -2.0773 + 1.4685i, \lambda_3 = 1.3998 - 0.4912i, \lambda_4 = 0,$$

and

$$\sigma_1 = 3.5278, \sigma_2 = 2.5360, \sigma_3 = 1.7673, \sigma_4 = 0.$$

According to Fact 1,  $\|A\|_2 = \sigma_1 = 3.5278$ . The following inequalities hold according to Fact 3:

$$7.2914 = |\lambda_1 \lambda_2| \leq \sigma_1 \sigma_2 = 8.9465.$$

$$10.8167 = |\lambda_1 \lambda_2 \lambda_3| \leq \sigma_1 \sigma_2 \sigma_3 = 15.8114.$$

Finally, applying Fact 5 with  $t = 3/2$  and  $k = 2$ , we obtain the inequality

$$8.9099 = |\lambda_1|^{3/2} + |\lambda_2|^{3/2} \leq \sigma_1^{3/2} + \sigma_2^{3/2} = 10.6646.$$

For  $t = 1$  and  $k = n$ , we get

$$2.8284 = |2 + 2i| = |\operatorname{tr}(A)| \leq \sum_{j=1}^4 \sigma_j = 7.8311.$$

## 14.4 Basic Determinantal Relations

The purpose of this section is to review some basic equalities and inequalities regarding the determinant of a matrix. For most of the facts mentioned here, see [Mey00, Chap. 6] and [HJ85, Chap. 0]. Definitions of many of the terms in this section are given in Sections 4.1 and 4.2; additional facts and examples are given there as well. Note that this section concludes with a couple of classical determinantal inequalities for positive semidefinite matrices; see Section 8.4 or [HJ85, Chap. 7] for more on this subject.

Following are some of the properties of determinants of  $n \times n$  matrices, as well as classical formulas for the determinant of  $A$  and its submatrices.

### Facts:

- Let  $A \in F^{n \times n}$ . The following are basic facts about the determinant. (See also Chapter 4.1.)
  - $\det A = \det A^T$ ; if  $F = \mathbb{C}$ , then  $\det A^* = \overline{\det A}$ .
  - If  $B$  is obtained from  $A$  by multiplying one row (or column) by a scalar  $c$ , then  $\det B = c \det A$ .
  - $\det(cA) = c^n \det A$  for any scalar  $c$ .
  - $\det(AB) = \det A \det B$ . If  $A$  is invertible, then  $\det A^{-1} = (\det A)^{-1}$ .
  - If  $B$  is obtained from  $A$  by adding nonzero multiples of one row (respectively, column) to other rows (respectively, columns), then  $\det B = \det A$ .
  - $\det A = \sum_{\sigma \in S_n} \operatorname{sgn}(\sigma) a_{1\sigma(1)} a_{2\sigma(2)} \cdots a_{n\sigma(n)}$ , where the summation is taken over all permutations  $\sigma$  of  $n$  letters, and where  $\operatorname{sgn}(\sigma)$  denotes the sign of the permutation  $\sigma$ .
  - Let  $A_{ij}$  denote the  $(n-1) \times (n-1)$  matrix obtained from  $A \in F^{n \times n}$  ( $n \geq 2$ ) by deleting row  $i$  and column  $j$ . The following formula is known as the **Laplace expansion of  $\det A$  along column  $j$** :

$$\det A = \sum_{i=1}^n (-1)^{i+j} a_{ij} \det A_{ij} \quad (j = 1, 2, \dots, n).$$

- (Cauchy–Binet) Let  $A \in F^{m,k}$ ,  $B \in F^{k \times n}$  and consider the matrix  $C = AB \in F^{m \times n}$ . Let also  $\alpha \subseteq \{1, 2, \dots, m\}$  and  $\beta \subseteq \{1, 2, \dots, n\}$  have cardinality  $r$ , where  $1 \leq r \leq \min\{m, k, n\}$ . Then the submatrix of  $C$  whose rows are indexed by  $\alpha$  and columns indexed by  $\beta$  satisfies

$$\det C[\alpha, \beta] = \sum_{\substack{\gamma \subseteq \{1, 2, \dots, k\} \\ |\gamma| = r}} \det A[\alpha, \gamma] \det B[\gamma, \beta].$$

- [Mey00, Sec. 6.1, p. 471] Let  $A = [a_{ij}(x)]$  be an  $n \times n$  matrix whose entries are complex differentiable functions of  $x$ . Let  $D_i$  ( $i = 1, 2, \dots, n$ ) denote the  $n \times n$  matrix obtained from  $A$  when the entries in its  $i$ th row are replaced by their derivatives with respect to  $x$ . Then

$$\frac{d}{dx}(\det A) = \sum_{i=1}^n \det D_i.$$

4. Let  $A = [a_{ij}]$  be an  $n \times n$  matrix and consider its entries as independent variables. Then

$$\frac{\partial(\det A)}{\partial a_{ij}} = \det A(\{i\}, \{j\}) \quad (i, j = 1, 2, \dots, n),$$

where  $A(\{i\}, \{j\})$  denotes the submatrix of  $A$  obtained from  $A$  by deleting row  $i$  and column  $j$ .

5. [Mey00, Sec. 6.2] Let  $A \in F^{n \times n}$  and  $\alpha \subseteq \{1, 2, \dots, n\}$ . If the submatrix of  $A$  whose rows and columns are indexed by  $\alpha$ ,  $A[\alpha]$ , is invertible, then

$$\det A = \det A[\alpha] \det(A/A[\alpha]).$$

In particular, if  $A$  is partitioned in blocks as

$$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix},$$

where  $A_{11}$  and  $A_{22}$  are square matrices, then

$$\det A = \begin{cases} \det A_{11} \det(A_{22} - A_{21}(A_{11})^{-1}A_{12}) & \text{if } A_{11} \text{ is invertible} \\ \det A_{22} \det(A_{11} - A_{12}(A_{22})^{-1}A_{21}) & \text{if } A_{22} \text{ is invertible.} \end{cases}$$

The following two facts for  $F = \mathbb{C}$  can be found in [Mey00, Sec. 6.2, pp. 475, 483] and [Mey00, Exer. 6.2.15, p. 485], respectively. The proofs are valid for arbitrary fields.

6. Let  $A \in F^{n \times n}$  be invertible and  $c, d \in F^n$ . Then

$$\det(A + cd^T) = \det(A)(1 + d^T A^{-1}c).$$

7. Let  $A \in F^{n \times n}$  be invertible,  $x, y \in F^n$ . Then

$$\det \begin{bmatrix} A & x \\ y^T & -1 \end{bmatrix} = -\det(A + xy^T).$$

8. [HJ85, Theorem 7.8.1 and Corollary 7.8.2] (Hadamard's inequalities) Let  $A = [a_{ij}] \in \mathbb{C}^{n \times n}$  be a positive semidefinite matrix. Then

$$\det A \leq \prod_{i=1}^n a_{ii}.$$

If  $A$  is positive definite, equality holds if and only if  $A$  is a diagonal matrix.

For a general matrix  $B = [b_{ij}] \in \mathbb{C}^{n \times n}$ , applying the above inequality to  $B^*B$  and  $BB^*$ , respectively, one obtains

$$|\det B| \leq \prod_{i=1}^n \left( \sum_{j=1}^n |b_{ij}|^2 \right)^{1/2} \quad \text{and} \quad |\det B| \leq \prod_{j=1}^n \left( \sum_{i=1}^n |b_{ij}|^2 \right)^{1/2}.$$

If  $B$  is nonsingular, equalities hold, respectively, if and only if the rows or the columns of  $B$  are orthogonal.

9. [HJ85, Theorem 7.8.3] (Fischer's inequality) Consider a positive definite matrix

$$A = \begin{bmatrix} X & Y \\ Y^* & Z \end{bmatrix},$$

partitioned so that  $X, Z$  are square and nonvacuous. Then

$$\det A \leq \det X \det Z.$$

**Examples:**

For examples relating to Facts 1, 2, and 5, see Chapter 4.

1. Let

$$A = \begin{bmatrix} 1 & 3 & -1 \\ 0 & 1 & 1 \\ -1 & 2 & 2 \end{bmatrix} \quad \text{and} \quad x = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}, y = \begin{bmatrix} 2 \\ 1 \\ -1 \end{bmatrix}.$$

Then, as noted by Fact 7,

$$\det \begin{bmatrix} A & x \\ y^T & -1 \end{bmatrix} = \begin{bmatrix} 1 & 3 & -1 & 1 \\ 0 & 1 & 1 & 1 \\ -1 & 2 & 2 & 1 \\ 2 & 1 & -1 & -1 \end{bmatrix} = -\det(A + xy^T) = \begin{bmatrix} 3 & 4 & -2 \\ 2 & 2 & 0 \\ 1 & 3 & 1 \end{bmatrix} = 10.$$

Next, letting  $c = [121]^T$  and  $d = [0 - 1 - 1]^T$ , by Fact 6, we have

$$\det(A + cd^T) = \det(A)(1 + d^T A^{-1}c) = (-4) \cdot (-1) = 4.$$

2. To illustrate Facts 8 and 9, let

$$A = \left[ \begin{array}{cc|c} 3 & 1 & 1 \\ 1 & 5 & 1 \\ 1 & 1 & 3 \end{array} \right] = \begin{bmatrix} X & Y \\ Y^* & Z \end{bmatrix}.$$

Note that  $A$  is positive definite and so Hadamard's inequality says that

$$\det A \leq 3 \cdot 5 \cdot 3 = 45;$$

in fact,  $\det A = 36$ . Fischer's inequality gives a smaller upper bound for the determinant:

$$\det A \leq \det X \det Z = 13 \cdot 3 = 39.$$

3. Consider the matrix

$$B = \begin{bmatrix} 1 & 2 & -2 \\ 4 & -1 & 1 \\ 0 & 1 & 1 \end{bmatrix}.$$

The first inequality about general matrices in Fact 8 applied to  $B$  gives

$$|\det B| \leq \sqrt{9 \cdot 18 \cdot 2} = 18.$$

As the rows of  $B$  are mutually orthogonal, we have that  $|\det B| = 18$ ; in fact,  $\det B = -18$ .

## 14.5 Rank and Nullity Equalities and Inequalities

---

Let  $A$  be a matrix over a field  $F$ . Here we present relations among the fundamental subspaces of  $A$  and their dimensions. As general references consult, e.g., [HJ85] and [Mey00, Sec. 4.2, 4.4, 4.5] (even though the matrices discussed there are complex, most of the proofs remain valid for any field). Additional material on rank and nullity can also be found in Section 2.4.

**Facts:**

- Let  $A \in F^{m \times n}$ . Then  $\text{rank}(A) = \dim \text{range } A = \dim \text{range } A^T$ .  
If  $F = \mathbb{C}$ , then  $\text{rank}(A) = \dim \text{range } A^* = \dim \overline{\text{range } A}$ .

2. If  $A \in \mathbb{C}^{m \times n}$ , then  $\text{range } A = (\ker A^*)^\perp$  and  $\text{range } A^* = (\ker A)^\perp$ .
3. If  $A \in F^{m \times n}$  and  $\text{rank}(A) = k$ , then there exist  $X \in F^{m \times k}$  and  $Y \in F^{k \times n}$  such that  $A = XY$ .
4. Let  $A, B \in F^{m \times n}$ . Then  $\text{rank}(A) = \text{rank}(B)$  if and only if there exist invertible matrices  $X \in F^{m \times m}$  and  $Y \in F^{n \times n}$  such that  $B = XAY$ .
5. (Dimension Theorem) Let  $A \in F^{m \times n}$ . Then

$$\text{rank}(A) + \text{null}(A) = n \quad \text{and} \quad \text{rank}(A) + \text{null}(A^T) = m.$$

If  $F = \mathbb{C}$ , then  $\text{rank}(A) + \text{null}(A^*) = m$ .

6. Let  $A, B \in F^{m \times n}$ . Then

$$\text{rank}(A) - \text{rank}(B) \leq \text{rank}(A + B) \leq \text{rank}(A) + \text{rank}(B).$$

7. Let  $A \in F^{m \times n}$ ,  $B \in F^{m \times k}$ , and  $C = [A|B] \in F^{m \times (n+k)}$ . Then

- $\text{rank}(C) = \text{rank}(A) + \text{rank}(B) - \dim(\text{range } A \cap \text{range } B)$ .
- $\text{null}(C) = \text{null}(A) + \text{null}(B) + \dim(\text{range } A \cap \text{range } B)$ .

8. Let  $A \in F^{m \times n}$  and  $B \in F^{n \times k}$ . Then

- $\text{rank}(AB) = \text{rank}(B) - \dim(\ker A \cap \text{range } B)$ .
- If  $F = \mathbb{C}$ , then  $\text{rank}(AB) = \text{rank}(A) - \dim(\ker B^* \cap \text{range } A^*)$ .
- Multiplication of a matrix from the left or right by an invertible matrix leaves the rank unchanged.
- $\text{null}(AB) = \text{null}(B) + \dim(\ker A \cap \text{range } B)$ .
- $\text{rank}(AB) \leq \min\{\text{rank}(A), \text{rank}(B)\}$ .
- $\text{rank}(AB) \geq \text{rank}(A) + \text{rank}(B) - n$ .

9. (Sylvester's law of nullity) Let  $A, B \in \mathbb{C}^{n \times n}$ . Then

$$\begin{aligned} \max\{\text{null}(A), \text{null}(B)\} &\leq \text{null}(AB) \\ &\leq \text{null}(A) + \text{null}(B). \end{aligned}$$

The above fact is valid *only* for square matrices.

10. (Frobenius inequality) Let  $A \in F^{m \times n}$ ,  $B \in F^{n \times k}$ , and  $C \in F^{k \times p}$ . Then

$$\text{rank}(AB) + \text{rank}(BC) \leq \text{rank}(B) + \text{rank}(ABC).$$

11. Let  $A \in \mathbb{C}^{m \times n}$ . Then

$$\text{rank}(A^*A) = \text{rank}(A) = \text{rank}(AA^*).$$

In fact,

$$\text{range}(A^*A) = \text{range } A^* \quad \text{and} \quad \text{range } A = \text{range}(AA^*),$$

as well as

$$\ker(A^*A) = \ker A \quad \text{and} \quad \ker(AA^*) = \ker A^*.$$

12. Let  $A \in F^{m \times n}$  and  $B \in F^{k \times p}$ . The rank of their direct sum is

$$\text{rank}(A \oplus B) = \text{rank} \begin{bmatrix} A & 0 \\ 0 & B \end{bmatrix} = \text{rank}(A) + \text{rank}(B).$$

13. Let  $A = [a_{ij}] \in F^{m \times n}$  and  $B \in F^{k \times p}$ . The rank of the Kronecker product  $A \otimes B = [a_{ij}B] \in F^{mk \times np}$  is

$$\text{rank}(A \otimes B) = \text{rank}(A)\text{rank}(B).$$

14. Let  $A = [a_{ij}] \in F^{m \times n}$  and  $B = [b_{ij}] \in F^{m \times n}$ . The rank of the Hadamard product  $A \circ B = [a_{ij}b_{ij}] \in F^{m \times n}$  satisfies

$$\text{rank}(A \circ B) \leq \text{rank}(A)\text{rank}(B).$$

**Examples:**

1. Consider the matrices

$$A = \begin{bmatrix} 1 & -1 & 1 \\ 2 & -1 & 0 \\ 3 & -2 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} 2 & 3 & 4 \\ 0 & 0 & -1 \\ 2 & 1 & 2 \end{bmatrix}, \quad \text{and} \quad C = \begin{bmatrix} 1 & 2 & -1 & 1 \\ 1 & 2 & -1 & 1 \\ 2 & 4 & -2 & 2 \end{bmatrix}.$$

We have that

$$\begin{aligned} \text{rank}(A) = 2, \quad \text{rank}(B) = 3, \quad \text{rank}(C) = 1, \quad \text{rank}(A + B) = 3, \\ \text{rank}(AB) = 2, \quad \text{rank}(BC) = 1, \quad \text{rank}(ABC) = 1. \end{aligned}$$

- As a consequence of Fact 5, we have

$$\begin{aligned} \text{null}(A) = 3 - 2 = 1, \quad \text{null}(B) = 3 - 3 = 0, \quad \text{null}(C) = 4 - 1 = 3, \\ \text{null}(A + B) = 3 - 3 = 0, \quad \text{null}(AB) = 3 - 2 = 1, \\ \text{null}(BC) = 3 - 1 = 2, \quad \text{null}(ABC) = 4 - 1 = 3. \end{aligned}$$

- Fact 6 states that

$$-1 = 2 - 3 = \text{rank}(A) - \text{rank}(B) \leq \text{rank}(A + B) = 0 \leq \text{rank}(A) + \text{rank}(B) = 5.$$

- Since  $\text{range} A \cap \text{range} B = \text{range} A$ , Fact 7 states that

$$\begin{aligned} \text{rank}([A|B]) &= \text{rank}(A) + \text{rank}(B) - \dim(\text{range} A \cap \text{range} B) = 2 + 3 - 2 = 3, \\ \text{null}([A|B]) &= \text{null}(A) + \text{null}(B) + \dim(\text{range} A \cap \text{range} B) = 1 + 0 + 2 = 3. \end{aligned}$$

- Since  $\ker A \cap \text{range} B = \ker A$ , Fact 8 states that

$$\begin{aligned} 2 &= \text{rank}(AB) = \text{rank}(B) - \dim(\ker A \cap \text{range} B) = 3 - 1 = 2. \\ 2 &= \text{rank}(AB) \leq \min\{\text{rank}(A), \text{rank}(B)\} = 2. \\ 2 &= \text{rank}(AB) \geq \text{rank}(A) + \text{rank}(B) - n = 2 + 3 - 3 = 2. \end{aligned}$$

- Fact 9 states that

$$\begin{aligned} 1 &= \max\{\text{null}(A), \text{null}(B)\} \leq \text{null}(AB) = 1 \\ &\leq \text{Null}(A) + \text{null}(B) = 1. \end{aligned}$$

Fact 9 can fail for nonsquare matrices. For example, if

$$D = [1 \quad 1],$$

then

$$1 = \max\{\text{null}(D), \text{null}(D^T)\} \not\leq \text{null}(DD^T) = 0.$$

- Fact 10 states that

$$3 = \text{rank}(AB) + \text{rank}(BC) \leq \text{rank}(B) + \text{rank}(ABC) = 4.$$

## 14.6 Useful Identities for the Inverse

---

This section presents facts and formulas related to inversion of matrices.

### Facts:

1. [Oue81, (1.9)], [HJ85, p. 18] Recall that  $A/A[\alpha]$  denotes the Schur complement of the principal submatrix  $A[\alpha]$  in  $A$ . (See Section 4.2 and Section 10.3.) If  $A \in F^{n \times n}$  is partitioned in blocks as

$$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix},$$

where  $A_{11}$  and  $A_{22}$  are square matrices, then, provided that  $A$ ,  $A_{11}$ , and  $A_{22}$  are invertible, we have that the Schur complements  $A/A_{11}$  and  $A/A_{22}$  are invertible and

$$A^{-1} = \begin{bmatrix} (A/A_{22})^{-1} & -A_{11}^{-1}A_{12}(A/A_{11})^{-1} \\ -(A/A_{11})^{-1}A_{21}A_{11}^{-1} & (A/A_{11})^{-1} \end{bmatrix}.$$

More generally, given an invertible  $A \in F^{n \times n}$  and  $\alpha \subseteq \{1, 2, \dots, n\}$  such that  $A[\alpha]$  and  $A(\alpha)$  are invertible,  $A^{-1}$  is obtained from  $A$  by replacing

- $A[\alpha]$  by  $(A/A(\alpha))^{-1}$ ,
  - $A[\alpha, \alpha^c]$  by  $-A[\alpha]^{-1}A[\alpha, \alpha^c](A/A[\alpha])^{-1}$ ,
  - $A[\alpha^c, \alpha]$  by  $-(A/A[\alpha])^{-1}A[\alpha^c, \alpha]A[\alpha]^{-1}$ , and
  - $A(\alpha)$  by  $(A/A[\alpha])^{-1}$ .
2. [HJ85, pp. 18–19] Let  $A \in F^{n \times n}$ ,  $X \in F^{n \times r}$ ,  $R \in F^{r \times r}$ , and  $Y \in F^{r \times n}$ . Let  $B = A + XRY$ . Suppose that  $A$ ,  $B$ , and  $R$  are invertible. Then

$$B^{-1} = (A + XRY)^{-1} = A^{-1} - A^{-1}X(R^{-1} + YA^{-1}X)^{-1}YA^{-1}.$$

3. (Sherman–Morrison) Let  $A \in F^{n \times n}$ ,  $x, y \in F^n$ . Let  $B = A + xy^T$ . Suppose that  $A$  and  $B$  are invertible. Then, if  $y^T A^{-1}x \neq -1$ ,

$$B^{-1} = (A + xy^T)^{-1} = A^{-1} - \frac{1}{1 + y^T A^{-1}x} A^{-1}xy^T A^{-1}.$$

In particular, if  $y^T x \neq -1$ , then

$$(I + xy^T)^{-1} = I - \frac{1}{1 + y^T x} xy^T.$$

4. Let  $A \in F^{n \times n}$ . Then the adjugate of  $A$  (see Section 4.2) satisfies

$$(\text{adj}A)A = A(\text{adj}A) = (\det A)I.$$

If  $A$  is invertible, then

$$A^{-1} = \frac{1}{\det A} \text{adj}A.$$

5. Let  $A \in F^{n \times n}$  be invertible and let its characteristic polynomial be  $p_A(x) = x^n + a_{n-1}x^{n-1} + a_{n-2}x^{n-2} + \cdots + a_1x + a_0$ . Then,

$$A^{-1} = \frac{(-1)^{n+1}}{\det A} (A^{n+1} + a_1A^n + a_2A^{n-1} + \cdots + a_{n-1}A).$$

6. [Mey00, Sec. 7.10, p. 618] Let  $A \in \mathbb{C}^{n \times n}$ . The following statements are equivalent.

- The **Neumann series**,  $I + A + A^2 + \cdots$ , converges.
- $(I - A)^{-1}$  exists and  $(I - A)^{-1} = \sum_{k=0}^{\infty} A^k$ .
- $\rho(A) < 1$ .
- $\lim_{k \rightarrow \infty} A^k = 0$ .

### Examples:

1. Consider the partitioned matrix

$$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} = \left[ \begin{array}{cc|c} 1 & 3 & -1 \\ 0 & 2 & 1 \\ \hline -1 & -1 & 1 \end{array} \right].$$

Since

$$(A/A_{22})^{-1} = \begin{bmatrix} 0 & 2 \\ 1 & 3 \end{bmatrix}^{-1} = \begin{bmatrix} -1.5 & 1 \\ 0.5 & 0 \end{bmatrix} \quad \text{and} \quad (A/A_{11})^{-1} = (-1)^{-1} = -1,$$

by Fact 1, we have

$$A^{-1} = \begin{bmatrix} (A/A_{22})^{-1} & -A_{11}^{-1}A_{12}(A/A_{11})^{-1} \\ -(A/A_{11})^{-1}A_{21}A_{11}^{-1} & (A/A_{11})^{-1} \end{bmatrix} = \left[ \begin{array}{cc|c} -1.5 & 1 & -2.5 \\ 0.5 & 0 & 0.5 \\ \hline -1 & 1 & -1 \end{array} \right].$$

2. To illustrate Fact 3, consider the invertible matrix

$$A = \begin{bmatrix} 1 & i & -1 \\ 1 & 0 & 1 \\ -2i & 1 & -2 \end{bmatrix}$$

and the vectors  $x = y = [1 \ 1 \ 1]^T$ . We have that

$$A^{-1} = \begin{bmatrix} 0.5i & 1 + 0.5i & 0.5 \\ -1 - i & -1 + i & i \\ -0.5i & -0.5i & -0.5 \end{bmatrix}.$$

Adding  $xy^T$  to  $A$  amounts to adding 1 to each entry of  $A$ ; since

$$1 + y^T A^{-1} x = i \neq 0,$$

the resulting matrix is invertible and its inverse is given by

$$\begin{aligned}(A + xy^T)^{-1} &= A^{-1} - \frac{1}{i} A^{-1} xy^T A^{-1} \\ &= \begin{bmatrix} 2.5 & -0.5 - 0.5i & -1 - i \\ -2 + 2i & 1 & 2 \\ -1.5 - i & 0.5 + 0.5i & i \end{bmatrix}.\end{aligned}$$

3. Consider the matrix

$$A = \begin{bmatrix} -1 & 1 & -1 \\ 1 & -1 & 3 \\ 1 & -1 & 2 \end{bmatrix}.$$

Since  $A^3 = 0$ ,  $A$  is a nilpotent matrix and, thus, all its eigenvalues equal 0. That is,  $\rho(A) = 0 < 1$ . As a consequence of Fact 6,  $I - A$  is invertible and

$$(I - A)^{-1} = I + A + A^2 = \begin{bmatrix} 1 & 0 & 1 \\ 2 & -1 & 5 \\ 1 & -1 & 3 \end{bmatrix}.$$

Ren-Cang Li

*University of Texas at Arlington*

There is a vast amount of material in matrix (operator) perturbation theory. Related books that are worth mentioning are [SS90], [Par98], [Bha96], [Bau85], and [Kat70]. In this chapter, we attempt to include the most fundamental results up to date, except those for linear systems and least squares problems for which the reader is referred to Section 38.1 and Section 39.6.

Throughout this chapter,  $\|\cdot\|_{\text{UI}}$  denotes a general unitarily invariant norm. Two commonly used ones are the spectral norm  $\|\cdot\|_2$  and the Frobenius norm  $\|\cdot\|_F$ .

### 15.1 Eigenvalue Problems

---

The reader is referred to Sections 4.3, 14.1, and 14.2 for more information on eigenvalues and their locations.

#### Definitions:

Let  $A \in \mathbb{C}^{n \times n}$ . A scalar–vector pair  $(\lambda, \mathbf{x}) \in \mathbb{C} \times \mathbb{C}^n$  is an **eigenpair** of  $A$  if  $\mathbf{x} \neq 0$  and  $A\mathbf{x} = \lambda\mathbf{x}$ . A vector–scalar–vector triplet  $(\mathbf{y}, \lambda, \mathbf{x}) \in \mathbb{C}^n \times \mathbb{C} \times \mathbb{C}^n$  is an **eigentriplet** if  $\mathbf{x} \neq 0$ ,  $\mathbf{y} \neq 0$ , and  $A\mathbf{x} = \lambda\mathbf{x}$ ,  $\mathbf{y}^*A = \lambda\mathbf{y}^*$ . The quantity

$$\text{cond}(\lambda) = \frac{\|\mathbf{x}\|_2 \|\mathbf{y}\|_2}{|\mathbf{y}^*\mathbf{x}|}$$

is the **individual condition number** for  $\lambda$ , where  $(\mathbf{y}, \lambda, \mathbf{x}) \in \mathbb{C}^n \times \mathbb{C} \times \mathbb{C}^n$  is an eigentriplet.

Let  $\sigma(A) = \{\lambda_1, \lambda_2, \dots, \lambda_n\}$ , the multiset of  $A$ 's eigenvalues, and set

$$\Lambda = \text{diag}(\lambda_1, \lambda_2, \dots, \lambda_n), \quad \Lambda_\tau = \text{diag}(\lambda_{\tau(1)}, \lambda_{\tau(2)}, \dots, \lambda_{\tau(n)}),$$

where  $\tau$  is a **permutation** of  $\{1, 2, \dots, n\}$ . For real  $\Lambda$ , i.e., all  $\lambda_j$ 's are real,

$$\Lambda^\uparrow = \text{diag}(\lambda_1^\uparrow, \lambda_2^\uparrow, \dots, \lambda_n^\uparrow).$$

$\Lambda^\uparrow$  is in fact a  $\Lambda_\tau$  for which the permutation  $\tau$  makes  $\lambda_{\tau(j)} = \lambda_j^\uparrow$  for all  $j$ .

Given two square matrices  $A_1$  and  $A_2$ , the **separation**  $\text{sep}(A_1, A_2)$  between  $A_1$  and  $A_2$  is defined as [SS90, p. 231]

$$\text{sep}(A_1, A_2) = \inf_{\|X\|_2=1} \|XA_1 - A_2X\|_2.$$

$A$  is perturbed to  $\tilde{A} = A + \Delta A$ . The same notation is adopted for  $\tilde{A}$ , except all symbols with tildes.

Let  $X, Y \in \mathbb{C}^{n \times k}$  with  $\text{rank}(X) = \text{rank}(Y) = k$ . The **canonical angles** between their column spaces are  $\theta_i = \arccos \sigma_i$ , where  $\{\sigma_i\}_{i=1}^k$  are the singular values of  $(Y^*Y)^{-1/2}Y^*X(X^*X)^{-1/2}$ . Define the **canonical angle matrix** between  $X$  and  $Y$  as

$$\Theta(X, Y) = \text{diag}(\theta_1, \theta_2, \dots, \theta_k).$$

For  $k = 1$ , i.e.,  $\mathbf{x}, \mathbf{y} \in \mathbb{C}^n$  (both nonzero), we use  $\angle(\mathbf{x}, \mathbf{y})$ , instead, to denote the canonical angle between the two vectors.

### Facts:

- [SS90, p. 168] (**Elsner**)  $\max_i \min_j |\tilde{\lambda}_i - \lambda_j| \leq (\|A\|_2 + \|\tilde{A}\|_2)^{1-1/n} \|\Delta A\|_2^{1/n}$ .
- [SS90, p. 170] (**Elsner**) There exists a permutation  $\tau$  of  $\{1, 2, \dots, n\}$  such that

$$\|\Lambda - \tilde{\Lambda}_\tau\|_2 \leq 2 \left\lfloor \frac{n}{2} \right\rfloor (\|A\|_2 + \|\tilde{A}\|_2)^{1-1/n} \|\Delta A\|_2^{1/n}.$$

- [SS90, p. 183] Let  $(\mathbf{y}, \mu, \mathbf{x})$  be an eigentriplet of  $A$ .  $\Delta A$  changes  $\mu$  to  $\mu + \Delta\mu$  with

$$\Delta\mu = \frac{\mathbf{y}^*(\Delta A)\mathbf{x}}{\mathbf{y}^*\mathbf{x}} + O(\|\Delta A\|_2^2),$$

and  $|\Delta\mu| \leq \text{cond}(\mu)\|\Delta A\|_2 + O(\|\Delta A\|_2^2)$ .

- [SS90, p. 205] If  $A$  and  $A + \Delta A$  are Hermitian, then

$$\|\Lambda^\uparrow - \tilde{\Lambda}^\uparrow\|_{\text{UI}} \leq \|\Delta A\|_{\text{UI}}.$$

- [Bha96, p. 165] (**Hoffman–Wielandt**) If  $A$  and  $A + \Delta A$  are normal, then there exists a permutation  $\tau$  of  $\{1, 2, \dots, n\}$  such that  $\|\Lambda - \tilde{\Lambda}_\tau\|_{\text{F}} \leq \|\Delta A\|_{\text{F}}$ .
- [Sun96] If  $A$  is normal, then there exists a permutation  $\tau$  of  $\{1, 2, \dots, n\}$  such that  $\|\Lambda - \tilde{\Lambda}_\tau\|_{\text{F}} \leq \sqrt{n}\|\Delta A\|_{\text{F}}$ .
- [SS90, p. 192] (**Bauer–Fike**) If  $A$  is diagonalizable and  $A = X\Lambda X^{-1}$  is its eigendecomposition, then

$$\max_i \min_j |\tilde{\lambda}_i - \lambda_j| \leq \|X^{-1}(\Delta A)X\|_p \leq \kappa_p(X)\|\Delta A\|_p.$$

- [BKL97] Suppose both  $A$  and  $\tilde{A}$  are diagonalizable and have eigendecompositions  $A = X\Lambda X^{-1}$  and  $\tilde{A} = \tilde{X}\tilde{\Lambda}\tilde{X}^{-1}$ .

(a) There exists a permutation  $\tau$  of  $\{1, 2, \dots, n\}$  such that

$$\|\Lambda - \tilde{\Lambda}_\tau\|_{\text{F}} \leq \sqrt{\kappa_2(X)\kappa_2(\tilde{X})}\|\Delta A\|_{\text{F}}.$$

(b)  $\|\Lambda^\uparrow - \tilde{\Lambda}^\uparrow\|_{\text{UI}} \leq \sqrt{\kappa_2(X)\kappa_2(\tilde{X})}\|\Delta A\|_{\text{UI}}$  for real  $\Lambda$  and  $\tilde{\Lambda}$ .

9. [KPJ82] Let residuals  $\mathbf{r} = A\tilde{\mathbf{x}} - \tilde{\mu}\tilde{\mathbf{x}}$  and  $\mathbf{s}^* = \tilde{\mathbf{y}}^*A - \tilde{\mu}\tilde{\mathbf{y}}^*$ , where  $\|\tilde{\mathbf{x}}\|_2 = \|\tilde{\mathbf{y}}\|_2 = 1$ , and let  $\varepsilon = \max\{\|\mathbf{r}\|_2, \|\mathbf{s}\|_2\}$ . The smallest error matrix  $\Delta A$  in the 2-norm, for which  $(\tilde{\mathbf{y}}, \tilde{\mu}, \tilde{\mathbf{x}})$  is an exact eigentriplet of  $\tilde{A} = A + \Delta A$ , satisfies  $\|\Delta A\|_2 = \varepsilon$ , and  $|\tilde{\mu} - \mu| \leq \text{cond}(\tilde{\mu})\varepsilon + O(\varepsilon^2)$  for some  $\mu \in \sigma(A)$ .
10. [KPJ82], [DK70],[Par98, pp. 73, 244] Suppose  $A$  is Hermitian, and let residual  $\mathbf{r} = A\tilde{\mathbf{x}} - \tilde{\mu}\tilde{\mathbf{x}}$  and  $\|\tilde{\mathbf{x}}\|_2 = 1$ .
- (a) The smallest Hermitian error matrix  $\Delta A$  (in the 2-norm), for which  $(\tilde{\mu}, \tilde{\mathbf{x}})$  is an exact eigenpair of  $\tilde{A} = A + \Delta A$ , satisfies  $\|\Delta A\|_2 = \|\mathbf{r}\|_2$ .
- (b)  $|\tilde{\mu} - \mu| \leq \|\mathbf{r}\|_2$  for some eigenvalue  $\mu$  of  $A$ .
- (c) Let  $\mu$  be the closest eigenvalue in  $\sigma(A)$  to  $\tilde{\mu}$  and  $\mathbf{x}$  be its associated eigenvector with  $\|\mathbf{x}\|_2 = 1$ , and let  $\eta = \min_{\mu \neq \lambda \in \sigma(A)} |\tilde{\mu} - \lambda|$ . If  $\eta > 0$ , then

$$|\tilde{\mu} - \mu| \leq \frac{\|\mathbf{r}\|_2^2}{\eta}, \quad \sin \angle(\tilde{\mathbf{x}}, \mathbf{x}) \leq \frac{\|\mathbf{r}\|_2}{\eta}.$$

11. Let  $A$  be Hermitian,  $X \in \mathbb{C}^{n \times k}$  have full column rank, and  $M \in \mathbb{C}^{k \times k}$  be Hermitian having eigenvalues  $\mu_1 \leq \mu_2 \leq \dots \leq \mu_k$ . Set

$$R = AX - XM.$$

There exist  $k$  eigenvalues  $\lambda_{i_1} \leq \lambda_{i_2} \leq \dots \leq \lambda_{i_k}$  of  $A$  such that the following inequalities hold. Note that subset  $\{\lambda_{i_j}\}_{j=1}^k$  may be different at different occurrences.

- (a) [Par98, pp. 253–260], [SS90, Remark 4.16, p. 207] (**Kahan–Cao–Xie–Li**)

$$\begin{aligned} \max_{1 \leq j \leq k} |\mu_j - \lambda_{i_j}| &\leq \frac{\|R\|_2}{\sigma_{\min}(X)}, \\ \sqrt{\sum_{j=1}^k (\mu_j - \lambda_{i_j})^2} &\leq \frac{\|R\|_F}{\sigma_{\min}(X)}. \end{aligned}$$

- (b) [SS90, pp. 254–257], [Sun91] If  $X^*X = I$  and  $M = X^*AX$ , and if all but  $k$  of  $A$ 's eigenvalues differ from every one of  $M$ 's by at least  $\eta > 0$  and  $\varepsilon_F = \|R\|_F/\eta < 1$ , then

$$\sqrt{\sum_{j=1}^k (\mu_k - \lambda_{i_j})^2} \leq \frac{\|R\|_F^2}{\eta\sqrt{1 - \varepsilon_F^2}}.$$

- (c) [SS90, pp. 254–257], [Sun91] If  $X^*X = I$  and  $M = X^*AX$ , and there is a number  $\eta > 0$  such that either all but  $k$  of  $A$ 's eigenvalues lie outside the open interval  $(\mu_1 - \eta, \mu_k + \eta)$  or all but  $k$  of  $A$ 's eigenvalues lie inside the closed interval  $[\mu_\ell + \eta, \mu_{\ell+1} - \eta]$  for some  $1 \leq \ell \leq k - 1$ , and  $\varepsilon = \|R\|_2/\eta < 1$ , then

$$\max_{1 \leq j \leq k} |\mu_j - \lambda_{i_j}| \leq \frac{\|R\|_2^2}{\eta\sqrt{1 - \varepsilon^2}}.$$

12. [DK70] Let  $A$  be Hermitian and have decomposition

$$\begin{bmatrix} X_1^* \\ X_2^* \end{bmatrix} A [X_1 \ X_2] = \begin{bmatrix} A_1 & \\ & A_2 \end{bmatrix},$$

where  $[X_1 \ X_2]$  is unitary and  $X_1 \in \mathbb{C}^{n \times k}$ . Let  $Q \in \mathbb{C}^{n \times k}$  have orthonormal columns and for a  $k \times k$  Hermitian matrix  $M$  set

$$R = AQ - QM.$$

Let  $\eta = \min |\mu - \nu|$  over all  $\mu \in \sigma(M)$  and  $\nu \in \sigma(A_2)$ . If  $\eta > 0$ , then  $\|\sin \Theta(X_1, Q)\|_F \leq \frac{\|R\|_F}{\eta}$ .

13. [LL05] Let

$$A = \begin{bmatrix} M & E^* \\ E & H \end{bmatrix}, \quad \tilde{A} = \begin{bmatrix} M & 0 \\ 0 & H \end{bmatrix}$$

be Hermitian, and set  $\eta = \min |\mu - \nu|$  over all  $\mu \in \sigma(M)$  and  $\nu \in \sigma(H)$ . Then

$$\max_{1 \leq j \leq n} |\lambda_j^\uparrow - \tilde{\lambda}_j^\uparrow| \leq \frac{2\|E\|_2^2}{\eta + \sqrt{\eta^2 + 4\|E\|_2^2}}.$$

14. [SS90, p. 230] Let  $[X_1 \ Y_2]$  be unitary and  $X_1 \in \mathbb{C}^{n \times k}$ , and let

$$\begin{bmatrix} X_1^* \\ Y_2^* \end{bmatrix} A [X_1 \ Y_2] = \begin{bmatrix} A_1 & G \\ E & A_2 \end{bmatrix}.$$

Assume that  $\sigma(A_1) \cap \sigma(A_2) = \emptyset$ , and set  $\eta = \text{sep}(A_1, A_2)$ . If  $\|G\|_2 \|E\|_2 < \eta^2/4$ , then there is a unique  $W \in \mathbb{C}^{(n-k) \times k}$ , satisfying  $\|W\|_2 \leq 2\|E\|_2/\eta$ , such that  $[\tilde{X}_1 \ \tilde{Y}_2]$  is unitary and

$$\begin{bmatrix} \tilde{X}_1^* \\ \tilde{Y}_2^* \end{bmatrix} A [\tilde{X}_1 \ \tilde{Y}_2] = \begin{bmatrix} \tilde{A}_1 & \tilde{G} \\ 0 & \tilde{A}_2 \end{bmatrix},$$

where

$$\begin{aligned} \tilde{X}_1 &= (X_1 + Y_2 W)(I + W^* W)^{-1/2}, \\ \tilde{Y}_2 &= (Y_2 - X_1 W^*)(I + W W^*)^{-1/2}, \\ \tilde{A}_1 &= (I + W^* W)^{1/2} (A_1 + G W) (I + W^* W)^{-1/2}, \\ \tilde{A}_2 &= (I + W W^*)^{-1/2} (A_2 - W G) (I + W W^*)^{1/2}. \end{aligned}$$

Thus,  $\|\tan \Theta(X_1, \tilde{X}_1)\|_2 < \frac{2\|E\|_2}{\eta}$ .

### Examples:

1. Bounds on  $\|\Lambda - \tilde{\Lambda}_\tau\|_{\text{UI}}$  are, in fact, bounds on  $\lambda_j - \lambda_{\tau(j)}$  in disguise, only more convenient and concise. For example, for  $\|\cdot\|_{\text{UI}} = \|\cdot\|_2$  (spectral norm),  $\|\Lambda - \tilde{\Lambda}_\tau\|_2 = \max_j |\lambda_j - \lambda_{\tau(j)}|$ , and for  $\|\cdot\|_{\text{UI}} = \|\cdot\|_F$  (Frobenius norm),  $\|\Lambda - \tilde{\Lambda}_\tau\|_F = \left[ \sum_{j=1}^n |\lambda_j - \lambda_{\tau(j)}|^2 \right]^{1/2}$ .
2. Let  $A, \tilde{A} \in \mathbb{C}^{n \times n}$  as follows, where  $\varepsilon > 0$ .

$$A = \begin{bmatrix} \mu & 1 & & & \\ & \mu & \ddots & & \\ & & \ddots & 1 & \\ & & & & \mu \end{bmatrix}, \quad \tilde{A} = \begin{bmatrix} \mu & 1 & & & \\ & \mu & \ddots & & \\ & & \ddots & 1 & \\ \varepsilon & & & & \mu \end{bmatrix}.$$

It can be seen that  $\sigma(A) = \{\mu, \dots, \mu\}$  (repeated  $n$  times) and the characteristic polynomial  $\det(tI - \tilde{A}) = (t - \mu)^n - \varepsilon$ , which gives  $\sigma(\tilde{A}) = \{\mu + \varepsilon^{1/n} e^{2ij\pi/n}, 0 \leq j \leq n-1\}$ . Thus,

$|\tilde{\lambda} - \mu| = \varepsilon^{1/n} = \|\Delta A\|_2^{1/n}$ . This shows that the fractional power  $\|\Delta A\|_2^{1/n}$  in Facts 1 and 2 cannot be removed in general.

3. Consider

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 0 & 4 & 5 \\ 0 & 0 & 4.001 \end{bmatrix} \text{ is perturbed by } \Delta A = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0.001 & 0 & 0 \end{bmatrix}.$$

$A$ 's eigenvalues are easily read off, and

$$\lambda_1 = 1, \mathbf{x}_1 = [1, 0, 0]^T, \mathbf{y}_1 = [0.8285, -0.5523, 0.0920]^T,$$

$$\lambda_2 = 4, \mathbf{x}_2 = [0.5547, 0.8321, 0]^T, \mathbf{y}_2 = [0, 0.0002, -1.0000]^T,$$

$$\lambda_3 = 4.001, \mathbf{x}_3 = [0.5547, 0.8321, 0.0002]^T, \mathbf{y}_3 = [0, 0, 1]^T.$$

On the other hand,  $\tilde{A}$ 's eigenvalues computed by MATLAB's `eig` are  $\tilde{\lambda}_1 = 1.0001, \tilde{\lambda}_2 = 3.9427, \tilde{\lambda}_3 = 4.0582$ . The following table gives  $|\tilde{\lambda}_j - \lambda_j|$  with upper bounds up to the 1st order by Fact 3.

$j$	$\text{cond}(\lambda_j)$	$\text{cond}(\lambda_j)\ \Delta A\ _2$	$ \tilde{\lambda}_j - \lambda_j $
1	1.2070	0.0012	0.0001
2	$6.0 \cdot 10^3$	6.0	0.057
3	$6.0 \cdot 10^3$	6.0	0.057

We see that  $\text{cond}(\lambda_j)\|\Delta A\|_2$  gives a fairly good error bound for  $j = 1$ , but dramatically worse for  $j = 2, 3$ . There are two reasons for this: One is in the choice of  $\Delta A$  and the other is that  $\Delta A$ 's order of magnitude is too big for the first order bound  $\text{cond}(\lambda_j)\|\Delta A\|_2$  to be effective for  $j = 2, 3$ . Note that  $\Delta A$  has the same order of magnitude as the difference between  $\lambda_2$  and  $\lambda_3$  and that is too big usually. For better understanding of this first order error bound, the reader may play with this example with  $\Delta A = \varepsilon \frac{\mathbf{y}_j \mathbf{x}_j^*}{\|\mathbf{y}_j\|_2 \|\mathbf{x}_j^*\|_2}$  for various tiny parameters  $\varepsilon$ .

4. Let  $\Sigma = \text{diag}(c_1, c_2, \dots, c_k)$  and  $\Gamma = \text{diag}(s_1, s_2, \dots, s_k)$ , where  $c_j, s_j \geq 0$  and  $c_j^2 + s_j^2 = 1$  for all  $j$ . The canonical angles between

$$X = Q \begin{bmatrix} I_k \\ 0 \\ 0 \end{bmatrix} V^*, \quad Y = Q \begin{bmatrix} \Sigma \\ \Gamma \\ 0 \end{bmatrix} U^*$$

are  $\theta_j = \arccos c_j, j = 1, 2, \dots, k$ , where  $Q, U, V$  are unitary. On the other hand, every pair of  $X, Y \in \mathbb{C}^{n \times k}$  with  $2k \leq n$  and  $X^*X = Y^*Y = I_k$ , having canonical angles  $\arccos c_j$ , can be represented this way [SS90, p. 40].

5. Fact 13 is most useful when  $\|E\|_2$  is tiny and the computation of  $A$ 's eigenvalues is then decoupled into two smaller ones. In eigenvalue computations, we often seek unitary  $[X_1 \ X_2]$  such that

$$\begin{bmatrix} X_1^* \\ X_2^* \end{bmatrix} A [X_1 \ X_2] = \begin{bmatrix} M & E^* \\ E & H \end{bmatrix}, \quad \begin{bmatrix} X_1^* \\ X_2^* \end{bmatrix} \tilde{A} [X_1 \ X_2] = \begin{bmatrix} M & 0 \\ 0 & H \end{bmatrix},$$

and  $\|E\|_2$  is tiny. Since a unitarily similarity transformation does not alter eigenvalues, Fact 13 still applies.

6. [LL05] Consider the  $2 \times 2$  Hermitian matrix

$$A = \begin{bmatrix} \alpha & \varepsilon \\ \varepsilon & \beta \end{bmatrix},$$

where  $\alpha > \beta$  and  $\varepsilon > 0$ . It has two eigenvalues

$$\lambda_{\pm} = \frac{\alpha + \beta \pm \sqrt{(\alpha - \beta)^2 + 4\varepsilon^2}}{2},$$

and

$$0 < \left\{ \begin{array}{l} \lambda_+ - \alpha \\ \beta - \lambda_- \end{array} \right\} = \frac{2\varepsilon^2}{(\alpha - \beta) + \sqrt{(\alpha - \beta)^2 + 4\varepsilon^2}}.$$

The inequalities in Fact 13 become equalities for the example.

## 15.2 Singular Value Problems

The reader is referred to Section 5.6, Chapters 17 and 45 for more information on singular value decompositions.

### Definitions:

$B \in \mathbb{C}^{m \times n}$  has a (first standard form) SVD  $B = U\Sigma V^*$ , where  $U \in \mathbb{C}^{m \times m}$  and  $V \in \mathbb{C}^{n \times n}$  are unitary, and  $\Sigma = \text{diag}(\sigma_1, \sigma_2, \dots) \in \mathbb{R}^{m \times n}$  is leading diagonal ( $\sigma_j$  starts in the top-left corner) with all  $\sigma_j \geq 0$ .

Let  $\text{sv}(B) = \{\sigma_1, \sigma_2, \dots, \sigma_{\min\{m,n\}}\}$ , the set of  $B$ 's singular values, and  $\sigma_1 \geq \sigma_2 \geq \dots \geq 0$ , and let  $\text{sv}_{\text{ext}}(B) = \text{sv}(B)$  unless  $m > n$  for which  $\text{sv}_{\text{ext}}(B) = \text{sv}(B) \cup \{0, \dots, 0\}$  (additional  $m - n$  zeros).

A vector–scalar–vector triplet  $(\mathbf{u}, \sigma, \mathbf{v}) \in \mathbb{C}^m \times \mathbb{R} \times \mathbb{C}^n$  is a **singular-triplet** if  $\mathbf{u} \neq 0$ ,  $\mathbf{v} \neq 0$ ,  $\sigma \geq 0$ , and  $B\mathbf{v} = \sigma\mathbf{u}$ ,  $B^*\mathbf{u} = \sigma\mathbf{v}$ .

$B$  is perturbed to  $\tilde{B} = B + \Delta B$ . The same notation is adopted for  $\tilde{B}$ , except all symbols with tildes.

### Facts:

1. [SS90, p. 204] (Mirsky)  $\|\Sigma - \tilde{\Sigma}\|_{\text{UI}} \leq \|\Delta B\|_{\text{UI}}$ .
2. Let residuals  $\mathbf{r} = B\tilde{\mathbf{v}} - \tilde{\mu}\tilde{\mathbf{u}}$  and  $\mathbf{s} = B^*\tilde{\mathbf{u}} - \tilde{\mu}\tilde{\mathbf{v}}$ , and  $\|\tilde{\mathbf{v}}\|_2 = \|\tilde{\mathbf{u}}\|_2 = 1$ .
  - (a) [Sun98] The smallest error matrix  $\Delta B$  (in the 2-norm), for which  $(\tilde{\mathbf{u}}, \tilde{\mu}, \tilde{\mathbf{v}})$  is an exact singular-triplet of  $\tilde{B} = B + \Delta B$ , satisfies  $\|\Delta B\|_2 = \varepsilon$ , where  $\varepsilon = \max\{\|\mathbf{r}\|_2, \|\mathbf{s}\|_2\}$ .
  - (b)  $|\tilde{\mu} - \mu| \leq \varepsilon$  for some singular value  $\mu$  of  $B$ .
  - (c) Let  $\mu$  be the closest singular value in  $\text{sv}_{\text{ext}}(B)$  to  $\tilde{\mu}$  and  $(\mathbf{u}, \sigma, \mathbf{v})$  be the associated singular-triplet with  $\|\mathbf{u}\|_2 = \|\mathbf{v}\|_2 = 1$ , and let  $\eta = \min|\tilde{\mu} - \sigma|$  over all  $\sigma \in \text{sv}_{\text{ext}}(B)$  and  $\sigma \neq \mu$ . If  $\eta > 0$ , then  $|\tilde{\mu} - \mu| \leq \varepsilon^2/\eta$ , and [SS90, p. 260]

$$\sqrt{\sin^2 \angle(\tilde{\mathbf{u}}, \mathbf{u}) + \sin^2 \angle(\tilde{\mathbf{v}}, \mathbf{v})} \leq \frac{\sqrt{\|\mathbf{r}\|_2^2 + \|\mathbf{s}\|_2^2}}{\eta}.$$

3. [LL05] Let

$$B = \begin{bmatrix} B_1 & F \\ E & B_2 \end{bmatrix} \in \mathbb{C}^{m \times n}, \quad \tilde{B} = \begin{bmatrix} B_1 & 0 \\ 0 & B_2 \end{bmatrix},$$

where  $B_1 \in \mathbb{C}^{k \times k}$ , and set  $\eta = \min|\mu - \nu|$  over all  $\mu \in \text{sv}(B_1)$  and  $\nu \in \text{sv}_{\text{ext}}(B_2)$ , and  $\varepsilon = \max\{\|E\|_2, \|F\|_2\}$ . Then

$$\max_j |\sigma_j - \tilde{\sigma}_j| \leq \frac{2\varepsilon^2}{\eta + \sqrt{\eta^2 + 4\varepsilon^2}}.$$

4. [SS90, p. 260] (**Wedin**) Let  $B, \tilde{B} \in \mathbb{C}^{m \times n}$  ( $m \geq n$ ) have decompositions

$$\begin{bmatrix} U_1^* \\ U_2^* \end{bmatrix} B [V_1 \ V_2] = \begin{bmatrix} B_1 & 0 \\ 0 & B_2 \end{bmatrix}, \quad \begin{bmatrix} \tilde{U}_1^* \\ \tilde{U}_2^* \end{bmatrix} \tilde{B} [\tilde{V}_1 \ \tilde{V}_2] = \begin{bmatrix} \tilde{B}_1 & 0 \\ 0 & \tilde{B}_2 \end{bmatrix},$$

where  $[U_1 \ U_2], [V_1 \ V_2], [\tilde{U}_1 \ \tilde{U}_2]$ , and  $[\tilde{V}_1 \ \tilde{V}_2]$  are unitary, and  $U_1, \tilde{U}_1 \in \mathbb{C}^{m \times k}, V_1, \tilde{V}_1 \in \mathbb{C}^{n \times k}$ . Set

$$R = B\tilde{V}_1 - \tilde{U}_1\tilde{B}_1, \quad S = B^*\tilde{U}_1 - \tilde{V}_1\tilde{B}_1.$$

If  $\text{sv}(\tilde{B}_1) \cap \text{sv}_{\text{ext}}(B_2) = \emptyset$ , then

$$\sqrt{\|\sin \Theta(U_1, \tilde{U}_1)\|_F^2 + \|\sin \Theta(V_1, \tilde{V}_1)\|_F^2} \leq \frac{\sqrt{\|R\|_F^2 + \|S\|_F^2}}{\eta},$$

where  $\eta = \min |\tilde{\mu} - \nu|$  over all  $\tilde{\mu} \in \text{sv}(\tilde{B}_1)$  and  $\nu \in \text{sv}_{\text{ext}}(B_2)$ .

**Examples:**

1. Let

$$B = \begin{bmatrix} 3 \cdot 10^{-3} & 1 \\ 2 & 4 \cdot 10^{-3} \end{bmatrix}, \quad \tilde{B} = \begin{bmatrix} 2 & 1 \\ 2 & 1 \end{bmatrix} = [\mathbf{e}_2 \ \mathbf{e}_1] \begin{bmatrix} 2 & \\ & 1 \end{bmatrix} \begin{bmatrix} \mathbf{e}_1^T \\ \mathbf{e}_2^T \end{bmatrix}.$$

Then  $\sigma_1 = 2.000012, \sigma_2 = 0.999988$ , and  $\tilde{\sigma}_1 = 2, \tilde{\sigma}_2 = 1$ . Fact 1 gives

$$\max_{1 \leq j \leq 2} |\sigma_j - \tilde{\sigma}_j| \leq 4 \cdot 10^{-3}, \quad \sqrt{\sum_{j=1}^2 |\sigma_j - \tilde{\sigma}_j|^2} \leq 5 \cdot 10^{-3}.$$

2. Let  $B$  be as in the previous example, and let  $\tilde{\mathbf{v}} = \mathbf{e}_1, \tilde{\mathbf{u}} = \mathbf{e}_2, \tilde{\mu} = 2$ . Then  $\mathbf{r} = B\tilde{\mathbf{v}} - \tilde{\mu}\tilde{\mathbf{u}} = 3 \cdot 10^{-3}\mathbf{e}_1$  and  $\mathbf{s} = B^*\tilde{\mathbf{u}} - \tilde{\mu}\tilde{\mathbf{v}} = 4 \cdot 10^{-3}\mathbf{e}_2$ . Fact 2 applies. Note that, without calculating  $\text{sv}(B)$ , one may bound  $\eta$  needed for Fact 2(c) from below as follows. Since  $B$  has two singular values that are near 1 and  $\tilde{\mu} = 2$ , respectively, with errors no bigger than  $4 \cdot 10^{-3}$ , then  $\eta \geq 2 - (1 + 4 \cdot 10^{-3}) = 1 - 4 \cdot 10^{-3}$ .
3. Let  $B$  and  $\tilde{B}$  be as in Example 1. Fact 3 gives  $\max_{1 \leq j \leq 2} |\sigma_j - \tilde{\sigma}_j| \leq 1.6 \cdot 10^{-5}$ , a much better bound than by Fact 1.
4. Let  $B$  and  $\tilde{B}$  be as in Example 1. Note  $\tilde{B}$ 's SVD there. Apply Fact 4 with  $k = 1$  to give a similar bound as by Fact 2(c).
5. Since unitary transformations do not change singular values, Fact 3 applies to  $B, \tilde{B} \in \mathbb{C}^{m \times n}$  having decompositions

$$\begin{bmatrix} U_1^* \\ U_2^* \end{bmatrix} B [V_1 \ V_2] = \begin{bmatrix} B_1 & F \\ E & B_2 \end{bmatrix}, \quad \begin{bmatrix} \tilde{U}_1^* \\ \tilde{U}_2^* \end{bmatrix} \tilde{B} [\tilde{V}_1 \ \tilde{V}_2] = \begin{bmatrix} \tilde{B}_1 & 0 \\ 0 & \tilde{B}_2 \end{bmatrix},$$

where  $[U_1 \ U_2]$  and  $[V_1 \ V_2]$  are unitary and  $U_1 \in \mathbb{C}^{m \times k}, V_1 \in \mathbb{C}^{n \times k}$ .

### 15.3 Polar Decomposition

The reader is referred to Chapter 17.1 for definition and for more information on polar decompositions.

**Definitions:**

$B \in \mathbb{F}^{m \times n}$  is perturbed to  $\tilde{B} = B + \Delta B$ , and their polar decompositions are

$$B = QH, \quad \tilde{B} = \tilde{Q}\tilde{H} = (Q + \Delta Q)(H + \Delta H),$$

where  $\mathbb{F} = \mathbb{R}$  or  $\mathbb{C}$ .  $\Delta B$  is restricted to  $\mathbb{F}$  for  $B \in \mathbb{F}$ .

Denote the singular values of  $B$  and  $\tilde{B}$  as  $\sigma_1 \geq \sigma_2 \geq \dots$  and  $\tilde{\sigma}_1 \geq \tilde{\sigma}_2 \geq \dots$ , respectively. The **condition numbers for the polar factors** in the Frobenius norm are defined as

$$\text{cond}_{\mathbb{F}}(X) = \lim_{\delta \rightarrow 0} \sup_{\|\Delta B\|_{\mathbb{F}} \leq \delta} \frac{\|\Delta X\|_{\mathbb{F}}}{\delta}, \quad \text{for } X = H \text{ or } Q.$$

$B$  is **multiplicatively perturbed** to  $\tilde{B}$  if  $\tilde{B} = D_L^* B D_R$  for some  $D_L \in \mathbb{F}^{m \times m}$  and  $D_R \in \mathbb{F}^{n \times n}$ .

$B$  is said to be **graded** if it can be scaled as  $B = GS$  such that  $G$  is “well-behaved” (i.e.,  $\kappa_2(G)$  is of modest magnitude), where  $S$  is a scaling matrix, often diagonal but not required so for the facts below. Interesting cases are when  $\kappa_2(G) \ll \kappa_2(B)$ .

### Facts:

- [CG00] The condition numbers  $\text{cond}_{\mathbb{F}}(Q)$  and  $\text{cond}_{\mathbb{F}}(H)$  are tabulated as follows, where  $\kappa_2(B) = \sigma_1/\sigma_n$ .

		$\mathbb{R}$	$\mathbb{C}$
Factor $Q$	$m = n$	$2/(\sigma_{n-1} + \sigma_n)$	$1/\sigma_n$
	$m > n$	$1/\sigma_n$	$1/\sigma_n$
Factor $H$	$m \geq n$	$\frac{\sqrt{2(1 + \kappa_2(B)^2)}}{1 + \kappa_2(B)}$	

- [Kit86]  $\|\Delta H\|_{\mathbb{F}} \leq \sqrt{2}\|\Delta B\|_{\mathbb{F}}$ .
- [Li95] If  $m = n$  and  $\text{rank}(B) = n$ , then

$$\|\Delta Q\|_{\text{UI}} \leq \frac{2}{\sigma_n + \tilde{\sigma}_n} \|\Delta B\|_{\text{UI}}.$$

- [Li95], [LS02] If  $\text{rank}(B) = n$ , then

$$\begin{aligned} \|\Delta Q\|_{\text{UI}} &\leq \left( \frac{2}{\sigma_n + \tilde{\sigma}_n} + \frac{1}{\max\{\sigma_n, \tilde{\sigma}_n\}} \right) \|\Delta B\|_{\text{UI}}, \\ \|\Delta Q\|_{\mathbb{F}} &\leq \frac{2}{\sigma_n + \tilde{\sigma}_n} \|\Delta B\|_{\mathbb{F}}. \end{aligned}$$

- [Mat93] If  $B \in \mathbb{R}^{n \times n}$ ,  $\text{rank}(B) = n$ , and  $\|\Delta B\|_2 < \sigma_n$ , then

$$\|\Delta Q\|_{\text{UI}} \leq -\frac{2\|\Delta B\|_{\text{UI}}}{\|\Delta B\|_2} \ln \left( 1 - \frac{\|\Delta B\|_2}{\sigma_n + \sigma_{n-1}} \right),$$

where  $\|\cdot\|_2$  is the **Ky Fan 2-norm**, i.e., the sum of the first two largest singular values. (See Chapter 17.3.)

- [LS02] If  $B \in \mathbb{R}^{n \times n}$ ,  $\text{rank}(B) = n$ , and  $\|\Delta B\|_2 < \sigma_n + \tilde{\sigma}_n$ , then

$$\|\Delta Q\|_{\mathbb{F}} \leq \frac{4}{\sigma_{n-1} + \sigma_n + \tilde{\sigma}_{n-1} + \tilde{\sigma}_n} \|\Delta B\|_{\mathbb{F}}.$$

- [Li97] Let  $B$  and  $\tilde{B} = D_L^* B D_R$  having full column rank. Then

$$\|\Delta Q\|_{\mathbb{F}} \leq \sqrt{\|I - D_L^{-1}\|_{\mathbb{F}}^2 + \|D_L - I\|_{\mathbb{F}}^2} + \sqrt{\|I - D_R^{-1}\|_{\mathbb{F}}^2 + \|D_R - I\|_{\mathbb{F}}^2}.$$

- [Li97], [Li05] Let  $B = GS$  and  $\tilde{B} = \tilde{G}S$  and assume that  $G$  and  $B$  have full column rank. If  $\|\Delta G\|_2 \|G^\dagger\|_2 < 1$ , then

$$\begin{aligned} \|\Delta Q\|_F &\leq \gamma \|G^\dagger\|_2 \|\Delta G\|_F, \\ \|(\Delta H)S^{-1}\|_F &\leq \left(\gamma \|G^\dagger\|_2 \|G\|_2 + 1\right) \|\Delta G\|_F, \end{aligned}$$

where  $\gamma = \sqrt{1 + (1 - \|G^\dagger\|_2 \|\Delta G\|_2)^{-2}}$ .

**Examples:**

1. Take both  $B$  and  $\tilde{B}$  to have orthonormal columns to see that some of the inequalities above on  $\Delta Q$  are attainable.
2. Let

$$B = \frac{1}{\sqrt{2}} \begin{bmatrix} 2.01 & 502 \\ -1.99 & -498 \end{bmatrix} = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} 10^{-2} & 2 \\ 2 & 5 \cdot 10^2 \end{bmatrix}$$

and

$$\tilde{B} = \begin{bmatrix} 1.4213 & 3.5497 \cdot 10^2 \\ -1.4071 & -3.5214 \cdot 10^2 \end{bmatrix}$$

obtained by rounding each entry of  $B$  to have five significant decimal digits.  $B = QH$  can be read off above and  $\tilde{B} = \tilde{Q}\tilde{H}$  can be computed by  $\tilde{Q} = \tilde{U}\tilde{V}^*$  and  $\tilde{H} = \tilde{V}\tilde{\Sigma}\tilde{V}^*$ , where  $\tilde{B}$ 's SVD is  $\tilde{U}\tilde{\Sigma}\tilde{V}^*$ . One has

$$sv(B) = \{5.00 \cdot 10^2, 2.00 \cdot 10^{-3}\}, sv(\tilde{B}) = \{5.00 \cdot 10^2, 2.04 \cdot 10^{-3}\}$$

and

$\ \Delta B\ _2$	$\ \Delta B\ _F$	$\ \Delta Q\ _2$	$\ \Delta Q\ _F$	$\ \Delta H\ _2$	$\ \Delta H\ _F$
$3 \cdot 10^{-3}$	$3 \cdot 10^{-3}$	$2 \cdot 10^{-6}$	$3 \cdot 10^{-6}$	$2 \cdot 10^{-3}$	$2 \cdot 10^{-3}$

Fact 2 gives  $\|\Delta H\|_F \leq 3 \cdot 10^{-3}$  and Fact 6 gives  $\|\Delta Q\|_F \leq 10^{-5}$ .

3. [Li97] and [Li05] have examples on the use of inequalities in Facts 7 and 8.

## 15.4 Generalized Eigenvalue Problems

The reader is referred to Section 43.1 for more information on generalized eigenvalue problems.

**Definitions:**

Let  $A, B \in \mathbb{C}^{m \times n}$ . A **matrix pencil** is a family of matrices  $A - \lambda B$ , parameterized by a (complex) number  $\lambda$ . The associated **generalized eigenvalue problem** is to find the nontrivial solutions of the equations

$$A\mathbf{x} = \lambda B\mathbf{x} \quad \text{and/or} \quad \mathbf{y}^* A = \lambda \mathbf{y}^* B,$$

where  $\mathbf{x} \in \mathbb{C}^n$ ,  $\mathbf{y} \in \mathbb{C}^m$ , and  $\lambda \in \mathbb{C}$ .

$A - \lambda B$  is **regular** if  $m = n$  and  $\det(A - \lambda B) \neq 0$  for some  $\lambda \in \mathbb{C}$ .

In what follows, all pencils in question are assumed regular.

An eigenvalue  $\lambda$  is conveniently represented by a nonzero number pair, so-called a **generalized eigenvalue**  $(\alpha, \beta)$ , interpreted as  $\lambda = \alpha/\beta$ .  $\beta = 0$  corresponds to eigenvalue infinity.

A **generalized eigenpair** of  $A - \lambda B$  refers to  $(\langle \alpha, \beta \rangle, \mathbf{x})$  such that  $\beta A \mathbf{x} = \alpha B \mathbf{x}$ , where  $\mathbf{x} \neq 0$  and  $|\alpha|^2 + |\beta|^2 > 0$ . A **generalized eigentriplet** of  $A - \lambda B$  refers to  $(\mathbf{y}, \langle \alpha, \beta \rangle, \mathbf{x})$  such that  $\beta A \mathbf{x} = \alpha B \mathbf{x}$  and  $\beta \mathbf{y}^* A = \alpha \mathbf{y}^* B$ , where  $\mathbf{x} \neq 0$ ,  $\mathbf{y} \neq 0$ , and  $|\alpha|^2 + |\beta|^2 > 0$ . The quantity

$$\text{cond}(\langle \alpha, \beta \rangle) = \frac{\|\mathbf{x}\|_2 \|\mathbf{y}\|_2}{\sqrt{|\mathbf{y}^* A \mathbf{x}|^2 + |\mathbf{y}^* B \mathbf{x}|^2}}$$

is the **individual condition number** for the generalized eigenvalue  $\langle \alpha, \beta \rangle$ , where  $(\mathbf{y}, \langle \alpha, \beta \rangle, \mathbf{x})$  is a generalized eigentriplet of  $A - \lambda B$ .

$A - \lambda B$  is perturbed to  $\tilde{A} - \lambda \tilde{B} = (A + \Delta A) - \lambda(B + \Delta B)$ .

Let  $\sigma(A, B) = \{\langle \alpha_1, \beta_1 \rangle, \langle \alpha_2, \beta_2 \rangle, \dots, \langle \alpha_n, \beta_n \rangle\}$  be the set of the generalized eigenvalues of  $A - \lambda B$ , and set  $Z = [A, B] \in \mathbb{C}^{2n \times n}$ .

$A - \lambda B$  is **diagonalizable** if it is equivalent to a diagonal pencil, i.e., there are nonsingular  $X, Y \in \mathbb{C}^{n \times n}$  such that  $Y^* A X = \Lambda$ ,  $Y^* B X = \Omega$ , where  $\Lambda = \text{diag}(\alpha_1, \alpha_2, \dots, \alpha_n)$  and  $\Omega = \text{diag}(\beta_1, \beta_2, \dots, \beta_n)$ .

$A - \lambda B$  is a **definite pencil** if both  $A$  and  $B$  are Hermitian and

$$\gamma(A, B) = \min_{\mathbf{x} \in \mathbb{C}^n, \|\mathbf{x}\|_2=1} |\mathbf{x}^* A \mathbf{x} + i \mathbf{x}^* B \mathbf{x}| > 0.$$

The same notation is adopted for  $\tilde{A} - \lambda \tilde{B}$ , except all symbols with tildes.

The **chordal distance** between two nonzero pairs  $\langle \alpha, \beta \rangle$  and  $\langle \tilde{\alpha}, \tilde{\beta} \rangle$  is

$$\chi(\langle \alpha, \beta \rangle, \langle \tilde{\alpha}, \tilde{\beta} \rangle) = \frac{|\tilde{\beta} \alpha - \tilde{\alpha} \beta|}{\sqrt{|\alpha|^2 + |\beta|^2} \sqrt{|\tilde{\alpha}|^2 + |\tilde{\beta}|^2}}.$$

### Facts:

- [SS90, p. 293] Let  $(\mathbf{y}, \langle \alpha, \beta \rangle, \mathbf{x})$  be a generalized eigentriplet of  $A - \lambda B$ .  $[\Delta A, \Delta B]$  changes  $\langle \alpha, \beta \rangle = \langle \mathbf{y}^* A \mathbf{x}, \mathbf{y}^* B \mathbf{x} \rangle$  to

$$\langle \tilde{\alpha}, \tilde{\beta} \rangle = \langle \alpha, \beta \rangle + \langle \mathbf{y}^* (\Delta A) \mathbf{x}, \mathbf{y}^* (\Delta B) \mathbf{x} \rangle + O(\varepsilon^2),$$

where  $\varepsilon = \|[\Delta A, \Delta B]\|_2$ , and  $\chi(\langle \alpha, \beta \rangle, \langle \tilde{\alpha}, \tilde{\beta} \rangle) \leq \text{cond}(\langle \alpha, \beta \rangle) \varepsilon + O(\varepsilon^2)$ .

- [SS90, p. 301], [Li88] If  $A - \lambda B$  is diagonalizable, then

$$\max_i \min_j \chi(\langle \alpha_i, \beta_i \rangle, \langle \tilde{\alpha}_j, \tilde{\beta}_j \rangle) \leq \kappa_2(X) \|\sin \Theta(Z^*, \tilde{Z}^*)\|_2.$$

- [Li94, Lemma 3.3] (**Sun**)

$$\|\sin \Theta(Z^*, \tilde{Z}^*)\|_{\text{UI}} \leq \frac{\|Z - \tilde{Z}\|_{\text{UI}}}{\max\{\sigma_{\min}(Z), \sigma_{\min}(\tilde{Z})\}},$$

where  $\sigma_{\min}(Z)$  is  $Z$ 's smallest singular value.

- The quantity  $\gamma(A, B)$  is the minimum distance of the numerical range  $W(A + iB)$  to the origin for definite pencil  $A - \lambda B$ .
- [SS90, p. 316] Suppose  $A - \lambda B$  is a definite pencil. If  $\tilde{A}$  and  $\tilde{B}$  are Hermitian and  $\|[\Delta A, \Delta B]\|_2 < \gamma(A, B)$ , then  $\tilde{A} - \lambda \tilde{B}$  is also a definite pencil and there exists a permutation  $\tau$  of  $\{1, 2, \dots, n\}$  such that

$$\max_{1 \leq j \leq n} \chi(\langle \alpha_j, \beta_j \rangle, \langle \tilde{\alpha}_{\tau(j)}, \tilde{\beta}_{\tau(j)} \rangle) \leq \frac{\|[\Delta A, \Delta B]\|_2}{\gamma(A, B)}.$$

- [SS90, p. 318] Definite pencil  $A - \lambda B$  is always diagonalizable:  $X^* A X = \Lambda$  and  $X^* B X = \Omega$ , and with real spectra. Facts 7 and 10 apply.

7. [Li03] Suppose  $A - \lambda B$  and  $\tilde{A} - \lambda \tilde{B}$  are diagonalizable with real spectra, i.e.,

$$Y^* A X = \Lambda, Y^* B X = \Omega \quad \text{and} \quad \tilde{Y}^* \tilde{A} \tilde{X} = \tilde{\Lambda}, \tilde{Y}^* \tilde{B} \tilde{X} = \tilde{\Omega},$$

and all  $\langle \alpha_j, \beta_j \rangle$  and all  $\langle \tilde{\alpha}_j, \tilde{\beta}_j \rangle$  are real. Then the follow statements hold, where

$$\Xi = \text{diag}(\chi(\langle \alpha_1, \beta_1 \rangle, \langle \tilde{\alpha}_{\tau(1)}, \tilde{\beta}_{\tau(1)} \rangle), \dots, \chi(\langle \alpha_n, \beta_n \rangle, \langle \tilde{\alpha}_{\tau(n)}, \tilde{\beta}_{\tau(n)} \rangle))$$

for some permutation  $\tau$  of  $\{1, 2, \dots, n\}$  (possibly depending on the norm being used). In all cases, the constant factor  $\pi/2$  can be replaced by 1 for the 2-norm and the Frobenius norm.

(a)  $\|\Xi\|_{\text{UI}} \leq \frac{\pi}{2} \sqrt{\kappa_2(X)\kappa_2(\tilde{X})} \|\sin \Theta(Z^*, \tilde{Z}^*)\|_{\text{UI}}.$

- (b) If all  $|\alpha_j|^2 + |\beta_j|^2 = |\tilde{\alpha}_j|^2 + |\tilde{\beta}_j|^2 = 1$  in their eigendecompositions, then

$$\|\Xi\|_{\text{UI}} \leq \frac{\pi}{2} \sqrt{\|X\|_2 \|Y^*\|_2 \|\tilde{X}\|_2 \|\tilde{Y}^*\|_2} \|\Delta A, \Delta B\|_{\text{UI}}.$$

8. Let residuals  $\mathbf{r} = \tilde{\beta} A \tilde{\mathbf{x}} - \tilde{\alpha} B \tilde{\mathbf{x}}$  and  $\mathbf{s}^* = \tilde{\beta} \tilde{\mathbf{y}}^* A - \tilde{\alpha} \tilde{\mathbf{y}}^* B$ , where  $\|\tilde{\mathbf{x}}\|_2 = \|\tilde{\mathbf{y}}\|_2 = 1$ . The smallest error matrix  $[\Delta A, \Delta B]$  in the 2-norm, for which  $(\tilde{\mathbf{y}}, \langle \tilde{\alpha}, \tilde{\beta} \rangle, \tilde{\mathbf{x}})$  is an exact generalized eigen triplet of  $\tilde{A} - \lambda \tilde{B}$ , satisfies  $\|[\Delta A, \Delta B]\|_2 = \varepsilon$ , where  $\varepsilon = \max\{\|\mathbf{r}\|_2, \|\mathbf{s}\|_2\}$ , and  $\chi(\langle \alpha, \beta \rangle, \langle \tilde{\alpha}, \tilde{\beta} \rangle) \leq \text{cond}(\langle \tilde{\alpha}, \tilde{\beta} \rangle) \varepsilon + O(\varepsilon^2)$  for some  $(\alpha, \beta) \in \sigma(A, B)$ .

9. [BDD00, p. 128] Suppose  $A$  and  $B$  are Hermitian and  $B$  is positive definite, and let residual  $\mathbf{r} = A \tilde{\mathbf{x}} - \tilde{\mu} B \tilde{\mathbf{x}}$  and  $\|\tilde{\mathbf{x}}\|_2 = 1$ .

- (a) For some eigenvalue  $\mu$  of  $A - \lambda B$ ,

$$|\tilde{\mu} - \mu| \leq \frac{\|\mathbf{r}\|_{B^{-1}}}{\|\tilde{\mathbf{x}}\|_B} \leq \|B^{-1}\|_2 \|\mathbf{r}\|_2,$$

where  $\|\mathbf{z}\|_M = \sqrt{\mathbf{z}^* M \mathbf{z}}$ .

- (b) Let  $\mu$  be the closest eigenvalue to  $\tilde{\mu}$  among all eigenvalues of  $A - \lambda B$  and  $\mathbf{x}$  its associated eigenvector with  $\|\mathbf{x}\|_2 = 1$ , and let  $\eta = \min |\tilde{\mu} - \nu|$  over all other eigenvalues  $\nu \neq \mu$  of  $A - \lambda B$ . If  $\eta > 0$ , then

$$|\tilde{\mu} - \mu| \leq \frac{1}{\eta} \cdot \left( \frac{\|\mathbf{r}\|_{B^{-1}}}{\|\tilde{\mathbf{x}}\|_B} \right)^2 \leq \|B^{-1}\|_2^2 \frac{\|\mathbf{r}\|_2^2}{\eta},$$

$$\sin \angle(\tilde{\mathbf{x}}, \mathbf{x}) \leq \|B^{-1}\|_2 \sqrt{2\kappa_2(B)} \frac{\|\mathbf{r}\|_2}{\eta}.$$

10. [Li94] Suppose  $A - \lambda B$  and  $\tilde{A} - \lambda \tilde{B}$  are diagonalizable and have eigendecompositions

$$\begin{bmatrix} Y_1^* \\ Y_2^* \end{bmatrix} A [X_1, X_2] = \begin{bmatrix} \Lambda_1 & \\ & \Lambda_2 \end{bmatrix}, \begin{bmatrix} Y_1^* \\ Y_2^* \end{bmatrix} B [X_1, X_2] = \begin{bmatrix} \Omega_1 & \\ & \Omega_2 \end{bmatrix},$$

$$X^{-1} = [W_1, W_2]^*,$$

and the same for  $\tilde{A} - \lambda \tilde{B}$  except all symbols with tildes, where  $X_1, Y_1, W_1 \in \mathbb{C}^{n \times k}$ ,  $\Lambda_1, \Omega_1 \in \mathbb{C}^{k \times k}$ . Suppose  $|\alpha_j|^2 + |\beta_j|^2 = |\tilde{\alpha}_j|^2 + |\tilde{\beta}_j|^2 = 1$  for  $1 \leq j \leq n$  in the eigendecompositions, and set  $\eta = \min \chi(\langle \alpha, \beta \rangle, \langle \tilde{\alpha}, \tilde{\beta} \rangle)$  taken over all  $(\alpha, \beta) \in \sigma(\Lambda_1, \Omega_1)$  and  $(\tilde{\alpha}, \tilde{\beta}) \in \sigma(\tilde{\Lambda}_2, \tilde{\Omega}_2)$ . If  $\eta > 0$ , then

$$\left\| \sin \Theta(X_1, \tilde{X}_1) \right\|_{\text{F}} \leq \frac{\|X_1^\dagger\|_2 \|\tilde{W}_2^\dagger\|_2}{\eta} \left\| \tilde{Y}_2^* (\tilde{Z} - Z) \begin{bmatrix} X_1 & \\ & X_1 \end{bmatrix} \right\|_{\text{F}}.$$

## 15.5 Generalized Singular Value Problems

### Definitions:

Let  $A \in \mathbb{C}^{m \times n}$  and  $B \in \mathbb{C}^{\ell \times n}$ . A matrix pair  $\{A, B\}$  is an  $(m, \ell, n)$ -**Grassmann matrix pair** if

$$\text{rank} \begin{pmatrix} A \\ B \end{pmatrix} = n.$$

In what follows, all matrix pairs are  $(m, \ell, n)$ -Grassmann matrix pairs.

A pair  $\langle \alpha, \beta \rangle$  is a **generalized singular value** of  $\{A, B\}$  if

$$\det(\beta^2 A^* A - \alpha^2 B^* B) = 0, \quad \langle \alpha, \beta \rangle \neq \langle 0, 0 \rangle, \quad \alpha, \beta \geq 0,$$

i.e.,  $\langle \alpha, \beta \rangle = \langle \sqrt{\mu}, \sqrt{\nu} \rangle$  for some generalized eigenvalue  $\langle \mu, \nu \rangle$  of matrix pencil  $A^* A - \lambda B^* B$ .

**Generalized Singular Value Decomposition (GSVD)** of  $\{A, B\}$ :

$$U^* A X = \Sigma_A, \quad V^* B X = \Sigma_B,$$

where  $U \in \mathbb{C}^{m \times m}$ ,  $V \in \mathbb{C}^{\ell \times \ell}$  are unitary,  $X \in \mathbb{C}^{n \times n}$  is nonsingular,  $\Sigma_A = \text{diag}(\alpha_1, \alpha_2, \dots)$  is **leading diagonal** ( $\alpha_j$  starts in the top left corner), and  $\Sigma_B = \text{diag}(\dots, \beta_{n-1}, \beta_n)$  is **trailing diagonal** ( $\beta_j$  ends in the bottom-right corner),  $\alpha_j, \beta_j \geq 0$  and  $\alpha_j^2 + \beta_j^2 = 1$  for  $1 \leq j \leq n$ . (Set some  $\alpha_j = 0$  and/or some  $\beta_j = 0$ , if necessary.)

$\{A, B\}$  is perturbed to  $\{\tilde{A}, \tilde{B}\} = \{A + \Delta A, B + \Delta B\}$ .

Let  $\text{sv}(A, B) = \{\langle \alpha_1, \beta_1 \rangle, \langle \alpha_2, \beta_2 \rangle, \dots, \langle \alpha_n, \beta_n \rangle\}$  be the set of the generalized singular values of  $\{A, B\}$ ,

and set  $Z = \begin{bmatrix} A \\ B \end{bmatrix} \in \mathbb{C}^{(m+\ell) \times n}$ .

The same notation is adopted for  $\{\tilde{A}, \tilde{B}\}$ , except all symbols with tildes.

### Facts:

1. If  $\{A, B\}$  is an  $(m, \ell, n)$ -Grassmann matrix pair, then  $A^* A - \lambda B^* B$  is a definite matrix pencil.
2. [Van76] The GSVD of an  $(m, \ell, n)$ -Grassmann matrix pair  $\{A, B\}$  exists.
3. [Li93] There exist permutations  $\tau$  and  $\omega$  of  $\{1, 2, \dots, n\}$  such that

$$\begin{aligned} \max_{1 \leq j \leq n} \chi(\langle \alpha_i, \beta_i \rangle, \langle \tilde{\alpha}_{\tau(i)}, \tilde{\beta}_{\tau(i)} \rangle) &\leq \|\sin \Theta(Z, \tilde{Z})\|_2, \\ \sqrt{\sum_{j=1}^n \left[ \chi(\langle \alpha_i, \beta_i \rangle, \langle \tilde{\alpha}_{\omega(i)}, \tilde{\beta}_{\omega(i)} \rangle) \right]^2} &\leq \|\sin \Theta(Z, \tilde{Z})\|_F. \end{aligned}$$

4. [Li94, Lemma 3.3] (**Sun**)

$$\|\sin \Theta(Z, \tilde{Z})\|_{\text{UI}} \leq \frac{\|Z - \tilde{Z}\|_{\text{UI}}}{\max\{\sigma_{\min}(Z), \sigma_{\min}(\tilde{Z})\}},$$

where  $\sigma_{\min}(Z)$  is  $Z$ 's smallest singular value.

5. [Pai84] If  $\alpha_i^2 + \beta_i^2 = \tilde{\alpha}_i^2 + \tilde{\beta}_i^2 = 1$  for  $i = 1, 2, \dots, n$ , then there exists a permutation  $\varpi$  of  $\{1, 2, \dots, n\}$  such that

$$\sqrt{\sum_{j=1}^n \left[ (\alpha_j - \tilde{\alpha}_{\varpi(j)})^2 + (\beta_j - \tilde{\beta}_{\varpi(j)})^2 \right]} \leq \min_{Q \text{ unitary}} \|Z_0 - \tilde{Z}_0 Q\|_F,$$

where  $Z_0 = Z(Z^* Z)^{-1/2}$  and  $\tilde{Z}_0 = \tilde{Z}(\tilde{Z}^* \tilde{Z})^{-1/2}$ .

6. [Li93], [Sun83] Perturbation bounds on generalized singular subspaces (those spanned by one or a few columns of  $U$ ,  $V$ , and  $X$  in GSVD) are also available, but it is quite complicated.

## 15.6 Relative Perturbation Theory for Eigenvalue Problems

### Definitions:

Let scalar  $\tilde{\alpha}$  be an approximation to  $\alpha$ , and  $1 \leq p \leq \infty$ . Define **relative distances** between  $\alpha$  and  $\tilde{\alpha}$  as follows. For  $|\alpha|^2 + |\tilde{\alpha}|^2 \neq 0$ ,

$$\begin{aligned} d(\alpha, \tilde{\alpha}) &= \left| \frac{\tilde{\alpha}}{\alpha} - 1 \right| = \frac{|\tilde{\alpha} - \alpha|}{|\alpha|}, & (\text{classical measure}) \\ \varrho_p(\alpha, \tilde{\alpha}) &= \frac{|\tilde{\alpha} - \alpha|}{\sqrt[p]{|\alpha|^p + |\tilde{\alpha}|^p}}, & ([\text{Li98}]) \\ \zeta(\alpha, \tilde{\alpha}) &= \frac{|\tilde{\alpha} - \alpha|}{\sqrt{|\alpha\tilde{\alpha}|}}, & ([\text{BD90}], [\text{DV92}]) \\ \varsigma(\alpha, \tilde{\alpha}) &= |\ln(\tilde{\alpha}/\alpha)|, \quad \text{for } \tilde{\alpha}\alpha > 0, & ([\text{LM99a}], [\text{Li99b}]) \end{aligned}$$

and  $d(0, 0) = \varrho_p(0, 0) = \zeta(0, 0) = \varsigma(0, 0) = 0$ .

$A \in \mathbb{C}^{n \times n}$  is **multiplicatively perturbed** to  $\tilde{A}$  if  $\tilde{A} = D_L^* A D_R$  for some  $D_L, D_R \in \mathbb{C}^{n \times n}$ .

Denote  $\sigma(A) = \{\lambda_1, \lambda_2, \dots, \lambda_n\}$  and  $\sigma(\tilde{A}) = \{\tilde{\lambda}_1, \tilde{\lambda}_2, \dots, \tilde{\lambda}_n\}$ .

$A \in \mathbb{C}^{n \times n}$  is said to be **graded** if it can be scaled as  $A = S^* H S$  such that  $H$  is “well-behaved” (i.e.,  $\kappa_2(H)$  is of modest magnitude), where  $S$  is a scaling matrix, often diagonal but not required so for the facts below. Interesting cases are when  $\kappa_2(H) \ll \kappa_2(A)$ .

### Facts:

1. [Bar00]  $\varrho_p(\cdot, \cdot)$  is a metric on  $\mathbb{C}$  for  $1 \leq p \leq \infty$ .
2. Let  $A, \tilde{A} = D^* A D \in \mathbb{C}^{n \times n}$  be Hermitian, where  $D$  is nonsingular.

(a) [HJ85, p. 224] (**Ostrowski**) There exists  $t_j$ , satisfying

$$\lambda_{\min}(D^* D) \leq t_j \leq \lambda_{\max}(D^* D),$$

such that  $\tilde{\lambda}_j^\uparrow = t_j \lambda_j^\uparrow$  for  $j = 1, 2, \dots, n$  and, thus,

$$\max_{1 \leq j \leq n} d(\lambda_j^\uparrow, \tilde{\lambda}_j^\uparrow) \leq \|I - D^* D\|_2.$$

(b) [LM99], [Li98]

$$\|\text{diag}(\varsigma(\lambda_1^\uparrow, \tilde{\lambda}_1^\uparrow), \dots, \varsigma(\lambda_n^\uparrow, \tilde{\lambda}_n^\uparrow))\|_{\text{UI}} \leq \|\ln(D^* D)\|_{\text{UI}},$$

$$\|\text{diag}(\zeta(\lambda_1^\uparrow, \tilde{\lambda}_1^\uparrow), \dots, \zeta(\lambda_n^\uparrow, \tilde{\lambda}_n^\uparrow))\|_{\text{UI}} \leq \|D^* - D^{-1}\|_{\text{UI}}.$$

3. [Li98], [LM99] Let  $A = S^* H S$  be a positive semidefinite Hermitian matrix, perturbed to  $\tilde{A} = S^*(H + \Delta H)S$ . Suppose  $H$  is positive definite and  $\|H^{-1/2}(\Delta H)H^{-1/2}\|_2 < 1$ , and set

$$M = H^{1/2} S S^* H^{1/2}, \quad \tilde{M} = D M D,$$

where  $D = [I + H^{-1/2}(\Delta H)H^{-1/2}]^{1/2} = D^*$ . Then  $\sigma(A) = \sigma(M)$  and  $\sigma(\tilde{A}) = \sigma(\tilde{M})$ , and the inequalities in Fact 2 above hold with  $D$  here. Note that

$$\begin{aligned} \|D - D^{-1}\|_{\text{UI}} &\leq \frac{\|H^{-1/2}(\Delta H)H^{-1/2}\|_{\text{UI}}}{\sqrt{1 - \|H^{-1/2}(\Delta H)H^{-1/2}\|_2}} \\ &\leq \frac{\|H^{-1}\|_2}{\sqrt{1 - \|H^{-1}\|_2\|\Delta H\|_2}} \|\Delta H\|_{\text{UI}}. \end{aligned}$$

4. [BD90], [VS93] Suppose  $A$  and  $\tilde{A}$  are Hermitian, and let  $|A| = (A^2)^{1/2}$  be the positive semidefinite square root of  $A^2$ . If there exists  $0 \leq \delta < 1$  such that

$$|\mathbf{x}^*(\Delta A)\mathbf{x}| \leq \delta \mathbf{x}^*|A|\mathbf{x} \quad \text{for all } \mathbf{x} \in \mathbb{C}^n,$$

then either  $\tilde{\lambda}_j^\uparrow = \lambda_j^\uparrow = 0$  or  $1 - \delta \leq \tilde{\lambda}_j^\uparrow/\lambda_j^\uparrow \leq 1 + \delta$ .

5. [Li99a] Let Hermitian  $A$ ,  $\tilde{A} = D^*AD$  have decompositions

$$\begin{bmatrix} X_1^* \\ X_2^* \end{bmatrix} A [X_1 \ X_2] = \begin{bmatrix} A_1 & \\ & A_2 \end{bmatrix}, \quad \begin{bmatrix} \tilde{X}_1^* \\ \tilde{X}_2^* \end{bmatrix} \tilde{A} [\tilde{X}_1 \ \tilde{X}_2] = \begin{bmatrix} \tilde{A}_1 & \\ & \tilde{A}_2 \end{bmatrix},$$

where  $[X_1 \ X_2]$  and  $[\tilde{X}_1 \ \tilde{X}_2]$  are unitary and  $X_1, \tilde{X}_1 \in \mathbb{C}^{n \times k}$ . If  $\eta_2 = \min_{\mu \in \sigma(A_1), \tilde{\mu} \in \sigma(\tilde{A}_2)} \varrho_2(\mu, \tilde{\mu}) > 0$ , then

$$\|\sin \Theta(X_1, \tilde{X}_1)\|_{\text{F}} \leq \frac{\sqrt{\|(I - D^{-1})X_1\|_{\text{F}}^2 + \|(I - D^*)X_1\|_{\text{F}}^2}}{\eta_2}.$$

6. [Li99a] Let  $A = S^*HS$  be a positive semidefinite Hermitian matrix, perturbed to  $\tilde{A} = S^*(H + \Delta H)S$ , having decompositions, in notation, the same as in Fact 5. Let  $D = [I + H^{-1/2}(\Delta H)H^{-1/2}]^{1/2}$ . Assume  $H$  is positive definite and  $\|H^{-1/2}(\Delta H)H^{-1/2}\|_2 < 1$ . If  $\eta_\zeta = \min_{\mu \in \sigma(A_1), \tilde{\mu} \in \sigma(\tilde{A}_2)} \zeta(\mu, \tilde{\mu}) > 0$ , then

$$\|\sin \Theta(X_1, \tilde{X}_1)\|_{\text{F}} \leq \frac{\|D - D^{-1}\|_{\text{F}}}{\eta_\zeta}.$$

### Examples:

1. [DK90], [EI95] Let  $A$  be a real symmetric tridiagonal matrix with zero diagonal and off-diagonal entries  $b_1, b_2, \dots, b_{n-1}$ . Suppose  $\tilde{A}$  is identical to  $A$  except for its off-diagonal entries which change to  $\beta_1 b_1, \beta_2 b_2, \dots, \beta_{n-1} b_{n-1}$ , where all  $\beta_i$  are real and supposedly close to 1. Then  $\tilde{A} = DAD$ , where  $D = \text{diag}(d_1, d_2, \dots, d_n)$  with

$$d_{2k} = \frac{\beta_1 \beta_3 \cdots \beta_{2k-1}}{\beta_2 \beta_4 \cdots \beta_{2k-2}}, \quad d_{2k+1} = \frac{\beta_2 \beta_4 \cdots \beta_{2k}}{\beta_1 \beta_3 \cdots \beta_{2k-1}}.$$

Let  $\beta = \prod_{j=1}^{n-1} \max\{\beta_j, 1/\beta_j\}$ . Then  $\beta^{-1}I \leq D^2 \leq \beta I$ , and Fact 2 and Fact 5 apply. Now if all  $1 - \varepsilon \leq \beta_j \leq 1 + \varepsilon$ , then  $(1 - \varepsilon)^{n-1} \leq \beta^{-1} \leq \beta \leq (1 + \varepsilon)^{n-1}$ .

2. Let  $A = SHS$  with  $S = \text{diag}(1, 10, 10^2, 10^3)$ , and

$$A = \begin{bmatrix} 1 & & & & \\ & 1 & & & \\ & & 10^2 & & \\ & & & 10^4 & \\ & & & & 10^6 \end{bmatrix}, \quad H = \begin{bmatrix} 1 & & & & \\ & 10^{-1} & & & \\ & & 1 & & \\ & & & 10^{-1} & \\ & & & & 1 \end{bmatrix}.$$

Suppose that each entry  $A_{ij}$  of  $A$  is perturbed to  $A_{ij}(1 + \delta_{ij})$  with  $|\delta_{ij}| \leq \varepsilon$ . Then  $|(\Delta H)_{ij}| \leq \varepsilon |H_{ij}|$  and thus  $\|\Delta H\|_2 \leq 1.2\varepsilon$ . Since  $\|H^{-1}\|_2 \leq 10/8$ , Fact 3 implies

$$\zeta(\lambda_j^\uparrow, \tilde{\lambda}_j^\uparrow) \leq 1.5\varepsilon/\sqrt{1 - 1.5\varepsilon} \approx 1.5\varepsilon.$$

## 15.7 Relative Perturbation Theory for Singular Value Problems

### Definitions:

$B \in \mathbb{C}^{m \times n}$  is **multiplicatively perturbed** to  $\tilde{B}$  if  $\tilde{B} = D_L^* B D_R$  for some  $D_L \in \mathbb{C}^{m \times m}$  and  $D_R \in \mathbb{C}^{n \times n}$ . Denote the singular values of  $B$  and  $\tilde{B}$  as

$$sv(B) = \{\sigma_1, \sigma_2, \dots, \sigma_{\min\{m,n\}}\}, \quad sv(\tilde{B}) = \{\tilde{\sigma}_1, \tilde{\sigma}_2, \dots, \tilde{\sigma}_{\min\{m,n\}}\}.$$

$B$  is said to be (highly) **graded** if it can be scaled as  $B = GS$  such that  $G$  is “well-behaved” (i.e.,  $\kappa_2(G)$  is of modest magnitude), where  $S$  is a scaling matrix, often diagonal but not required so for the facts below. Interesting cases are when  $\kappa_2(G) \ll \kappa_2(B)$ .

### Facts:

1. Let  $B, \tilde{B} = D_L^* B D_R \in \mathbb{C}^{m \times n}$ , where  $D_L$  and  $D_R$  are nonsingular.
  - (a) [EI95] For  $1 \leq j \leq n$ ,  $\frac{\sigma_j}{\|D_L^{-1}\|_2 \|D_R^{-1}\|_2} \leq \tilde{\sigma}_j \leq \sigma_j \|D_L\|_2 \|D_R\|_2$ .
  - (b) [Li98], [LM99]

$$\begin{aligned} & \|\text{diag}(\zeta(\sigma_1, \tilde{\sigma}_1), \dots, \zeta(\sigma_n, \tilde{\sigma}_n))\|_{\text{UI}} \\ & \leq \frac{1}{2} \|D_L^* - D_L^{-1}\|_{\text{UI}} + \frac{1}{2} \|D_R^* - D_R^{-1}\|_{\text{UI}}. \end{aligned}$$

2. [Li99a] Let  $B, \tilde{B} = D_L^* B D_R \in \mathbb{C}^{m \times n}$  ( $m \geq n$ ) have decompositions

$$\begin{bmatrix} U_1^* \\ U_2^* \end{bmatrix} B [V_1 \ V_2] = \begin{bmatrix} B_1 & 0 \\ 0 & B_2 \end{bmatrix}, \quad \begin{bmatrix} \tilde{U}_1^* \\ \tilde{U}_2^* \end{bmatrix} \tilde{B} [\tilde{V}_1 \ \tilde{V}_2] = \begin{bmatrix} \tilde{B}_1 & 0 \\ 0 & \tilde{B}_2 \end{bmatrix},$$

where  $[U_1 \ U_2], [V_1 \ V_2], [\tilde{U}_1 \ \tilde{U}_2]$ , and  $[\tilde{V}_1 \ \tilde{V}_2]$  are unitary, and  $U_1, \tilde{U}_1 \in \mathbb{C}^{m \times k}$ ,  $V_1, \tilde{V}_1 \in \mathbb{C}^{n \times k}$ . Set  $\Theta_U = \Theta(U_1, \tilde{U}_1)$ ,  $\Theta_V = \Theta(V_1, \tilde{V}_1)$ . If  $sv(B_1) \cap sv_{\text{ext}}(\tilde{B}_2) = \emptyset$ , then

$$\begin{aligned} & \sqrt{\|\sin \Theta_U\|_{\text{F}}^2 + \|\sin \Theta_V\|_{\text{F}}^2} \\ & \leq \frac{1}{\eta_2} [\|(I - D_L^*)U_1\|_{\text{F}}^2 + \|(I - D_L^{-1})U_1\|_{\text{F}}^2 \\ & \quad + \|(I - D_R^*)V_1\|_{\text{F}}^2 + \|(I - D_R^{-1})V_1\|_{\text{F}}^2]^{1/2}, \end{aligned}$$

where  $\eta_2 = \min \varrho_2(\mu, \tilde{\mu})$  over all  $\mu \in sv(B_1)$  and  $\tilde{\mu} \in sv_{\text{ext}}(\tilde{B}_2)$ .

3. [Li98], [Li99a], [LM99] Let  $B = GS$  and  $\tilde{B} = \tilde{G}S$  be two  $m \times n$  matrices, where  $\text{rank}(G) = n$ , and let  $\Delta G = \tilde{G} - G$ . Then  $\tilde{B} = DB$ , where  $D = I + (\Delta G)G^\dagger$ . Fact 1 and Fact 2 apply with  $D_L = D$  and  $D_R = I$ . Note that

$$\|D^* - D^{-1}\|_{\text{UI}} \leq \left(1 + \frac{1}{1 - \|(\Delta G)G^\dagger\|_2}\right) \frac{\|(\Delta G)G^\dagger\|_{\text{UI}}}{2}.$$

**Examples:**

- [BD90], [DK90], [EI95]  $B$  is a real bidiagonal matrix with diagonal entries  $a_1, a_2, \dots, a_n$  and off-diagonal (the one above the diagonal) entries are  $b_1, b_2, \dots, b_{n-1}$ .  $\tilde{B}$  is the same as  $B$ , except for its diagonal entries, which change to  $\alpha_1 a_1, \alpha_2 a_2, \dots, \alpha_n a_n$ , and its off-diagonal entries, which change to  $\beta_1 b_1, \beta_2 b_2, \dots, \beta_{n-1} b_{n-1}$ . Then  $\tilde{B} = D_L^* B D_R$  with

$$D_L = \text{diag} \left( \alpha_1, \frac{\alpha_1 \alpha_2}{\beta_1}, \frac{\alpha_1 \alpha_2 \alpha_3}{\beta_1 \beta_2}, \dots \right),$$

$$D_R = \text{diag} \left( 1, \frac{\beta_1}{\alpha_1}, \frac{\beta_1 \beta_2}{\alpha_1 \alpha_2}, \dots \right).$$

Let  $\alpha = \prod_{j=1}^n \max\{\alpha_j, 1/\alpha_j\}$  and  $\beta = \prod_{j=1}^{n-1} \max\{\beta_j, 1/\beta_j\}$ . Then

$$(\alpha\beta)^{-1} \leq (\|D_L^{-1}\|_2 \|D_R^{-1}\|_2)^{-1} \leq \|D_L\|_2 \|D_R\|_2 \leq \alpha\beta,$$

and Fact 1 and Fact 2 apply. Now if all  $1 - \varepsilon \leq \alpha_i, \beta_j \leq 1 + \varepsilon$ , then  $(1 - \varepsilon)^{2n-1} \leq (\alpha\beta)^{-1} \leq (\alpha\beta) \leq (1 + \varepsilon)^{2n-1}$ .

- Consider block partitioned matrices

$$B = \begin{bmatrix} B_{11} & B_{12} \\ 0 & B_{22} \end{bmatrix},$$

$$\tilde{B} = \begin{bmatrix} B_{11} & 0 \\ 0 & B_{22} \end{bmatrix} = B \begin{bmatrix} I & -B_{11}^{-1} B_{12} \\ 0 & I \end{bmatrix} = B D_R.$$

By Fact 2,  $\zeta(\sigma_j, \tilde{\sigma}_j) \leq \frac{1}{2} \|B_{11}^{-1} B_{12}\|_2$ . Interesting cases are when  $\|B_{11}^{-1} B_{12}\|_2$  is tiny enough to be treated as zero and so  $\text{sv}(\tilde{B})$  approximates  $\text{sv}(B)$  well. This situation occurs in computing the SVD of a bidiagonal matrix.

Mark Embree  
*Rice University*

Eigenvalues often provide great insight into the behavior of matrices, precisely explaining, for example, the *asymptotic* character of functions of matrices like  $A^k$  and  $e^{tA}$ . Yet many important applications produce matrices whose behavior cannot be explained by eigenvalues alone. In such circumstances further information can be gleaned from broader sets in the complex plane, such as the numerical range (see Chapter 18), the polynomial numerical hull [Nev93], [Gre02], and the subject of this section, pseudospectra.

The  $\varepsilon$ -pseudospectrum is a subset of the complex plane that always includes the spectrum, but can potentially contain points far from any eigenvalue. Unlike the spectrum, pseudospectra vary with choice of norm and, thus, for a given application one must take care to work in a physically appropriate norm. Unless otherwise noted, throughout this chapter we assume that  $A \in \mathbb{C}^{n \times n}$  is a square matrix with complex entries, and that  $\|\cdot\|$  denotes a vector space norm and the matrix norm it induces. When speaking of a norm associated with an inner product, we presume that adjoints and normal and unitary matrices are defined with respect to that inner product. All computational examples given here use the 2-norm.

For further details about theoretical aspects of this subject and the application of pseudospectra to a variety of problems see [TE05]; for applications in control theory, see [HP05]; and for applications in perturbation theory see [CCF96].

### 16.1 Fundamentals of Pseudospectra

---

#### Definitions:

The  $\varepsilon$ -**pseudospectrum** of a matrix  $A \in \mathbb{C}^{n \times n}$ ,  $\varepsilon > 0$ , is the set

$$\sigma_\varepsilon(A) = \{z \in \mathbb{C} : z \in \sigma(A + E) \text{ for some } E \in \mathbb{C}^{n \times n} \text{ with } \|E\| < \varepsilon\}.$$

(This definition is sometimes written with a weak inequality,  $\|E\| \leq \varepsilon$ ; for matrices the difference has little significance, but the strict inequality proves to be convenient for infinite-dimensional operators.)

If  $\|Av - zv\| < \varepsilon\|v\|$  for some  $v \neq 0$ , then  $z$  is an  $\varepsilon$ -**pseudoeigenvalue** of  $A$  with corresponding  $\varepsilon$ -**pseudoeigenvector**  $v$ .

The **resolvent** of the matrix  $A \in \mathbb{C}^{n \times n}$  at a point  $z \notin \sigma(A)$  is the matrix  $(zI - A)^{-1}$ .

**Facts:** [TE05]

1. Equivalent definitions. The set  $\sigma_\varepsilon(A)$  can be equivalently defined as:

(a) The subset of the complex plane bounded within the  $1/\varepsilon$  level set of the norm of the resolvent:

$$\sigma_\varepsilon(A) = \{z \in \mathbb{C} : \|(zI - A)^{-1}\| > \varepsilon^{-1}\}, \quad (16.1)$$

with the convention that  $\|(zI - A)^{-1}\| = \infty$  when  $zI - A$  is not invertible, i.e., when  $z \in \sigma(A)$ .

(b) The set of all  $\varepsilon$ -pseudoeigenvalues of  $A$ :

$$\sigma_\varepsilon(A) = \{z \in \mathbb{C} : \|Av - zv\| < \varepsilon \text{ for some unit vector } v \in \mathbb{C}^n\}.$$

2. For finite  $\varepsilon > 0$ ,  $\sigma_\varepsilon(A)$  is a bounded open set in  $\mathbb{C}$  containing no more than  $n$  connected components, and  $\sigma(A) \subset \sigma_\varepsilon(A)$ . Each connected component must contain at least one eigenvalue of  $A$ .

3. Pseudospectral mapping theorems.

(a) For any  $\alpha, \gamma \in \mathbb{C}$  with  $\gamma \neq 0$ ,  $\sigma_\varepsilon(\alpha I + \gamma A) = \alpha + \sigma_{\varepsilon/|\gamma|}(A)$ .

(b) [Lui03] Suppose  $f$  is a function analytic on  $\sigma_\varepsilon(A)$  for some  $\varepsilon > 0$ , and define  $\gamma(\varepsilon) = \sup_{\|E\| \leq \varepsilon} \|f(A+E) - f(A)\|$ . Then  $f(\sigma_\varepsilon(A)) \subseteq \sigma_{\gamma(\varepsilon)}(f(A))$ . See [Lui03] for several more inclusions of this type.

4. Stability of pseudospectra. For any  $\varepsilon > 0$  and  $E$  such that  $\|E\| < \varepsilon$ ,

$$\sigma_{\varepsilon - \|E\|}(A) \subseteq \sigma_\varepsilon(A + E) \subseteq \sigma_{\varepsilon + \|E\|}(A).$$

5. Properties of pseudospectra as  $\varepsilon \rightarrow 0$ .

(a) If  $\lambda$  is a eigenvalue of  $A$  with index  $k$ , then there exist constants  $d$  and  $C$  such that  $\|(zI - A)^{-1}\| \leq C|z - \lambda|^{-k}$  for all  $z$  such that  $|z - \lambda| < d$ .

(b) Any two matrices with the same  $\varepsilon$ -pseudospectra for all  $\varepsilon > 0$  have the same minimal polynomial.

6. Suppose  $\|\cdot\|$  is the natural norm in an inner product space.

(a) The matrix  $A$  is normal (see Section 7.2) if and only if  $\sigma_\varepsilon(A)$  equals the union of open  $\varepsilon$ -balls about each eigenvalue for all  $\varepsilon > 0$ .

(b) For any  $A \in \mathbb{C}^{n \times n}$ ,  $\sigma_\varepsilon(A^*) = \overline{\sigma_\varepsilon(A)}$ .

7. [BLO03] Suppose  $\|\cdot\|$  is the natural norm in an inner product space. The point  $z = x + iy$ ,  $x, y \in \mathbb{R}$ , is on the boundary of  $\sigma_\varepsilon(A)$  provided  $iy$  is an eigenvalue of the Hamiltonian matrix

$$\begin{bmatrix} xI - A^* & \varepsilon I \\ -\varepsilon I & A - xI \end{bmatrix}.$$

This fact implies that the boundary of  $\sigma_\varepsilon(A)$  cannot contain a segment of any vertical line or, substituting  $e^{i\theta}A$  for  $A$ , a segment of any straight line.

8. The following results provide lower and upper bounds on the  $\varepsilon$ -pseudospectrum;  $\Delta_\delta$  denotes the open unit ball of radius  $\delta$  in  $\mathbb{C}$ , and  $\kappa(X) = \|X\|\|X^{-1}\|$ .

(a) For all  $\varepsilon > 0$ ,  $\sigma(A) + \Delta_\varepsilon \subseteq \sigma_\varepsilon(A)$ .

(b) For any nonsingular  $S \in \mathbb{C}^{n \times n}$  and all  $\varepsilon > 0$ ,

$$\sigma_{\varepsilon/\kappa(S)}(SAS^{-1}) \subseteq \sigma_\varepsilon(A) \subseteq \sigma_{\varepsilon\kappa(S)}(SAS^{-1}).$$

(c) (Bauer–Fike Theorems [BF60], [Dem97]) Let  $\|\cdot\|$  denote a monotone norm. If  $A$  is diagonalizable,  $A = V\Lambda V^{-1}$ , then for all  $\varepsilon > 0$ ,

$$\sigma_\varepsilon(A) \subseteq \sigma(A) + \Delta_{\varepsilon\kappa(V)}.$$

If  $A \in \mathbb{C}^{n \times n}$  has  $n$  distinct eigenvalues  $\lambda_1, \dots, \lambda_n$ , then for all  $\varepsilon > 0$ ,

$$\sigma_\varepsilon(A) \subseteq \bigcup_{j=1}^n (\lambda_j + \Delta_{\varepsilon n \kappa(\lambda_j)}),$$

where  $\kappa(\lambda_j)$  here denotes the eigenvalue condition number of  $\lambda_j$  (i.e.,  $\kappa(\lambda_j) = 1/|\widehat{\mathbf{v}}_j^* \mathbf{v}_j|$ , where  $\widehat{\mathbf{v}}_j$  and  $\mathbf{v}_j$  are unit-length left and right eigenvectors of  $A$  corresponding to the eigenvalue  $\lambda_j$ ).

- (d) If  $\|\cdot\|$  is the natural norm in an inner product space, then for any  $\varepsilon > 0$ ,  $\sigma_\varepsilon(A) \subseteq W(A) + \Delta_\varepsilon$ , where  $W(\cdot)$  denotes the numerical range (Chapter 18).
- (e) If  $\|\cdot\|$  is the natural norm in an inner product space and  $U$  is a unitary matrix, then  $\sigma_\varepsilon(U^*AU) = \sigma_\varepsilon(A)$  for all  $\varepsilon > 0$ .
- (f) If  $\|\cdot\|$  is unitarily invariant, then  $\sigma_\varepsilon(A) \subseteq \sigma(A) + \Delta_{\varepsilon + \text{dep}(A)}$ , where  $\text{dep}(\cdot)$  denotes Henrici's departure from normality (i.e., the norm of the off-diagonal part of the triangular factor in a Schur decomposition, minimized over all such decompositions).
- (g) (Geršgorin Theorem for pseudospectra [ET01]) Using the induced matrix 2-norm, for any  $\varepsilon > 0$ ,

$$\sigma_\varepsilon(A) \subseteq \bigcup_{j=1}^n (a_{jj} + \Delta_{r_j + \varepsilon \sqrt{n}}),$$

where  $r_j = \sum_{k=1, k \neq j}^n |a_{jk}|$ .

9. The following results bound  $\sigma_\varepsilon(A)$  by pseudospectra of smaller matrices. Here  $\|\cdot\|$  is the natural norm in an inner product space.

- (a) [GL02] If  $A$  has the block-triangular form

$$A = \begin{bmatrix} B & C \\ D & E \end{bmatrix},$$

then

$$\sigma_\varepsilon(A) \subseteq \sigma_\delta(B) \cup \sigma_\delta(E),$$

where  $\delta = (\varepsilon + \|D\|)\sqrt{1 + \|C\|/(\varepsilon + \|D\|)}$ . Provided  $\varepsilon > \|D\|$ ,

$$\sigma_\gamma(B) \cup \sigma_\gamma(E) \subseteq \sigma_\varepsilon(A),$$

where  $\gamma = \varepsilon - \|D\|$ .

- (b) If the columns of  $V \in \mathbb{C}^{n \times m}$  form a basis for an invariant subspace of  $A$ , and  $\widehat{V} \in \mathbb{C}^{n \times m}$  is such that  $\widehat{V}^*V = I$ , then  $\sigma_\varepsilon(\widehat{V}^*AV) \subseteq \sigma_\varepsilon(A)$ . In particular, if the columns of  $U$  form an orthonormal basis for an invariant subspace of  $A$ , then  $\sigma_\varepsilon(U^*AU) \subseteq \sigma_\varepsilon(A)$ .
- (c) [ET01] If  $U \in \mathbb{C}^{n \times m}$  has orthonormal columns and  $AU = UH + R$ , then  $\sigma(H) \subseteq \sigma_\varepsilon(A)$  for  $\varepsilon = \|R\|$ .
- (d) (Arnoldi factorization) If  $AU = [U \mathbf{u}]H$ , where  $H \in \mathbb{C}^{(m+1) \times m}$  is an upper Hessenberg matrix ( $h_{jk} = 0$  if  $j > k + 1$ ) and the columns of  $[U \mathbf{u}] \in \mathbb{C}^{n \times (m+1)}$  are orthonormal, then  $\sigma_\varepsilon(H) \subseteq \sigma_\varepsilon(A)$ . (The  $\varepsilon$ -pseudospectrum of a rectangular matrix is defined in section 16.5 below.)

**Examples:**

The plots of pseudospectra that follow show the boundary of  $\sigma_\varepsilon(A)$  for various values of  $\varepsilon$ , with the smallest values of  $\varepsilon$  corresponding to those boundaries closest to the eigenvalues. In all cases,  $\|\cdot\|$  is the 2-norm.

- 1. The following three matrices all have the same eigenvalues,  $\sigma(A) = \{1, \pm i\}$ , yet their pseudospectra, shown in Figure 16.1, differ considerably:

$$\begin{bmatrix} 0 & -1 & 10 \\ 1 & 0 & 5 \\ 0 & 0 & 1 \end{bmatrix}, \quad \begin{bmatrix} 0 & -1 & 10 \\ 1 & 0 & 5i \\ 0 & 0 & 1 \end{bmatrix}, \quad \begin{bmatrix} 2 & -5 & 10 \\ 1 & -2 & 5i \\ 0 & 0 & 1 \end{bmatrix}.$$

FIGURE 16.1 Spectra (solid dots) and  $\varepsilon$ -pseudospectra of the three matrices of Example 1, each with  $\sigma(A) = \{1, i, -i\}$ ;  $\varepsilon = 10^{-1}, 10^{-1.5}, 10^{-2}$ .

- [RT92] For any matrix that is zero everywhere except the first superdiagonal,  $\sigma_\varepsilon(A)$  consists of an open disk centered at zero whose radius depends on  $\varepsilon$  for all  $\varepsilon > 0$ . Figure 16.2 shows pseudospectra for two such examples of dimension  $n = 50$ :

$$\begin{bmatrix} 0 & 1 & & & \\ & 0 & 1 & & \\ & & \ddots & \ddots & \\ & & & 0 & 1 \\ & & & & 0 \end{bmatrix}, \quad \begin{bmatrix} 0 & 3 & & & \\ & 0 & 3/2 & & \\ & & \ddots & \ddots & \\ & & & 0 & 3/(n-1) \\ & & & & 0 \end{bmatrix}.$$

Though these matrices have the same minimal polynomial, the pseudospectra differ considerably.

- It is evident from Figure 16.1 that the components of  $\sigma_\varepsilon(A)$  need not be convex. In fact, they need not be simply connected; that is,  $\sigma_\varepsilon(A)$  can have “holes.” This is illustrated in Figure 16.3 for the following examples, a circulant (hence, normal) matrix and a defective matrix constructed

FIGURE 16.2 Spectra (solid dots) and  $\varepsilon$ -pseudospectra of the matrices in Example 2 for  $\varepsilon = 10^{-1}, 10^{-2}, \dots, 10^{-20}$ .

FIGURE 16.3 Spectra (solid dots) and  $\varepsilon$ -pseudospectra (gray regions) of the matrices in Example 3 for  $\varepsilon = .5$  (left) and  $\varepsilon = 10^{-3}$  (right). Both plotted pseudospectra are doubly connected.

by Demmel [Dem87]:

$$\begin{bmatrix} 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \quad \begin{bmatrix} -1 & -100 & -10000 \\ 0 & -1 & -100 \\ 0 & 0 & -1 \end{bmatrix}.$$

## 16.2 Toeplitz Matrices

Given the rich variety of important applications in which Toeplitz matrices arise, we are fortunate that so much is now understood about their spectral properties. Nonnormal Toeplitz matrices are prominent examples of matrices whose eigenvalues provide only limited insight into system behavior. The spectra of infinite-dimensional Toeplitz matrices are easily characterized, and one would hope to use these results to approximate the spectra of more recalcitrant large, finite-dimensional examples. For generic problems, the spectra of finite-dimensional Toeplitz matrices do not converge to the spectrum of the corresponding infinite-dimensional Toeplitz operator. However, the  $\varepsilon$ -pseudospectra do converge in the  $n \rightarrow \infty$  limit for all  $\varepsilon > 0$ , and, moreover, for banded Toeplitz matrices this convergence is especially striking as the resolvent grows exponentially with  $n$  in certain regions. Comprehensive references addressing the pseudospectra of Toeplitz matrices include the books [BS99] and [BG05]. For a generalization of these results to “twisted Toeplitz matrices,” where the entries on each diagonal are samples of a smoothly varying function, see [TC04].

### Definitions:

A **Toeplitz operator** is a singly infinite matrix with constant entries on each diagonal:

$$T = \begin{bmatrix} a_0 & a_{-1} & a_{-2} & a_{-3} & \cdots \\ a_1 & a_0 & a_{-1} & a_{-2} & \ddots \\ a_2 & a_1 & a_0 & a_{-1} & \ddots \\ a_3 & a_2 & a_1 & a_0 & \ddots \\ \vdots & \ddots & \ddots & \ddots & \ddots \end{bmatrix}$$

for  $a_0, a_{\pm 1}, a_{\pm 2}, \dots \in \mathbb{C}$ .

Provided it is well defined for all  $z$  on the unit circle  $\mathbb{T}$  in the complex plane, the function  $a(z) = \sum_{k=-\infty}^{\infty} a_k z^k$  is called the **symbol** of  $T$ .

The set  $a(\mathbb{T}) \subset \mathbb{C}$  is called the **symbol curve**.

Given a symbol  $a$ , the corresponding  $n$ -dimensional **Toeplitz matrix** takes the form

$$T_n = \begin{bmatrix} a_0 & a_{-1} & a_{-2} & \cdots & a_{1-n} \\ a_1 & a_0 & a_{-1} & \ddots & \vdots \\ a_2 & a_1 & a_0 & \ddots & a_{-2} \\ \vdots & \ddots & \ddots & \ddots & a_{-1} \\ a_{n-1} & \cdots & a_2 & a_1 & a_0 \end{bmatrix} \in \mathbb{C}^{n \times n}.$$

For a symbol  $a(z) = \sum_{k=-\infty}^{\infty} a_k z^k$ , the set  $\{T_n\}_{n \geq 1}$  is called a **family of Toeplitz matrices**.

A family of Toeplitz matrices with symbol  $a$  is **banded** if there exists some  $m \geq 0$  such that  $a_{\pm k} = 0$  for all  $k \geq m$ .

**Facts:**

- [Böt94] (Convergence of pseudospectra) Let  $\|\cdot\|$  denote any  $p$  norm. If the symbol  $a$  is a continuous function on  $\mathbb{T}$ , then

$$\lim_{n \rightarrow \infty} \sigma_\varepsilon(T_n) \rightarrow \sigma_\varepsilon(T)$$

as  $n \rightarrow \infty$ , where  $T$  is the infinite-dimensional Toeplitz operator with symbol  $a$  acting on the space  $\ell_p$ , and its  $\varepsilon$ -pseudospectrum is a natural generalization of the first definition in section 16.1. The convergence of sets is understood in the Hausdorff sense [Hau91, p. 167], i.e., the distance between bounded sets  $\Sigma_1, \Sigma_2 \subseteq \mathbb{C}$  is given by

$$d(\Sigma_1, \Sigma_2) = \max \left\{ \sup_{s_1 \in \Sigma_1} \inf_{s_2 \in \Sigma_2} |s_1 - s_2|, \sup_{s_2 \in \Sigma_2} \inf_{s_1 \in \Sigma_1} |s_2 - s_1| \right\}.$$

- [BS99] Provided the symbol  $a$  is a continuous function on  $\mathbb{T}$ , the spectrum  $\sigma(T)$  of the infinite dimensional Toeplitz operator  $T$  on  $\ell_p$  comprises  $a(\mathbb{T})$  together with all points  $z \in \mathbb{C} \setminus a(\mathbb{T})$  that  $a(\mathbb{T})$  encloses with winding number

$$\frac{1}{2\pi i} \int_{a(\mathbb{T})} \frac{1}{\zeta - z} d\zeta$$

nonzero. From the previous fact, we deduce that  $\|(zI - T_n)^{-1}\| \rightarrow \infty$  as  $n \rightarrow \infty$  if  $z \in \sigma(T)$  and that, for any fixed  $\varepsilon > 0$ , there exists some  $N \geq 1$  such that  $\sigma(T) \subseteq \sigma_\varepsilon(T_n)$  for all  $n \geq N$ .

- [RT92] (Exponential growth of the resolvent) If the family of Toeplitz matrices  $T_n$  is banded, then for any fixed  $z \in \mathbb{C}$  such that the winding number of  $a(\mathbb{T})$  with respect to  $z$  is nonzero, there exists some  $\gamma > 1$  and  $N \geq 1$  such that  $\|(zI - T_n)^{-1}\| \geq \gamma^n$  for all  $n \geq N$ .

**Examples:**

- Consider the family of Toeplitz matrices with symbol

$$a(t) = t - \frac{1}{2} - \frac{1}{16}t^{-1}.$$

For any dimension  $n$ , the spectrum  $\sigma(T_n(a))$  is contained in the line segment  $[-\frac{1}{2} - \frac{1}{2}i, -\frac{1}{2} + \frac{1}{2}i]$  in the complex plane. This symbol was selected so that  $\sigma(A)$  falls in both the left half-plane and the unit disk, while even for relatively small values of  $\varepsilon$ ,  $\sigma_\varepsilon(A)$  contains both points in the right half-plane and points outside the unit disk for all but the smallest values of  $n$ ; see Figure 16.4 for  $n = 50$ .

FIGURE 16.4 Spectrum (solid dots, so close they appear to be a thick line segment with real part  $-1/2$ ) and  $\varepsilon$ -pseudospectra of the Toeplitz matrix  $T_{50}$  from Example 1;  $\varepsilon = 10^{-1}, 10^{-3}, \dots, 10^{-15}$ . The dashed lines show the unit circle and the imaginary axis.

2. Pseudospectra of matrices with the symbols

$$a(t) = it^4 + t^2 + 2t + 5t^{-2} + it^{-5}$$

and

$$a(t) = 3it^4 + t + t^{-1} + 3it^{-4}$$

are shown in Figure 16.5.

FIGURE 16.5 Spectra (solid dots) and  $\varepsilon$ -pseudospectra of Toeplitz matrices from Example 2 with the first symbol on the left ( $n = 100$ ) and the second symbol on the right ( $n = 200$ ), both with  $\varepsilon = 10^0, 10^{-2}, \dots, 10^{-8}$ . In each plot, the gray region is the spectrum of the underlying infinite dimensional Toeplitz operator.

**FIGURE 16.6** Spectra (solid dots) and  $\varepsilon$ -pseudospectra of Toeplitz matrices for the discretization of a convection-diffusion operator described in Application 1 with  $v = 1/50$  and three values of  $n$ ;  $\varepsilon = 10^{-1}, 10^{-2}, \dots, 10^{-6}$ . The gray dots and lines in each plot show eigenvalues and pseudospectra of the differential operator to which the matrix spectra and pseudospectra converge.

### Applications:

1. [RT94] Discretization of the one-dimensional convection-diffusion equation

$$vu''(x) + u'(x) = f(x), \quad u(0) = u(1) = 0$$

for  $x \in [0, 1]$  with second-order centered finite differences on a uniform grid with spacing  $h = 1/(n+1)$  between grid points results in an  $n \times n$  Toeplitz matrix with symbol

$$a(t) = \left( \frac{v}{h^2} + \frac{1}{2h} \right) t - \left( \frac{2v}{h^2} \right) + \left( \frac{v}{h^2} - \frac{1}{2h} \right) t^{-1}.$$

On the right-most part of the spectrum, both the eigenvalues and pseudospectra of the discretization matrix converge to those of the underlying differential operator

$$\mathcal{L}u = vu'' + u'$$

whose domain is the space of functions that are square-integrable over  $[0, 1]$  and satisfy the boundary conditions  $u(0) = u(1) = 0$ ; see Figure 16.6.

## 16.3 Behavior of Functions of Matrices

In practice, pseudospectra are most often used to investigate the behavior of a function of a matrix. Does the solution  $\mathbf{x}(t) = e^{tA}\mathbf{x}(0)$  or  $\mathbf{x}_k = A^k\mathbf{x}_0$  of the linear dynamical system  $\mathbf{x}'(t) = A\mathbf{x}(t)$  or  $\mathbf{x}_{k+1} = A\mathbf{x}_k$  grow or decay as  $t, k \rightarrow \infty$ ? Eigenvalues provide an answer: If  $\sigma(A)$  lies in the open unit disk or left half-plane, the solution must eventually decay. However, the results described in this section show that if  $\varepsilon$ -pseudoeigenvalues of  $A$  extend well beyond the unit disk or left half-plane for small values of  $\varepsilon$ , then the system must exhibit transient growth for some initial states. While such growth is notable even for purely linear problems, it should spark special caution when observed for a dynamical system that arises from the linearization of a nonlinear system about a steady state based on the assumption that disturbances from that state are small in magnitude. This reasoning has been applied extensively in recent years in fluid dynamics; see, e.g., [TTRD93].

### Definitions:

The  $\varepsilon$ -pseudospectral abscissa of  $A$  measures the rightmost extent of  $\sigma_\varepsilon(A)$ :  $\alpha_\varepsilon(A) = \sup_{z \in \sigma_\varepsilon(A)} \operatorname{Re} z$ .

The  $\varepsilon$ -pseudospectral radius of  $A$  measures the maximum magnitude in  $\sigma_\varepsilon(A)$ :  $\rho_\varepsilon(A) = \sup_{z \in \sigma_\varepsilon(A)} |z|$ .

**Facts:** [TE05, §§14–19]

1. For  $\varepsilon > 0$ ,  $\sup_{t \in \mathbb{R}, t \geq 0} \|e^{tA}\| \geq \alpha_\varepsilon(A)/\varepsilon$ .
2. For  $\varepsilon > 0$ ,  $\sup_{k \in \mathbb{N}, k \geq 0} \|A^k\| \geq (\rho_\varepsilon(A) - 1)/\varepsilon$ .
3. For any function  $f$  that is analytic on the spectrum of  $A$ ,

$$\|f(A)\| \geq \max_{\lambda \in \sigma(A)} |f(\lambda)|.$$

Equality holds when  $\|\cdot\|$  is the natural norm in an inner product space in which  $A$  is normal.

4. In the special case of matrix exponentials  $e^{tA}$  and matrix powers  $A^k$ , this last fact implies that

$$\|e^{tA}\| \geq e^{t\alpha(A)}, \quad \|A^k\| \geq \rho(A)^k$$

for all  $t \geq 0$  and integers  $k \geq 0$ , where  $\alpha(A) = \max_{\lambda \in \sigma(A)} \operatorname{Re} \lambda$  is the spectral abscissa and  $\rho(A) = \max_{\lambda \in \sigma(A)} |\lambda|$  is the spectral radius.

5. Let  $\Gamma_\varepsilon$  be a finite union of Jordan curves containing  $\sigma_\varepsilon(A)$  in their collective interior for some  $\varepsilon > 0$ , and suppose  $f$  is a function analytic on  $\Gamma_\varepsilon$  and its interior. Then

$$\|f(A)\| \leq \frac{L_\varepsilon}{2\pi\varepsilon} \max_{z \in \Gamma_\varepsilon} |f(z)|,$$

where  $L_\varepsilon$  denotes the arc-length of  $\Gamma_\varepsilon$ .

6. In the special case of matrix exponentials  $e^{tA}$  and matrix powers  $A^k$ , this last fact implies that for all  $t \geq 0$  and integers  $k \geq 0$ ,

$$\|e^{tA}\| \leq \frac{L_\varepsilon}{2\pi\varepsilon} e^{t\alpha_\varepsilon(A)}, \quad \|A^k\| \leq \rho_\varepsilon(A)^{k+1}/\varepsilon.$$

In typical cases, larger values of  $\varepsilon$  give superior bounds for small  $t$  and  $k$ , while smaller values of  $\varepsilon$  yield more descriptive bounds for larger  $t$  and  $k$ ; see Figure 16.7.

7. Suppose  $z \in \mathbb{C} \setminus \sigma(A)$  with  $a \equiv \operatorname{Re} z$  and  $\varepsilon \equiv 1/\|(zI - A)^{-1}\|$ . Provided  $a > \varepsilon$ , then for any fixed  $\tau > 0$ ,

$$\sup_{0 < t \leq \tau} \|e^{tA}\| \geq \frac{ae^{\tau a}}{a + \varepsilon(e^{\tau a} - 1)}.$$

8. Suppose  $z \in \mathbb{C} \setminus \sigma(A)$  with  $a \equiv \operatorname{Re} z$  and  $\varepsilon \equiv 1/\|(zI - A)^{-1}\|$ , and that  $\|e^{\tau A}\| \leq M$  for all  $\tau > 0$  with  $M \geq a/\varepsilon$ . Then for any  $t > 0$ ,

$$\|e^{tA}\| \geq e^{ta}(1 - \varepsilon M/a) + \varepsilon M/a.$$

9. Suppose  $z \in \mathbb{C} \setminus \sigma(A)$  with  $r \equiv |z|$  and  $\varepsilon \equiv 1/\|(zI - A)^{-1}\|$ . Provided  $r > 1 + \varepsilon$ , then for any fixed integer  $\kappa \geq 1$ ,

$$\sup_{0 < k \leq \kappa} \|A^k\| \geq \frac{r^\kappa(r - 1 - \varepsilon) + \varepsilon r^{\kappa-1}}{(r - 1 - \varepsilon) + \varepsilon r^{\kappa-1}}.$$

10. Suppose  $z \in \mathbb{C} \setminus \sigma(A)$  with  $r \equiv |z|$  and  $\varepsilon \equiv 1/\|(zI - A)^{-1}\|$ , and that  $\|A^\kappa\| \leq M$  for all integers  $\kappa \geq 0$  with  $M \geq (r - 1)/\varepsilon$ . Then for any integer  $k \geq 0$ ,

$$\|A^k\| \geq r^k(r - 1 - \varepsilon M) + \varepsilon M.$$

11. For any  $A \in \mathbb{C}^{n \times n}$ ,

$$\|A^k\| < e(k + 1) \sup_{\varepsilon > 0} \frac{\rho_\varepsilon(A) - 1}{\varepsilon}.$$

12. (Kreiss Matrix Theorem) For any  $A \in \mathbb{C}^{n \times n}$ ,

$$\sup_{\varepsilon > 0} \frac{\rho_\varepsilon(A) - 1}{\varepsilon} \leq \sup_{k \geq 0} \|A^k\| \leq en \sup_{\varepsilon > 0} \frac{\rho_\varepsilon(A) - 1}{\varepsilon}.$$

13. [GT93] There exist matrices  $A$  and  $B$  such that, in the induced 2-norm,  $\sigma_\varepsilon(A) = \sigma_\varepsilon(B)$  for all  $\varepsilon > 0$ , yet  $\|f(A)\|_2 \neq \|f(B)\|_2$  for some polynomial  $f$ ; see Example 2. That is, even if the 2-norm of the resolvents of  $A$  and  $B$  are identical for all  $z \in \mathbb{C}$ , the norms of other matrix functions in  $A$  and  $B$  need not agree. (Curiously, if the *Frobenius* norm of the resolvents of  $A$  and  $B$  agree for all  $z \in \mathbb{C}$ , then  $\|f(A)\|_F = \|f(B)\|_F$  for all polynomials  $f$ .)

**FIGURE 16.7** The functions  $\|e^{tA}\|$  and  $\|A^k\|$  exhibit transient growth before exponential decay for the Toeplitz matrix of dimension  $n = 50$ , whose pseudospectra were illustrated in Figure 16.4. The horizontal dashed lines show the lower bounds on maximal growth given in Facts 1 and 2, while the lower dashed lines show the lower bounds of Fact 4. The gray lines show the upper bounds in Fact 6 for  $\varepsilon = 10^{-1}, 10^{-2}, \dots, 10^{-28}$  (ordered by decreasing slope).

**Examples:**

1. Consider the tridiagonal Toeplitz matrix of dimension  $n = 50$  from Example 1 of the last section, whose pseudospectra were illustrated in Figure 16.4. Since all the eigenvalues of this matrix are contained in both the left half-plane and the unit disk,  $e^{tA} \rightarrow 0$  as  $t \rightarrow \infty$  and  $A^k \rightarrow 0$  as  $k \rightarrow \infty$ . However,  $\sigma_\varepsilon(A)$  extends far into the right half-plane and beyond the unit disk even for  $\varepsilon$  as small as  $10^{-7}$ . Consequently, the lower bounds in Facts 1 and 2 guarantee that  $\|e^{tA}\|$  and  $\|A^k\|$  exhibit transient growth before their eventual decay; results such as Fact 6 limit the extent of the transient growth. These bounds are illustrated in Figure 16.7. (For a similar example involving a different matrix, see the “Transient” demonstration in [Wri02b].)
2. [GT93] The matrices

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \sqrt{2} \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix},$$

have the same 2-norm  $\varepsilon$ -pseudospectra for all  $\varepsilon > 0$ . However,  $\|A\|_2 = \sqrt{2} > 1 = \|B\|_2$ .

**Applications:**

1. Fact 5 leads to a convergence result for the GMRES algorithm (Chapter 41), which constructs estimates  $\mathbf{x}_k$  to the solution  $\mathbf{x}$  of the linear system  $A\mathbf{x} = \mathbf{b}$ . The  $k$ th residual  $\mathbf{r}_k = \mathbf{b} - A\mathbf{x}_k$  is bounded by

$$\frac{\|\mathbf{r}_k\|_2}{\|\mathbf{r}_0\|_2} \leq \frac{L_\varepsilon}{2\pi\varepsilon} \min_{\substack{p \in \mathbb{C}[z;k] \\ p(0)=1}} \max_{z \in \Gamma_\varepsilon} |p(z)|,$$

where  $\mathbb{C}[z;k]$  denotes the set of polynomials of degree  $k$  or less,  $\Gamma_\varepsilon$  is a finite union of Jordan curves containing  $\sigma_\varepsilon(A)$  in their collective interior for some  $\varepsilon > 0$ , and  $L_\varepsilon$  is the arc-length of  $\Gamma_\varepsilon$ .

2. For further examples of the use of pseudospectra to analyze matrix iterations and the stability of discretizations of differential equations, see [TE05, §§24–34].

## 16.4 Computation of Pseudospectra

---

This section describes techniques for computing and approximating pseudospectra, focusing primarily on the induced matrix 2-norm, the case most studied in the literature and for which very satisfactory algorithms exist. For further details, see [Tre99], [TE05, §§39–44], or [Wri02a].

**Facts:** [TE05]

1. There are two general approaches to computing pseudospectra, both based on the expression for  $\sigma_\varepsilon(A)$  in Fact 1(a) of Section 16.1. The most widely-used method computes the resolvent norm,  $\|(zI - A)^{-1}\|_2$ , on a grid of points in the complex plane and submits the results to a contour-plotting program; the second approach uses a curve-tracing algorithm to track the  $\varepsilon^{-1}$ -level curve of the resolvent norm ([Brü96]). Both approaches exploit the fact that the 2-norm of the resolvent is the reciprocal of the minimum singular value of  $zI - A$ . A third approach, based on the characterization of  $\sigma_\varepsilon(A)$  as the set of all  $\varepsilon$ -pseudoeigenvalues, approximates  $\sigma_\varepsilon(A)$  by the union of the eigenvalues of  $A + E$  for randomly generated  $E \in \mathbb{C}^{n \times n}$  with  $\|E\| < \varepsilon$ .
2. For dense matrices  $A$ , the computation of the minimum singular value of  $zI - A$  requires  $\mathcal{O}(n^3)$  floating point operations for each distinct value of  $z$ . Hence, the contour-plotting approach to computing pseudospectra based on a grid of  $m \times m$  points in the complex plane, implemented via the most naive method, requires  $\mathcal{O}(m^2n^3)$  operations.
3. [Lui97] Improved efficiency is obtained through the use of iterative methods for computing the minimum singular value of the resolvent. The most effective methods (inverse iteration or the inverse Lanczos method) require matrix-vector products of the form  $(zI - A)^{-1}\mathbf{x}$  at each iteration. For dense  $A$ , this approach requires  $\mathcal{O}(n^3)$  operations per grid point. One can decrease this labor to  $\mathcal{O}(n^2)$  by first reducing  $A$  to Schur form,  $A = UTU^*$ , and then noting that  $\|(zI - A)^{-1}\|_2 = \|(zI - T)^{-1}\|_2$ . Vectors of the form  $(zI - T)^{-1}\mathbf{x}$  can be computed in  $\mathcal{O}(n^2)$  operations since  $T$  is triangular. As the inverse iteration and inverse Lanczos methods typically converge to the minimum singular value in a small number of iterations at each grid point, the total complexity of the contour-plotting approach is  $\mathcal{O}(n^3 + m^2n^2)$ .
4. For large-scale problems (say,  $n > 1000$ ), the cost of preliminary triangularization can be prohibitive. Several alternatives are available: Use sparse direct or iterative methods to compute  $(zI - A)^{-1}\mathbf{x}$  at each grid point, or reduce the dimension of the problem by replacing  $A$  with a smaller matrix, such as the  $(m+1) \times m$  upper Hessenberg matrix in an Arnoldi decomposition, or  $U^*AU$ , where the columns of  $U \in \mathbb{C}^{n \times m}$  form an orthonormal basis for an invariant subspace corresponding to physically relevant eigenvalues, with  $m \ll n$ . As per results stated in Fact 9 of Section 16.1, the pseudospectra of these smaller matrices provide a lower bounds on the pseudospectra of  $A$ .

5. [Wri02b] EigTool is a freely available MATLAB package based on a highly-efficient, robust implementation of the grid-based method with preliminary triangularization and inverse Lanczos iteration. For large-scale problems, EigTool uses ARPACK (Chapter 76), to compute a subspace that includes an invariant subspace associated with eigenvalues in a given region of the complex plane. The EigTool software, which was used to compute the pseudospectra shown throughout this section, can be downloaded from <http://www.comlab.ox.ac.uk/pseudospectra/eigtool>.
6. Curve-tracing algorithms can also benefit from iterative computation of the resolvent norm, though the standard implementation requires both left and right singular vectors associated with the minimal singular value ([Brü96]). Robust implementations require measures to ensure that all components of  $\sigma_\varepsilon(A)$  have been located and to handle cusps in the boundary; see, e.g., [BG01].
7. Software for computing 2-norm pseudospectra can be used to compute pseudospectra in any norm induced by an inner product. Suppose the inner product of  $\mathbf{x}$  and  $\mathbf{y}$  is given by  $(\mathbf{x}, \mathbf{y})_W = (W\mathbf{x}, \mathbf{y})$ , where  $(\cdot, \cdot)$  denotes the Euclidean inner product and  $W = LL^*$ , where  $L^*$  denotes the conjugate transpose of  $L$ . Then the  $W$ -norm pseudospectra of  $A$  are equal to the 2-norm pseudospectra of  $L^*AL^{-*}$ .
8. For norms not associated with inner products, all known grid-based algorithms require  $\mathcal{O}(n^3)$  operations per grid point, typically involving the construction of the resolvent  $(zI - A)^{-1}$ . Higham and Tisseur ([HT00]) have proposed an efficient approach for approximating 1-norm pseudospectra using a norm estimator.
9. [BLO03],[MO05] There exist efficient algorithms, based on Fact 7 of section 16.1, for computing the 2-norm pseudospectral radius and abscissa without first determining the entire pseudospectrum.

## 16.5 Extensions

The previous sections address the standard formulation of the  $\varepsilon$ -pseudospectrum, the union of all eigenvalues of  $A + E$  for a square matrix  $A$  and general complex perturbations  $E$ , with  $\|E\| < \varepsilon$ . Natural modifications restrict the structure of  $E$  or adapt the definition to more general eigenvalue problems. The former topic has attracted considerable attention in the control theory literature and is presented in detail in [HP05].

### Definitions:

The **spectral value set**, or **structured  $\varepsilon$ -pseudospectrum**, of the matrix triplet  $(A, B, C)$ ,  $A \in \mathbb{C}^{n \times n}$ ,  $B \in \mathbb{C}^{n \times m}$ ,  $C \in \mathbb{C}^{p \times n}$ , for  $\varepsilon > 0$  is the set

$$\sigma_\varepsilon(A; B, C) = \{z \in \mathbb{C} : z \in \sigma(A + BEC) \text{ for some } E \in \mathbb{C}^{m \times p} \text{ with } \|E\| < \varepsilon\}.$$

The **real structured  $\varepsilon$ -pseudospectrum** of  $A \in \mathbb{R}^{n \times n}$  is the set

$$\sigma_\varepsilon^{\mathbb{R}}(A) = \{z \in \sigma(A + E) : E \in \mathbb{R}^{n \times n}, \|E\| < \varepsilon\}.$$

The  **$\varepsilon$ -pseudospectrum of a rectangular matrix**  $A \in \mathbb{C}^{n \times m}$  ( $n \geq m$ ) for  $\varepsilon > 0$  is the set

$$\sigma_\varepsilon(A) = \{z \in \mathbb{C} : (A + E)\mathbf{x} = z\mathbf{x} \text{ for some } \mathbf{x} \neq 0 \text{ and } \|E\| < \varepsilon\}.$$

[Ruh95] For  $A \in \mathbb{C}^{n \times n}$  and invertible  $B \in \mathbb{C}^{n \times n}$ , the  **$\varepsilon$ -pseudospectrum of the matrix pencil**  $A - \lambda B$  (or generalized eigenvalue problem  $A\mathbf{x} = \lambda B\mathbf{x}$ ) for  $\varepsilon > 0$  is the set

$$\sigma_\varepsilon(A, B) = \sigma_\varepsilon(B^{-1}A).$$

[TH01] The  $\varepsilon$ -**pseudospectrum of the matrix polynomial**  $P(\lambda)$  (or polynomial eigenvalue problem  $P(\lambda)\mathbf{x} = \mathbf{0}$ ), where  $P(\lambda) = \lambda^p A_p + \lambda^{p-1} A_{p-1} + \cdots + A_0$  and  $\varepsilon > 0$ , is the set

$$\sigma_\varepsilon(P) = \{z \in \mathbb{C} : z \in \sigma(P + E) \text{ for some} \\ E(\lambda) = \lambda^p E_p + \cdots + E_0, \|E_j\| \leq \varepsilon \alpha_j, \quad j = 0, \dots, p\},$$

for values  $\alpha_0, \dots, \alpha_p$ . For most applications, one would either take  $\alpha_j = 1$  for all  $j$ , or  $\alpha_j = \|A_j\|$ . (This definition differs considerably from the one given for the pseudospectrum of a matrix pencil. In particular, when  $p = 1$  the present definition *does not* reduce to the above definition for the pencil; see Fact 6 below.)

### Facts:

1. [HP92, HK93] The above definition of the spectral value set  $\sigma_\varepsilon(A; B, C)$  is equivalent to

$$\sigma_\varepsilon(A; B, C) = \{z \in \mathbb{C} : \|C(zI - A)^{-1}B\| > \varepsilon^{-1}\}.$$

2. [Kar03] The above definition of the real structured  $\varepsilon$ -pseudospectrum  $\sigma_\varepsilon^R(A)$  is equivalent to

$$\sigma_\varepsilon^R(A) = \{z \in \mathbb{C} : r(A, z) < \varepsilon\},$$

where

$$r(A, z)^{-1} = \inf_{\gamma \in (0,1)} \sigma_2 \left( \begin{bmatrix} \operatorname{Re}(zI - A)^{-1} & -\gamma \operatorname{Im}(zI - A)^{-1} \\ \gamma^{-1} \operatorname{Im}(zI - A)^{-1} & \operatorname{Re}(zI - A)^{-1} \end{bmatrix} \right)$$

and  $\sigma_2(\cdot)$  denotes the second largest singular value. From this formulation, one can derive algorithms for computing  $\sigma_\varepsilon^R(A)$  akin to those used for computing  $\sigma_\varepsilon(A)$ .

3. The definition of  $\sigma_\varepsilon^R(A)$  suggests similar formulations that impose different restrictions upon  $E$ , such as a sparsity pattern, Toeplitz structure, nonnegativity or stochasticity of  $A + E$ , etc. Such structured pseudospectra are often difficult to compute or approximate.
4. [WT02] The above definition of the  $\varepsilon$ -pseudospectrum  $\sigma_\varepsilon(A)$  of a rectangular matrix  $A \in \mathbb{C}^{n \times m}$ ,  $n \geq m$ , is equivalent to

$$\sigma_\varepsilon(A) = \{z \in \mathbb{C} : \|(z\tilde{I} - A)^\dagger\| > \varepsilon^{-1}\},$$

where  $(\cdot)^\dagger$  denotes the Moore–Penrose pseudoinverse and  $\tilde{I}$  denotes the  $n \times m$  matrix that has the  $m \times m$  identity in the first  $m$  rows and is zero elsewhere.

5. The following facts apply to the  $\varepsilon$ -pseudospectrum of a rectangular matrix  $A \in \mathbb{C}^{m \times n}$ ,  $m \geq n$ .
  - (a) [WT02] It is possible that  $\sigma_\varepsilon(A) = \emptyset$ .
  - (b) [BLO04] For  $A \in \mathbb{C}^{m \times n}$ ,  $m \geq n$ , and any  $\varepsilon > 0$ , the set  $\sigma_\varepsilon(A)$  contains no more than  $2n^2 - n + 1$  connected components.
6. [TE05] Alternative definitions have been proposed for the pseudospectrum of the matrix pencil  $A - \lambda B$ . The definition presented above has the advantage that the pseudospectrum is invariant to premultiplication of the pencil by a nonsingular matrix, which is consistent with the fact that premultiplication of the differential equation  $B\mathbf{x}' = A\mathbf{x}$  does not affect the solution  $\mathbf{x}$ . Here are two alternative definitions, *neither of which are equivalent to the previous definition*.
  - (a) [Rie94] If  $B$  is Hermitian positive definite with Cholesky factorization  $B = LL^*$ , then the pseudospectrum of the pencil can be defined in terms of the standard pseudospectrum of a transformed problem:

$$\sigma_\varepsilon(A, B) = \sigma_\varepsilon(L^{-1}AL^{-*}).$$

**FIGURE 16.8** Spectrum (solid dot) and real structured  $\varepsilon$ -pseudospectra  $\sigma_\varepsilon^R(A)$  (left) and unstructured  $\varepsilon$ -pseudospectra  $\sigma_\varepsilon(A)$  of the second matrix of Example 3 in section 16.1 for  $\varepsilon = 10^{-3}, 10^{-4}$ .

(b) [FGNT96, TH01] The following definition is more appropriate for the study of eigenvalue perturbations:

$$\sigma_\varepsilon(A, B) = \{z \in \mathbb{C} : (A + E_0)\mathbf{x} = z(B + E_1)\mathbf{x} \text{ for some } \mathbf{x} \neq \mathbf{0} \text{ and } E_0, E_1 \text{ with } \|E_0\| < \varepsilon\alpha_0, \|E_1\| < \varepsilon\alpha_1\},$$

where generally either  $\alpha_j = 1$  for  $j = 0, 1$ , or  $\alpha_0 = \|A\|$  and  $\alpha_1 = \|B\|$ . This is a special case of the definition given above for the pseudospectrum of a matrix polynomial.

7. [TH01] The above definition of the  $\varepsilon$ -pseudospectrum of a matrix polynomial,  $\sigma_\varepsilon(P)$ , is equivalent to

$$\sigma_\varepsilon(P) = \{z \in \mathbb{C} : \|P(z)^{-1}\| > 1/(\varepsilon\phi(|z|))\},$$

where  $\phi(z) = \sum_{j=0}^p \alpha_j z^j$  for the same values of  $\alpha_0, \dots, \alpha_p$  used in the earlier definition.

**FIGURE 16.9**  $\varepsilon$ -pseudospectra of the rectangular matrix in Example 2 with  $\delta = 0.02$  (left),  $\delta = 0.01$  (middle),  $\delta = 0.005$  (right), and  $\varepsilon = 10^{-1}, 10^{-1.5}$ , and  $10^{-2}$ . Note that in the first two plots,  $\sigma_\varepsilon(A) = \emptyset$  for  $\varepsilon = 10^{-2}$ .

**Examples:**

1. Figure 16.8 compares real structured  $\varepsilon$ -pseudospectra  $\sigma_\varepsilon^R(A)$  to the (unstructured) pseudospectra  $\sigma_\varepsilon(A)$  for the second matrix in Example 3 of Section 16.1; cf. [TE05, Fig. 50.3].
2. Figure 16.9 shows pseudospectra of the rectangular matrix

$$A = \begin{bmatrix} 2 & -5 & 10 \\ 1 & -2 & 5i \\ 0 & 0 & 1 \\ \delta & \delta & \delta \end{bmatrix},$$

which is the third matrix in Example 1 of Section 16.1, but with an extra row appended.

### 17.1 Definitions and Characterizations

---

Singular values and the singular value decomposition are defined in Chapter 5.6. Additional information on computation of the singular value decomposition can be found in Chapter 45. A brief history of the singular value decomposition and early references can be found in [HJ91, Chap. 3].

Throughout this chapter,  $q = \min\{m, n\}$ , and if  $A \in \mathbb{C}^{n \times n}$  has real eigenvalues, then they are ordered  $\lambda_1(A) \geq \dots \geq \lambda_n(A)$ .

#### Definitions:

For  $A \in \mathbb{C}^{m \times n}$ , define the **singular value vector**  $sv(A) = (\sigma_1(A), \dots, \sigma_q(A))$ .

For  $A \in \mathbb{C}^{m \times n}$ , define  $r_1(A) \geq \dots \geq r_m(A)$  and  $c_1(A) \geq \dots \geq c_n(A)$  to be the ordered Euclidean row and column lengths of  $A$ , that is, the square roots of the ordered diagonal entries of  $AA^*$  and  $A^*A$ .

For  $A \in \mathbb{C}^{m \times n}$  define  $|A|_{pd} = (A^*A)^{1/2}$ . This is called the **spectral absolute value** of  $A$ . (This is also called the **absolute value**, but the latter term will not be used in this chapter due to potential confusion with the entry-wise absolute value of  $A$ , denoted  $|A|$ .)

A **polar decomposition** or **polar form** of the matrix  $A \in \mathbb{C}^{m \times n}$  with  $m \geq n$  is a factorization  $A = UP$ , where  $P \in \mathbb{C}^{n \times n}$  is positive semidefinite and  $U \in \mathbb{C}^{m \times n}$  satisfies  $U^*U = I_n$ .

**Facts:**

The following facts can be found in most books on matrix theory, for example [HJ91, Chap. 3] or [Bha97].

1. Take  $A \in \mathbb{C}^{m \times n}$ , and set

$$B = \begin{bmatrix} A & 0 \\ 0 & 0 \end{bmatrix}.$$

Then  $\sigma_i(A) = \sigma_i(B)$  for  $i = 1, \dots, q$  and  $\sigma_i(B) = 0$  for  $i > q$ . We may choose the zero blocks in  $B$  to ensure that  $B$  is square. In this way we can often generalize results on the singular values of square matrices to rectangular matrices. For simplicity of exposition, in this chapter we will sometimes state a result for square matrices rather than the more general result for rectangular matrices.

2. (Unitary invariance) Take  $A \in \mathbb{C}^{m \times n}$ . Then for any unitary  $U \in \mathbb{C}^{m \times m}$  and  $V \in \mathbb{C}^{n \times n}$ ,

$$\sigma_i(A) = \sigma_i(UAV), \quad i = 1, 2, \dots, q.$$

3. Take  $A, B \in \mathbb{C}^{m \times n}$ . There are unitary matrices  $U \in \mathbb{C}^{m \times m}$  and  $V \in \mathbb{C}^{n \times n}$  such that  $A = UB$  if and only if  $\sigma_i(A) = \sigma_i(B)$ ,  $i = 1, 2, \dots, q$ .
4. Let  $A \in \mathbb{C}^{m \times n}$ . Then  $\sigma_i^2(A) = \lambda_i(AA^*) = \lambda_i(A^*A)$  for  $i = 1, 2, \dots, q$ .
5. Let  $A \in \mathbb{C}^{m \times n}$ . Let  $\mathcal{S}_i$  denote the set of subspaces of  $\mathbb{C}^n$  of dimension  $i$ . Then for  $i = 1, 2, \dots, q$ ,

$$\sigma_i(A) = \min_{\mathcal{X} \in \mathcal{S}_{n-i+1}} \max_{\mathbf{x} \in \mathcal{X}, \|\mathbf{x}\|_2=1} \|\mathbf{A}\mathbf{x}\|_2 = \min_{\mathcal{Y} \in \mathcal{S}_{i-1}} \max_{\mathbf{x} \perp \mathcal{Y}, \|\mathbf{x}\|_2=1} \|\mathbf{A}\mathbf{x}\|_2,$$

$$\sigma_i(A) = \max_{\mathcal{X} \in \mathcal{S}_i} \min_{\mathbf{x} \in \mathcal{X}, \|\mathbf{x}\|_2=1} \|\mathbf{A}\mathbf{x}\|_2 = \max_{\mathcal{Y} \in \mathcal{S}_{n-i}} \min_{\mathbf{x} \perp \mathcal{Y}, \|\mathbf{x}\|_2=1} \|\mathbf{A}\mathbf{x}\|_2.$$

6. Let  $A \in \mathbb{C}^{m \times n}$  and define the Hermitian matrix

$$J = \begin{bmatrix} 0 & A \\ A^* & 0 \end{bmatrix} \in \mathbb{C}^{m+n, m+n}.$$

The eigenvalues of  $J$  are  $\pm\sigma_1(A), \dots, \pm\sigma_q(A)$  together with  $|m-n|$  zeros. The matrix  $J$  is called the Jordan–Wielandt matrix. Its use allows one to deduce singular value results from results for eigenvalues of Hermitian matrices.

7. Take  $m \geq n$  and  $A \in \mathbb{C}^{m \times n}$ . Let  $A = UP$  be a polar decomposition of  $A$ . Then  $\sigma_i(A) = \lambda_i(P)$ ,  $i = 1, 2, \dots, q$ .
8. Let  $A \in \mathbb{C}^{m \times n}$  and  $1 \leq k \leq q$ . Then

$$\sum_{i=1}^k \sigma_i(A) = \max\{\operatorname{Re} \operatorname{tr} U^*AV : U \in \mathbb{C}^{m \times k}, V \in \mathbb{C}^{n \times k}, U^*U = V^*V = I_k\},$$

$$\prod_{i=1}^k \sigma_i(A) = \max\{|\det U^*AV| : U \in \mathbb{C}^{m \times k}, V \in \mathbb{C}^{n \times k}, U^*U = V^*V = I_k\}.$$

If  $m = n$ , then

$$\sum_{i=1}^n \sigma_i(A) = \max\left\{ \sum_{i=1}^n |(U^*AU)_{ii}| : U \in \mathbb{C}^{n \times n}, U^*U = I_n \right\}.$$

We cannot replace the  $n$  by a general  $k \in \{1, \dots, n\}$ .

9. Let  $A \in \mathbb{C}^{m \times n}$ .  $A$  yields

(a)  $\sigma_i(A^T) = \sigma_i(A^*) = \sigma_i(\bar{A}) = \sigma_i(A)$ , for  $i = 1, 2, \dots, q$ .

(b) Let  $k = \text{rank}(A)$ . Then  $\sigma_i(A^\dagger) = \sigma_{k-i+1}^{-1}(A)$  for  $i = 1, \dots, k$ , and  $\sigma_i(A^\dagger) = 0$  for  $i = k + 1, \dots, q$ . In particular, if  $m = n$  and  $A$  is invertible, then

$$\sigma_i(A^{-1}) = \sigma_{n-i+1}^{-1}(A), \quad i = 1, \dots, n.$$

(c) For any  $j \in \mathbb{N}$

$$\sigma_i((A^*A)^j) = \sigma_i^{2j}(A), \quad i = 1, \dots, q;$$

$$\sigma_i((A^*A)^j A^*) = \sigma_i(A(A^*A)^j) = \sigma_i^{2j+1}(A) \quad i = 1, \dots, q.$$

10. Let  $UP$  be a polar decomposition of  $A \in \mathbb{C}^{m \times n}$  ( $m \geq n$ ). The positive semidefinite factor  $P$  is uniquely determined and is equal to  $|A|_{pd}$ . The factor  $U$  is uniquely determined if  $A$  has rank  $n$ . If  $A$  has singular value decomposition  $A = U_1 \Sigma U_2^*$  ( $U_1 \in \mathbb{C}^{m \times n}$ ,  $U_2 \in \mathbb{C}^{n \times n}$ ), then  $P = U_2 \Sigma U_2^*$ , and  $U$  may be taken to be  $U_1 U_2^*$ .

11. Take  $A, U \in \mathbb{C}^{n \times n}$  with  $U$  unitary. Then  $A = U|A|_{pd}$  if and only if  $A = |A^*|_{pd}U$ .

### Examples:

1. Take

$$A = \begin{bmatrix} 11 & -3 & -5 & 1 \\ 1 & -5 & -3 & 11 \\ -5 & 1 & 11 & -3 \\ -3 & 11 & 1 & -5 \end{bmatrix}.$$

The singular value decomposition of  $A$  is  $A = U \Sigma V^*$ , where  $\Sigma = \text{diag}(20, 12, 8, 4)$ , and

$$U = \frac{1}{2} \begin{bmatrix} -1 & 1 & -1 & 1 \\ -1 & -1 & 1 & 1 \\ 1 & -1 & -1 & 1 \\ 1 & 1 & 1 & 1 \end{bmatrix} \quad \text{and} \quad V = \frac{1}{2} \begin{bmatrix} -1 & 1 & -1 & 1 \\ 1 & 1 & 1 & 1 \\ 1 & -1 & -1 & 1 \\ -1 & -1 & 1 & 1 \end{bmatrix}.$$

The singular values of  $A$  are 20, 12, 8, 4. Let  $Q$  denote the permutation matrix that takes  $(x_1, x_2, x_3, x_4)$  to  $(x_1, x_4, x_3, x_2)$ . Let  $P = |A|_{pd} = QA$ . The polar decomposition of  $A$  is  $A = QP$ . (To see this, note that a permutation matrix is unitary and that  $P$  is positive definite by Geršgorin's theorem.) Note also that  $|A|_{pd} \neq |A^*|_{pd} = AQ$ .

## 17.2 Singular Values of Special Matrices

In this section, we present some matrices where the singular values (or some of the singular values) are known, and facts about the singular values of certain structured matrices.

### Facts:

The following results can be obtained by straightforward computations if no specific reference is given.

1. Let  $D = \text{diag}(\alpha_1, \dots, \alpha_n)$ , where the  $\alpha_i$  are integers, and let  $H_1$  and  $H_2$  be Hadamard matrices. (See Chapter 32.2.) Then the matrix  $H_1 D H_2$  has integer entries and has integer singular values  $n|\alpha_1|, \dots, n|\alpha_n|$ .

2. ( $2 \times 2$  matrix) Take  $A \in \mathbb{C}^{2 \times 2}$ . Set  $D = |\det(A)|^2$ ,  $N = \|A\|_F^2$ . The singular values of  $A$  are

$$\sqrt{\frac{N \pm \sqrt{N^2 - 4D}}{2}}.$$

3. Let  $X \in \mathbb{C}^{m \times n}$  have singular values  $\sigma_1 \geq \dots \geq \sigma_q$  ( $q = \min\{m, n\}$ ). Set

$$A = \begin{bmatrix} I & 2X \\ 0 & I \end{bmatrix} \in \mathbb{C}^{m+n, m+n}.$$

The  $m + n$  singular values of  $A$  are

$$\sigma_1 + \sqrt{\sigma_1^2 + 1}, \dots, \sigma_q + \sqrt{\sigma_q^2 + 1}, 1, \dots, 1, \sqrt{\sigma_q^2 + 1} - \sigma_q, \dots, \sqrt{\sigma_1^2 + 1} - \sigma_1.$$

4. [HJ91, Theorem 4.2.15] Let  $A \in \mathbb{C}^{m_1 \times n_1}$  and  $B \in \mathbb{C}^{m_2 \times n_2}$  have rank  $m$  and  $n$ . The nonzero singular values of  $A \otimes B$  are  $\sigma_i(A)\sigma_j(B)$ ,  $i = 1, \dots, m$ ,  $j = 1, \dots, n$ .
5. Let  $A \in \mathbb{C}^{n \times n}$  be normal with eigenvalues  $\lambda_1, \dots, \lambda_n$ , and let  $p$  be a polynomial. Then the singular values of  $p(A)$  are  $|p(\lambda_k)|$ ,  $k = 1, \dots, n$ . In particular, if  $A$  is a circulant with first row  $a_0, \dots, a_{n-1}$ , then  $A$  has singular values

$$\left| \sum_{j=0}^{n-1} a_j e^{-2\pi i j k / n} \right|, \quad k = 1, \dots, n.$$

6. Take  $A \in \mathbb{C}^{n \times n}$  and nonzero  $\mathbf{x} \in \mathbb{C}^n$ . If  $A\mathbf{x} = \lambda\mathbf{x}$  and  $\mathbf{x}^*A = \lambda\mathbf{x}^*$ , then  $|\lambda|$  is a singular value of  $A$ . In particular, if  $A$  is doubly stochastic, then  $\sigma_1(A) = 1$ .
7. [Kit95] Let  $A$  be the companion matrix corresponding to the monic polynomial  $p(t) = t^n + a_{n-1}t^{n-1} + \dots + a_1t + a_0$ . Set  $N = 1 + \sum_{i=0}^{n-1} |a_i|^2$ . The  $n$  singular values of  $A$  are

$$\sqrt{\frac{N + \sqrt{N^2 - 4|a_0|^2}}{2}}, 1, \dots, 1, \sqrt{\frac{N - \sqrt{N^2 - 4|a_0|^2}}{2}}.$$

8. [Hig96, p. 167] Take  $s, c \in \mathbb{R}$  such that  $s^2 + c^2 = 1$ . The matrix

$$A = \text{diag}(1, s, \dots, s^{n-1}) \begin{bmatrix} 1 & -c & -c & \cdots & -c \\ & 1 & -c & \cdots & -c \\ & & \ddots & \ddots & \vdots \\ & & & \ddots & -c \\ & & & & 1 \end{bmatrix}$$

is called a Kahan matrix. If  $c$  and  $s$  are positive, then  $\sigma_{n-1}(A) = s^{n-2}\sqrt{1+c}$ .

9. [GE95, Lemma 3.1] Take  $0 = d_1 < d_2 < \dots < d_n$  and  $0 \neq z_i \in \mathbb{C}$ . Let

$$A = \begin{bmatrix} z_1 & & & \\ z_2 & d_2 & & \\ \vdots & & \ddots & \\ z_n & & & d_n \end{bmatrix}.$$

The singular values of  $A$  satisfy the equation

$$f(t) = 1 + \sum_{i=1}^n \frac{|z_i|^2}{d_i^2 - t^2} = 0$$

and exactly one lies in each of the intervals  $(d_1, d_2), \dots, (d_{n-1}, d_n), (d_n, d_n + \|z\|_2)$ . Let  $\sigma_i = \sigma_i(A)$ . The left and right  $i$ th singular vectors of  $A$  are  $\mathbf{u}/\|\mathbf{u}\|_2$  and  $\mathbf{v}/\|\mathbf{v}\|_2$  respectively, where

$$\mathbf{u} = \left[ \frac{z_1}{d_1^2 - \sigma_i^2}, \dots, \frac{z_n}{d_n^2 - \sigma_i^2} \right]^T \quad \text{and} \quad \mathbf{v} = \left[ -1, \frac{d_2 z_2}{d_2^2 - \sigma_i^2}, \dots, \frac{d_n z_n}{d_n^2 - \sigma_i^2} \right]^T.$$

10. (*Bidiagonal*) Take

$$B = \begin{bmatrix} \alpha_1 & \beta_1 & & & \\ & \alpha_2 & \ddots & & \\ & & \ddots & \beta_{n-1} & \\ & & & & \alpha_n \end{bmatrix} \in \mathbb{C}^{n \times n}.$$

If all the  $\alpha_i$  and  $\beta_i$  are nonzero, then  $B$  is called an *unreduced bidiagonal matrix* and

- The singular values of  $B$  are distinct.
  - The singular values of  $B$  depend only on the moduli of  $\alpha_1, \dots, \alpha_n, \beta_1, \dots, \beta_{n-1}$ .
  - The largest singular value of  $B$  is a strictly increasing function of the modulus of each of the  $\alpha_i$  and  $\beta_i$ .
  - The smallest singular value of  $B$  is a strictly increasing function of the modulus of each of the  $\alpha_i$  and a strictly decreasing function of the modulus of each of the  $\beta_i$ .
  - (High relative accuracy) Take  $\tau > 1$  and multiply one of the entries of  $B$  by  $\tau$  to give  $\hat{B}$ . Then  $\tau^{-1}\sigma_i(B) \leq \sigma_i(\hat{B}) \leq \tau\sigma_i(B)$ .
11. [HJ85, Sec. 4.4, prob. 26] Let  $A \in \mathbb{C}^{n \times n}$  be skew-symmetric (and possibly complex). The nonzero singular values of  $A$  occur in pairs.

## 17.3 Unitarily Invariant Norms

Throughout this section,  $q = \min\{m, n\}$ .

### Definitions:

A vector norm  $\|\cdot\|$  on  $\mathbb{C}^{m \times n}$  is **unitarily invariant** (*u.i.*) if  $\|A\| = \|UAV\|$  for any unitary  $U \in \mathbb{C}^{m \times m}$  and  $V \in \mathbb{C}^{n \times n}$  and any  $A \in \mathbb{C}^{m \times n}$ .

$\|\cdot\|_{UI}$  is used to denote a **general unitarily invariant norm**.

A function  $g: \mathbb{R}^n \rightarrow \mathbb{R}_0^+$  is a **permutation invariant absolute norm** if it is a norm, and in addition  $g(x_1, \dots, x_n) = g(|x_1|, \dots, |x_n|)$  and  $g(\mathbf{x}) = g(P\mathbf{x})$  for all  $\mathbf{x} \in \mathbb{R}^n$  and all permutation matrices  $P \in \mathbb{R}^{n \times n}$ . (Many authors call a permutation invariant absolute norm a symmetric gauge function.)

The **Ky Fan  $k$  norms** of  $A \in \mathbb{C}^{m \times n}$  are

$$\|A\|_{K,k} = \sum_{i=1}^k \sigma_i(A), \quad k = 1, 2, \dots, q.$$

The **Schatten- $p$  norms** of  $A \in \mathbb{C}^{m \times n}$  are

$$\|A\|_{S,p} = \left( \sum_{i=1}^q \sigma_i^p(A) \right)^{1/p} = (\operatorname{tr} |A|_{pd}^p)^{1/p} \quad 0 \leq p < \infty$$

$$\|A\|_{S,\infty} = \sigma_1(A).$$

The **trace norm** of  $A \in \mathbb{C}^{m \times n}$  is

$$\|A\|_{tr} = \sum_{i=1}^q \sigma_i(A) = \|A\|_{K,q} = \|A\|_{S,1} = \text{tr} |A|_{pd}.$$

Other norms discussed in this section, such as the **spectral norm**  $\|\cdot\|_2$  ( $\|A\|_2 = \sigma_1(A) = \max_{x \neq 0} \frac{\|Ax\|_2}{\|x\|_2}$ ) and the **Frobenius norm**  $\|\cdot\|_F$  ( $\|A\|_F = (\sum_{i=1}^q \sigma_i^2(A))^{1/2} = (\sum_{i=1}^m \sum_{j=1}^n |a_{ij}|^2)^{1/2}$ ), are defined in Section 7.1. and discussed extensively in Chapter 37.

*Warning:* There is potential for considerable confusion. For example,  $\|A\|_2 = \|A\|_{K,1} = \|A\|_{S,\infty}$ , while  $\|\cdot\|_\infty \neq \|\cdot\|_{S,\infty}$  (unless  $m = 1$ ), and generally  $\|A\|_2, \|A\|_{S,2}$  and  $\|A\|_{K,2}$  are all different, as are  $\|A\|_1, \|A\|_{S,1}$  and  $\|A\|_{K,1}$ . Nevertheless, many authors use  $\|\cdot\|_k$  for  $\|\cdot\|_{K,k}$  and  $\|\cdot\|_p$  for  $\|\cdot\|_{S,p}$ .

**Facts:**

The following standard facts can be found in many texts, e.g., [HJ91, §3.5] and [Bha97, Chap. IV].

1. Let  $\|\cdot\|$  be a norm on  $\mathbb{C}^{m \times n}$ . It is unitarily invariant if and only if there is a permutation invariant absolute norm  $g$  on  $\mathbb{R}^q$  such that  $\|A\| = g(\sigma_1(A), \dots, \sigma_q(A))$  for all  $A \in \mathbb{C}^{m \times n}$ .
2. Let  $\|\cdot\|$  be a unitarily invariant norm on  $\mathbb{C}^{m \times n}$ , and let  $g$  be the corresponding permutation invariant absolute norm  $g$ . Then the dual norms (see Chapter 37) satisfy  $\|A\|^D = g^D(\sigma_1(A), \dots, \sigma_q(A))$ .
3. [HJ91, Prob. 3.5.18] The spectral norm and trace norm are duals, while the Frobenius norm is self dual. The dual of  $\|\cdot\|_{S,p}$  is  $\|\cdot\|_{S,\tilde{p}}$ , where  $1/p + 1/\tilde{p} = 1$  and

$$\|A\|_{K,k}^D = \max \left\{ \|A\|_2, \frac{\|A\|_{tr}}{k} \right\}, \quad k = 1, \dots, q.$$

4. For any  $A \in \mathbb{C}^{m \times n}$ ,  $q^{-1/2} \|A\|_F \leq \|A\|_2 \leq \|A\|_F$ .
5. If  $\|\cdot\|$  is a u.i. norm on  $\mathbb{C}^{m \times n}$ , then  $N(A) = \|A^*A\|^{1/2}$  is a u.i. norm on  $\mathbb{C}^{n \times n}$ . A norm that arises in this way is called a *Q-norm*.
6. Let  $A, B \in \mathbb{C}^{m \times n}$  be given. The following are equivalent
  - (a)  $\|A\|_{UI} \leq \|B\|_{UI}$  for all unitarily invariant norms  $\|\cdot\|_{UI}$ .
  - (b)  $\|A\|_{K,k} \leq \|B\|_{K,k}$  for  $k = 1, 2, \dots, q$ .
  - (c)  $(\sigma_1(A), \dots, \sigma_q(A)) \leq_w (\sigma_1(B), \dots, \sigma_q(B))$ . ( $\leq_w$  is defined in Preliminaries)

The equivalence of the first two conditions is Fan's Dominance Theorem.

7. The Ky–Fan- $k$  norms can be represented in terms of an extremal problem involving the spectral norm and the trace norm. Take  $A \in \mathbb{C}^{m \times n}$ . Then

$$\|A\|_{K,k} = \min\{\|X\|_{tr} + k\|Y\|_2 : X + Y = A\} \quad k = 1, \dots, q.$$

8. [HJ91, Theorem 3.3.14] Take  $A, B \in \mathbb{C}^{m \times n}$ . Then

$$|\text{tr} AB^*| \leq \sum_{i=1}^q \sigma_i(A) \sigma_i(B).$$

This is an important result in developing the theory of unitarily invariant norms.

**Examples:**

1. The matrix  $A$  in Example 1 of Section 17.1 has singular values 20, 12, 8, and 4. So

$$\begin{aligned}\|A\|_2 &= 20, & \|A\|_F &= \sqrt{624}, & \|A\|_{tr} &= 44; \\ \|A\|_{K,1} &= 20, & \|A\|_{K,2} &= 32, & \|A\|_{K,3} &= 40, & \|A\|_{K,4} &= 44; \\ \|A\|_{S,1} &= 44, & \|A\|_{S,2} &= \sqrt{624}, & \|A\|_{S,3} &= \sqrt[3]{10304} = 21.7605, & \|A\|_{S,\infty} &= 20.\end{aligned}$$

## 17.4 Inequalities

Throughout this section,  $q = \min\{m, n\}$  and if  $A \in \mathbb{C}^{m \times n}$  has real eigenvalues, then they are ordered  $\lambda_1(A) \geq \dots \geq \lambda_n(A)$ .

**Definitions:**

**Pinching** is defined recursively. If

$$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \in \mathbb{C}^{m \times n}, \quad B = \begin{bmatrix} A_{11} & 0 \\ 0 & A_{22} \end{bmatrix} \in \mathbb{C}^{m \times n},$$

then  $B$  is a pinching of  $A$ . (Note that we do not require the  $A_{ii}$  to be square.) Furthermore, any pinching of  $B$  is a pinching of  $A$ .

For positive  $\alpha, \beta$ , define the **measure of relative separation**  $\chi(\alpha, \beta) = |\sqrt{\alpha/\beta} - \sqrt{\beta/\alpha}|$ .

**Facts:**

The following facts can be found in standard references, for example [HJ91, Chap. 3], unless another reference is given.

1. (*Submatrices*) Take  $A \in \mathbb{C}^{m \times n}$  and let  $B$  denote  $A$  with one of its rows or columns deleted. Then  $\sigma_{i+1}(A) \leq \sigma_i(B) \leq \sigma_i(A)$ ,  $i = 1, \dots, q-1$ .
2. Take  $A \in \mathbb{C}^{m \times n}$  and let  $B$  be  $A$  with a row *and* a column deleted. Then

$$\sigma_{i+2}(A) \leq \sigma_i(B) \leq \sigma_i(A), \quad i = 1, \dots, q-2.$$

The  $i+2$  cannot be replaced by  $i+1$ . (Example 2)

3. Take  $A \in \mathbb{C}^{m \times n}$  and let  $B$  be an  $(m-k) \times (n-l)$  submatrix of  $A$ . Then

$$\sigma_{i+k+l}(A) \leq \sigma_i(B) \leq \sigma_i(A), \quad i = 1, \dots, q-(k+l).$$

4. Take  $A \in \mathbb{C}^{m \times n}$  and let  $B$  be  $A$  with some of its rows and/or columns set to zero. Then  $\sigma_i(B) \leq \sigma_i(A)$ ,  $i = 1, \dots, q$ .
5. Let  $B$  be a pinching of  $A$ . Then  $\text{sv}(B) \leq_w \text{sv}(A)$ . The inequalities  $\prod_{i=1}^k \sigma_i(B) \leq \prod_{i=1}^k \sigma_i(A)$  and  $\sigma_k(B) \leq \sigma_k(A)$  are not necessarily true for  $k > 1$ . (Example 1)
6. (*Singular values of  $A+B$* ) Let  $A, B \in \mathbb{C}^{m \times n}$ .

(a)  $\text{sv}(A+B) \leq_w \text{sv}(A) + \text{sv}(B)$ , or equivalently

$$\sum_{i=1}^k \sigma_i(A+B) \leq \sum_{i=1}^k \sigma_i(A) + \sum_{i=1}^k \sigma_i(B), \quad i = 1, \dots, q.$$

(b) If  $i+j-1 \leq q$  and  $i, j \in \mathbb{N}$ , then  $\sigma_{i+j-1}(A+B) \leq \sigma_i(A) + \sigma_j(B)$ .

- (c) We have the weak majorization  $|sv(A + B) - sv(A)| \leq_w sv(B)$  or, equivalently, if  $1 \leq i_1 < \dots < i_k \leq q$ , then

$$\sum_{j=1}^k |\sigma_{i_j}(A + B) - \sigma_{i_j}(A)| \leq \sum_{j=1}^k \sigma_{i_j}(B),$$

$$\sum_{i=1}^k \sigma_{i_j}(A) - \sum_{j=1}^k \sigma_j(B) \leq \sum_{j=1}^k \sigma_{i_j}(A + B) \leq \sum_{i=1}^k \sigma_{i_j}(A) + \sum_{j=1}^k \sigma_j(B).$$

- (d) [Tho75] (Thompson's Standard Additive Inequalities) If  $1 \leq i_1 < \dots < i_k \leq q$ ,  $1 \leq i_1 < \dots < i_k \leq q$  and  $i_k + j_k \leq q + k$ , then

$$\sum_{s=1}^k \sigma_{i_s + j_s - s}(A + B) \leq \sum_{s=1}^k \sigma_{i_s}(A) + \sum_{s=1}^k \sigma_{j_s}(B).$$

7. (Singular values of  $AB$ ) Take  $A, B \in \mathbb{C}^{n \times n}$ .

- (a) For all  $k = 1, 2, \dots, n$  and all  $p > 0$ , we have

$$\prod_{i=n-k+1}^{i=n-k+1} \sigma_i(A) \sigma_i(B) \leq \prod_{i=n-k+1}^{i=n-k+1} \sigma_i(AB),$$

$$\prod_{i=1}^k \sigma_i(AB) \leq \prod_{i=1}^k \sigma_i(A) \sigma_i(B),$$

$$\sum_{i=1}^k \sigma_i^p(AB) \leq \sum_{i=1}^k \sigma_i^p(A) \sigma_i^p(B).$$

- (b) If  $i, j \in \mathbb{N}$  and  $i + j - 1 \leq n$ , then  $\sigma_{i+j-1}(AB) \leq \sigma_i(A) \sigma_j(B)$ .

- (c)  $\sigma_n(A) \sigma_i(B) \leq \sigma_i(AB) \leq \sigma_1(A) \sigma_i(B)$ ,  $i = 1, 2, \dots, n$ .

- (d) [LM99] Take  $1 \leq j_1 < \dots < j_k \leq n$ . If  $A$  is invertible and  $\sigma_{j_i}(B) > 0$ , then  $\sigma_{j_i}(AB) > 0$  and

$$\prod_{i=n-k+1}^n \sigma_i(A) \leq \prod_{i=1}^k \max \left\{ \frac{\sigma_{j_i}(AB)}{\sigma_{j_i}(B)}, \frac{\sigma_{j_i}(B)}{\sigma_{j_i}(AB)} \right\} \leq \prod_{i=1}^k \sigma_i(A).$$

- (e) [LM99] Take invertible  $S, T \in \mathbb{C}^{n \times n}$ . Set  $\tilde{A} = SAT$ . Let the singular values of  $A$  and  $\tilde{A}$  be  $\sigma_1 \geq \dots \geq \sigma_n$  and  $\tilde{\sigma}_1 \geq \dots \geq \tilde{\sigma}_n$ . Then

$$\|\text{diag}(\chi(\sigma_1, \tilde{\sigma}_1), \dots, \chi(\sigma_n, \tilde{\sigma}_n))\|_{UI} \leq \frac{1}{2} (\|S^* - S^{-1}\|_{UI} + \|T^* - T^{-1}\|_{UI}).$$

- (f) [TT73] (Thompson's Standard Multiplicative Inequalities) Take  $1 \leq i_1 < \dots < i_m \leq n$  and  $1 \leq j_1 < \dots < j_m \leq n$ . If  $i_m + j_m \leq m + n$ , then

$$\prod_{s=1}^m \sigma_{i_s + j_s - s}(AB) \leq \prod_{s=1}^m \sigma_{i_s}(A) \prod_{s=1}^m \sigma_{j_s}(B).$$

8. [Bha97, §IX.1] Take  $A, B \in \mathbb{C}^{n \times n}$ .

- (a) If  $AB$  is normal, then

$$\prod_{i=1}^k \sigma_i(AB) \leq \prod_{i=1}^k \sigma_i(BA), \quad k = 1, \dots, q,$$

and, consequently,  $sv(AB) \leq_w sv(BA)$ , and  $\|AB\|_{UI} \leq \|BA\|_{UI}$ .

(b) If  $AB$  is Hermitian, then  $\text{sv}(AB) \leq_w \text{sv}(H(BA))$  and  $\|AB\|_{UI} \leq \|H(BA)\|_{UI}$ , where  $H(X) = (X + X^*)/2$ .

9. (Term-wise singular value inequalities) [Zha02, p. 28] Take  $A, B \in \mathbb{C}^{m \times n}$ . Then

$$2\sigma_i(AB^*) \leq \sigma_i(A^*A + B^*B), \quad i = 1, \dots, q$$

and, more generally, if  $p, \bar{p} > 0$  and  $1/p + 1/\bar{p} = 1$ , then

$$\sigma_i(AB^*) \leq \sigma_i \left( \frac{(A^*A)^{p/2}}{p} + \frac{(B^*B)^{\bar{p}/2}}{\bar{p}} \right) = \sigma_i \left( \frac{|A|_{pd}^p}{p} + \frac{|B|_{pd}^{\bar{p}}}{\bar{p}} \right).$$

The inequalities  $2\sigma_1(A^*B) \leq \sigma_1(A^*A + B^*B)$  and  $\sigma_1(A + B) \leq \sigma_1(|A|_{pd} + |B|_{pd})$  are not true in general (Example 3), but we do have

$$\|A^*B\|_{UI}^2 \leq \|A^*A\|_{UI} \|B^*B\|_{UI}.$$

10. [Bha97, Prop. III.5.1] Take  $A \in \mathbb{C}^{n \times n}$ . Then  $\lambda_i(A + A^*) \leq 2\sigma_i(A)$ ,  $i = 1, 2, \dots, n$ .

11. [LM02] (Block triangular matrices) Let  $A = \begin{bmatrix} R & 0 \\ S & T \end{bmatrix} \in \mathbb{C}^{n \times n}$  ( $R \in \mathbb{C}^{p \times p}$ ) have singular values  $\alpha_1 \geq \dots \geq \alpha_n$ . Let  $k = \min\{p, n - p\}$ . Then

(a) If  $\sigma_{\min}(R) \geq \sigma_{\max}(T)$ , then

$$\begin{aligned} \sigma_i(R) &\leq \alpha_i, \quad i = 1, \dots, p \\ \alpha_i &\leq \sigma_{i-p}(T), \quad i = p + 1, \dots, n. \end{aligned}$$

(b)  $(\sigma_1(S), \dots, \sigma_k(S)) \leq_w (\alpha_1 - \alpha_n, \dots, \alpha_k - \alpha_{n-k+1})$ .

(c) If  $A$  is invertible, then

$$\begin{aligned} (\sigma_1(T^{-1}SR^{-1}), \dots, \sigma_k(T^{-1}SR^{-1})) &\leq_w (\alpha_n^{-1} - \alpha_1^{-1}, \dots, \alpha_{n-k+1}^{-1} - \alpha_k^{-1}), \\ (\sigma_1(T^{-1}S), \dots, \sigma_k(T^{-1}S)) &\leq_w \frac{1}{2} \left( \frac{\alpha_1}{\alpha_n} - \frac{\alpha_n}{\alpha_1}, \dots, \frac{\alpha_k}{\alpha_{n-k+1}} - \frac{\alpha_{n-k+1}}{\alpha_k} \right). \end{aligned}$$

12. [LM02] (Block positive semidefinite matrices) Let  $A = \begin{bmatrix} A_{11} & A_{12} \\ A_{12}^* & A_{22} \end{bmatrix} \in \mathbb{C}^{n \times n}$  be positive definite with eigenvalues  $\lambda_1 \geq \dots \geq \lambda_n$ . Assume  $A_{11} \in \mathbb{C}^{p \times p}$ . Set  $k = \min\{p, n - p\}$ . Then

$$\begin{aligned} \prod_{i=1}^j \sigma_i^2(A_{12}) &\leq \prod_{i=1}^j \sigma_i(A_{11}) \sigma_i(A_{22}), \quad j = 1, \dots, k, \\ (\sigma_1(A_{11}^{-1/2}A_{12}), \dots, \sigma_k(A_{11}^{-1/2}A_{12})) &\leq_w \left( \sqrt{\lambda_1} - \sqrt{\lambda_n}, \dots, \sqrt{\lambda_k} - \sqrt{\lambda_{n-k+1}} \right), \\ (\sigma_1(A_{11}^{-1}A_{12}), \dots, \sigma_k(A_{11}^{-1}A_{12})) &\leq_w \frac{1}{2} (\chi(\lambda_1, \lambda_n), \dots, \chi(\lambda_k, \lambda_{n-k+1})). \end{aligned}$$

If  $k = n/2$ , then

$$\|A_{12}\|_{UI}^2 \leq \|A_{11}\|_{UI} \|A_{22}\|_{UI}.$$

13. (Singular values and eigenvalues) Let  $A \in \mathbb{C}^{n \times n}$ . Assume  $|\lambda_1(A)| \geq \dots \geq |\lambda_n(A)|$ . Then

(a)  $\prod_{i=1}^k |\lambda_i(A)| \leq \prod_{i=1}^k \sigma_i(A)$ ,  $k = 1, \dots, n$ , with equality for  $k = n$ .

(b) Fix  $p > 0$ . Then for  $k = 1, 2, \dots, n$ ,

$$\sum_{i=1}^k |\lambda_i^p(A)| \leq \sum_{i=1}^k \sigma_i^p(A).$$

Equality holds with  $k = n$  if and only if equality holds for all  $k = 1, 2, \dots, n$ , if and only if  $A$  is normal.

(c) [HJ91, p. 180] (Yamamoto's theorem)  $\lim_{k \rightarrow \infty} (\sigma_i(A^k))^{1/k} = |\lambda_i(A)|$ ,  $i = 1, \dots, n$ .

14. [LM01] Let  $\lambda_i \in \mathbb{C}$  and  $\sigma_i \in \mathbb{R}_0^+$ ,  $i = 1, \dots, n$  be ordered in nonincreasing absolute value. There is a matrix  $A$  with eigenvalues  $\lambda_1, \dots, \lambda_n$  and singular values  $\sigma_1, \dots, \sigma_n$  if and only if

$$\prod_{i=1}^k |\lambda_i| \leq \prod_{i=1}^k \sigma_i, \quad k = 1, \dots, n, \quad \text{with equality for } k = n.$$

In addition:

- (a) The matrix  $A$  can be taken to be upper triangular with the eigenvalues on the diagonal in any order.
  - (b) If the complex entries in  $\lambda_1, \dots, \lambda_n$  occur in conjugate pairs, then  $A$  may be taken to be in real Schur form, with the  $1 \times 1$  and  $2 \times 2$  blocks on the diagonal in any order.
  - (c) There is a finite construction of the upper triangular matrix in cases (a) and (b).
  - (d) If  $n > 2$ , then  $A$  cannot always be taken to be bidiagonal. (Example 5)
15. [Zha02, Chap. 2] (*Singular values of  $A \circ B$* ) Take  $A, B \in \mathbb{C}^{n \times n}$ .
- (a)  $\sigma_i(A \circ B) \leq \min\{r_i(A), c_i(B)\} \cdot \sigma_i(B)$ ,  $i = 1, 2, \dots, n$ .
  - (b) We have the following weak majorizations:

$$\begin{aligned} \sum_{i=1}^k \sigma_i(A \circ B) &\leq \sum_{i=1}^k \min\{r_i(A), c_i(A)\} \sigma_i(B), \quad k = 1, \dots, n, \\ \sum_{i=1}^k \sigma_i(A \circ B) &\leq \sum_{i=1}^k \sigma_i(A) \sigma_i(B), \quad k = 1, \dots, n, \\ \prod_{i=1}^k \sigma_i^2(A \circ B) &\leq \prod_{i=1}^k \sigma_i((A^*A) \circ (B^*B)), \quad k = 1, \dots, n. \end{aligned}$$

(c) Take  $X, Y \in \mathbb{C}^{n \times n}$ . If  $A = X^*Y$ , then we have the weak majorization

$$\sum_{i=1}^k \sigma_i(A \circ B) \leq \sum_{i=1}^k c_i(X) c_i(Y) \sigma_i(B), \quad k = 1, \dots, n.$$

(d) If  $B$  is positive semidefinite with diagonal entries  $b_{11} \geq \dots \geq b_{nn}$ , then

$$\sum_{i=1}^k \sigma_i(A \circ B) \leq \sum_{i=1}^k b_{ii} \sigma_i(A), \quad k = 1, \dots, n.$$

(e) If both  $A$  and  $B$  are positive definite, then so is  $A \circ B$  (Schur product theorem). In this case the singular values of  $A, B$  and  $A \circ B$  are their eigenvalues and  $BA$  has positive eigenvalues and we have the weak multiplicative majorizations

$$\prod_{i=k}^n \lambda_i(B) \lambda_i(A) \leq \prod_{i=k}^n b_{ii} \lambda_i(A) \leq \prod_{i=k}^n \lambda_i(BA) \leq \prod_{i=k}^n \lambda_i(A \circ B), \quad k = 1, 2, \dots, n.$$

The inequalities are still valid if we replace  $A \circ B$  by  $A \circ B^T$ . (Note  $B^T$  is not necessarily the same as  $B^* = B$ .)

16. Let  $A \in \mathbb{C}^{m \times n}$ . The following are equivalent:

- (a)  $\sigma_1(A \circ B) \leq \sigma_1(B)$  for all  $B \in \mathbb{C}^{m \times n}$ .
- (b)  $\sum_{i=1}^k \sigma_i(A \circ B) \leq \sum_{i=1}^k \sigma_i(B)$  for all  $B \in \mathbb{C}^{m \times n}$  and all  $k = 1, \dots, q$ .
- (c) There are positive semidefinite  $P \in \mathbb{C}^{n \times n}$  and  $Q \in \mathbb{C}^{m \times m}$  such that

$$\begin{bmatrix} P & A \\ A^* & Q \end{bmatrix}$$

is positive semidefinite, and has diagonal entries at most 1.

17. (*Singular values and matrix entries*) Take  $A \in \mathbb{C}^{m \times n}$ . Then

$$\begin{aligned} (|a_{11}|^2, |a_{12}|^2, \dots, |a_{mn}|^2) &\leq (\sigma_1^2(A), \dots, \sigma_q^2(A), 0, \dots, 0), \\ \sum_{i=1}^q \sigma_i^p(A) &\leq \sum_{i=1}^m \sum_{j=1}^n |a_{ij}|^p, \quad 0 \leq p \leq 2, \\ \sum_{i=1}^m \sum_{j=1}^n |a_{ij}|^p &\leq \sum_{i=1}^q \sigma_i^p(A), \quad 2 \leq p < \infty. \end{aligned}$$

If  $\sigma_1(A) = |a_{ij}|$ , then all the other entries in row  $i$  and column  $j$  of  $A$  are 0.

18. Take  $\sigma_1 \geq \dots \geq \sigma_n \geq 0$  and  $\alpha_1 \geq \dots \geq \alpha_n \geq 0$ . Then

$$\exists A \in \mathbb{R}^{n \times n} \text{ s.t. } \sigma_i(A) = \sigma_i \quad \text{and} \quad c_i(A) = \alpha_i \Leftrightarrow (\alpha_1^2, \dots, \alpha_n^2) \leq (\sigma_1^2, \dots, \sigma_n^2).$$

This statement is still true if we replace  $\mathbb{R}^{n \times n}$  by  $\mathbb{C}^{n \times n}$  and/or  $c_i(\cdot)$  by  $r_i(\cdot)$ .

19. Take  $A \in \mathbb{C}^{n \times n}$ . Then

$$\prod_{i=k}^n \sigma_i(A) \leq \prod_{i=k}^n c_i(A), \quad k = 1, 2, \dots, n.$$

The case  $k = 1$  is Hadamard's Inequality:  $|\det(A)| \leq \prod_{i=1}^n c_i(A)$ .

20. [Tho77] Take  $F = \mathbb{C}$  or  $\mathbb{R}$  and  $d_1, \dots, d_n \in F$  such that  $|d_1| \geq \dots \geq |d_n|$ , and  $\sigma_1 \geq \dots \geq \sigma_n \geq 0$ . There is a matrix  $A \in F^{n \times n}$  with diagonal entries  $d_1, \dots, d_n$  and singular values  $\sigma_1, \dots, \sigma_n$  if and only if

$$(|d_1|, \dots, |d_n|) \leq_w (\sigma_1(A), \dots, \sigma_n(A)) \quad \text{and} \quad \sum_{j=1}^{n-1} |d_j| - |d_n| \leq \sum_{j=1}^{n-1} \sigma_j(A) - \sigma_n(A).$$

21. (*Nonnegative matrices*) Take  $A = [a_{ij}] \in \mathbb{C}^{m \times n}$ .

- (a) If  $B = [|a_{ij}|]$ , then  $\sigma_1(A) \leq \sigma_1(B)$ .
- (b) If  $A$  and  $B$  are real and  $0 \leq a_{ij} \leq b_{ij} \quad \forall i, j$ , then  $\sigma_1(A) \leq \sigma_1(B)$ . The condition  $0 \leq a_{ij}$  is essential. (Example 4)
- (c) The condition  $0 \leq b_{ij} \leq 1 \quad \forall i, j$  does not imply  $\sigma_1(A \circ B) \leq \sigma_1(A)$ . (Example 4)

22. (*Bound on  $\sigma_1$* ) Let  $A \in \mathbb{C}^{m \times n}$ . Then  $\|A\|_2 = \sigma_1(A) \leq \sqrt{\|A\|_1 \|A\|_\infty}$ .

23. [Zha99] (*Cartesian decomposition*) Let  $C = A + iB \in \mathbb{C}^{n \times n}$ , where  $A$  and  $B$  are Hermitian. Let  $A, B, C$  have singular values  $\alpha_j, \beta_j, \gamma_j, j = 1, \dots, n$ . Then

$$(\gamma_1, \dots, \gamma_n) \leq_w \sqrt{2}(|\alpha_1 + i\beta_1|, \dots, |\alpha_n + i\beta_n|) \leq_w 2(\gamma_1, \dots, \gamma_n).$$

**Examples:**

1. Take

$$A = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & 1 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

Then  $B$  is a pinching of  $A$ , and  $C$  is a pinching of both  $A$  and  $B$ . The matrices  $A, B, C$  have singular values  $\alpha = (3, 0, 0)$ ,  $\beta = (2, 1, 0)$ , and  $\gamma = (1, 1, 1)$ . As stated in Fact 5,  $\gamma \preceq_w \beta \preceq_w \alpha$ . In fact, since the matrices are all positive semidefinite, we may replace  $\preceq_w$  by  $\preceq$ . However, it is not true that  $\gamma_i \leq \alpha_i$  except for  $i = 1$ . Nor is it true that  $|\det(C)| \leq |\det(A)|$ .

2. The matrices

$$A = \begin{bmatrix} 11 & -3 & -5 & 1 \\ 1 & -5 & -3 & 11 \\ -5 & 1 & 11 & -3 \\ -3 & 11 & 1 & -5 \end{bmatrix}, \quad B = \begin{bmatrix} 11 & -3 & -5 & 1 \\ 1 & -5 & -3 & 11 \\ -5 & 1 & 11 & -3 \end{bmatrix}, \quad C = \begin{bmatrix} 11 & -3 & -5 \\ 1 & -5 & -3 \\ -5 & 1 & 11 \end{bmatrix}$$

have singular values  $\alpha = (20, 12, 8, 4)$ ,  $\beta = (17.9, 10.5, 6.0)$ , and  $\gamma = (16.7, 6.2, 4.5)$  (to 1 decimal place). The singular values of  $B$  interlace those of  $A$  ( $\alpha_4 \leq \beta_3 \leq \alpha_3 \leq \beta_2 \leq \alpha_2 \leq \beta_1 \leq \alpha_1$ ), but those of  $C$  do not. In particular,  $\alpha_3 \not\leq \gamma_2$ . It is true that  $\alpha_{i+2} \leq \gamma_i \leq \alpha_i$  ( $i = 1, 2$ ).

3. Take

$$A = \begin{bmatrix} 1 & 0 \\ 1 & 0 \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} 0 & 1 \\ 0 & 1 \end{bmatrix}.$$

Then  $\|A + B\|_2 = \sigma_1(A + B) = 2 \not\leq \sqrt{2} = \sigma_1(|A|_{pd} + |B|_{pd}) = \| |A|_{pd} + |B|_{pd} \|_2$ . Also,  $2\sigma_1(A^*B) = 4 \not\leq 2 = \sigma_1(A^*A + B^*B)$ .

4. Setting entries of a matrix to zero can increase the largest singular value. Take

$$A = \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix}, \quad \text{and} \quad B = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}.$$

Then  $\sigma_1(A) = \sqrt{2} < (1 + \sqrt{5})/2 = \sigma_1(B)$ .

5. A bidiagonal matrix
- $B$
- cannot have eigenvalues 1, 1, 1 and singular values 1/2, 1/2, 4. If
- $B$
- is unreduced bidiagonal, then it cannot have repeated singular values. (See Fact 10, section 17.2.) However, if
- $B$
- were reduced, then it would have a singular value equal to 1.

## 17.5 Matrix Approximation

Recall that  $\|\cdot\|_{UI}$  denotes a general unitarily invariant norm, and that  $q = \min\{m, n\}$ .

**Facts:**

The following facts can be found in standard references, for example, [HJ91, Chap. 3], unless another reference is given.

1. (
- Best rank  $k$  approximation.*
- ) Let
- $A \in \mathbb{C}^{m \times n}$
- and
- $1 \leq k \leq q - 1$
- . Let
- $A = U\Sigma V^*$
- be a singular value decomposition of
- $A$
- . Let
- $\tilde{\Sigma}$
- be equal to
- $\Sigma$
- except that
- $\tilde{\Sigma}_{ii} = 0$
- for
- $i > k$
- , and let
- $\tilde{A} = U\tilde{\Sigma}V^*$
- . Then
- $\text{rank}(\tilde{A}) \leq k$
- , and

$$\|\Sigma - \tilde{\Sigma}\|_{UI} = \|A - \tilde{A}\|_{UI} = \min\{\|A - B\|_{UI} : \text{rank}(B) \leq k\}.$$

In particular, for the spectral norm and the Frobenius norm, we have

$$\begin{aligned}\sigma_{k+1}(A) &= \min\{\|A - B\|_2 : \text{rank}(B) \leq k\}, \\ \left(\sum_{i=k+1}^q \sigma_{k+1}^2(A)\right)^{1/2} &= \min\{\|A - B\|_F : \text{rank}(B) \leq k\}.\end{aligned}$$

2. [Bha97, p. 276] (*Best unitary approximation*) Take  $A, W \in \mathbb{C}^{n \times n}$  with  $W$  unitary. Let  $A = UP$  be a polar decomposition of  $A$ . Then

$$\|A - U\|_{UI} \leq \|A - W\|_{UI} \leq \|A + U\|_{UI}.$$

3. [GV96, §12.4.1] [HJ85, Ex. 7.4.8] (*Orthogonal Procrustes problem*) Let  $A, B \in \mathbb{C}^{m \times n}$ . Let  $B^*A$  have a polar decomposition  $B^*A = UP$ . Then

$$\|A - BU\|_F = \min\{\|A - BW\|_F : W \in \mathbb{C}^{n \times n}, W^*W = I\}.$$

This result is not true if  $\|\cdot\|_F$  is replaced by  $\|\cdot\|_{UI}$  ([Mat93, §4]).

4. [Hig89] (*Best PSD approximation*) Take  $A \in \mathbb{C}^{n \times n}$ . Set  $A_H = (A + A^*)/2$ ,  $B = (A_H + |A_H|)/2$ . Then  $B$  is positive semidefinite and is the unique solution to

$$\min\{\|A - X\|_F : X \in \mathbb{C}^{n \times n}, X \in \text{PSD}\}.$$

There is also a formula for the best PSD approximation in the spectral norm.

5. Let  $A, B \in \mathbb{C}^{m \times n}$  have singular value decompositions  $A = U_A \Sigma_A V_A^*$  and  $B = U_B \Sigma_B V_B^*$ . Let  $U \in \mathbb{C}^{m \times m}$  and  $V \in \mathbb{C}^{n \times n}$  be any unitary matrices. Then

$$\|\Sigma_A - \Sigma_B\|_{UI} \leq \|A - UB V^*\|_{UI}.$$

## 17.6 Characterization of the Eigenvalues of Sums of Hermitian Matrices and Singular Values of Sums and Products of General Matrices

There are necessary and sufficient conditions for three sets of numbers to be the eigenvalues of Hermitian  $A, B, C = A + B \in \mathbb{C}^{n \times n}$ , or the singular values of  $A, B, C = A + B \in \mathbb{C}^{m \times n}$ , or the singular values of nonsingular  $A, B, C = AB \in \mathbb{C}^{n \times n}$ . The key results in this section were first proved by Klyachko ([Kly98]) and Knutson and Tao ([KT99]). The results presented here are from a survey by Fulton [Ful00]. Bhatia has written an expository paper on the subject ([Bha01]).

### Definitions:

The inequalities are in terms of the sets  $T_r^n$  of triples  $(I, J, K)$  of subsets of  $\{1, \dots, n\}$  of the same cardinality  $r$ , defined by the following inductive procedure. Set

$$U_r^n = \left\{ (I, J, K) \mid \sum_{i \in I} i + \sum_{j \in J} j = \sum_{k \in K} k + r(r+1)/2 \right\}.$$

When  $r = 1$ , set  $T_1^n = U_1^n$ . In general,

$$T_r^n = \left\{ (I, J, K) \in U_r^n \mid \text{for all } p < r \text{ and all} \right.$$

$$\left. (F, G, H) \in T_p^n, \sum_{i \in F} i_f + \sum_{g \in G} j_g \leq \sum_{h \in H} k_h + p(p+1)/2 \right\}.$$

In this section, the vectors  $\alpha, \beta, \gamma$  will have real entries ordered in nonincreasing order.

**Facts:**

The following facts are in [Ful00]:

1. A triple  $(\alpha, \beta, \gamma)$  of real  $n$ -vectors occurs as eigenvalues of Hermitian  $A, B, C = A + B \in \mathbb{C}^{n \times n}$  if and only if  $\sum \gamma_i = \sum \alpha_i + \sum \beta_i$  and the inequalities

$$\sum_{k \in K} \gamma_k \leq \sum_{i \in I} \alpha_i + \sum_{j \in J} \beta_j$$

hold for every  $(I, J, K)$  in  $T_r^n$ , for all  $r < n$ . Furthermore, the statement is true if  $\mathbb{C}^{n \times n}$  is replaced by  $\mathbb{R}^{n \times n}$ .

2. Take Hermitian  $A, B \in \mathbb{C}^{n \times n}$  (not necessarily PSD). Let the vectors of eigenvalues of  $A, B, C = A + B$  be  $\alpha, \beta$ , and  $\gamma$ . Then we have the (nonlinear) inequality

$$\min_{\pi \in S_n} \prod_{i=1}^n (\alpha_i + \beta_{\pi(i)}) \leq \prod_{i=1}^n \gamma_i \leq \max_{\pi \in S_n} \prod_{i=1}^n (\alpha_i + \beta_{\pi(i)}).$$

3. Fix  $m, n$  and set  $q = \min\{m, n\}$ . For any subset  $X$  of  $\{1, \dots, m+n\}$ , define  $X_q = \{i : i \in X, i \leq q\}$  and  $X'_q = \{i : i \leq q, m+n+1-i \in X\}$ . A triple  $(\alpha, \beta, \gamma)$  occurs as the singular values of  $A, B, C = A + B \in \mathbb{C}^{m \times n}$ , if and only if the inequalities

$$\sum_{k \in K_q} \gamma_k - \sum_{k \in K'_q} \gamma_k \leq \sum_{i \in I} \alpha_i - \sum_{i \in I'_q} \alpha_i + \sum_{j \in J_q} \beta_j - \sum_{j \in J'_q} \beta_j$$

are satisfied for all  $(I, J, K)$  in  $T_r^{m+n}$ , for all  $r < m+n$ . This statement is not true if  $\mathbb{C}^{m \times n}$  is replaced by  $\mathbb{R}^{m \times n}$ . (See Example 1.)

4. A triple of positive real  $n$ -vectors  $(\alpha, \beta, \gamma)$  occurs as the singular values of  $n$  by  $n$  matrices  $A, B, C = AB \in \mathbb{C}^{n \times n}$  if and only if  $\gamma_1 \cdots \gamma_n = \alpha_1 \cdots \alpha_n \beta_1 \cdots \beta_n$  and

$$\prod_{k \in K} \gamma_k \leq \prod_{i \in I} \alpha_i \cdot \prod_{j \in J} \beta_j$$

for all  $(I, J, K)$  in  $T_r^n$ , and all  $r < n$ . This statement is still true if  $\mathbb{C}^{n \times n}$  is replaced by  $\mathbb{R}^{n \times n}$ .

**Example:**

1. There are  $A, B, C = A + B \in \mathbb{C}^{2 \times 2}$  with singular values  $(1, 1), (1, 0)$ , and  $(1, 1)$ , but there are no  $A, B, C = A + B \in \mathbb{R}^{2 \times 2}$  with these singular values.

In the complex case, take  $A = \text{diag}(1, 1/2 + (\sqrt{3}/2)i)$ ,  $B = \text{diag}(0, -1)$ .

Now suppose that  $A$  and  $B$  are real  $2 \times 2$  matrices such that  $A$  and  $C = A + B$  both have singular values  $(1, 1)$ . Then  $A$  and  $C$  are orthogonal. Consider  $BC^T = AC^T - CC^T = AC^T - I$ . Because  $AC^T$  is real, it has eigenvalues  $\alpha, \bar{\alpha}$  and so  $BC^T$  has eigenvalues  $\alpha - 1, \bar{\alpha} - 1$ . Because  $AC^T$  is orthogonal, it is normal and, hence, so is  $BC^T$ , and so its singular values are  $|\alpha - 1|$  and  $|\bar{\alpha} - 1|$ , which are equal and, in particular, cannot be  $(1, 0)$ .

## 17.7 Miscellaneous Results and Generalizations

---

Throughout this section  $F$  can be taken to be either  $\mathbb{R}$  or  $\mathbb{C}$ .

**Definitions:**

Let  $\mathcal{X}, \mathcal{Y}$  be subspaces of  $\mathbb{C}^r$  of dimension  $m$  and  $n$ . The **principal angles**  $0 \leq \theta_1 \leq \dots \leq \theta_q \leq \pi/2$  between  $\mathcal{X}$  and  $\mathcal{Y}$  and **principal vectors**  $\mathbf{u}_1, \dots, \mathbf{u}_q$  and  $\mathbf{v}_1, \dots, \mathbf{v}_q$  are defined inductively:

$$\cos(\theta_1) = \max\{|\mathbf{x}^* \mathbf{y}| : \mathbf{x} \in \mathcal{X}, \max_{\mathbf{y} \in \mathcal{Y}} \|\mathbf{x}\|_2 = \|\mathbf{y}\|_2 = 1\}.$$

Let  $\mathbf{u}_1$  and  $\mathbf{v}_1$  be a pair of maximizing vectors. For  $k = 2, \dots, q$ ,

$$\cos(\theta_k) = \max\{|\mathbf{x}^* \mathbf{y}| : \mathbf{x} \in \mathcal{X}, \mathbf{y} \in \mathcal{Y}, \|\mathbf{x}\|_2 = \|\mathbf{y}\|_2 = 1, \mathbf{x}^* \mathbf{u}_i = \mathbf{y}^* \mathbf{v}_i = 0, i = 1, \dots, k-1\}.$$

Let  $\mathbf{u}_k$  and  $\mathbf{v}_k$  be a pair of maximizing vectors. (Principal angles are also called **canonical angles**, and the cosines of the principal angles are called **canonical correlations**.)

### Facts:

1. (*Principal Angles*) Let  $\mathcal{X}, \mathcal{Y}$  be subspaces of  $\mathbb{C}^r$  of dimension  $m$  and  $n$ .
  - (a) [BG73] The principal vectors obtained by the process above are not necessarily unique, but the principal angles are unique (and, hence, independent of the chosen principal vectors).
  - (b) Let  $m = n \leq r/2$  and  $X, Y$  be matrices whose columns form orthonormal bases for the subspaces  $\mathcal{X}$  and  $\mathcal{Y}$ , respectively.
    - i. The singular values of  $X^* Y$  are the cosines of the principal angles between the subspaces  $\mathcal{X}$  and  $\mathcal{Y}$ .
    - ii. There are unitary matrices  $U \in \mathbb{C}^{r \times r}$  and  $V_X$  and  $V_Y \in \mathbb{C}^{n \times n}$  such that

$$U X V_X = \begin{bmatrix} I_n \\ 0_n \\ 0_{r-n,n} \end{bmatrix}, \quad U Y V_Y = \begin{bmatrix} \Gamma \\ \Sigma \\ 0_{r-n,n} \end{bmatrix},$$

where  $\Gamma$  and  $\Sigma$  are nonnegative diagonal matrices. Their diagonal entries are the cosines and sines respectively of the principal angles between  $\mathcal{X}$  and  $\mathcal{Y}$ .

- (c) [QZL05] Take  $m = n$ . For any permutation invariant absolute norm  $g$  on  $\mathbb{R}^m$ ,

$$g(\sin(\theta_1), \dots, \sin(\theta_m)), \quad g(2 \sin(\theta_1/2), \dots, 2 \sin(\theta_m/2)), \quad \text{and} \quad g(\theta_1, \dots, \theta_m)$$

are metrics on the set of subspaces of dimension  $n$  of  $\mathbb{C}^{r \times r}$ .

2. [GV96, Theorem 2.6.2] (*CS decomposition*) Let  $W \in F^{n \times n}$  be unitary. Take a positive integer  $l$  such that  $2l \leq n$ . Then there are unitary matrices  $U_{11}, V_{11} \in F^{l \times l}$  and  $U_{22}, V_{22} \in F^{(n-l) \times (n-l)}$  such that

$$\begin{bmatrix} U_{11} & 0 \\ 0 & U_{22} \end{bmatrix} W \begin{bmatrix} V_{11} & 0 \\ 0 & V_{22} \end{bmatrix} = \begin{bmatrix} \Gamma & -\Sigma & 0 \\ \Sigma & \Gamma & 0 \\ 0 & 0 & I_{n-2l} \end{bmatrix},$$

where  $\Gamma = \text{diag}(\gamma_1, \dots, \gamma_l)$  and  $\Sigma = \text{diag}(\sigma_1, \dots, \sigma_l)$  are nonnegative and  $\Gamma^2 + \Sigma^2 = I$ .

3. [GV96, Theorem 8.7.4] (*Generalized singular value decomposition*) Take  $A \in F^{p \times n}$  and  $B \in F^{m \times n}$  with  $p \geq n$ . Then there is an invertible  $X \in F^{n \times n}$ , unitary  $U \in F^{p \times p}$  and  $V \in F^{m \times m}$ , and nonnegative diagonal matrices  $\Sigma_A \in \mathbb{R}^{n \times n}$  and  $\Sigma_B \in \mathbb{R}^{q \times q}$  ( $q = \min\{m, n\}$ ) such that  $A = U \Sigma_A X$  and  $B = V \Sigma_B X$ .

Chi-Kwong Li  
*College of William and Mary*

The numerical range  $W(A)$  of an  $n \times n$  complex matrix  $A$  is the collection of complex numbers of the form  $\mathbf{x}^* A \mathbf{x}$ , where  $\mathbf{x} \in \mathbb{C}^n$  is a unit vector. It can be viewed as a “picture” of  $A$  containing useful information of  $A$ . Even if the matrix  $A$  is not known explicitly, the “picture”  $W(A)$  would allow one to “see” many properties of the matrix. For example, the numerical range can be used to locate eigenvalues, deduce algebraic and analytic properties, obtain norm bounds, help find dilations with simple structure, etc. Related to the numerical range are the numerical radius of  $A$  defined by  $w(A) = \max_{\mu \in W(A)} |\mu|$  and the distance of  $W(A)$  to the origin denoted by  $\tilde{w}(A) = \min_{\mu \in W(A)} |\mu|$ . The quantities  $w(A)$  and  $\tilde{w}(A)$  are useful in studying perturbation, convergence, stability, and approximation problems.

Note that the spectrum  $\sigma(A)$  can be viewed as another useful “picture” of the matrix  $A \in M_n$ . There are interesting relations between  $\sigma(A)$  and  $W(A)$ .

### 18.1 Basic Properties and Examples

---

#### Definitions and Notation:

Let  $A \in \mathbb{C}^{n \times n}$ . The **numerical range** (also known as **the field of values**) of  $A$  is defined by

$$W(A) = \{\mathbf{x}^* A \mathbf{x} : \mathbf{x} \in \mathbb{C}^n, \mathbf{x}^* \mathbf{x} = 1\}.$$

The **numerical radius** of  $A$  and the **distance** of  $W(A)$  to the origin are the quantities

$$w(A) = \max\{|\mu| : \mu \in W(A)\} \quad \text{and} \quad \tilde{w}(A) = \min\{|\mu| : \mu \in W(A)\}.$$

Furthermore, let

$$\overline{W(A)} = \{\bar{a} : a \in W(A)\}.$$

**Facts:**

The following basic facts can be found in most references on numerical ranges such as [GR96], [Hal82], and [HJ91].

1. Let  $A \in \mathbb{C}^{n \times n}$ ,  $a, b \in \mathbb{C}$ . Then  $W(aA + bI) = aW(A) + b$ .
2. Let  $A \in \mathbb{C}^{n \times n}$ . Then  $W(U^*AU) = W(A)$  for any unitary  $U \in \mathbb{C}^{n \times n}$ .
3. Let  $A \in \mathbb{C}^{n \times n}$ . Suppose  $k \in \{1, \dots, n-1\}$  and  $X \in \mathbb{C}^{n \times k}$  satisfies  $X^*X = I_k$ . Then

$$W(X^*AX) \subseteq W(A).$$

In particular, for any  $k \times k$  principal submatrix  $B$  of  $A$ , we have  $W(B) \subseteq W(A)$ .

4. Let  $A \in \mathbb{C}^{n \times n}$ . Then  $W(A)$  is a compact convex set in  $\mathbb{C}$ .
5. If  $A_1 \oplus A_2 \in M_n$ , then  $W(A) = \text{conv} \{W(A_1) \cup W(A_2)\}$ .
6. Let  $A \in M_n$ . Then  $W(A) = W(A^T)$  and  $W(A^*) = \overline{W(A)}$ .
7. If  $A \in \mathbb{C}^{2 \times 2}$  has eigenvalues  $\lambda_1, \lambda_2$ , then  $W(A)$  is an elliptical disk with foci  $\lambda_1, \lambda_2$ , and minor axis with length  $\{\text{tr}(A^*A) - |\lambda_1|^2 - |\lambda_2|^2\}^{1/2}$ . Consequently, if  $A = \begin{bmatrix} \lambda_1 & b \\ 0 & \lambda_2 \end{bmatrix}$ , then the minor axis of the elliptical disk  $W(A)$  has length  $|b|$ .
8. Let  $A \in \mathbb{C}^{n \times n}$ . Then  $W(A)$  is a subset of a straight line if and only if there are  $a, b \in \mathbb{C}$  with  $a \neq 0$  such that  $aA + bI$  is Hermitian. In particular, we have the following:
  - (a)  $A = aI$  if and only if  $W(A) = \{a\}$ .
  - (b)  $A = A^*$  if and only if  $W(A) \subseteq \mathbb{R}$ .
  - (c)  $A = A^*$  is positive definite if and only if  $W(A) \subseteq (0, \infty)$ .
  - (d)  $A = A^*$  is positive semidefinite if and only if  $W(A) \subseteq [0, \infty)$ .
9. If  $A \in \mathbb{C}^{n \times n}$  is normal, then  $W(A) = \text{conv} \sigma(A)$  is a convex polygon. The converse is true if  $n \leq 4$ .
10. Let  $A \in \mathbb{C}^{n \times n}$ . The following conditions are equivalent.
  - (a)  $W(A) = \text{conv} \sigma(A)$ .
  - (b)  $W(A)$  is a convex polygon with vertices  $\mu_1, \dots, \mu_k$ .
  - (c)  $A$  is unitarily similar to  $\text{diag}(\mu_1, \dots, \mu_k) \oplus B$  such that  $W(B) \subseteq \text{conv} \{\mu_1, \dots, \mu_k\}$ .
11. Let  $A \in \mathbb{C}^{n \times n}$ . Then  $A$  is unitary if and only if all eigenvalues of  $A$  have modulus one and  $W(A) = \text{conv} \sigma(A)$ .
12. Suppose  $A = (A_{ij})_{1 \leq i, j \leq m} \in M_n$  is a block matrix such that  $A_{11}, \dots, A_{mm}$  are square matrices and  $A_{ij} = 0$  whenever  $(i, j) \notin \{(1, 2), \dots, (m-1, m), (m, 1)\}$ . Then  $W(A) = cW(A)$  for any  $c \in \mathbb{C}$  satisfying  $c^m = 1$ . If  $A_{m,1}$  is also zero, then  $W(A)$  is a circular disk centered at 0 with the radius equal to the largest eigenvalue of  $(A + A^*)/2$ .

**Examples:**

1. Let  $A = \text{diag}(1, 0)$ . Then  $W(A) = [0, 1]$ .
2. Let  $A = \begin{bmatrix} 0 & 2 \\ 0 & 0 \end{bmatrix}$ . Then  $W(A)$  is the closed unit disk  $\mathbf{D} = \{a \in \mathbb{C} : |a| \leq 1\}$ .
3. Let  $A = \begin{bmatrix} 2 & 2 \\ 0 & 1 \end{bmatrix}$ . Then by Fact 7 above,  $W(A)$  is the convex set whose boundary is the ellipse with foci 1 and 2 and minor axis 2, as shown in Figure 18.1.
4. Let  $A = \text{diag}(1, i, -1, -i) \oplus \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}$ . By Facts 5 and 7, the boundary of  $W(A)$  is the square with vertices  $1, i, -1, -i$ .

FIGURE 18.1 Numerical range of the matrix  $A$  in Example 3.

**Applications:**

1. By Fact 6, if  $A$  is real, then  $W(A)$  is symmetric about the real axis, i.e.,  $W(A) = \overline{W(A)}$ .
2. Suppose  $A \in \mathbb{C}^{n \times n}$ , and there are  $a, b \in \mathbb{C}$  such that  $(A - aI)(A - bI) = 0_n$ . Then  $A$  is unitarily similar to a matrix of the form

$$aI_r \oplus bI_s \oplus \begin{bmatrix} a & d_1 \\ 0 & b \end{bmatrix} \oplus \cdots \oplus \begin{bmatrix} a & d_t \\ 0 & b \end{bmatrix}$$

with  $d_1 \geq \cdots \geq d_t > 0$ , where  $r + s + 2t = n$ . By Facts 1, 5, and 7, the set  $W(A)$  is the elliptical disk with foci  $a, b$  and minor axis of length  $d$ , where

$$d = d_1 = \{(\|A\|_2^2 - |a|^2)(\|A\|_2^2 - |b|^2)\}^{1/2} / \|A\|_2$$

if  $t \geq 1$ , and  $d = 0$  otherwise.

3. By Fact 12, if  $A \in \mathbb{C}^{n \times n}$  is the basic circulant matrix  $E_{12} + E_{23} + \cdots + E_{n-1,n} + E_{n1}$ , then  $W(A) = \text{conv}\{c \in \mathbb{C} : c^n = 1\}$ ; if  $A \in M_n$  is the Jordan block of zero  $J_n(0)$ , then  $W(A) = \{c \in \mathbb{C} : |c| \leq \cos(\pi/(n+1))\}$ .
4. Suppose  $A \in \mathbb{C}^{n \times n}$  is a primitive nonnegative matrix. Then  $A$  is permutationally similar to a block matrix  $(A_{ij})$  as described in Fact 12 and, thus,  $W(A) = cW(A)$  for any  $c \in \mathbb{C}$  satisfying  $c^m = 1$ .

## 18.2 The Spectrum and Special Boundary Points

---

**Definitions and Notation:**

Let  $\partial\mathcal{S}$  and  $\text{int}(\mathcal{S})$  be the boundary and the interior of a convex compact subset  $\mathcal{S}$  of  $\mathbb{C}$ .

A **support line**  $\ell$  of  $\mathcal{S}$  is a line that intersects  $\partial\mathcal{S}$  such that  $\mathcal{S}$  lies entirely within one of the closed half-planes determined by  $\ell$ .

A boundary point  $\mu$  of  $\mathcal{S}$  is **nondifferentiable** if there is more than one support line of  $\mathcal{S}$  passing through  $\mu$ .

An eigenvalue  $\lambda$  of  $A \in \mathbb{C}^{n \times n}$  is a **reducing eigenvalue** if  $A$  is unitarily similar to  $[\lambda] \oplus A_2$ .

**Facts:**

The following facts can be found in [GR96],[Hal82], and [HJ91].

1. Let  $A \in \mathbb{C}^{n \times n}$ . Then

$$\sigma(A) \subseteq W(A) \subseteq \{a \in \mathbb{C} : |a| \leq \|A\|_2\}.$$

2. Let  $A, E \in \mathbb{C}^{n \times n}$ . We have

$$\begin{aligned} \sigma(A + E) &\subseteq W(A + E) \subseteq W(A) + W(E) \\ &\subseteq \{a + b \in \mathbb{C} : a \in W(A), \quad b \in \mathbb{C} \quad \text{with} \quad |b| \leq \|E\|_2\}. \end{aligned}$$

3. Let  $A \in \mathbb{C}^{n \times n}$  and  $a \in \mathbb{C}$ . Then  $a \in \sigma(A) \cap \partial W(A)$  if and only if  $A$  is unitarily similar to  $aI_k \oplus B$  such that  $a \notin \sigma(B) \cup \text{int}(W(B))$ .
4. Let  $A \in \mathbb{C}^{n \times n}$  and  $a \in \mathbb{C}$ . Then  $a$  is a nondifferentiable boundary point of  $W(A)$  if and only if  $A$  is unitarily similar to  $aI_k \oplus B$  such that  $a \notin W(B)$ . In particular,  $a$  is a reducing eigenvalue of  $A$ .
5. Let  $A \in \mathbb{C}^{n \times n}$ . If  $W(A)$  has at least  $n - 1$  nondifferentiable boundary points or if at least  $n - 1$  eigenvalues of  $A$  (counting multiplicities) lie in  $\partial W(A)$ , then  $A$  is normal.

### Examples:

1. Let  $A = [1] \oplus \begin{bmatrix} 0 & 2 \\ 0 & 0 \end{bmatrix}$ . Then  $W(A)$  is the unit disk centered at the origin, and 1 is a reducing eigenvalue of  $A$  lying on the boundary of  $W(A)$ .
2. Let  $A = [2] \oplus \begin{bmatrix} 0 & 2 \\ 0 & 0 \end{bmatrix}$ . Then  $W(A)$  is the convex hull of unit disk centered at the origin of the number 2, and 2 is a nondifferentiable boundary point of  $W(A)$ .

### Applications:

1. By Fact 1, if  $A \in \mathbb{C}^{n \times n}$  and  $0 \notin W(A)$ , then  $0 \notin \sigma(A)$  and, thus,  $A$  is invertible.
2. By Fact 4, if  $A \in \mathbb{C}^{n \times n}$ , then  $W(A)$  has at most  $n$  nondifferentiable boundary points.
3. While  $W(A)$  does not give a very tight containment region for  $\sigma(A)$  as shown in the examples in the last section. Fact 2 shows that the numerical range can be used to estimated the spectrum of the resulting matrix when  $A$  is under a perturbation  $E$ . In contrast,  $\sigma(A)$  and  $\sigma(E)$  usually do not carry much information about  $\sigma(A + E)$  in general. For example, let  $A = \begin{bmatrix} 0 & M \\ 0 & 0 \end{bmatrix}$  and  $E = \begin{bmatrix} 0 & 0 \\ \varepsilon & 0 \end{bmatrix}$ . Then  $\sigma(A) = \sigma(E) = \{0\}$ ,  $\sigma(A + E) = \{\pm\sqrt{M\varepsilon}\} \subseteq W(A + E)$ , which is the elliptical disk with foci  $\pm\sqrt{M\varepsilon}$  and length of minor axis equal to  $||M| - |\varepsilon||$ .

## 18.3 Location of the Numerical Range

---

### Facts:

The following facts can be found in [HJ91].

1. Let  $A \in \mathbb{C}^{n \times n}$  and  $t \in [0, 2\pi)$ . Suppose  $\mathbf{x}_t \in \mathbb{C}^n$  is a unit eigenvector corresponding to the largest eigenvalue  $\lambda_1(t)$  of  $e^{it}A + e^{-it}A^*$ , and

$$\mathcal{P}_t = \{a \in \mathbb{C} : e^{it}a + e^{-it}\bar{a} \leq \lambda_1(t)\}.$$

Then

$$e^{it}W(A) \subseteq \mathcal{P}_t, \quad \lambda_t = \mathbf{x}_t^* A \mathbf{x}_t \in \partial W(A) \cap \partial \mathcal{P}_t$$

and

$$W(A) = \bigcap_{r \in [0, 2\pi)} e^{-ir} \mathcal{P}_r = \text{conv} \{ \lambda_r : r \in [0, 2\pi) \}.$$

If  $T = \{t_1, \dots, t_k\}$  with  $0 \leq t_1 < \dots < t_k < 2\pi$  and  $k > 2$  such that  $t_k - t_1 > \pi$ , then

$$P_T^O(A) = \bigcap_{r \in T} e^{-ir} P_r \quad \text{and} \quad P_T^I(A) = \text{conv} \{ \lambda_r : r \in T \}$$

are two polygons in  $\mathbb{C}$  such that

$$P_T^I(A) \subseteq W(A) \subseteq P_T^O(A).$$

Moreover, both the area  $W(A) \setminus P_T^I(A)$  and the area of  $P_T^O(A) \setminus W(A)$  converge to 0 as  $\max\{t_j - t_{j-1} : 1 \leq j \leq k + 1\}$  converges to 0, where  $t_0 = 0, t_{k+1} = 2\pi$ .

- Let  $A = (a_{ij}) \in \mathbb{C}^{n \times n}$ . For each  $j = 1, \dots, n$ , let

$$g_j = \sum_{i \neq j} (|a_{ij}| + |a_{ji}|) / 2 \quad \text{and} \quad G_j(A) = \{ a \in \mathbb{C} : |a - a_{jj}| \leq g_j \}.$$

Then

$$W(A) \subseteq \text{conv} \bigcup_{j=1}^n G_j(A).$$

**Examples:**

- Let  $A = \begin{bmatrix} 2 & 2 \\ 0 & 2 \end{bmatrix}$ . Then  $W(A)$  is the circular disk centered at 2 with radius 1. In Figure 18.2,  $W(A)$  is approximated by  $P_T^O(A)$  with  $T = \{2k\pi/100 : 0 \leq k \leq 99\}$ . If  $T = \{0, \pi/2, \pi, 3\pi/2\}$ , then the polygon  $P_T^O(A)$  in Fact 1 is bounded by the four lines  $\{3 + bi : b \in \mathbb{R}\}, \{a + i : a \in \mathbb{R}\}, \{1 + bi : b \in \mathbb{R}\}, \{a - i : a \in \mathbb{R}\}$ , and the polygon  $P_T^I(A)$  equals the convex hull of  $\{2, 1 + i, 0, 1 - i\}$ .
- Let  $A = \begin{bmatrix} 5i & 2 & 3 \\ 4 & -3i & -2 \\ 1 & 3 & 9 \end{bmatrix}$ . In Figure 18.3,  $W(A)$  is approximated by  $P_T^O(A)$  with  $T = \{2k\pi/100 : 0 \leq k \leq 99\}$ . By Fact 2,  $W(A)$  lies in the convex hull of the circles  $G_1 = \{a \in \mathbb{C} : |a - 5i| \leq 5\}, G_2 = \{a \in \mathbb{C} : |a + 3i| \leq 5.5\}, G_3 = \{a \in \mathbb{C} : |a - 9| \leq 4.5\}$ .

FIGURE 18.2 Numerical range of the matrix  $A$  in Example 1.

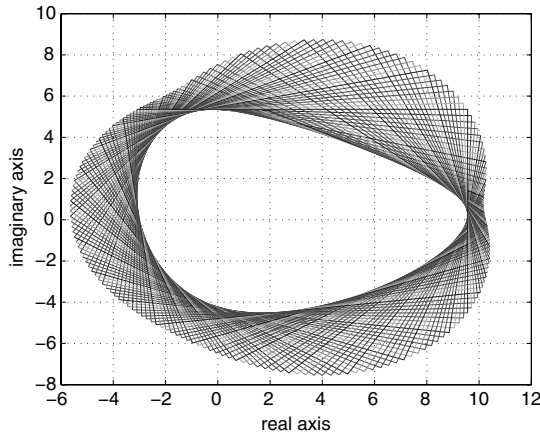

FIGURE 18.3 Numerical range of the matrix  $A$  in Example 2.

### Applications:

1. Let  $A = H + iG$ , where  $H, G \in \mathbb{C}^{n \times n}$  are Hermitian. Then

$$W(A) \subseteq W(H) + iW(G) = \{a + ib : a \in W(H), b \in W(G)\},$$

which is  $P_T^O(A)$  for  $T = \{0, \pi/2, \pi, 3\pi/2\}$ .

2. Let  $A = H + iG$ , where  $H, G \in \mathbb{C}^{n \times n}$  are Hermitian. Denote by  $\lambda_1(X) \geq \dots \geq \lambda_n(X)$  for a Hermitian matrix  $X \in \mathbb{C}^{n \times n}$ . By Fact 1,

$$w(A) = \max\{\lambda_1(\cos tH + \sin tG) : t \in [0, 2\pi)\}.$$

If  $0 \notin W(A)$ , then

$$\tilde{w}(A) = \max\{\{\lambda_n(\cos tH + \sin tG) : t \in [0, 2\pi)\} \cup \{0\}\}.$$

3. By Fact 2, if  $A = (a_{ij}) \in \mathbb{C}^{n \times n}$ , then

$$w(A) \leq \max\{|a_{jj}| + g_j : 1 \leq j \leq n\}.$$

In particular, if  $A$  is nonnegative, then  $w(A) = \lambda_1(A + A^T)/2$ .

## 18.4 Numerical Radius

---

### Definitions:

Let  $N$  be a vector norm on  $\mathbb{C}^{n \times n}$ . It is **submultiplicative** if

$$N(AB) \leq N(A)N(B) \quad \text{for all } A, B \in \mathbb{C}^{n \times n}.$$

It is **unitarily invariant** if

$$N(UAV) = N(A) \quad \text{for all } A \in \mathbb{C}^{n \times n} \text{ and unitary } U, V \in \mathbb{C}^{n \times n}.$$

It is **unitary similarity invariant** (also known as **weakly unitarily invariant**) if

$$N(U^*AU) = N(A) \quad \text{for all } A \in \mathbb{C}^{n \times n} \text{ and unitary } U \in \mathbb{C}^{n \times n}.$$

**Facts:**

The following facts can be found in [GR96] and [HJ91].

1. The numerical radius  $w(\cdot)$  is a unitary similarity invariant vector norm on  $\mathbb{C}^{n \times n}$ , and it is not unitarily invariant.
2. For any  $A \in \mathbb{C}^{n \times n}$ , we have

$$\rho(A) \leq w(A) \leq \|A\|_2 \leq 2w(A).$$

3. Suppose  $A \in \mathbb{C}^{n \times n}$  is nonzero and the minimal polynomial of  $A$  has degree  $m$ . The following conditions are equivalent.
  - (a)  $\rho(A) = w(A)$ .
  - (b) There exists  $k \geq 1$  such that  $A$  is unitarily similar to  $\gamma U \oplus B$  for a unitary  $U \in \mathbb{C}^{k \times k}$  and  $B \in \mathbb{C}^{(n-k) \times (n-k)}$  with  $w(B) \leq w(A) = \gamma$ .
  - (c) There exists  $s \geq m$  such that  $w(A^s) = w(A)^s$ .
4. Suppose  $A \in \mathbb{C}^{n \times n}$  is nonzero and the minimal polynomial of  $A$  has degree  $m$ . The following conditions are equivalent.
  - (a)  $\rho(A) = \|A\|_2$ .
  - (b)  $w(A) = \|A\|_2$ .
  - (c) There exists  $k \geq 1$  such that  $A$  is unitarily similar to  $\gamma U \oplus B$  for a unitary  $U \in \mathbb{C}^{k \times k}$  and a  $B \in \mathbb{C}^{(n-k) \times (n-k)}$  with  $\|B\|_2 \leq \|A\|_2 = \gamma$ .
  - (d) There exists  $s \geq m$  such that  $\|A^s\|_2 = \|A\|_2^s$ .
5. Suppose  $A \in \mathbb{C}^{n \times n}$  is nonzero. The following conditions are equivalent.
  - (a)  $\|A\|_2 = 2w(A)$ .
  - (b)  $W(A)$  is a circular disk centered at origin with radius  $\|A\|_2/2$ .
  - (c)  $A/\|A\|_2$  is unitarily similar to  $A_1 \oplus A_2$  such that  $A_1 = \begin{bmatrix} 0 & 2 \\ 0 & 0 \end{bmatrix}$  and  $w(A_2) \leq 1$ .
6. The vector norm  $4w$  on  $\mathbb{C}^{n \times n}$  is submultiplicative, i.e.,

$$4w(AB) \leq (4w(A))(4w(B)) \quad \text{for all } A, B \in \mathbb{C}^{n \times n}.$$

The equality holds if

$$X = Y^T = \begin{bmatrix} 0 & 2 \\ 0 & 0 \end{bmatrix}.$$

7. Let  $A \in \mathbb{C}^{n \times n}$  and  $k$  be a positive integer. Then

$$w(A^k) \leq w(A)^k.$$

8. Let  $N$  be a unitary similarity invariant vector norm on  $\mathbb{C}^{n \times n}$  such that  $N(A^k) \leq N(A)^k$  for any  $A \in \mathbb{C}^{n \times n}$  and positive integer  $k$ . Then

$$w(A) \leq N(A) \quad \text{for all } A \in \mathbb{C}^{n \times n}.$$

9. Suppose  $N$  is a unitarily invariant vector norm on  $\mathbb{C}^{n \times n}$ . Let

$$D = \begin{cases} 2I_k \oplus 0_k & \text{if } n = 2k, \\ 2I_k \oplus I_1 \oplus 0_k & \text{if } n = 2k + 1. \end{cases}$$

Then  $a = N(E_{11})$  and  $b = N(D)$  are the best (largest and smallest) constants such that

$$aw(A) \leq N(A) \leq bw(A) \quad \text{for all } A \in \mathbb{C}^{n \times n}.$$

10. Let  $A \in \mathbb{C}^{n \times n}$ . The following are equivalent:

- (a)  $w(A) \leq 1$ .
- (b)  $\lambda_1(e^{it}A + e^{-it}A^*)/2 \leq 1$  for all  $t \in [0, 2\pi)$ .
- (c) There is  $Z \in \mathbb{C}^{n \times n}$  such that  $\begin{bmatrix} I_n + Z & A \\ A^* & I_n - Z \end{bmatrix}$  is positive semidefinite.
- (d) There exists  $X \in \mathbb{C}^{2n \times n}$  satisfying  $X^*X = I_n$  and

$$A = X^* \begin{bmatrix} 0_n & 2I_n \\ 0_n & 0_n \end{bmatrix} X.$$

## 18.5 Products of Matrices

---

### Facts:

The following facts can be found in [GR96] and [HJ91].

1. Let  $A, B \in \mathbb{C}^{n \times n}$  be such that  $\tilde{w}(A) > 0$ . Then

$$\sigma(A^{-1}B) \subseteq \{b/a : a \in W(A), b \in W(B)\}.$$

2. Let  $0 \leq t_1 < t_2 < t_1 + \pi$  and  $S = \{re^{it} : r > 0, t \in [t_1, t_2]\}$ . Then  $\sigma(A) \subseteq S$  if and only if there is a positive definite  $B \in \mathbb{C}^{n \times n}$  such that  $W(AB) \subseteq S$ .
3. Let  $A, B \in \mathbb{C}^{n \times n}$ .
  - (a) If  $AB = BA$ , then  $w(AB) \leq 2w(A)w(B)$ .
  - (b) If  $A$  or  $B$  is normal such that  $AB = BA$ , then  $w(AB) \leq w(A)w(B)$ .
  - (c) If  $A^2 = aI$  and  $AB = BA$ , then  $w(AB) \leq \|A\|_2 w(B)$ .
  - (d) If  $AB = BA$  and  $AB^* = B^*A$ , then  $w(AB) \leq \min\{w(A)\|B\|_2, \|A\|_2 w(B)\}$ .
4. Let  $A$  and  $B$  be square matrices such that  $A$  or  $B$  is normal. Then

$$W(A \circ B) \subseteq W(A \otimes B) = \text{conv}\{W(A)W(B)\}.$$

Consequently,

$$w(A \circ B) \leq w(A \otimes B) = w(A)w(B).$$

(See Chapter 8.5 and 10.4 for the definitions of  $A \circ B$  and  $A \otimes B$ .)

5. Let  $A$  and  $B$  be square matrices. Then

$$w(A \circ B) \leq w(A \otimes B) \leq \min\{w(A)\|B\|_2, \|A\|_2 w(B)\} \leq 2w(A)w(B).$$

6. Let  $A \in \mathbb{C}^{n \times n}$ . Then

$$w(A \circ X) \leq w(X) \quad \text{for all } X \in \mathbb{C}^{n \times n}$$

if and only if  $A = B^*WB$  such that  $W$  satisfies  $\|W\| \leq 1$  and all diagonal entries of  $B^*B$  are bounded by 1.

**Examples:**

- Let  $A \in \mathbb{C}^{9 \times 9}$  be the Jordan block of zero  $J_9(0)$ , and  $B = A^3 + A^7$ . Then  $w(A) = w(B) = \cos(\pi/10) < 1$  and  $w(AB) = 1 > \|A\|_2 w(B)$ . So, even if  $AB = BA$ , we may not have  $w(AB) \leq \min\{w(A)\|B\|_2, \|A\|_2 w(B)\}$ .
- Let  $A = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$ . Then  $W(A) = \{a \in \mathbb{C} : |a - 1| \leq 1/2\}$  and

$$W(A^2) = \{a \in \mathbb{C} : |a - 1| \leq 1\},$$

whereas

$$\text{conv } W(A)^2 \subseteq \{se^{it} \in \mathbb{C} : s \in [0.25, 2.25], t \in [-\pi/3, \pi/3]\}.$$

So,  $W(A^2) \not\subseteq \text{conv } W(A)^2$ .

- Let  $A = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$  and  $B = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$ . Then  $\sigma(AB) = \{i, -i\}$ ,  $W(AB) = i[-1, 1]$ , and  $W(A) = W(B) = W(A)W(B) = [-1, 1]$ . So,  $\sigma(AB) \not\subseteq \text{conv } W(A)W(B)$ .

**Applications:**

- If  $C \in \mathbb{C}^{n \times n}$  is positive definite, then  $W(C^{-1}) = W(C)^{-1} = \{c^{-1} : c \in W(C)\}$ . Applying Fact 1 with  $A = C^{-1}$ ,

$$\sigma(CB) \subseteq W(C)W(B).$$

- If  $C \in \mathbb{C}^{n \times n}$  satisfies  $\tilde{w}(C) > 0$ , then for every unit vector  $\mathbf{x} \in \mathbb{C}^n$   $\mathbf{x}^* C^{-1} \mathbf{x} = \mathbf{y}^* C^* C^{-1} C \mathbf{y}$  with  $\mathbf{y} = C^{-1} \mathbf{x}$  and, hence,

$$W(C^{-1}) \subseteq \{rb : r \geq 0, b \in W(C^*)\} = \{r\bar{b} : r \geq 0, b \in W(C)\}.$$

Applying this observation and Fact 1 with  $A = C^{-1}$ , we have

$$\sigma(AB) \subseteq \{rab : r \geq 0, a \in W(A), b \in W(B)\}.$$

## 18.6 Dilations and Norm Estimation

---

**Definitions:**

A matrix  $A \in \mathbb{C}^{n \times n}$  has a **dilation**  $B \in \mathbb{C}^{m \times m}$  if there is  $X \in \mathbb{C}^{m \times n}$  such that  $X^* X = I_n$  and  $X^* B X = A$ .  
 A matrix  $A \in \mathbb{C}^{n \times n}$  is a **contraction** if  $\|A\|_2 \leq 1$ .

**Facts:**

The following facts can be found in [CL00],[CL01] and their references.

- $A$  has a dilation  $B$  if and only if  $B$  is unitarily similar to a matrix of the form

$$\begin{bmatrix} A & * \\ * & * \end{bmatrix}.$$

- Suppose  $B \in \mathbb{C}^{3 \times 3}$  has a reducing eigenvalue, or  $B \in \mathbb{C}^{2 \times 2}$ . If  $W(A) \subseteq W(B)$ , then  $A$  has a dilation of the form  $B \otimes I_m$ .

3. Let  $r \in [-1, 1]$ . Suppose  $A \in \mathbb{C}^{n \times n}$  is a contraction with

$$W(A) \subseteq \mathcal{S} = \{a \in \mathbb{C} : a + \bar{a} \leq 2r\}.$$

Then  $A$  has a unitary dilation  $U \in \mathbb{C}^{2n \times 2n}$  such that  $W(U) \subseteq \mathcal{S}$ .

4. Let  $A \in \mathbb{C}^{n \times n}$ . Then

$$W(A) = \cap \{W(B) : B \in \mathbb{C}^{2n \times 2n} \text{ is a normal dilation of } A\}.$$

If  $A$  is a contraction, then

$$W(A) = \cap \{W(U) : U \in \mathbb{C}^{2n \times 2n} \text{ is a unitary dilation of } A\}.$$

5. Let  $A \in \mathbb{C}^{n \times n}$ .

- (a) If  $W(A)$  lies in an triangle with vertices  $z_1, z_2, z_3$ , then

$$\|A\|_2 \leq \max\{|z_1|, |z_2|, |z_3|\}.$$

- (b) If  $W(A)$  lies in an ellipse  $\mathcal{E}$  with foci  $\lambda_1, \lambda_2$ , and minor axis of length  $b$ , then

$$\|A\|_2 \leq \{\sqrt{(|\lambda_1| + |\lambda_2|)^2 + b^2} + \sqrt{(|\lambda_1| - |\lambda_2|)^2 + b^2}\}/2.$$

More generally, if  $W(A)$  lies in the convex hull of the ellipse  $\mathcal{E}$  and the point  $z_0$ , then

$$\|A\|_2 \leq \max \left\{ |z_0|, \frac{\sqrt{(|\lambda_1| + |\lambda_2|)^2 + b^2} + \sqrt{(|\lambda_1| - |\lambda_2|)^2 + b^2}}{2} \right\}.$$

6. Let  $A \in \mathbb{C}^{n \times n}$ . Suppose there is  $t \in [0, 2\pi)$  such that  $e^{it}W(A)$  lies in a rectangle  $R$  centered at  $z_0 \in \mathbb{C}$  with vertices  $z_0 \pm \alpha \pm i\beta$  and  $z_0 \pm \alpha \mp i\beta$ , where  $\alpha, \beta > 0$ , so that  $z_1 = z_0 + \alpha + i\beta$  has the largest magnitude. Then

$$\|A\|_2 \leq \begin{cases} |z_1| & \text{if } R \subseteq \text{conv}\{z_1, \bar{z}_1, -\bar{z}_1\}, \\ \alpha + \beta & \text{otherwise.} \end{cases}$$

The bound in each case is attainable.

### Examples:

1. Let  $A = \begin{bmatrix} 0 & \sqrt{2} \\ 0 & 0 \end{bmatrix}$ . Suppose

$$B = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix} \quad \text{or} \quad B = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & i & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -i \end{bmatrix}.$$

Then  $W(A) \subseteq W(B)$ . However,  $A$  does not have a dilation of the form  $B \otimes I_m$  for either of the matrices because

$$\|A\|_2 = \sqrt{2} > 1 = \|B\|_2 = \|B \otimes I_m\|_2.$$

So, there is no hope to further extend Fact 1 in this section to arbitrary  $B \in \mathbb{C}^{3 \times 3}$  or normal matrix  $B \in \mathbb{C}^{4 \times 4}$ .

## 18.7 Mappings on Matrices

---

### Definitions:

Let  $\phi : \mathbb{C}^{n \times n} \rightarrow \mathbb{C}^{m \times m}$  be a linear map. It is **unital** if  $\phi(I_n) = I_m$ ; it is **positive** if  $\phi(A)$  is positive semidefinite whenever  $A$  is positive semidefinite.

### Facts:

The following facts can be found in [GR96] unless another reference is given.

1. [HJ91] Let  $\mathcal{P}(\mathbb{C})$  be the set of subsets of  $\mathbb{C}$ . Suppose a function  $F : \mathbb{C}^{n \times n} \rightarrow \mathcal{P}(\mathbb{C})$  satisfies the following three conditions.
  - (a)  $F(A)$  is compact and convex for every  $A \in \mathbb{C}^{n \times n}$ .
  - (b)  $F(aA + bI) = aF(A) + b$  for any  $a, b \in \mathbb{C}$  and  $A \in \mathbb{C}^{n \times n}$ .
  - (c)  $F(A) \subseteq \{a \in \mathbb{C} : a + \bar{a} \geq 0\}$  if and only if  $A + A^*$  is positive semidefinite.

Then  $F(A) = W(A)$  for all  $A \in \mathbb{C}^{n \times n}$ .

2. Use the usual topology on  $\mathbb{C}^{n \times n}$  and the Hausdorff metric on two compact sets  $A, B$  of  $\mathbb{C}$  defined by

$$d(A, B) = \max \left\{ \max_{a \in A} \min_{b \in B} |a - b|, \max_{b \in B} \min_{a \in A} |a - b| \right\}$$

The mapping  $A \mapsto W(A)$  is continuous.

3. Suppose  $f(x + iy) = (ax + by + c) + i(dx + ey + f)$  for some real numbers  $a, b, c, d, e, f$ . Define  $f(H + iG) = (aH + bG + cI) + i(dH + eG + fI)$  for any two Hermitian matrices  $H, G \in \mathbb{C}^{n \times n}$ . We have

$$W(f(H + iG)) = f(W(A)) = \{f(x + iy) : x + iy \in W(A)\}.$$

4. Let  $\mathbf{D} = \{a \in \mathbb{C} : |a| \leq 1\}$ . Suppose  $f : \mathbf{D} \rightarrow \mathbb{C}$  is analytic in the interior of  $\mathbf{D}$  and continuous on the boundary of  $\mathbf{D}$ .
  - (a) If  $f(\mathbf{D}) \subseteq \mathbf{D}$  and  $f(0) = 0$ , then  $W(f(A)) \subseteq \mathbf{D}$  whenever  $W(A) \subseteq \mathbf{D}$ .
  - (b) If  $f(\mathbf{D}) \subseteq \mathbb{C}_+ = \{a \in \mathbb{C} : a + \bar{a} \geq 0\}$ , then  $W(f(A)) \subseteq \mathbb{C}_+ \setminus \{(f(0) + \overline{f(0)})/2\}$  whenever  $W(A) \subseteq \mathbf{D}$ .
5. Suppose  $\phi : \mathbb{C}^{n \times n} \rightarrow \mathbb{C}^{n \times n}$  is a unital positive linear map. Then  $W(\phi(A)) \subseteq W(A)$  for all  $A \in \mathbb{C}^{n \times n}$ .
6. [Pel75] Let  $\phi : \mathbb{C}^{n \times n} \rightarrow \mathbb{C}^{n \times n}$  be linear. Then

$$W(A) = W(\phi(A)) \quad \text{for all } A \in \mathbb{C}^{n \times n}$$

if and only if there is a unitary  $U \in \mathbb{C}^{n \times n}$  such that  $\phi$  has the form

$$X \mapsto U^* X U \quad \text{or} \quad X \mapsto U^* X^T U.$$

7. [Li87] Let  $\phi : \mathbb{C}^{n \times n} \rightarrow \mathbb{C}^{n \times n}$  be linear. Then  $w(A) = w(\phi(A))$  for all  $A \in \mathbb{C}^{n \times n}$  if and only if there exist a unitary  $U \in \mathbb{C}^{n \times n}$  and a complex unit  $\mu$  such that  $\phi$  has the form

$$X \mapsto \mu U^* X U \quad \text{or} \quad X \mapsto \mu U^* X^T U.$$

## Matrix Stability and Inertia

---

	19.1 Inertia .....	19-2
	19.2 Stability .....	19-3
	19.3 Multiplicative $D$ -Stability .....	19-5
	19.4 Additive $D$ -Stability .....	19-7
	19.5 Lyapunov Diagonal Stability .....	19-9
Daniel Hershkowitz <i>Technion - Israel Institute of Technology</i>	References .....	19-10

Much is known about spectral properties of square (complex) matrices. There are extensive studies of eigenvalues of matrices in certain classes. Some of the studies concentrate on the inertia of the matrices, that is, distribution of the eigenvalues in half-planes.

A special inertia case is of stable matrices, that is, matrices whose spectrum lies in the open left or right half-plane. These, and other related types of matrix stability, play an important role in various applications. For this reason, matrix stability has been intensively investigated in the past two centuries.

A. M. Lyapunov, called by F. R. Gantmacher “the founder of the modern theory of stability,” studied the asymptotic stability of solutions of differential systems. In 1892, he proved a theorem that was restated (first, apparently, by Gantmacher in 1953) as a necessary and sufficient condition for stability of a matrix. In 1875, E. J. Routh introduced an algorithm that provides a criterion for stability. An independent solution was given by A. Hurwitz. This solution is known nowadays as the Routh–Hurwitz criterion for stability. Another criterion for stability, which has a computational advantage over the Routh–Hurwitz criterion, was proved in 1914 by Liénard and Chipart. The equivalent of the Routh–Hurwitz and Liénard–Chipart criteria was observed by M. Fujiwara. The related problem of requiring the eigenvalues to be within the unit circle was solved separately in the early 1900s by I. Schur and Cohn. The above-mentioned studies have motivated an intensive search for conditions for matrix stability.

An interesting question, related to stability, is the following one: Given a square matrix  $A$ , can we find a diagonal matrix  $D$  such that the matrix  $DA$  is stable? This question can be asked in full generality, as suggested above, or with some restrictions on the matrix  $D$ , such as positivity of the diagonal elements. A related problem is characterizing matrices  $A$  such that for every positive diagonal matrix  $D$ , the matrix  $DA$  is stable. Such matrices are called multiplicative  $D$ -stable matrices. This type of matrix stability, as well as two other related types, namely additive  $D$ -stability and Lyapunov diagonal (semi)stability, have important applications in many disciplines. Thus, they are very important to characterize. While regular stability is a spectral property (it is always possible to check whether a given matrix is stable or not by evaluating its eigenvalues), none of the other three types of matrix stability can be characterized by the spectrum of the matrix. This problem has been solved for certain classes of matrices. For example, for  $Z$ -matrices all the stability types are equivalent. Another case in which these characterization problems have been solved is the case of acyclic matrices.

Several surveys handle the above-mentioned types of matrix stability, e.g., the books [HJ91] and [KB00], and the articles [Her92], [Her98], and [BH85]. Finally, the mathematical literature has studies of other types of matrix stability, e.g., the above-mentioned Schur–Cohn stability (where all the eigenvalues lie within the unit circle), e.g., [Sch17] and [Zah92];  $H$ -stability, e.g., [OS62], [Car68], and [HM98];  $L_2$ -stability and strict  $H$ -stability, e.g., [Tad81]; and scalar stability, e.g., [HM98].

## 19.1 Inertia

Much is known about spectral properties of square matrices. In this chapter, we concentrate on the distribution of the eigenvalues in half-planes. In particular, we refer to results that involve the expression  $AH + HA^*$ , where  $A$  is a square complex matrix and  $H$  is a Hermitian matrix.

### Definitions:

For a square complex matrix  $A$ , we denote by  $\pi(A)$  the number of eigenvalues of  $A$  with positive real part, by  $\delta(A)$  the number of eigenvalues of  $A$  on the imaginary axis, and by  $\nu(A)$  the number of eigenvalues of  $A$  with negative real part. The **inertia** of  $A$  is defined as the triple  $\text{in}(A) = (\pi(A), \nu(A), \delta(A))$ .

### Facts:

All the facts are proven in [OS62].

1. Let  $A$  be a complex square matrix. There exists a Hermitian matrix  $H$  such that the matrix  $AH + HA^*$  is positive definite if and only if  $\delta(A) = 0$ . Furthermore, in such a case the inertias of  $A$  and  $H$  are the same.
2. Let  $\{\lambda_1, \dots, \lambda_n\}$  be the eigenvalues of an  $n \times n$  matrix  $A$ . If  $\prod_{i,j=1}^n (\lambda_i + \overline{\lambda_j}) \neq 0$ , then for any positive definite matrix  $P$  there exists a unique Hermitian matrix  $H$  such that  $AH + HA^* = P$ . Furthermore, the inertias of  $A$  and  $H$  are the same.
3. Let  $A$  be a complex square matrix. We have  $\delta(A) = \pi(A) = 0$  if and only if there exists an  $n \times n$  positive definite Hermitian matrix such that the matrix  $-(AH + HA^*)$  is positive definite.

### Examples:

1. It follows from Fact 1 above that a complex square matrix  $A$  has all of its eigenvalues in the right half-plane if and only if there exists a positive definite matrix  $H$  such that the matrix  $AH + HA^*$  is positive definite. This fact, associating us with the discussion of the next section, is due to Lyapunov, originally proven in [L1892] for systems of differential equations. The matrix formulation is due to [Gan60].
2. In order to demonstrate that both the existence and uniqueness claims of Fact 2 may be false without the condition on the eigenvalues, consider the matrix

$$A = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix},$$

for which the condition of Fact 2 is not satisfied. One can check that the only positive definite matrices  $P$  for which the equation  $AH + HA^* = P$  has Hermitian solutions are matrices of the type  $P = \begin{bmatrix} p_{11} & 0 \\ 0 & p_{22} \end{bmatrix}$ ,  $p_{11}, p_{22} > 0$ . Furthermore, for  $P = \begin{bmatrix} 2 & 0 \\ 0 & 4 \end{bmatrix}$  it is easy to verify that the Hermitian solutions of  $AH + HA^* = P$  are all matrices  $H$  of the type

$$\begin{bmatrix} 1 & c \\ \bar{c} & -2 \end{bmatrix}, \quad c \in \mathbb{C}.$$

If we now choose

$$A = \begin{bmatrix} 1 & 0 \\ 0 & -2 \end{bmatrix},$$

then here the condition of Fact 2 is satisfied. Indeed, for  $H = \begin{bmatrix} a & c \\ \bar{c} & b \end{bmatrix}$  we have

$$AH + HA^* = \begin{bmatrix} 2a & -c \\ -\bar{c} & -4b \end{bmatrix},$$

which can clearly be solved uniquely for any Hermitian matrix  $P$ ; specifically, for  $P = \begin{bmatrix} 2 & 0 \\ 0 & 4 \end{bmatrix}$ ,

the unique Hermitian solution  $H$  of  $AH + HA^* = P$  is  $\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$ .

## 19.2 Stability

---

### Definitions:

A complex polynomial is **negative stable** [**positive stable**] if its roots lie in the open left [right] half-plane. A complex square matrix  $A$  is **negative stable** [**positive stable**] if its characteristic polynomial is negative stable [positive stable].

We shall use the term **stable matrix** for positive stable matrix.

For an  $n \times n$  matrix  $A$  and for an integer  $k$ ,  $1 \leq k \leq n$ , we denote by  $S_k(A)$  the sum of all principal minors of  $A$  of order  $k$ .

The **Routh–Hurwitz matrix** associated with  $A$  is defined to be the matrix

$$\begin{bmatrix} S_1(A) & S_3(A) & S_5(A) & \cdot & \cdot & \cdot & \cdot & 0 & 0 \\ 1 & S_2(A) & S_4(A) & & & & & \cdot & \cdot \\ 0 & S_1(A) & S_3(A) & \cdot & & & & \cdot & \cdot \\ 0 & 1 & S_2(A) & \cdot & \cdot & & & \cdot & \cdot \\ 0 & 0 & S_1(A) & \cdot & \cdot & \cdot & & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & 0 & 0 \\ \cdot & \cdot & \cdot & & & \cdot & \cdot & S_n(A) & 0 \\ \cdot & \cdot & \cdot & & & \cdot & \cdot & S_{n-1}(A) & 0 \\ 0 & 0 & 0 & \cdot & \cdot & \cdot & \cdot & S_{n-2}(A) & S_n(A) \end{bmatrix}.$$

A square complex matrix is a  **$P$ -matrix** if it has positive principal minors.

A square complex matrix is a  **$P_0^+$ -matrix** if it has nonnegative principal minors and at least one principal minor of each order is positive.

A principal minor of a square matrix is a **leading principal minor** if it is based on consecutive rows and columns, starting with the first row and column of the matrix.

An  $n \times n$  real matrix  $A$  is **sign symmetric** if it satisfies

$$\det A[\alpha, \beta] \det A[\beta, \alpha] \geq 0, \quad \forall \alpha, \beta \subseteq \{1, \dots, n\}, |\alpha| = |\beta|.$$

An  $n \times n$  real matrix  $A$  is **weakly sign symmetric** if it satisfies

$$\det A[\alpha, \beta] \det A[\beta, \alpha] \geq 0, \quad \forall \alpha, \beta \subseteq \{1, \dots, n\}, |\alpha| = |\beta| = |\alpha \cap \beta| + 1.$$

A square real matrix is a  **$Z$ -matrix** if it has nonpositive off-diagonal elements.

A  $Z$ -matrix with positive principal minors is an  $M$ -matrix. (See Section 24.5 for more information and an equivalent definition.)

### Facts:

Lyapunov studied the asymptotic stability of solutions of differential systems. In 1892 he proved in his paper [L1892] a theorem which yields a necessary and sufficient condition for stability of a complex matrix. The matrix formulation of Lyapunov's Theorem is apparently due to Gantmacher [Gan60], and is given as Fact 1 below. The theorem in [Gan60] was proven for real matrices; however, as was also remarked in [Gan60], the generalization to the complex case is immediate.

1. **The Lyapunov Stability Criterion:** A complex square matrix  $A$  is stable if and only if there exists a positive definite Hermitian matrix  $H$  such that the matrix  $AH + HA^*$  is positive definite.
2. [OS62] A complex square matrix  $A$  is stable if and only if for every positive definite matrix  $G$  there exists a positive definite matrix  $H$  such that the matrix  $AH + HA^* = G$ .
3. [R1877], [H1895] **The Routh–Hurwitz Stability Criterion:** An  $n \times n$  complex matrix  $A$  with a real characteristic polynomial is stable if and only if the leading principal minors of the Routh–Hurwitz matrix associated with  $A$  are all positive.
4. [LC14] (see also [Fuj26]) **The Liénard–Chipart Stability Criterion:** Let  $A$  be an  $n \times n$  complex matrix with a real characteristic polynomial. The following are equivalent:
  - (a)  $A$  is stable.
  - (b)  $S_n(A), S_{n-2}(A), \dots > 0$  and the odd order leading principal minors of the Routh–Hurwitz matrix associated with  $A$  are positive.
  - (c)  $S_n(A), S_{n-2}(A), \dots > 0$  and the even order leading principal minors of the Routh–Hurwitz matrix associated with  $A$  are positive.
  - (d)  $S_n(A), S_{n-1}(A), S_{n-3}(A), \dots > 0$  and the odd order leading principal minors of the Routh–Hurwitz matrix associated with  $A$  are positive.
  - (e)  $S_n(A), S_{n-1}(A), S_{n-3}(A), \dots > 0$  and the even order leading principal minors of the Routh–Hurwitz matrix associated with  $A$  are positive.
5. [Car74] Sign symmetric  $P$ -matrices are stable.
6. [HK2003] Sign symmetric stable matrices are  $P$ -matrices.
7. [Hol99] Weakly sign symmetric  $P$ -matrices of order less than 6 are stable. Nevertheless, in general, weakly sign symmetric  $P$ -matrices need not be stable.
8. (For example, [BVW78]) A  $Z$ -matrix is stable if and only if it is a  $P$ -matrix (that is, it is an  $M$ -matrix).
9. [FHR05] Let  $A$  be a stable real square matrix. Then either all the diagonal elements of  $A$  are positive or  $A$  has at least one positive diagonal element and one positive off-diagonal element.
10. [FHR05] Let  $\zeta$  be an  $n$ -tuple of complex numbers,  $n > 1$ , consisting of real numbers and conjugate pairs. There exists a real stable  $n \times n$  matrix  $A$  with exactly two positive entries such that  $\zeta$  is the spectrum of  $A$ .

### Examples:

1. Let

$$A = \begin{bmatrix} 2 & 2 & 3 \\ 2 & 5 & 4 \\ 3 & 4 & 5 \end{bmatrix}.$$

The Routh–Hurwitz matrix associated with  $A$  is

$$\begin{bmatrix} 12 & 1 & 0 \\ 1 & 16 & 0 \\ 0 & 12 & 1 \end{bmatrix}.$$

It is immediate to check that the latter matrix has positive leading principal minors. It, thus, follows that  $A$  is stable. Indeed, the eigenvalues of  $A$  are 1.4515, 0.0657, and 10.4828.

2. Stable matrices do not form a convex set, as is easily demonstrated by the stable matrices

$$\begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}, \quad \begin{bmatrix} 1 & 0 \\ 9 & 1 \end{bmatrix},$$

whose sum  $\begin{bmatrix} 2 & 1 \\ 9 & 2 \end{bmatrix}$  has eigenvalues  $-1$  and  $5$ . Clearly, convex sets of stable matrices do exist. An example of such a set is the set of upper (or lower) triangular matrices with diagonal elements in the open right half-plane. Nevertheless, there is no obvious link between matrix stability and convexity or conic structure. Some interesting results on stable convex hulls can be found in [Bia85], [FB87], [FB88], [CL97], and [HS90]. See also the survey in [Her98].

3. In view of Facts 5 and 7 above, it would be natural to ask whether stability of a matrix implies that the matrix is a  $P$ -matrix or a weakly sign symmetric matrix. The answer to this question is negative as is demonstrated by the matrix

$$A = \begin{bmatrix} -1 & 1 \\ -5 & 3 \end{bmatrix}.$$

The eigenvalues of  $A$  are  $1 \pm i$ , and so  $A$  is stable. Nevertheless,  $A$  is neither a  $P$ -matrix nor a weakly sign symmetric matrix.

4. Sign symmetric  $P_0^+$ -matrices are not necessarily stable, as is demonstrated by the sign symmetric  $P_0^+$ -matrix

$$A = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 \end{bmatrix}.$$

The matrix  $A$  is not stable, having the eigenvalues  $\left\{ e^{\pm \frac{2\pi i}{3}}, 1, 1, 1 \right\}$ .

5. A  $P$ -matrix is not necessarily stable as is demonstrated by the matrix

$$\begin{bmatrix} 1 & 0 & 3 \\ 3 & 1 & 0 \\ 0 & 3 & 1 \end{bmatrix}.$$

For extensive study of spectra of  $P$ -matrices look at [HB83], [Her83], [HJ86], [HS93], and [HK2003].

### 19.3 Multiplicative $D$ -Stability

Multiplicative  $D$ -stability appears in various econometric models, for example, in the study of stability of multiple markets [Met45].

**Definitions:**

A real square matrix  $A$  is **multiplicative  $D$ -stable** if  $DA$  is stable for every positive diagonal matrix  $D$ .

In the literature, multiplicative  $D$ -stable matrices are usually referred to as just  **$D$ -stable** matrices.

A real square matrix  $A$  is **inertia preserving** if the inertia of  $AD$  is equal to the inertia of  $D$  for every nonsingular real diagonal matrix  $D$ .

The **graph**  $G(A)$  of an  $n \times n$  matrix  $A$  is the simple graph whose vertex set is  $\{1, \dots, n\}$ , and where there is an edge between two vertices  $i$  and  $j$  ( $i \neq j$ ) if and only if  $a_{ij} \neq 0$  or  $a_{ji} \neq 0$ . (See Chapter 28 more information on graphs.)

The matrix  $A$  is said to be **acyclic** if  $G(A)$  is a forest.

### Facts:

The problem of characterizing multiplicative  $D$ -stability for certain classes and for matrices of order less than 5 is dealt with in several publications (e.g., [Cai76], [CDJ82], [Cro78], and [Joh74b]). However, in general, this problem is still open. Multiplicative  $D$ -stability is characterized in [BH84] for acyclic matrices. That result generalizes the handling of tridiagonal matrices in [CDJ82]. Characterization of multiplicative  $D$ -stability using cones is given in [HSh88]. See also the survey in [Her98].

1. Tridiagonal matrices are acyclic, since their graphs are paths or unions of disjoint paths.
2. [FF58] For a real square matrix  $A$  with positive leading principal minors there exists a positive diagonal matrix  $D$  such that  $DA$  is stable.
3. [Her92] For a complex square matrix  $A$  with positive leading principal minors there exists a positive diagonal matrix  $D$  such that  $DA$  is stable.
4. [Cro78] Multiplicative  $D$ -stable matrices are  $P_0^+$ -matrices.
5. [Cro78] A  $2 \times 2$  real matrix is multiplicative  $D$ -stable if and only if it is a  $P_0^+$ -matrix.
6. [Cai76] A  $3 \times 3$  real matrix  $A$  is multiplicative  $D$ -stable if and only if  $A + D$  is multiplicative  $D$ -stable for every nonnegative diagonal matrix  $D$ .
7. [Joh75] A real square matrix  $A$  is multiplicative  $D$ -stable if and only if  $A \pm iD$  is nonsingular for every positive diagonal matrix  $D$ .
8. (For example, [BVW78]) A  $Z$ -matrix is multiplicative  $D$ -stable if and only if it is a  $P$ -matrix (that is, it is an  $M$ -matrix).
9. [BS91] Inertia preserving matrices are multiplicative  $D$ -stable.
10. [BS91] An irreducible acyclic matrix is multiplicative  $D$ -stable if and only if it is inertia preserving.
11. [HK2003] Let  $A$  be a sign symmetric square matrix. The following are equivalent:
  - (a) The matrix  $A$  is stable.
  - (b) The matrix  $A$  has positive leading principal minors.
  - (c) The matrix  $A$  is a  $P$ -matrix.
  - (d) The matrix  $A$  is multiplicative  $D$ -stable.
  - (e) There exists a positive diagonal matrix  $D$  such that the matrix  $DA$  is stable.

### Examples:

1. In order to illustrate Fact 2, let

$$A = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 1 & 1 \\ 4 & 1 & 2 \end{bmatrix}.$$

The matrix  $A$  is not stable, having the eigenvalues 4.0606 and  $-0.0303 \pm 0.4953i$ . Nevertheless, since  $A$  has positive leading minors, by Fact 2 there exists a positive diagonal matrix  $D$  such that the matrix  $DA$  is stable. Indeed, the eigenvalues of

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0.1 \end{bmatrix} \begin{bmatrix} 1 & 1 & 1 \\ 0 & 1 & 1 \\ 4 & 1 & 2 \end{bmatrix} = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 1 & 1 \\ 0.4 & 0.1 & 0.2 \end{bmatrix}$$

are 1.7071, 0.2929, and 0.2.

2. In order to illustrate Fact 4, let

$$A = \begin{bmatrix} 1 & 1 & 0 \\ -1 & 0 & 1 \\ 0 & 1 & 2 \end{bmatrix}.$$

The matrix  $A$  is stable, having the eigenvalues  $0.3376 \pm 0.5623i$  and  $2.3247$ . Yet, we have  $\det A\{2, 3\} < 0$ , and so  $A$  is not a  $P_0^+$ -matrix. Indeed, observe that the matrix

$$\begin{bmatrix} 0.1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 1 & 0 \\ -1 & 0 & 1 \\ 0 & 1 & 2 \end{bmatrix} = \begin{bmatrix} 0.1 & 0.1 & 0 \\ -1 & 0 & 1 \\ 0 & 1 & 2 \end{bmatrix}$$

is not stable, having the eigenvalues  $-0.1540 \pm 0.1335i$  and  $2.408$ .

3. While stability is a spectral property, and so it is always possible to check whether a given matrix is stable or not by evaluating its eigenvalues, multiplicative  $D$ -stability cannot be characterized by the spectrum of the matrix, as is demonstrated by the following two matrices

$$A = \begin{bmatrix} 1 & 0 \\ 0 & 2 \end{bmatrix}, \quad B = \begin{bmatrix} -1 & 2 \\ -3 & 4 \end{bmatrix}.$$

The matrices  $A$  and  $B$  have the same spectrum. Nevertheless, while  $A$  is multiplicative  $D$ -stable,  $B$  is not, since it is not a  $P_0^+$ -matrix. Indeed, the matrix

$$\begin{bmatrix} 5 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} -1 & 2 \\ -3 & 4 \end{bmatrix} = \begin{bmatrix} -5 & 10 \\ -3 & 4 \end{bmatrix}$$

has eigenvalues  $-0.5 \pm 3.1225i$ .

4. It is shown in [BS91] that the converse of Fact 9 is not true, using the following example from [Har80]:

$$A = \begin{bmatrix} 1 & 0 & -50 \\ 1 & 1 & 0 \\ 1 & 1 & 1 \end{bmatrix}.$$

The matrix  $A$  is multiplicative  $D$ -stable (by the characterization of  $3 \times 3$  multiplicative  $D$ -stable matrices, proven in [Cai76]). However, for  $D = \text{diag}(-1, 3, -1)$  the matrix  $AD$  is stable and, hence,  $A$  is not inertia preserving. In fact, it is shown in [BS91] that even  $P$ -matrices that are both  $D$ -stable and Lyapunov diagonally semistable (see section 19.5) are not necessarily inertia preserving.

## 19.4 Additive $D$ -Stability

Applications of additive  $D$ -stability may be found in linearized biological systems, e.g., [Had76].

### Definitions:

A real square matrix  $A$  is said to be **additive  $D$ -stable** if  $A + D$  is stable for every nonnegative diagonal matrix  $D$ .

In some references additive  $D$ -stable matrices are referred to as **strongly stable** matrices.

### Facts:

The problem of characterizing additive  $D$ -stability for certain classes and for matrices of order less than 5 is dealt with in several publications (e.g., [Cai76], [CDJ82], [Cro78], and [Joh74b]). However, in general,

this problem is still open. Additive  $D$ -stability is characterized in [Her86] for acyclic matrices. That result generalizes the handling of tridiagonal matrices in [Car84].

1. [Cro78] Additive  $D$ -stable matrices are  $P_0^+$ -matrices.
2. [Cro78] A  $2 \times 2$  real matrix is additive  $D$ -stable if and only if it is a  $P_0^+$ -matrix.
3. [Cro78] A  $3 \times 3$  real matrix  $A$  is additive  $D$ -stable if and only if it is a  $P_0^+$ -matrix and stable.
4. (For example, [BVW78]) A  $Z$ -matrix is additive  $D$ -stable if and only if it is a  $P$ -matrix (that is, it is an  $M$ -matrix).
5. An additive  $D$ -stable matrix need not be multiplicative  $D$ -stable (cf. Example 3).
6. [Tog80] A multiplicative  $D$ -stable matrix need not be additive  $D$ -stable.

### Examples:

1. In order to illustrate Fact 1, let

$$A = \begin{bmatrix} 1 & 1 & 0 \\ -1 & 0 & 1 \\ 0 & 1 & 2 \end{bmatrix}.$$

The matrix  $A$  is stable, having the eigenvalues  $0.3376 \pm 0.5623i$  and  $2.3247$ . Yet, we have  $\det A[2, 3|2, 3] < 0$ , and so  $A$  is not a  $P_0^+$ -matrix. Indeed, observe that the matrix

$$\begin{bmatrix} 1 & 1 & 0 \\ -1 & 0 & 1 \\ 0 & 1 & 2 \end{bmatrix} + \begin{bmatrix} 2 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} = \begin{bmatrix} 3 & 1 & 0 \\ -1 & 0 & 1 \\ 0 & 1 & 2 \end{bmatrix}$$

is not stable, having the eigenvalues  $2.5739 \pm 0.3690i$  and  $-0.1479$ .

2. While stability is a spectral property, and so it is always possible to check whether a given matrix is stable or not by evaluating its eigenvalues, additive  $D$ -stability cannot be characterized by the spectrum of the matrix, as is demonstrated by the following two matrices:

$$A = \begin{bmatrix} 1 & 0 \\ 0 & 2 \end{bmatrix}, \quad B = \begin{bmatrix} -1 & 2 \\ -3 & 4 \end{bmatrix}.$$

The matrices  $A$  and  $B$  have the same spectrum. Nevertheless, while  $A$  is additive  $D$ -stable,  $B$  is not, since it is not a  $P_0^+$ -matrix. Indeed, the matrix

$$\begin{bmatrix} -1 & 2 \\ -3 & 4 \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & 3 \end{bmatrix} = \begin{bmatrix} -1 & 2 \\ -3 & 7 \end{bmatrix}$$

has eigenvalues  $-0.1623$  and  $6.1623$ .

3. In order to demonstrate Fact 5, consider the matrix

$$A = \begin{bmatrix} 0.25 & 1 & 0 \\ -1 & 0.5 & 1 \\ 2.1 & 1 & 2 \end{bmatrix},$$

which is a  $P_0^+$  matrix and is stable, having the eigenvalues  $0.0205709 \pm 1.23009i$  and  $2.70886$ . Thus,  $A$  is additively  $D$ -stable by Fact 3. Nevertheless,  $A$  is not multiplicative  $D$ -stable, as the eigenvalues of

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 5 & 0 \\ 0 & 0 & 4 \end{bmatrix} \begin{bmatrix} 0.25 & 1 & 0 \\ -1 & 0.5 & 1 \\ 2.1 & 1 & 2 \end{bmatrix} = \begin{bmatrix} 0.25 & 1 & 0 \\ -5 & 2.5 & 5 \\ 8.4 & 4 & 8 \end{bmatrix}$$

are  $-0.000126834 \pm 2.76183i$  and  $10.7503$ .

## 19.5 Lyapunov Diagonal Stability

Lyapunov diagonally stable matrices play an important role in various applications, for example, predator-prey systems in ecology, e.g., [Goh76], [Goh77], and [RZ82]; dynamical systems, e.g., [Ara75]; and economic models, e.g., [Joh74a] and the references in [BBP78].

### Definitions:

A real square matrix  $A$  is said to be **Lyapunov diagonally stable** [**semistable**] if there exists a positive diagonal matrix  $D$  such that  $AD + DA^T$  is positive definite [semidefinite]. In this case, the matrix  $D$  is called a **Lyapunov scaling factor** of  $A$ .

In some references Lyapunov diagonally stable matrices are referred to as just **diagonally stable** matrices or as **Volterra–Lyapunov stable**.

An  $n \times n$  matrix  $A$  is said to be an  **$H$ -matrix** if the **comparison matrix**  $M(A)$  defined by

$$M(A)_{ij} = \begin{cases} |a_{ii}|, & i = j \\ -|a_{ij}|, & i \neq j \end{cases}$$

is an  $M$ -matrix.

A real square matrix  $A$  is said to be **strongly inertia preserving** if the inertia of  $AD$  is equal to the inertia of  $D$  for every (not necessarily nonsingular) real diagonal matrix  $D$ .

### Facts:

The problem of characterizing Lyapunov diagonal stability is, in general, an open problem. It is solved in [BH83] for acyclic matrices. Lyapunov diagonal semistability of acyclic matrices is characterized in [Her88]. Characterization of Lyapunov diagonal stability and semistability using cones is given in [HSh88]; see also the survey in [Her98]. For a book combining theoretical results, applications, and examples, look at [KB00].

1. [BBP78], [Ple77] Lyapunov diagonally stable matrices are  $P$ -matrices.
2. [Goh76] A  $2 \times 2$  real matrix is Lyapunov diagonally stable if and only if it is a  $P$ -matrix.
3. [BVW78] A real square matrix  $A$  is Lyapunov diagonally stable if and only if for every nonzero real symmetric positive semidefinite matrix  $H$ , the matrix  $HA$  has at least one positive diagonal element.
4. [QR65] Lyapunov diagonally stable matrices are multiplicative  $D$ -stable.
5. [Cro78] Lyapunov diagonally stable matrices are additive  $D$ -stable.
6. [AK72], [Tar71] A  $Z$ -matrix is Lyapunov diagonally stable if and only if it is a  $P$ -matrix (that is, it is an  $M$ -matrix).
7. [HS85a] An  $H$ -matrix  $A$  is Lyapunov diagonally stable if and only if  $A$  is nonsingular and the diagonal elements of  $A$  are nonnegative.
8. [BS91] Lyapunov diagonally stable matrices are strongly inertia preserving.
9. [BH83] Acyclic matrices are Lyapunov diagonally stable if and only if they are  $P$ -matrices.
10. [BS91] Acyclic matrices are Lyapunov diagonally stable if and only if they are strongly inertia preserving.

### Examples:

1. Multiplicative  $D$ -stable and additive  $D$ -stable matrices are not necessarily diagonally stable, as is demonstrated by the matrix

$$\begin{bmatrix} 1 & -1 \\ 1 & 0 \end{bmatrix}.$$

2. Another example, given in [BH85] is the matrix

$$\begin{bmatrix} 0 & 1 & 0 & 0 \\ -1 & 1 & 1 & 0 \\ 0 & 1 & a & b \\ 0 & 0 & -b & 0 \end{bmatrix}, \quad a \geq 1, b \neq 0,$$

which is not Lyapunov diagonally stable, but is multiplicative  $D$ -stable if and only if  $a > 1$ , and is additive  $D$ -stable whenever  $a = 1$  and  $b \neq 1$ .

3. Stability is a spectral property, and so it is always possible to check whether a given matrix is stable or not by evaluating its eigenvalues; Lyapunov diagonal stability cannot be characterized by the spectrum of the matrix, as is demonstrated by the following two matrices:

$$A = \begin{bmatrix} 1 & 0 \\ 0 & 2 \end{bmatrix}, \quad B = \begin{bmatrix} -1 & 2 \\ -3 & 4 \end{bmatrix}.$$

The matrices  $A$  and  $B$  have the same spectrum. Nevertheless, while  $A$  is Lyapunov diagonal stable,  $B$  is not, since it is not a  $P$ -matrix. Indeed, for every positive diagonal matrix  $D$ , the element of  $AD + DA^T$  in the  $(1, 1)$  position is negative and, hence,  $AD + DA^T$  cannot be positive definite.

4. Let  $A$  be a Lyapunov diagonally stable matrix and let  $D$  be a Lyapunov scaling factor of  $A$ . Using continuity arguments, it follows that every positive diagonal matrix that is close enough to  $D$  is a Lyapunov scaling factor of  $A$ . Hence, a Lyapunov scaling factor of a Lyapunov diagonally stable matrix is not unique (up to a positive scalar multiplication). The Lyapunov scaling factor is not necessarily unique even in cases of Lyapunov diagonally semistable matrices, as is demonstrated by the zero matrix and the following more interesting example. Let

$$A = \begin{bmatrix} 2 & 2 & 3 \\ 2 & 2 & 3 \\ 1 & 1 & 2 \end{bmatrix}.$$

One can check that  $D = \text{diag}(1, 1, d)$  is a scaling factor of  $A$  whenever  $\frac{1}{9} \leq d \leq 1$ . On the other hand, it is shown in [HS85b] that the identity matrix is the unique Lyapunov scaling factor of the matrix

$$\begin{bmatrix} 1 & 1 & 2 & 0 \\ 1 & 1 & 0 & 0 \\ 0 & 2 & 1 & 2 \\ 2 & 2 & 0 & 1 \end{bmatrix}.$$

Further study of Lyapunov scaling factors can be found in [HS85b], [HS85c], [SB87], [HS88], [SH88], [SB88], and [CHS92].

Alberto Borobia  
*UNED*

In general, an **inverse eigenvalue problem** (IEP) consists of the construction of a matrix with prescribed structural and spectral constraints. This is a two-level problem: (1) on a theoretical level the target is to determine if the IEP is solvable, that is, to find necessary and sufficient conditions for the existence of at least one **solution matrix** (a matrix with the given constraints); and (2) on a practical level, the target is the effective construction of a solution matrix when the IEP is solvable. IEPs are classified into different types according to the specific constraints. We will consider three topics: IEPs with prescribed entries, nonnegative IEPs, and affine parameterized IEPs. Other important topics include pole assignment problems, Jacobi IEPs, inverse singular value problems, etc. For interested readers, we refer to the survey [CG02] where an account of IEPs with applications and extensive bibliography can be found.

### 20.1 IEPs with Prescribed Entries

---

The underlying question for an IEP with prescribed entries (PEIEPs) is to understand how the prescription of some entries of a matrix can have repercussions on its spectral properties. A classical result on this subject is the Schur–Horn Theorem allowing the construction of a real symmetric matrix with prescribed diagonal, prescribed eigenvalues, and subject to some restrictions (see Fact 1 below). Here we consider PEIEPs that require finding a matrix with some prescribed entries and with prescribed eigenvalues or characteristic polynomial; no structural constraints are imposed on the solution matrices.

Most of the facts of Sections 20.1 and 20.2 appear in [IC00], an excellent survey that describes finite step procedures for constructing solution matrices.

**Definitions:**

An **IEP with prescribed entries** (PEIEP) has the following standard formulation:

Given:

- (a) A field  $F$ .
- (b)  $n$  elements  $\lambda_1, \dots, \lambda_n$  of  $F$  (respectively, a monic polynomial  $f \in F[x]$  of degree  $n$ ).
- (c)  $t$  elements  $p_1, \dots, p_t$  of  $F$ .
- (d) A set  $\mathcal{Q} = \{(i_1, j_1), \dots, (i_t, j_t)\}$  of  $t$  positions of an  $n \times n$  matrix.

Find: A matrix  $A = [a_{ij}] \in F^{n \times n}$  with  $a_{i_k j_k} = p_k$  for  $1 \leq k \leq t$  and such that  $\sigma(A) = \{\lambda_1, \dots, \lambda_n\}$  (respectively, such that  $p_A(x) = f$ ).

**Facts:** [IC00]

1. (Schur–Horn Theorem) Given any real numbers  $\lambda_1 \geq \dots \geq \lambda_n$  and  $d_1 \geq \dots \geq d_n$  satisfying

$$\sum_{i=1}^k \lambda_i \geq \sum_{i=1}^k d_i \quad \text{for } k = 1, \dots, n-1 \quad \text{and} \quad \sum_{i=1}^n \lambda_i = \sum_{i=1}^n d_i,$$

there exists a real symmetric  $n \times n$  matrix with diagonal  $(d_1, \dots, d_n)$  and eigenvalues  $\lambda_1, \dots, \lambda_n$ ; and any Hermitian matrix satisfies these conditions on its eigenvalues and diagonal entries.

2. A finite step algorithm is provided in [CL83] for the construction of a solution matrix for the Schur–Horn Theorem.
3. Consider the following classes of PEIEPs:

(1.1)	$F$	$\lambda_1, \dots, \lambda_n$	$p_1, \dots, p_{n-1}$	$ \mathcal{Q}  = n - 1$
(1.2)	$F$	$f = x^n + c_1 x^{n-1} + \dots + c_n$	$p_1, \dots, p_{n-1}$	$ \mathcal{Q}  = n - 1$
(2.1)	$F$	$\lambda_1, \dots, \lambda_n$	$p_1, \dots, p_n$	$ \mathcal{Q}  = n$
(2.2)	$F$	$f = x^n + c_1 x^{n-1} + \dots + c_n$	$p_1, \dots, p_n$	$ \mathcal{Q}  = n$
(3.1)	$F$	$\lambda_1, \dots, \lambda_n$	$p_1, \dots, p_{2n-3}$	$ \mathcal{Q}  = 2n - 3$

- [dO73a] Each PEIEP of class (1.1) is solvable.
- [Dds74] Each PEIEP of class (1.2) is solvable except if all off-diagonal entries in one row or column are prescribed to be zero and  $f$  has no root on  $F$ .
- [dO73b] Each PEIEP of class (2.1) is solvable with the following exceptions: (1) all entries in the diagonal are prescribed and their sum is different from  $\lambda_1 + \dots + \lambda_n$ ; (2) all entries in one row or column are prescribed, with zero off-diagonal entries and diagonal entry different from  $\lambda_1, \dots, \lambda_n$ ; and (3)  $n = 2$ ,  $\mathcal{Q} = \{(1, 2), (2, 1)\}$ , and  $x^2 - (\lambda_1 + \lambda_2)x + p_1 p_2 + \lambda_1 \lambda_2 \in F[x]$  is irreducible over  $F$ .
- [Zab86] For  $n > 4$ , each PEIEP of class (2.2) is solvable with the following exceptions: (1) all entries in the diagonal are prescribed and their sum is different from  $-c_1$ ; (2) all entries in a row or column are prescribed, with zero off-diagonal entries and diagonal entry which is not a root of  $f$ ; and (3) all off-diagonal entries in one row or column are prescribed to be zero and  $f$  has no root on  $F$ . The case  $n \leq 4$  is solved but there are more exceptions.
- [Her83] Each PEIEP of class (3.1) is solvable with the following exceptions: (1) all entries in the diagonal are prescribed and their sum is different from  $\lambda_1 + \dots + \lambda_n$ ; and (2) all entries in one row or column are prescribed, with zero off-diagonal entries and diagonal entry different from  $\lambda_1, \dots, \lambda_n$ .
- [Her83] The result for PEIEPs of class (3.1) cannot be improved to  $|\mathcal{Q}| > 2n - 3$  since a lot of specific nonsolvable situations appear, and, therefore, a closed result seems to be quite inaccessible.
- A gradient flow approach is proposed in [CDS04] to explore the existence of solution matrices when the set of prescribed entries has arbitrary cardinality.

4. The important case  $\mathcal{Q} = \{(i, j) : i \neq j\}$  is discussed in section 20.9.
5. Let  $\{p_{ij} : 1 \leq i \leq j \leq n\}$  be a set of  $\frac{n^2+n}{2}$  elements of a field  $F$ . Define the set  $\{r_1, \dots, r_s\}$  of all those integers  $r$  such that  $p_{ij} = 0$  whenever  $1 \leq i \leq r < j \leq n$ . Assume that  $0 = r_0 < r_1 < \dots < r_s < r_{s+1} = n$  and define  $\beta_t = \sum_{r_{t-1} < k \leq r_t} p_{kk}$  for  $t = 1, \dots, s + 1$ . The following PEIEPs have been solved:
  - [BGRS90] Let  $\lambda_1, \dots, \lambda_n$  be  $n$  elements of  $F$ . Then there exists  $A = [a_{ij}] \in F^{n \times n}$  with  $a_{ij} = p_{ij}$  for  $1 \leq i \leq j \leq n$  and  $\sigma(A) = \{\lambda_1, \dots, \lambda_n\}$  if and only if  $\{1, \dots, n\}$  has a partition  $N_1 \cup \dots \cup N_{s+1}$  such that  $|N_t| = r_t - r_{t-1}$  and  $\sum_{k \in N_t} \lambda_k = \beta_t$  for each  $t = 1, \dots, s + 1$ .
  - [Sil93] Let  $f \in F[x]$  be a monic polynomial of degree  $n$ . Then there exists  $A = [a_{ij}] \in F^{n \times n}$  with  $a_{ij} = p_{ij}$  for  $1 \leq i \leq j \leq n$  and  $p_A(x) = f$  if and only if  $f = f_1 \cdots f_{s+1}$ , where  $f_t = x^{r_t - r_{t-1}} - \beta_t x^{r_t - r_{t-1} - 1} + \dots \in F[x]$  for  $t = 1, \dots, s + 1$ .
6. [Fil69] Let  $d_1, \dots, d_n$  be elements of a field  $F$ , and let  $A \in F^{n \times n}$  with  $A \neq \lambda I_n$  for all  $\lambda \in F$  and  $\text{tr}(A) = \sum_{i=1}^n d_i$ . Then  $A$  is similar to a matrix with diagonal  $(d_1, \dots, d_n)$ .

**Examples:**

1. [dO73b] Given:
  - (a) A field  $F$ .
  - (b)  $\lambda_1, \dots, \lambda_n \in F$ .
  - (c)  $p_1, \dots, p_n \in F$ .
  - (d)  $\mathcal{Q} = \{(1, 1), \dots, (n, n)\}$ .

If  $\sum_{i=1}^n \lambda_i = \sum_{i=1}^n p_i$ , then  $A = [a_{ij}] \in F^{n \times n}$  with

$$\begin{aligned}
 a_{ii} &= p_i, & a_{ij} &= 0 \quad \text{if } i \leq j - 2, \\
 a_{i,i+1} &= \sum_{k=1}^i \lambda_k - \sum_{k=1}^i p_k, & a_{ij} &= p_j - \lambda_{j+1} \quad \text{if } i > j,
 \end{aligned}$$

has diagonal  $(p_1, \dots, p_n)$  and its spectrum is  $\sigma(A) = \{\lambda_1, \dots, \lambda_n\}$ .

## 20.2 PEIEPs of $2 \times 2$ Block Type

---

In the 1970s, de Oliveira posed the problem of determining all possible spectra of a  $2 \times 2$  block matrix  $A$  or all possible characteristic polynomials of  $A$  or all possible invariant polynomials of  $A$  when some of the blocks are prescribed and the rest vary (*invariant polynomial* is a synonym for *invariant factor*, cf. Section 6.6).

**Definitions:**

Let  $F$  be a field and let  $A$  be the  $2 \times 2$  block matrix

$$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \in F^{n \times n} \quad \text{with} \quad A_{11} \in F^{l \times l} \quad \text{and} \quad A_{22} \in F^{m \times m}.$$

*Notation:*

- $\text{deg}(f)$ : degree of  $f \in F[x]$ .
- $g|f$ : polynomial  $g$  divides the polynomial  $f$ .
- $ip(B)$ : invariant polynomials of the square matrix  $B$ .

**Facts:** [IC00]

1. [dO71] Let  $A_{11}$  and a monic polynomial  $f \in F[x]$  of degree  $n$  be given. Let  $iP(A_{11}) = g_1 | \cdots | g_l$ . Then  $p_A(x) = f$  is possible except if  $l > m$  and  $g_1 \cdots g_{l-m}$  is not a divisor of  $f$ .
2. [dS79], [Tho79] Let  $A_{11}$  and  $n$  monic polynomials  $f_1, \dots, f_n \in F[x]$  with  $f_1 | \cdots | f_n$  and  $\sum_{i=1}^n \deg(f_i) = n$  be given. Let  $iP(A_{11}) = g_1 | \cdots | g_l$ . Then  $iP(A) = f_1 | \cdots | f_n$  is possible if and only if  $f_i | g_i | f_{i+2m}$  for each  $i = 1, \dots, l$  where  $f_k = 0$  for  $k > n$ .
3. [dO75] Let  $A_{12}$  and a monic polynomial  $f \in F[x]$  of degree  $n$  be given. Then  $p_A(x) = f$  is possible except if  $A_{12} = 0$  and  $f$  has no divisor of degree  $l$ .
4. [Zab89], [Sil90] Let  $A_{12}$  and  $n$  monic polynomials  $f_1, \dots, f_n \in F[x]$  with  $f_1 | \cdots | f_n$  and  $\sum_{i=1}^n \deg(f_i) = n$  be given. Let  $r = \text{rank}(A_{12})$  and  $s$  the number of polynomials in  $f_1, \dots, f_n$  which are different from 1. Then  $iP(A) = f_1 | \cdots | f_n$  is possible if and only if  $r \leq n - s$  with the following exceptions:
  - (a)  $r = 0$  and  $\prod_{i=1}^n f_i$  has no divisor of degree  $l$ .
  - (b)  $r \geq 1, l - r$  odd and  $f_{n-s+1} = \cdots = f_n$  with  $f_n$  irreducible of degree 2.
  - (c)  $r = 1$  and  $f_{n-s+1} = \cdots = f_n$  with  $f_n$  irreducible of degree  $k \geq 3$  and  $k|l$ .
5. [Wim74] Let  $A_{11}, A_{12}$ , and a monic polynomial  $f \in F[x]$  of degree  $n$  be given. Let  $h_1 | \cdots | h_l$  be the invariant factors of  $[xI_l - A_{11} | -A_{12}]$ . Then  $p_A(x) = f$  is possible if and only if  $h_1 \cdots h_l | f$ .
6. All possible invariant polynomials of  $A$  are characterized in [Zab87] when  $A_{11}$  and  $A_{12}$  are given. The statement of this result contains a majorization inequality involving the *controllability indices* of the pair  $(A_{11}, A_{12})$ .
7. [Sil87b] Let  $A_{11}, A_{22}$ , and  $n$  elements  $\lambda_1, \dots, \lambda_n$  of  $F$  be given. Assume that  $l \geq m$  and let  $iP(A_{11}) = g_1 | \cdots | g_l$ . Then  $\sigma(A) = \{\lambda_1, \dots, \lambda_n\}$  is possible if and only if all the following conditions are satisfied:
  - (a)  $\text{tr}(A_{11}) + \text{tr}(A_{22}) = \lambda_1 + \cdots + \lambda_n$ .
  - (b) If  $l > m$ , then  $g_1 \cdots g_{l-m} | (x - \lambda_1) \cdots (x - \lambda_n)$ .
  - (c) If  $A_{11} = aI_l$  and  $A_{22} = dI_m$ , then there exists a permutation  $\tau$  of  $\{1, \dots, n\}$  such that  $\lambda_{\tau(2i-1)} + \lambda_{\tau(2i)} = a + d$  for  $1 \leq i \leq m$  and  $\lambda_{\tau(j)} = a$  for  $2m + 1 \leq j \leq n$ .
8. [Sil87a] Let  $A_{12}, A_{21}$ , and  $n$  elements  $\lambda_1, \dots, \lambda_n$  of  $F$  be given. Then  $\sigma(A) = \{\lambda_1, \dots, \lambda_n\}$  is possible except if, simultaneously,  $l = m = 1, A_{12} = [b], A_{21} = [c]$  and the polynomial  $x^2 - (\lambda_1 + \lambda_2)x + bc + \lambda_1\lambda_2 \in F[x]$  is irreducible over  $F$ .
9. Let  $A_{12}, A_{21}$ , and a monic polynomial  $f \in F[x]$  of degree  $n$  be given:
  - [Fri77] If  $F$  is algebraically closed then  $p_A(x) = f$  is always possible.
  - [MS00] If  $F = \mathbb{R}$  and  $n \geq 3$  then  $p_A(x) = f$  is possible if and only if either  $\min\{\text{rank}(A_{12}), \text{rank}(A_{21})\} > 0$  or  $f$  has a divisor of degree  $l$ .
  - If  $F = \mathbb{R}, A_{12} = [b], A_{21} = [c]$  and  $f = x^2 + c_1x + c_2 \in \mathbb{R}[x]$  then  $p_A(x) = f$  is possible if and only if  $x^2 + c_1x + c_2 + bc$  has a root in  $\mathbb{R}$ .
10. [Sil91] Let  $A_{11}, A_{12}, A_{22}$ , and  $n$  elements  $\lambda_1, \dots, \lambda_n$  of  $F$  be given. Let  $k_1 | \cdots | k_l$  be the invariant factors of  $[xI_l - A_{11} | -A_{12}]$ ,  $h_1 | \cdots | h_m$  the invariant factors of  $[xI_m - A_{12} | -A_{22}]$ , and  $g = k_1 \cdots k_l h_1 \cdots h_m$ . Then  $\sigma(A) = \{\lambda_1, \dots, \lambda_n\}$  is possible if and only if all the following conditions hold:
  - (a)  $\text{tr}(A_{11}) + \text{tr}(A_{22}) = \lambda_1 + \cdots + \lambda_n$ .
  - (b)  $g | (x - \lambda_1) \cdots (x - \lambda_n)$ .
  - (c) If  $A_{11}A_{12} + A_{12}A_{22} = \eta A_{12}$  for some  $\eta \in F$ , then there exists a permutation  $\tau$  of  $\{1, \dots, n\}$  such that  $\lambda_{\tau(2i-1)} + \lambda_{\tau(2i)} = \eta$  for  $1 \leq i \leq t$  where  $t = \text{rank}(A_{12})$  and  $\lambda_{\tau(2t+1)}, \dots, \lambda_{\tau(n)}$  are the roots of  $g$ .
11. If a problem of block type is solved for prescribed characteristic polynomial then the solution for prescribed spectrum easily follows.

12. The book [GKvS95] deals with PEIEPs of block type from an operator point of view.
13. A description is given in [FS98] of all the possible characteristic polynomials of a square matrix with an arbitrary prescribed submatrix.

## 20.3 Nonnegative IEP (NIEP)

Nonnegative matrices appear naturally in many different mathematical areas, both pure and applied, such as numerical analysis, statistics, economics, social sciences, etc. One of the most intriguing problems in this field is the so-called **nonnegative IEP** (NIEP). Its origin goes back to A.N. Kolmogorov, who in 1938 posed the problem of determining which individual complex numbers belong to the spectrum of some  $n \times n$  nonnegative matrix with its spectral radius normalized to be 1. Kolmogorov's problem was generalized in 1949 by H. R. Suleĭmanova, who posed the NIEP: To determine which  $n$ -tuples of complex numbers are spectra of  $n \times n$  nonnegative matrices. For definitions and additional facts about nonnegative matrices, see Chapter 9.

### Definitions:

Let  $\Pi_n$  denote the compact subset of  $\mathbb{C}$  bounded by the regular  $n$ -sided polygon inscribed in the unit circle of  $\mathbb{C}$  and with one vertex at  $1 \in \mathbb{C}$ .

Let  $\Theta_n$  denote the subset of  $\mathbb{C}$  composed of those complex numbers  $\lambda$  such that  $\lambda$  is an eigenvalue of some  $n \times n$  row stochastic matrix.

A **circulant matrix** is a matrix in which every row is obtained by a single cyclic shift of the previous row.

### Facts:

All the following facts appear in [Min88].

1. A complex nonzero number  $\lambda$  is an eigenvalue of a nonnegative  $n \times n$  matrix with positive spectral radius  $\rho$  if and only if  $\lambda/\rho \in \Theta_n$ .
2. [DD45], [DD46]  $\Theta_3 = \Pi_2 \cup \Pi_3$ .
3. [Mir63] Each point in  $\Pi_2 \cup \Pi_3 \cup \dots \cup \Pi_n$  is an eigenvalue of a doubly stochastic  $n \times n$  matrix.
4. [Kar51] The set  $\Theta_n$  is symmetric relative to the real axis and is contained within the circle  $|z| \leq 1$ . It intersects  $|z| = 1$  at the points  $e^{\frac{2\pi i a}{b}}$  where  $a$  and  $b$  run over all integers satisfying  $0 \leq a < b \leq n$ . The boundary of  $\Theta_n$  consists of the curvilinear arcs connecting these points in circular order. For  $n \geq 4$ , each arc is given by one of the following parametric equations:

$$\begin{aligned} z^q (z^p - t)^r &= (1 - t)^r, \\ (z^c - t)^d &= (1 - t)^d z^q, \end{aligned}$$

where the real parameter  $t$  runs over the interval  $0 \leq t \leq 1$ , and  $c, d, p, q, r$  are natural numbers defined by certain rules (explicitly stated in [Min88]).

### Examples:

1. [LL78] The circulant matrix

$$\frac{1}{3} \begin{bmatrix} 1 + 2r \cos \theta & 1 - 2r \cos(\frac{\pi}{3} + \theta) & 1 - 2r \cos(\frac{\pi}{3} - \theta) \\ 1 - 2r \cos(\frac{\pi}{3} - \theta) & 1 + 2r \cos \theta & 1 - 2r \cos(\frac{\pi}{3} + \theta) \\ 1 - 2r \cos(\frac{\pi}{3} + \theta) & 1 - 2r \cos(\frac{\pi}{3} - \theta) & 1 + 2r \cos \theta \end{bmatrix}$$

has spectrum  $\{1, r e^{i\theta}, r e^{-i\theta}\}$ , and it is doubly stochastic if and only if  $r e^{i\theta} \in \Pi_3$ .

## 20.4 Spectra of Nonnegative Matrices

### Definitions:

- $\mathcal{N}_n \equiv \{\sigma = \{\lambda_1, \dots, \lambda_n\} \subset \mathbb{C} : \exists A \geq 0 \text{ with spectrum } \sigma\}$ .  
 $\mathcal{R}_n \equiv \{\sigma = \{\lambda_1, \dots, \lambda_n\} \subset \mathbb{R} : \exists A \geq 0 \text{ with spectrum } \sigma\}$ .  
 $\mathcal{S}_n \equiv \{\sigma = \{\lambda_1, \dots, \lambda_n\} \subset \mathbb{R} : \exists A \geq 0 \text{ symmetric with spectrum } \sigma\}$ .  
 $\mathcal{R}_n^* \equiv \{(1, \lambda_2, \dots, \lambda_n) \in \mathbb{R}^n : \{1, \lambda_2, \dots, \lambda_n\} \in \mathcal{R}_n; 1 \geq \lambda_2 \geq \dots \geq \lambda_n\}$ .  
 $\mathcal{S}_n^* \equiv \{(1, \lambda_2, \dots, \lambda_n) \in \mathbb{R}^n : \{1, \lambda_2, \dots, \lambda_n\} \in \mathcal{S}_n; 1 \geq \lambda_2 \geq \dots \geq \lambda_n\}$ .  
 For any set  $\sigma = \{\lambda_1, \dots, \lambda_n\} \subset \mathbb{C}$ , let

$$\rho(\sigma) = \max_{1 \leq i \leq n} |\lambda_i| \quad \text{and} \quad s_k = \sum_{i=1}^n \lambda_i^k \quad \text{for each } k \in \mathbb{N}.$$

A set  $S \subset \mathbb{R}^n$  is **star-shaped** from  $p \in S$  if every line segment drawn from  $p$  to another point in  $S$  lies entirely in  $S$ .

### Facts:

Most of the following facts appear in [ELN04].

- [Joh81] If  $\sigma = \{\lambda_1, \dots, \lambda_n\} \in \mathcal{N}_n$ , then  $\sigma$  is the spectrum of a  $n \times n$  nonnegative matrix with all row sums equal to  $\rho(\sigma)$ .
- If  $\sigma = \{\lambda_1, \dots, \lambda_n\} \in \mathcal{N}_n$ , then the following conditions hold:
  - $\rho(\sigma) \in \sigma$ .
  - $\bar{\sigma} = \sigma$ .
  - $s_i \geq 0$  for  $i \geq 1$ .
  - [LL78], [Joh81]  $s_k^m \leq n^{m-1} s_{km}$  for  $k, m \geq 1$ .
- $\mathcal{N}_n$  is known for  $n \leq 3$ ,  $\mathcal{R}_n$  and  $\mathcal{S}_n$  are known for  $n \leq 4$ :
  - $\mathcal{N}_2 = \mathcal{R}_2 = \mathcal{S}_2 = \{\sigma = \{\lambda_1, \lambda_2\} \subset \mathbb{R} : s_1 \geq 0\}$ .
  - $\mathcal{R}_3 = \mathcal{S}_3 = \{\sigma = \{\lambda_1, \lambda_2, \lambda_3\} \subset \mathbb{R} : \rho(\sigma) \in \sigma; s_1 \geq 0\}$ .
  - [LL78]  $\mathcal{N}_3 = \{\sigma = \{\lambda_1, \lambda_2, \lambda_3\} \subset \mathbb{C} : \bar{\sigma} = \sigma; \rho(\sigma) \in \sigma; s_1 \geq 0; s_1^2 \leq 3s_2\}$ .
  - $\mathcal{R}_4 = \mathcal{S}_4 = \{\sigma = \{\lambda_1, \lambda_2, \lambda_3, \lambda_4\} \subset \mathbb{R} : \rho(\sigma) \in \sigma; s_1 \geq 0\}$ .
- [JLL96]  $\mathcal{R}_n$  and  $\mathcal{S}_n$  are not always equal sets.
  - [ELN04]  $\sigma = \{97, 71, -44, -54, -70\} \in \mathcal{R}_5$  but  $\sigma \notin \mathcal{S}_5$ .
  - [ELN04] provides symmetric matrices for all known elements of  $\mathcal{S}_5$ .
- [Rea96] Let  $\sigma = \{\lambda_1, \lambda_2, \lambda_3, \lambda_4\} \subset \mathbb{C}$  with  $s_1 = 0$ . Then  $\sigma \in \mathcal{N}_4$  if and only if  $s_2 \geq 0$ ,  $s_3 \geq 0$  and  $4s_4 \geq s_2^2$ . Moreover,  $\sigma$  is the spectrum of

$$\begin{bmatrix} 0 & 1 & 0 & 0 \\ \frac{s_2}{4} & 0 & 1 & 0 \\ \frac{s_3}{4} & 0 & 0 & 1 \\ \frac{4s_4 - s_2^2}{16} & \frac{s_3}{12} & \frac{s_2}{4} & 0 \end{bmatrix}.$$

- [LM99] Let  $\sigma = \{\lambda_1, \lambda_2, \lambda_3, \lambda_4, \lambda_5\} \subset \mathbb{C}$  with  $s_1 = 0$ . Then  $\sigma \in \mathcal{N}_5$  if and only if the following conditions are satisfied:
  - $s_i \geq 0$  for  $i = 2, 3, 4, 5$ .
  - $4s_4 \geq s_2^2$ .
  - $12s_5 - 5s_2s_3 + 5s_3\sqrt{4s_4 - s_2^2} \geq 0$ .

The proof of the sufficient part is constructive.

7. (a)  $\mathcal{R}_n^*$  and  $\mathcal{S}_n^*$  are star-shaped from  $(1, \dots, 1)$ .
- (b) [BM97]  $\mathcal{R}_n^*$  is star-shaped from  $(1, 0, \dots, 0)$ .
- (c) [KM01], [Mou03]  $\mathcal{R}_n^*$  and  $\mathcal{S}_n^*$  are not convex sets for  $n \geq 5$ .

**Examples:**

1. We show that  $\sigma = \{5, 5, -3, -3, -3\} \notin \mathcal{N}_5$ . Suppose  $A$  is a nonnegative matrix with spectrum  $\sigma$ . By the Perron–Frobenius Theorem,  $A$  is reducible and  $\sigma$  can be partitioned into two nonempty subsets, each one being the spectrum of a nonnegative matrix with Perron root equal to 5. This is not possible since one of the subsets must contain numbers with negative sum.
2.  $\{6, 1, 1, -4, -4\} \in \mathcal{N}_5$  by Fact 6.

## 20.5 Nonzero Spectra of Nonnegative Matrices

---

For the definitions and additional facts about primitive matrices see Section 29.6 and Chapter 9.

**Definitions:**

The **Möbius function**  $\mu : \mathbb{N} \mapsto \{-1, 0, 1\}$  is defined by  $\mu(1) = 1$ ,  $\mu(m) = (-1)^e$  if  $m$  is a product of  $e$  distinct primes, and  $\mu(m) = 0$  otherwise.

The  $k^{\text{th}}$  **net trace** of  $\sigma = \{\lambda_1, \dots, \lambda_n\} \subset \mathbb{C}$  is  $\text{tr}_k(\sigma) = \sum_{d|k} \mu\left(\frac{k}{d}\right) s_d$ .

The set  $\sigma = \{\lambda_1, \dots, \lambda_n\} \subset \mathbb{C}$  with  $0 \notin \sigma$  is the **nonzero spectrum** of a matrix if there exists a  $t \times t$  matrix,  $t \geq n$ , whose spectrum is  $\{\lambda_1, \dots, \lambda_n, 0, \dots, 0\}$  with  $t - n$  zeros.

The set  $\sigma = \{\lambda_1, \dots, \lambda_n\} \subset \mathbb{C}$  has a **Perron value** if  $\rho(\sigma) \in \sigma$  and there exists a unique index  $i$  with  $\lambda_i = \rho(\sigma)$ .

**Facts:**

1. [BH91] Spectral Conjecture: Let  $\mathbb{S}$  be a unital subring of  $\mathbb{R}$ . The set  $\sigma = \{\lambda_1, \dots, \lambda_n\} \subset \mathbb{C}$  with  $0 \notin \sigma$  is the nonzero spectrum of some primitive matrix over  $\mathbb{S}$  if and only if the following conditions hold:
  - (a)  $\sigma$  has a Perron value.
  - (b) All the coefficients of the polynomial  $\prod_{i=1}^n (x - \lambda_i)$  lie in  $\mathbb{S}$ .
  - (c) If  $\mathbb{S} = \mathbb{Z}$ , then  $\text{tr}_k(\sigma) \geq 0$  for all positive integers  $k$ .
  - (d) If  $\mathbb{S} \neq \mathbb{Z}$ , then  $s_k \geq 0$  for all  $k \in \mathbb{N}$  and  $s_m > 0$  implies  $s_{mp} > 0$  for all  $m, p \in \mathbb{N}$ .
2. [BH91] Subtuple Theorem: Let  $\mathbb{S}$  be a unital subring of  $\mathbb{R}$ . Suppose that  $\sigma = \{\lambda_1, \dots, \lambda_n\} \subset \mathbb{C}$  with  $0 \notin \sigma$  has  $\rho(\sigma) = \lambda_1$  and satisfies conditions (a) to (d) of the spectral conjecture. If for some  $j \leq n$  the set  $\{\lambda_1, \dots, \lambda_j\}$  is the nonzero spectrum of a nonnegative matrix over  $\mathbb{S}$ , then  $\sigma$  is the nonzero spectrum of a primitive matrix over  $\mathbb{S}$ .
3. The spectral conjecture is true for  $\mathbb{S} = \mathbb{R}$  by the subtuple theorem.
4. [KOR00] The spectral conjecture is true for  $\mathbb{S} = \mathbb{Z}$  and  $\mathbb{S} = \mathbb{Q}$ .
5. [BH91] The set  $\sigma = \{\lambda_1, \dots, \lambda_n\} \subset \mathbb{C}$  with  $0 \notin \sigma$  is the nonzero spectrum of a positive matrix if and only if the following conditions hold:
  - (a)  $\sigma$  has a Perron value.
  - (b) All coefficients of  $\prod_{i=1}^n (x - \lambda_i)$  are real.
  - (c)  $s_k > 0$  for all  $k \in \mathbb{N}$ .

**Examples:**

1. Let  $\sigma_\epsilon = \{5, 4 + \epsilon, -3, -3, -3\}$ . Then:
  - (a)  $\sigma_\epsilon$  for  $\epsilon < 0$  is not the nonzero spectrum of a nonnegative matrix since  $s_1 < 0$ .
  - (b)  $\sigma_0$  is the nonzero spectrum of a nonnegative matrix by Fact 2.
  - (c)  $\sigma_1$  is not the nonzero spectrum of a nonnegative matrix by arguing as in Example 1 of Section 20.4.
  - (d)  $\sigma_\epsilon$  for  $\epsilon > 0, \epsilon \neq 1$ , is the nonzero spectrum of a positive matrix by Fact 5.

## 20.6 Some Merging Results for Spectra of Nonnegative Matrices

---

**Facts:**

1. If  $\{\lambda_1, \dots, \lambda_n\} \in \mathcal{N}_n$  and  $\{\mu_1, \dots, \mu_m\} \in \mathcal{N}_m$ , then  $\{\lambda_1, \dots, \lambda_n, \mu_1, \dots, \mu_m\} \in \mathcal{N}_{n+m}$ .
2. [Fie74] Let  $\sigma = \{\lambda_1, \dots, \lambda_n\} \in \mathcal{S}_n$  with  $\rho(\sigma) = \lambda_1$  and  $\tau = \{\mu_1, \dots, \mu_m\} \in \mathcal{S}_m$  with  $\rho(\tau) = \mu_1$ . Then  $\{\lambda_1 + \epsilon, \lambda_2, \dots, \lambda_n, \mu_1 - \epsilon, \mu_2, \dots, \mu_m\} \in \mathcal{S}_{n+m}$  for any  $\epsilon \geq 0$  if  $\lambda_1 \geq \mu_1$ . The proof is constructive.
3. [Šmi04] Let  $A$  be a nonnegative matrix with spectrum  $\{\lambda_1, \dots, \lambda_n\}$  and maximal diagonal element  $d$ , and let  $\tau = \{\mu_1, \dots, \mu_m\} \in \mathcal{N}_m$  with  $\rho(\tau) = \mu_1$ . If  $d \geq \mu_1$ , then  $\{\lambda_1, \dots, \lambda_n, \mu_2, \dots, \mu_m\} \in \mathcal{N}_{n+m-1}$ . The proof is constructive.
4. Let  $\sigma = \{\lambda_1, \dots, \lambda_n\} \in \mathcal{N}_n$  with  $\rho(\sigma) = \lambda_1$  and let  $\epsilon \geq 0$ . Then:
  - (a) [Wuw97]  $\{\lambda_1 + \epsilon, \lambda_2, \dots, \lambda_n\} \in \mathcal{N}_n$ .
  - (b) If  $\lambda_2 \in \mathbb{R}$ , then not always  $\{\lambda_1, \lambda_2 + \epsilon, \lambda_3, \dots, \lambda_n\} \in \mathcal{N}_n$  (see the previous example).
  - (c) [Wuw97] If  $\lambda_2 \in \mathbb{R}$ , then  $\{\lambda_1 + \epsilon, \lambda_2 \pm \epsilon, \lambda_3, \dots, \lambda_n\} \in \mathcal{N}_n$  (the proof is not constructive).

**Examples:**

1. Let  $\sigma = \{\lambda_1, \dots, \lambda_n\} \in \mathcal{N}_n$  with  $\rho(\sigma) = \lambda_1$ , and  $\tau = \{\mu_1, \dots, \mu_m\} \in \mathcal{N}_m$  with  $\rho(\tau) = \mu_1$ . By Fact 1 of section 20.4 there exists  $A \geq 0$  with spectrum  $\sigma$  and row sums  $\lambda_1$ , and  $B \geq 0$  with spectrum  $\tau$  and row sums  $\mu_1$ . [BMS04] If  $\lambda_1 \geq \mu_1$  and  $\epsilon \geq 0$ , then the nonnegative matrix

$$\left[ \begin{array}{c|c} A & \epsilon \mathbf{e} \mathbf{e}_1^T \\ \hline (\lambda_1 - \mu_1 + \epsilon) \mathbf{e} \mathbf{e}_1^T & B \end{array} \right] \geq 0$$

has row sums  $\lambda_1 + \epsilon$  and spectrum  $\{\lambda_1 + \epsilon, \lambda_2, \dots, \lambda_n, \mu_1 - \epsilon, \mu_2, \dots, \mu_m\}$ .

## 20.7 Sufficient Conditions for Spectra of Nonnegative Matrices

---

**Definitions:**

The set  $\{\lambda_1, \dots, \lambda_{i-1}, \alpha, \beta, \lambda_{i+1}, \dots, \lambda_n\}$  is a **negative subdivision** of  $\{\lambda_1, \dots, \lambda_n\}$  if  $\alpha + \beta = \lambda_i$  with  $\alpha, \beta, \lambda_i < 0$ .

**Facts:**

Most of the following facts appear in [ELN04] and [SBM05].

1. [Sul49] Let  $\sigma = \{\lambda_1, \dots, \lambda_n\} \subset \mathbb{R}$  with  $\lambda_1 \geq \dots \geq \lambda_n$ . Then  $\sigma \in \mathcal{R}_n$  if

$$(\text{Su}) \left\{ \begin{array}{l} \bullet \lambda_1 \geq 0 \geq \lambda_2 \geq \dots \geq \lambda_n \\ \bullet \lambda_1 + \dots + \lambda_n \geq 0 \end{array} \right.$$

2. [BMS04] Complex version of (Su). Let  $\sigma = \{\lambda_1, \dots, \lambda_n\} \subset \mathbb{C}$  be a set that satisfies:

- (a)  $\bar{\sigma} = \sigma$ .
- (b)  $\rho(\sigma) = \lambda_1$ .
- (c)  $\lambda_1 + \dots + \lambda_n \geq 0$ .
- (d)  $\{\lambda_2, \dots, \lambda_n\} \subset \{z \in \mathbb{C} : \operatorname{Re} z \leq 0, |\operatorname{Re} z| \geq |\operatorname{Im} z|\}$ .

Then  $\sigma \in \mathcal{N}_n$  and the proof is constructive.

3. [Sou83] Let  $\sigma = \{\lambda_1, \dots, \lambda_n\} \subset \mathbb{R}$  with  $\lambda_1 \geq \dots \geq \lambda_n$ . Then there exists a symmetric doubly stochastic matrix  $D$  such that  $\lambda_1 D$  has spectrum  $\sigma$  if

$$(\text{Sou}) \quad \left\{ \frac{1}{n} \lambda_1 + \frac{n-m-1}{n(m+1)} \lambda_2 + \sum_{k=1}^m \frac{\lambda_{n-2k+2}}{(k+1)k} \geq 0 \quad \text{where } m = \left\lfloor \frac{n-1}{2} \right\rfloor \right.$$

and the proof is constructive.

4. [Kel71] Let  $\sigma = \{\lambda_1, \dots, \lambda_n\} \subset \mathbb{R}$  with  $\lambda_1 \geq \dots \geq \lambda_n$ . Let  $r$  be the greatest index for which  $\lambda_r \geq 0$  and let  $\delta_i = \lambda_{n+2-i}$  for  $2 \leq i \leq n-r+1$ . Define  $K = \{i : 2 \leq i \leq \min\{r, n-r+1\} \text{ and } \lambda_i + \delta_i < 0\}$ . Then  $\sigma \in \mathcal{R}_n$  if

$$(\text{Ke}) \quad \left\{ \begin{array}{l} \bullet \lambda_1 + \sum_{i \in K, i < k} (\lambda_i + \delta_i) + \delta_k \geq 0 \text{ for all } k \in K \\ \bullet \lambda_1 + \sum_{i \in K} (\lambda_i + \delta_i) + \sum_{j=r+1}^{n-r+1} \delta_j \geq 0 \end{array} \right.$$

5. [Bor95] Let  $\sigma = \{\lambda_1, \dots, \lambda_n\} \subset \mathbb{R}$  with  $\lambda_1 \geq \dots \geq \lambda_n$ . Then  $\sigma \in \mathcal{R}_n$  if

$$(\text{Bo}) \quad \left\{ \begin{array}{l} \bullet \exists \tau = \{\beta_1, \dots, \beta_d\} \subset \mathbb{R} \text{ with } d \leq n \text{ that satisfies conditions (Ke)} \\ \bullet \sigma \text{ is obtained from } \tau \text{ after } n-d \text{ negative subdivisions} \end{array} \right.$$

6. [Sot03] Let  $\sigma = \{\lambda_1, \dots, \lambda_n\} \subset \mathbb{R}$ . For any partition  $\sigma = \sigma^{(1)} \cup \dots \cup \sigma^{(t)}$  where  $\sigma^{(k)} = \{\lambda_1^{(k)}, \dots, \lambda_{n_k}^{(k)}\}$  with  $\lambda_1^{(k)} \geq \dots \geq \lambda_{n_k}^{(k)}$  define

$$R_j^{(k)} = \lambda_j^{(k)} + \lambda_{n_k-j+1}^{(k)} \text{ for } 2 \leq j \leq \left\lfloor \frac{n_k}{2} \right\rfloor \text{ and } R_{\frac{n_k+1}{2}}^{(k)} = \lambda_{\frac{n_k+1}{2}}^{(k)} \text{ if } n_k \text{ odd;}$$

$$T^{(k)} = \lambda_1^{(k)} + \lambda_{n_k}^{(k)} + \sum_{R_j^{(k)} < 0} R_j^{(k)}.$$

Then  $\sigma \in \mathcal{R}_n$  if

$$(\text{Sot}) \quad \left\{ \begin{array}{l} \text{there exists a partition } \sigma = \sigma^{(1)} \cup \dots \cup \sigma^{(t)} \text{ such that} \\ \lambda_1^{(1)} + \sum_{T^{(k)} < 0, k=2}^t T^{(k)} \geq \max \left\{ \lambda_1^{(1)} - T^{(1)}, \max_{2 \leq k \leq t} \{\lambda_1^{(k)}\} \right\} \end{array} \right.$$

and the proof is constructive.

- 7. [SBM05] (Su)  $\Rightarrow$  (Ke)  $\Rightarrow$  (Bo)  $\Rightarrow$  (Sot) and no opposite implication is true.
- 8. [Rad96] (Sou) and (Ke) are not comparable (see Example 2 below).
- 9. [Rad96] If  $\sigma$  satisfies (Bo), then  $\sigma \in \mathcal{S}_n$ .
- 10. [RS03] Let  $\sigma = \{\lambda_1, \dots, \lambda_n\} \subset \mathbb{C}$  with  $\bar{\sigma} = \sigma$  and  $d = -\sum_{i=2}^n \lambda_i > 0$ . Let  $c_1, \dots, c_n$  be defined by  $(x-d) \prod_{i=2}^n (x-\lambda_i) = x^n + \sum_{k=1}^n c_k x^{n-k}$ . If  $\lambda_1 \geq d(1 + \sum_{c_k > 0} \frac{c_k}{d^k})$ , then  $\sigma \in \mathcal{N}_n$ . The proof is constructive.

**Examples:**

- 1. If  $\sigma = \{\lambda_1, \dots, \lambda_n\} \subset \mathbb{R}$  satisfies (Su), then the companion matrix of the polynomial  $\prod_{i=1}^n (x - \lambda_i)$  is nonnegative with spectrum  $\sigma$ .

2.  $\{5, 3, -2, -2, -4\}$  satisfies (Ke), but not (Sou), and  $\{5, 3, -2, -2, -2, -2\}$  satisfies (Sou), but not (Ke).
3.  $\sigma = \{8, 4, -3, -3, -3, -3\}$  does not satisfy (Ke), but it satisfies (Bo) since  $\sigma$  is obtained from  $\tau = \{8, 4, -6, -6\}$  after two negative subdivisions and  $\tau$  satisfies (Ke).
4.  $\sigma = \{9, 7, 2, 2, -5, -5, -5, -5\}$  does not satisfy (Bo), but it satisfies (Sot) with  $\sigma^{(1)} = \{9, 2, -5, -5\}$  and  $\sigma^{(2)} = \{7, 2, -5, -5\}$ .
5.  $\sigma = \{6, 1, 1, -4, -4\}$  does not satisfy (Sot), but  $\sigma \in \mathcal{R}_5$  (Example 2 of section 20.4).

## 20.8 Affine Parameterized IEPs (PIEPs)

---

The set  $F^{n \times n}$  of  $n \times n$  matrices over the field  $F$  is naturally identified with the vector space  $F^{n^2}$ . An affine parameterized IEP requires finding within a given affine subspace of  $F^{n \times n}$  a matrix with prescribed spectrum. Here we will consider that the given affine subspace is  $n$ -dimensional and  $F = \mathbb{R}$  or  $F = \mathbb{C}$ . Especially interesting is the case where the affine subspace contains only real symmetric matrices. Some important motivating applications, including the Sturn–Liouville problem, inverse vibration problems, and nuclear spectroscopy are discussed in [FNO87].

Most of the facts of Sections 20.8, 20.9, and 20.10 appear in [Dai98].

### Definitions:

An **affine parameterized IEP** (PIEP) has the following standard formulation:

*Given:* A field  $F$ ;  $n + 1$  matrices  $A, A_1, \dots, A_n \in F^{n \times n}$ , and  $n$  elements  $\lambda_1, \dots, \lambda_n \in F$ .

*Find:*  $\mathbf{c} = (c_1, \dots, c_n)^T \in F^n$  such that  $\{\lambda_1, \dots, \lambda_n\}$  is the spectrum of the matrix

$$A(\mathbf{c}) = A + c_1 A_1 + \dots + c_n A_n.$$

In particular, a  $\text{PIEP}(\mathbb{C})$  is a PIEP with  $F = \mathbb{C}$ , a  $\text{PIEP}(\mathbb{R})$  is a PIEP with  $F = \mathbb{R}$ , and a  $\text{PIEP}(\mathbb{R}\mathbb{S})$  is a PIEP with  $F = \mathbb{R}$  and with all given matrices symmetric.

**Facts:** [Dai98]

1. [Xu92] Almost all  $\text{PIEP}(\mathbb{C})$  are solvable.
2. [SY86] Almost all  $\text{PIEP}(\mathbb{R})$  and almost all  $\text{PIEP}(\mathbb{R}\mathbb{S})$  are unsolvable in the presence of multiple eigenvalues.
3. All known sufficient conditions for the solvability of a  $\text{PIEP}(\mathbb{R})$  or a  $\text{PIEP}(\mathbb{R}\mathbb{S})$  require that the eigenvalues should be sufficiently pairwise separated. An account of necessary and of sufficient conditions can be found in [Dai98].

## 20.9 Relevant PIEPs Which are Solvable Everywhere

---

### Definitions:

**Additive IEP** (AIEP): Given  $A \in \mathbb{C}^{n \times n}$  and  $\lambda_1, \dots, \lambda_n \in \mathbb{C}$ , find a diagonal matrix  $D \in \mathbb{C}^{n \times n}$  such that  $\sigma(A + D) = \{\lambda_1, \dots, \lambda_n\}$ .

**Multiplicative IEP** (MIEP): Given  $B \in \mathbb{C}^{n \times n}$  and  $\lambda_1, \dots, \lambda_n \in \mathbb{C}$ , find a diagonal matrix  $D \in \mathbb{C}^{n \times n}$  such that  $\sigma(BD) = \{\lambda_1, \dots, \lambda_n\}$ .

**Toeplitz IEP** (ToIEP): Given  $\lambda_1, \dots, \lambda_n \in \mathbb{R}$ , find  $\mathbf{c} = [c_1, \dots, c_n]^T \in \mathbb{R}^n$  such that  $[t_{ij}]_{i,j=1}^n$  with  $t_{ij} = c_{|i-j|+1}$  has spectrum  $\{\lambda_1, \dots, \lambda_n\}$ .

**Facts:** [Dai98]

1. Each AIEP is a PIEP( $\mathbb{C}$ ) with  $A_k = \mathbf{e}_k \mathbf{e}_k^T$  for  $k = 1, \dots, n$ . Each AIEP is also an IEP with prescribed (off-diagonal) entries.
2. [Fri77] For any  $A \in \mathbb{C}^{n \times n}$  and any  $\lambda_1, \dots, \lambda_n \in \mathbb{C}$ , the corresponding AIEP is solvable, with the number of solutions not exceeding  $n!$ . Moreover, for almost all  $\lambda_1, \dots, \lambda_n$  there are exactly  $n!$  solutions.
3. Each MIEP is a PIEP( $\mathbb{C}$ ) with  $A = 0$  and  $A_k = \mathbf{v}_k \mathbf{e}_k^T$  for  $k = 1, \dots, n$ , where  $\mathbf{v}_1, \dots, \mathbf{v}_n \in \mathbb{C}^n$  and  $B = [\mathbf{v}_1 \cdots \mathbf{v}_n] \in \mathbb{C}^{n \times n}$ .
4. [Fri75] Assume that all principal minors of  $B \in \mathbb{C}^{n \times n}$  are nonzero. For any  $\lambda_1, \dots, \lambda_n \in \mathbb{C}$ , the corresponding MIEP is solvable, with the number of solutions not exceeding  $n!$ . Moreover, for almost all  $\lambda_1, \dots, \lambda_n$  there are exactly  $n!$  solutions.
5. Each ToIEP is a PIEP( $\mathbb{R}$ S) with  $A = 0$  and  $A_k = [a_{ij}^{(k)}]_{i,j=1}^n$ , where  $a_{ij}^{(k)} = 1$  if  $|i - j| + 1 = k$  and  $a_{ij}^{(k)} = 0$  otherwise.
6. [Lan94] For any  $\lambda_1, \dots, \lambda_n \in \mathbb{R}$  the corresponding ToIEP is solvable.

## 20.10 Numerical Methods for PIEPs

---

**Facts:** [Dai98]

1. For a given PIEP( $\mathbb{R}$ S), it is possible to order both the eigenvalues  $\lambda_1 \leq \dots \leq \lambda_n$  and the eigenvalues  $\lambda_1(\mathbf{c}) \leq \dots \leq \lambda_n(\mathbf{c})$  of  $A(\mathbf{c})$ . Then solving the PIEP( $\mathbb{R}$ S) is equivalent to solving the nonlinear system

$$f(\mathbf{c}) = (\lambda_1(\mathbf{c}) - \lambda_1, \dots, \lambda_n(\mathbf{c}) - \lambda_n)^T = 0.$$

Assume that a solution  $\mathbf{c}^*$  exists and that the given eigenvalues are distinct:

- **Method 1a.** Newton's method provides a locally quadratically convergent (l.q.c.) algorithm, and it is usually l.q.c. even in the presence of multiple eigenvalues ([FNO87]). Each iteration in Newton's method involves the solution of an eigenvalue–eigenvector problem.
  - **Method 1b.** A Newton-like method is given in [FNO87]. Newton's method is modified by using the inverse power method to find approximate eigenvectors in each iteration. The new algorithm maintains l.q.c. (see [CXZ99]).
  - **Method 1c.** An inexact Newton-like method is given in [CCX03]. The last iterations of the inverse power method are truncated avoiding oversolving. The algorithm converges superlinearly, but the overall cost is reduced. In particular, for ToIEPs, this improved algorithm has better performance than specific known algorithms.
2. For a given PIEP( $\mathbb{R}$ ) or PIEP( $\mathbb{C}$ ), complex eigenvalues can appear. Assume that for the corresponding PIEP a solution  $\mathbf{c}^*$  exists:

- **Method 2.** In [BK81], Newton's method is applied to solve

$$f(\mathbf{c}) = (\det(A(\mathbf{c}) - \lambda_1 I_n), \dots, \det(A(\mathbf{c}) - \lambda_n I_n))^T = 0.$$

The algorithm is l.q.c. and is suitable for the case of distinct eigenvalues.

- **Method 3.** Newton's method is applied in [Xu96] to solve

$$f(\mathbf{c}) = (\sigma_{\min}(A(\mathbf{c}) - \lambda_1 I_n), \dots, \sigma_{\min}(A(\mathbf{c}) - \lambda_n I_n))^T = 0,$$

where  $\sigma_{\min}$  denotes the smallest singular value. The algorithm is l.q.c. under mild conditions even when multiple eigenvalues are present.

- **Method 4a.** An l.q.c. algorithm based on the  $QR$  decomposition theory is given in [Li92] that is suitable for the case of distinct eigenvalues.
  - **Method 4b.** Method 4a is extended in [Dai99] to the case of multiple eigenvalues for any  $\text{PIEP}(\mathbb{R})$ . The new algorithm is l.q.c. and is based on  $QR$ -like decomposition theory and least square techniques. Methods 4a and 4b are given in a more general context.
3. All previous methods require starting from an initial point close to a solution in order to guarantee convergence.
- **Method 5.** A homotopy approach has been considered for complex symmetric matrices (see [Chu90], [Xu93]), which in theory provides a globally convergent algorithm by which all solutions can be found.

Shaun M. Fallat  
*University of Regina*

Total positivity has been a recurring theme in linear algebra and other aspects of mathematics for the past 80 years. Totally positive matrices, in fact, originated from studying small oscillations in mechanical systems [GK60], and from investigating relationships between the number of sign changes of the vectors  $\mathbf{x}$  and  $A\mathbf{x}$  for fixed  $A$  [Sch30]. Since then this class (and the related class of sign-regular matrices) has arisen in such a wide range of applications (see [GM96] for an incredible compilation of interesting articles dealing with a long list of relevant applications of totally positive matrices) that over the years many convenient points of view for total positivity have been offered and later defended by many prominent mathematicians.

After F.R. Gantmacher and M.G. Krein [GK60], totally positive matrices were seen and further developed in connection with spline functions, collocation matrices, and generating totally positive sequences (Polya frequency sequences). Then in 1968 came one of the most important and influential references in this area, namely the book *Total Positivity* by S. Karlin [Kar68]. Karlin approached total positivity by considering the analytic properties of totally positive functions. Along these lines, he studied totally positive kernels, sign-regular functions, and Polya frequency functions. Karlin also notes the importance of total positivity in the field of statistics.

The next significant view point can be seen in T. Ando's survey paper [And87]. Ando's contribution was to consider a multilinear approach to this subject, namely making use of skew-symmetric products and Schur complements as his underlying tools. More recently, it has become clear that factorizations of totally positive matrices are a fruitful avenue for research on this class. Coupled with matrix factorizations, totally positive matrices have taken on a new combinatorial form known as Planar networks. Karlin and G. McGregor [KM59] were some of the pioneers of this view point on total positivity (see also [Bre95][Lin73]), and there has since been a revolution of sorts with many new and exciting advances and additional applications (e.g., positive elements in reductive Lie groups, computer-aided geometric design, shape-preserving designs).

This area is not only a historically significant one in linear algebra, but it will continue to produce many important advances and spawn many more worthwhile applications.

## 21.1 Basic Properties

---

In this section, we present many basic, yet fundamental, properties associated with the important class of totally positive and totally nonnegative matrices.

### Definitions:

An  $m \times n$  real matrix  $A$  is **totally nonnegative** (TN) if the determinant of every square submatrix (i.e., minor) is nonnegative.

An  $m \times n$  real matrix  $A$  is **totally positive** (TP) if every minor of  $A$  is positive.

An  $n \times n$  matrix  $A$  is **oscillatory** if  $A$  is totally nonnegative and  $A^k$  is totally positive for some integer  $k \geq 1$ .

An  $m \times n$  real matrix is **in double echelon form** if

(a) Each row of  $A$  has one of the following forms (\* indicates a nonzero entry):

1.  $(*, *, \dots, *)$ ,
2.  $(*, \dots, *, 0, \dots, 0)$ ,
3.  $(0, \dots, 0, *, \dots, *)$ , or
4.  $(0, \dots, 0, *, \dots, *, 0, \dots, 0)$ .

(b) The first and last nonzero entries in row  $i + 1$  are not to the left of the first and last nonzero entries in row  $i$ , respectively ( $i = 1, 2, \dots, n - 1$ ).

### Facts:

1. Every totally positive matrix is a totally nonnegative matrix.
2. Suppose  $A$  is a totally nonnegative (positive) rectangular matrix. Then
  - (a)  $A^T$ , the transpose of  $A$ , is totally nonnegative (positive),
  - (b)  $A[\alpha, \beta]$  is totally nonnegative (positive) for any row index set  $\alpha$  and column index set  $\beta$ .
3. (Section 4.2) Cauchy–Binet Identity: Since any  $k \times k$  minor of the product  $AB$  is a sum of products of  $k \times k$  minors of  $A$  and  $B$ , it follows that if all the  $k \times k$  minors of two  $n \times n$  matrices are positive, then all the  $k \times k$  minors of their product are positive.
4. [GK02, p .74], [And87] The set of all totally nonnegative (positive) matrices is closed under multiplication.
5. Let  $A$  be TP (TN) and  $D_1$  and  $D_2$  be positive diagonal matrices. Then  $D_1 A D_2$  is TP (TN).
6. [GK02, p .75] If  $A$  is a square invertible totally nonnegative (or is totally positive) matrix, then  $S A^{-1} S$  is totally nonnegative (positive) for  $S = \text{diag}(1, -1, \dots, \pm 1)$ . Hence, if  $A$  is a square invertible totally nonnegative matrix (or is totally positive), then the unsigned adjugate matrix of  $A$  (or the  $(n - 1)$ st compound of  $A$ ) is totally nonnegative (positive).
7. [And87], [Fal99] If  $A$  is a square totally nonnegative (positive) matrix, then, assuming  $A[\alpha^c]$  is invertible,  $A/A[\alpha^c] = A[\alpha] - A[\alpha, \alpha^c](A[\alpha^c])^{-1}A[\alpha^c, \alpha]$ , the Schur complement of  $A[\alpha^c]$  in  $A$ , is totally nonnegative (positive), for all index sets  $\alpha$  based on consecutive indices. Recall that  $\alpha^c$  denotes the complement of the set  $\alpha$ .
8. [And87], [Fal01], [Whi52], [Kar68, p. 98] The closure of the totally positive matrices (in the usual topology on  $\mathbb{R}^{m \times n}$ ) is the totally nonnegative matrices.
9. [Fal99], [JS00] Let  $A = [\mathbf{a}_1, \mathbf{a}_2, \dots, \mathbf{a}_n]$  be an  $m \times n$  totally nonnegative (positive) matrix whose  $i^{\text{th}}$  column is  $\mathbf{a}_i$  ( $i = 1, 2, \dots, n$ ). Suppose  $C$  denotes the set of all column vectors  $\mathbf{b}$  for which

the  $m \times (n + 1)$  matrix  $\hat{A} = [\mathbf{a}_1, \dots, \mathbf{a}_k, \mathbf{b}, \mathbf{a}_{k+1}, \dots, \mathbf{a}_n]$  is a totally nonnegative (positive) matrix (here  $k$  is fixed but arbitrary). Then  $C$  is a nonempty convex cone.

10. [Fal99] If  $A$  is an  $m \times n$  totally nonnegative (positive) matrix, then increasing the  $(1,1)$  or the  $(m,n)$  entries of  $A$  results in a totally nonnegative (positive) matrix. In general these are the only two entries in a TN matrix with this property (see [FJS00]).
11. [And87] Let  $P$  denote the  $n \times n$  permutation matrix induced by the permutation  $i \rightarrow n - i + 1$ ,  $(1 \leq i \leq n)$ , and suppose  $A$  is an  $n \times n$  totally nonnegative (positive) matrix. Then  $PAP$  is a totally nonnegative (positive) matrix.
12. Any irreducible tridiagonal matrix with nonzero main diagonal is in double echelon form.
13. [Fal99] Let  $A$  be an  $m \times n$  totally nonnegative matrix with no zero rows or columns. Then  $A$  is in double echelon form.
14. [Rad68], [Fal99] An  $n \times n$  totally nonnegative matrix  $A = [a_{ij}]$  is irreducible if and only if  $a_{i,i+1} > 0$  and  $a_{i+1,i} > 0$ , for  $i = 1, 2, \dots, n - 1$ .

**Examples:**

1. Consider the following  $3 \times 3$  matrix:  $A = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 2 & 4 \\ 1 & 3 & 9 \end{bmatrix}$ . It is not difficult to check that all minors of  $A$  are positive.
2. (Inverse tridiagonal matrix) From Fact 6 above, the inverse of a TN tridiagonal matrix is signature similar to a TN matrix. Such matrices are referred to as “single-pair” matrices in [GK02, pp. 78–80], are very much related to “Green’s matrices” (see [Kar68, pp. 110–112]), and are similar to matrices of type D found in [Mar70a].
3. (Vandermonde matrix) Vandermonde matrices arise in the problem of determining a polynomial of degree at most  $n - 1$  that interpolates  $n$  data points. Suppose that  $n$  data points  $(x_i, y_i)_{i=1}^n$  are given. The goal is to construct a polynomial  $p(x) = a_0 + a_1x + \dots + a_{n-1}x^{n-1}$  that satisfies  $p(x_i) = y_i$  for  $i = 1, 2, \dots, n$ , which can be expressed as

$$\begin{bmatrix} 1 & x_1 & x_1^2 & \cdots & x_1^{n-1} \\ 1 & x_2 & x_2^2 & \cdots & x_2^{n-1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & x_n & x_n^2 & \cdots & x_n^{n-1} \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ \vdots \\ a_{n-1} \end{bmatrix} = \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix}. \tag{21.1}$$

The  $n \times n$  coefficient matrix in (21.1) is called a *Vandermonde matrix*, and we denote it by  $\mathcal{V}(x_1, \dots, x_n)$ . The determinant of the  $n \times n$  Vandermonde matrix in (21.1) is given by the formula  $\prod_{i>j} (x_i - x_j)$ ; see [MM64, pp. 15–16]. Thus, if  $0 < x_1 < x_2 < \dots < x_n$ , then  $\mathcal{V}(x_1, \dots, x_n)$  has positive entries, positive leading principal minors, and positive determinant. More generally, it is known [GK02, p. 111] that if  $0 < x_1 < x_2 < \dots < x_n$ , then  $\mathcal{V}(x_1, \dots, x_n)$  is TP. Example 1 above is a Vandermonde matrix.

4. Let  $f(x) = \sum_{i=0}^n a_i x^i$  be an  $n^{\text{th}}$  degree polynomial in  $x$ . The *Routh–Hurwitz matrix* is the  $n \times n$  matrix given by

$$A = \begin{bmatrix} a_1 & a_3 & a_5 & a_7 & \cdots & 0 & 0 \\ a_0 & a_2 & a_4 & a_6 & \cdots & 0 & 0 \\ 0 & a_1 & a_3 & a_5 & \cdots & 0 & 0 \\ 0 & a_0 & a_2 & a_4 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \cdots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & a_{n-1} & 0 \\ 0 & 0 & 0 & 0 & \cdots & a_{n-2} & a_n \end{bmatrix}.$$

A specific example of a Routh–Hurwitz matrix for an arbitrary polynomial of degree six,  $f(x) = \sum_{i=0}^6 a_i x^i$ , is given by

$$A = \begin{bmatrix} a_1 & a_3 & a_5 & 0 & 0 & 0 \\ a_0 & a_2 & a_4 & a_6 & 0 & 0 \\ 0 & a_1 & a_3 & a_5 & 0 & 0 \\ 0 & a_0 & a_2 & a_4 & a_6 & 0 \\ 0 & 0 & a_1 & a_3 & a_5 & 0 \\ 0 & 0 & a_0 & a_2 & a_4 & a_6 \end{bmatrix}.$$

A polynomial  $f(x)$  is *stable* if all the zeros of  $f(x)$  have negative real parts. It is proved in [Asn70] that  $f(x)$  is stable if and only if the Routh–Hurwitz matrix formed from  $f$  is totally nonnegative.

5. (Cauchy matrix) An  $n \times n$  matrix  $C = [c_{ij}]$  is called a *Cauchy matrix* if the entries of  $C$  are given by

$$c_{ij} = \frac{1}{x_i + y_j},$$

where  $x_1, x_2, \dots, x_n$  and  $y_1, y_2, \dots, y_n$  are two sequences of numbers (chosen so that  $c_{ij}$  is well-defined). A Cauchy matrix is totally positive if and only if  $0 < x_1 < x_2 < \dots < x_n$  and  $0 < y_1 < y_2 < \dots < y_n$  ([GK02, pp. 77–78]).

6. (Pascal matrix) Consider the  $4 \times 4$  matrix  $P_4 = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 2 & 3 & 4 \\ 1 & 3 & 6 & 10 \\ 1 & 4 & 10 & 20 \end{bmatrix}$ . The matrix  $P_4$  is called the

*symmetric  $4 \times 4$  Pascal matrix* because of its connection with Pascal's triangle (see Example 4 of section 21.2 for a definition of  $P_n$  for general  $n$ ). Then  $P_4$  is TP, and the inverse of  $P_4$  is given by

$$P_4^{-1} = \begin{bmatrix} 4 & -6 & 4 & -1 \\ -6 & 14 & -11 & 3 \\ 4 & -11 & 10 & -3 \\ -1 & 3 & -3 & 1 \end{bmatrix}.$$

Notice that the inverse of the  $4 \times 4$  Pascal matrix is integral. Moreover, deleting the signs by forming

$$SP_4^{-1}S, \text{ where } S = \text{diag}(1, -1, 1, -1), \text{ results in the TP matrix } \begin{bmatrix} 4 & 6 & 4 & 1 \\ 6 & 14 & 11 & 3 \\ 4 & 11 & 10 & 3 \\ 1 & 3 & 3 & 1 \end{bmatrix}.$$

### Applications:

1. (Tridiagonal matrices) When Gantmacher and Krein were studying the oscillatory properties of an elastic segmental continuum (no supports between the endpoints  $a$  and  $b$ ) under small transverse oscillations, they were able to generate a system of linear equations that define the frequency of the oscillation (see [GK60]). The system of equations thus found can be represented in what is known as the influence-coefficient matrix, whose properties are analogous to those governing the segmental continuum. This process of obtaining the properties of the segmental continuum from the influence-coefficient matrix was only possible due to the inception of the theory of oscillatory matrices. A special case involves tridiagonal matrices (or Jacobi matrices as they were called in [GK02]). Tridiagonal matrices are not only interesting in their own right as a model example of oscillatory matrices, but they also naturally arise in studying small oscillations in certain mechanical systems, such as torsional oscillations of a system of disks fastened to a shaft. In [GK02, pp. 81–82] they prove that an irreducible tridiagonal matrix is totally nonnegative if and only if its entries are nonnegative and its leading principal minors are nonnegative.

## 21.2 Factorizations

Recently, there has been renewed interest in total positivity partly motivated by the so-called “bidiagonal factorization,” namely, the fact that any totally positive matrix can be factored into entry-wise nonnegative bidiagonal matrices. This result has proven to be a very useful and tremendously powerful property for this class. (See Section 1.6 for basic information on LU factorizations.)

### Definitions:

An **elementary bidiagonal matrix** is an  $n \times n$  matrix whose main diagonal entries are all equal to one, and there is, at most, one nonzero off-diagonal entry and this entry must occur on the super- or subdiagonal. The lower elementary bidiagonal matrix whose elements are given by

$$c_{ij} = \begin{cases} 1, & \text{if } i = j, \\ \mu, & \text{if } i = k, j = k - 1, \\ 0, & \text{otherwise} \end{cases}$$

is denoted by  $E_k(\mu) = [c_{ij}]$  ( $2 \leq k \leq n$ ).

A triangular matrix is  $\Delta\text{TP}$  if all of its nontrivial minors are positive. (Here a trivial minor is one which is zero only because of the zero pattern of a triangular matrix.)

### Facts:

1.  $(E_k(\mu))^{-1} = E_k(-\mu)$ .
2. [Cry73] Let  $A$  be an  $n \times n$  matrix. Then  $A$  is totally positive if and only if  $A$  has an  $LU$  factorization such that both  $L$  and  $U$  are  $n \times n$   $\Delta\text{TP}$  matrices.
3. [And87], [Cry76] Let  $A$  be an  $n \times n$  matrix. Then  $A$  is totally nonnegative if and only if  $A$  has an  $LU$  factorization such that both  $L$  and  $U$  are  $n \times n$  totally nonnegative matrices.
4. [Whi52] Suppose  $A = [a_{ij}]$  is an  $n \times n$  matrix with  $a_{j1}, a_{j+1,1} > 0$ , and  $a_{k1} = 0$  for  $k > j + 1$ . Let  $B$  be the  $n \times n$  matrix obtained from  $A$  by using row  $j$  to eliminate  $a_{j+1,1}$ . Then  $A$  is TN if and only if  $B$  is TN. Note that  $B$  is equal to  $E_{j+1}(-a_{j+1,1}/a_{j1})A_j$  and, hence,  $A = (E_{j+1}(-a_{j+1,1}/a_{j1}))^{-1}B = E_{j+1}(a_{j+1,1}/a_{j1})B$ .
5. [Loe55], [GP96], [BFZ96], [FZ00], [Fal01] Let  $A$  be an  $n \times n$  nonsingular totally nonnegative matrix. Then  $A$  can be written as

$$A = (E_2(l_k))(E_3(l_{k-1})E_2(l_{k-2})) \cdots (E_n(l_{n-1}) \cdots E_3(l_2)E_2(l_1))D \\ (E_2^T(u_1)E_3^T(u_2) \cdots E_n^T(u_{n-1})) \cdots (E_2^T(u_{k-2})E_3^T(u_{k-1}))(E_2^T(u_k)), \quad (21.2)$$

where  $k = \binom{n}{2}$ ;  $l_i, u_j \geq 0$  for all  $i, j \in \{1, 2, \dots, k\}$ ; and  $D$  is a positive diagonal matrix.

6. [Cry76] Any  $n \times n$  totally nonnegative matrix  $A$  can be written as

$$A = \prod_{i=1}^M L^{(i)} \prod_{j=1}^N U^{(j)}, \quad (21.3)$$

where the matrices  $L^{(i)}$  and  $U^{(j)}$  are, respectively, lower and upper bidiagonal totally nonnegative matrices with at most one nonzero entry off the main diagonal.

7. [Cry76], [RH72] If  $A$  is an  $n \times n$  totally nonnegative matrix, then there exists a totally nonnegative matrix  $S$  and a tridiagonal totally nonnegative matrix  $T$  such that

(a)  $TS = SA$ .

(b) The matrices  $A$  and  $T$  have the same eigenvalues.

Moreover, if  $A$  is nonsingular, then  $S$  is nonsingular.

**Examples:**

- Let  $P_4$  be the matrix given in Example 6 of section 21.1. Then  $P_4$  is TP, and a (unique up to a positive diagonal scaling)  $LU$  factorization of  $P_4$  is given by

$$P_4 = LU = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 1 & 2 & 1 & 0 \\ 1 & 3 & 3 & 1 \end{bmatrix} \begin{bmatrix} 1 & 1 & 1 & 1 \\ 0 & 1 & 2 & 3 \\ 0 & 0 & 1 & 3 \\ 0 & 0 & 0 & 1 \end{bmatrix}.$$

Observe that the rows of  $L$ , or the columns of  $U$ , come from the rows of Pascal's triangle (ignoring the zeros); hence, the name Pascal matrix (see Example 4 for a definition of  $P_n$ ).

- The  $3 \times 3$  Vandermonde matrix  $A$  in Example 1 of Section 21.1 can be factored as

$$A = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 1 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 2 \end{bmatrix} \\ \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 2 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix}. \tag{21.4}$$

- In fact, we can write  $\mathcal{V}(x_1, x_2, x_3)$  as

$$\mathcal{V}(x_1, x_2, x_3) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 1 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & \frac{(x_3-x_2)}{(x_2-x_1)} & 1 \end{bmatrix} \\ \begin{bmatrix} 1 & 0 & 0 \\ 0 & x_2 - x_1 & 0 \\ 0 & 0 & (x_3 - x_2)(x_3 - x_1) \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & x_2 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & x_1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & x_1 \\ 0 & 0 & 1 \end{bmatrix}.$$

- Consider the factorization (21.2) from Fact 5 of a  $4 \times 4$  matrix in which all of the variables are equal to one. The resulting matrix is  $P_4$ , which is necessarily TP. On the other hand, consider the  $n \times n$  matrix  $P_n = [p_{ij}]$  whose first row and column entries are all ones, and for  $2 \leq i, j \leq n$  let  $p_{ij} = p_{i-1,j} + p_{i,j-1}$ . In fact, the relation  $p_{ij} = p_{i-1,j} + p_{i,j-1}$  implies [Fal01] that  $P_n$  can be written as

$$P_n = E_n(1) \cdots E_2(1) \begin{bmatrix} 1 & 0 \\ 0 & P_{n-1} \end{bmatrix} E_2^T(1) \cdots E_n^T(1).$$

Hence, by induction,  $P_n$  has the factorization (21.2) in which the variables involved are all equal to one. Consequently, the symmetric Pascal matrix  $P_n$  is TP for all  $n \geq 1$ . Furthermore, since in general  $(E_k(\mu))^{-1} = E_k(-\mu)$  (Fact 1), it follows that  $P_n^{-1}$  is not only signature similar to a TP matrix, but it is also integral.

### 21.3 Recognition and Testing

In practice, how can one determine if a given  $n \times n$  matrix is TN or TP? One could calculate every minor, but that would involve evaluating  $\sum_{k=1}^n \binom{n}{k}^2 \sim 4^n / \sqrt{\pi n}$  determinants. Is there a smaller collection of minors whose nonnegativity or positivity implies the nonnegativity or positivity of all minors?

**Definitions:**

For  $\alpha = \{i_1, i_2, \dots, i_k\} \subseteq N = \{1, 2, \dots, n\}$ , with  $i_1 < i_2 < \dots < i_k$ , the **dispersion** of  $\alpha$ , denoted by  $d(\alpha)$ , is defined to be  $\sum_{j=1}^{k-1} (i_{j+1} - i_j - 1) = i_k - i_1 - (k - 1)$ , with the convention that  $d(\alpha) = 0$ , when  $\alpha$  is a singleton.

If  $\alpha$  and  $\beta$  are two contiguous index sets with  $|\alpha| = |\beta| = k$ , then the minor  $\det A[\alpha, \beta]$  is called **initial** if  $\alpha$  or  $\beta$  is  $\{1, 2, \dots, k\}$ . A minor is called a **leading principal minor** if it is an initial minor with both  $\alpha = \beta = \{1, 2, \dots, k\}$ .

An upper right (lower left) **corner minor** of  $A$  is one of the form  $\det A[\alpha, \beta]$  in which  $\alpha$  consists of the first  $k$  (last  $k$ ) and  $\beta$  consists of the last  $k$  (first  $k$ ) indices,  $k = 1, 2, \dots, n$ .

**Facts:**

1. The dispersion of a set  $\alpha$  represents a measure of the “gaps” in the set  $\alpha$ . In particular, observe that  $d(\alpha) = 0$  if and only if  $\alpha$  is a contiguous subset of  $N$ .
2. [Fek13] (Fekete’s Criterion) An  $m \times n$  matrix  $A$  is totally positive if and only if  $\det A[\alpha, \beta] > 0$ , for all  $\alpha \subseteq \{1, 2, \dots, m\}$  and  $\beta \subseteq \{1, 2, \dots, n\}$ , with  $|\alpha| = |\beta|$  and  $d(\alpha) = d(\beta) = 0$ . (Reduces the number of minors to be checked for total positivity to roughly  $n^3$ .)
3. [GP96], [FZ00] If all initial minors of  $A$  are positive, then  $A$  is TP. (Reduces the number of minors to be checked for total positivity to  $n^2$ .)
4. [SS95], [Fal04] Suppose that  $A$  is TN. Then  $A$  is TP if and only if all corner minors of  $A$  are positive.
5. [GP96] Let  $A \in \mathbb{R}^{n \times n}$  be nonsingular.
  - (a)  $A$  is TN if and only if for each  $k = 1, 2, \dots, n$ ,
    - i.  $\det A[\{1, 2, \dots, k\}] > 0$ .
    - ii.  $\det A[\alpha, \{1, 2, \dots, k\}] \geq 0$ , for every  $\alpha \subseteq \{1, 2, \dots, n\}$ ,  $|\alpha| = k$ .
    - iii.  $\det A[\{1, 2, \dots, k\}, \beta] \geq 0$ , for every  $\beta \subseteq \{1, 2, \dots, n\}$ ,  $|\beta| = k$ .
  - (b)  $A$  is TP if and only if for each  $k = 1, 2, \dots, n$ ,
    - i.  $\det A[\alpha, \{1, 2, \dots, k\}] > 0$ , for every  $\alpha \subseteq \{1, 2, \dots, n\}$  with  $|\alpha| = k$ ,  $d(\alpha) = 0$ .
    - ii.  $\det A[\{1, 2, \dots, k\}, \beta] > 0$ , for every  $\beta \subseteq \{1, 2, \dots, n\}$  with  $|\beta| = k$ ,  $d(\beta) = 0$ .
6. [GK02, p. 100] An  $n \times n$  totally nonnegative matrix  $A = [a_{ij}]$  is oscillatory if and only if
  - (a)  $A$  is nonsingular.
  - (b)  $a_{i,i+1} > 0$  and  $a_{i+1,i} > 0$ , for  $i = 1, 2, \dots, n - 1$ .
7. [Fal04] Suppose  $A$  is an  $n \times n$  invertible totally nonnegative matrix. Then  $A$  is oscillatory if and only if a parameter from at least one of the bidiagonal factors  $E_k$  and  $E_k^T$  is positive, for each  $k = 2, 3, \dots, n$  in the elementary bidiagonal factorization of  $A$  given in Fact 5 of section 21.2.

**Examples:**

1. Unfortunately, Fekete’s Criterion, Fact 2, does not hold in general if “totally positive” is replaced with “totally nonnegative” and “ $> 0$ ” is replaced with “ $\geq 0$ .” Consider the following simple example:

$A = \begin{bmatrix} 1 & 0 & 2 \\ 1 & 0 & 1 \\ 2 & 0 & 1 \end{bmatrix}$ . It is not difficult to verify that every minor of  $A$  based on contiguous row and column sets is nonnegative, but  $\det A[\{1, 3\}] = -3$ . For an invertible and irreducible example

consider  $A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix}$ .

## 21.4 Spectral Properties

Approximately 60 years ago, Gantmacher and Krein [GK60], who were originally interested in oscillation dynamics, undertook a careful study into the theory of totally nonnegative matrices. Of the many topics they considered, one was the properties of the eigenvalues of totally nonnegative matrices.

### Facts:

- [GK02, pp. 86–91] Let  $A$  be an  $n \times n$  oscillatory matrix. Then the eigenvalues of  $A$  are positive, real, and distinct. Moreover, an eigenvector  $\mathbf{x}_k$  corresponding to the  $k^{\text{th}}$  largest eigenvalue has exactly  $k - 1$  variations in sign for  $k = 1, 2, \dots, n$ . Furthermore, assuming we choose the first entry of each eigenvector to be positive, the positions of the sign change in each successive eigenvector interlace. (See Preliminaries for the definition of interlace.)
- [And87] Let  $A$  be an  $n \times n$  totally nonnegative matrix. Then the eigenvalues of  $A$  are real and nonnegative.
- [FGJ00] Let  $A$  be an  $n \times n$  irreducible totally nonnegative matrix. Then the positive eigenvalues of  $A$  are distinct.
- [GK02, pp. 107–108] If  $A$  is an  $n \times n$  oscillatory matrix, then the eigenvalues of  $A$  are distinct and strictly interlace the eigenvalues of the two principal submatrices of order  $n - 1$  obtained from  $A$  by deleting the first row and column or the last row and column. If  $A$  is an  $n \times n$  TN matrix, then nonstrict interlacing holds between the eigenvalues of  $A$  and the two principal submatrices of order  $n - 1$  obtained from  $A$  by deleting the first row and column or the last row and column.
- [Pin98] If  $A$  is an  $n \times n$  totally positive matrix with eigenvalues  $\lambda_1 > \lambda_2 > \dots > \lambda_n$  and  $A(k)$  is the  $(n - 1) \times (n - 1)$  principal submatrix obtained from  $A$  by deleting the  $k$ th row and column with eigenvalues  $\mu_1 > \mu_2 > \dots > \mu_{n-1}$ , then for  $j = 1, 2, \dots, n - 1$ ,  $\lambda_{j-1} > \mu_j > \lambda_{j+1}$ , where  $\lambda_0 = \lambda_1$ . In the usual Cauchy interlacing inequalities [MM64, p. 119] for positive semidefinite matrices,  $\lambda_{j-1}$  is replaced by  $\lambda_j$ . The nonstrict inequalities need not hold for TN matrices. The extreme cases ( $j = 1, n - 1$ ) of this interlacing result were previously proved in [Fri85].
- [Gar82] Let  $n \geq 2$  and  $A = [a_{ij}]$  be an oscillatory matrix. Then the main diagonal entries of  $A$  are majorized by the eigenvalues of  $A$ . (See Preliminaries for the definition of majorization.)

### Examples:

- Consider the  $4 \times 4$  TP matrix  $P_4 = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 2 & 3 & 4 \\ 1 & 3 & 6 & 10 \\ 1 & 4 & 10 & 20 \end{bmatrix}$ . Then the eigenvalues of  $P_4$  are 26.305, 2.203, .454, and .038, with respective eigenvectors

$$\begin{bmatrix} .06 \\ .201 \\ .458 \\ .864 \end{bmatrix}, \begin{bmatrix} .53 \\ .64 \\ .392 \\ -.394 \end{bmatrix}, \begin{bmatrix} .787 \\ -.163 \\ -.532 \\ .265 \end{bmatrix}, \begin{bmatrix} .309 \\ -.723 \\ .595 \\ -.168 \end{bmatrix}.$$

- The irreducible, singular TN (Hessenberg) matrix given by  $H = \begin{bmatrix} 1 & 1 & 0 & 0 \\ 1 & 1 & 1 & 0 \\ 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \end{bmatrix}$  has eigenvalues equal to 3, 1, 0, 0. Notice the positive eigenvalues of  $H$  are distinct.
- Using the TP matrix  $P_4$  in Example 1, the eigenvalues of  $P_4(\{1\})$  are 26.213, 1.697, and .09. Observe that the usual Cauchy interlacing inequalities are satisfied in this case.

## 21.5 Deeper Properties

In this section, we explore more advanced topics that are not only interesting in their own right, but continue to demonstrate the delicate structure of these matrices.

### Definitions:

For a given vector  $\mathbf{c} = (c_1, c_2, \dots, c_n)^T \in \mathbb{R}^n$  we define two quantities associated with the number of sign changes of the vector  $\mathbf{c}$ . These are:

$V^-(\mathbf{c})$  — the **number of sign changes in the sequence**  $c_1, c_2, \dots, c_n$  with the zero elements discarded; and

$V^+(\mathbf{c})$  — the **maximum number of sign changes in the sequence**  $c_1, c_2, \dots, c_n$ , where the zero elements are arbitrarily assigned the values  $+1$  and  $-1$ .

For example,  $V^-((1, 0, 1, -1, 0, 1)^T) = 2$  and  $V^+((1, 0, 1, -1, 0, 1)^T) = 4$ .

We use  $<, \leq$  to denote the usual entry-wise partial order on matrices; i.e., for  $A = [a_{ij}], B = [b_{ij}] \in \mathbb{R}^{m \times n}$ ,  $A \leq (<) B$  means  $a_{ij} \leq (<) b_{ij}$ , for all  $i, j$ .

Let  $S$  be the signature matrix whose diagonal entries alternate in sign beginning with  $+$ . For  $A, B \in \mathbb{R}^{m \times n}$ , we write  $A \stackrel{*}{\leq} B$  if and only if  $SAS \leq SBS$  and  $A \stackrel{*}{<} B$  if and only if  $SAS < SBS$ , and we call this the “**checkerboard**” partial order on real matrices.

### Facts:

- [Sch30] Let  $A$  be an  $m \times n$  real matrix with  $m \geq n$ . If  $A$  is totally positive, then  $V^+(A\mathbf{x}) \leq V^-(\mathbf{x})$ , for all nonzero  $\mathbf{x} \in \mathbb{R}^n$ .
- Let  $A = [a_{ij}]$  be an  $n \times n$  totally nonnegative matrix. Then:
  - Hadamard: [GK02, pp. 91–97], [Kot53]  $\det A \leq \prod_{i=1}^n a_{ii}$ ,
  - Fischer: [GK02, pp. 91–97], [Kot53] Let  $S \subseteq N = \{1, 2, \dots, n\}$ ,  $\det A \leq \det A[S] \cdot \det A[N \setminus S]$ ,
  - Koteljanskii: [Kot53] Let  $S, T \subseteq N$ ,  $\det A[S \cup T] \cdot \det A[S \cap T] \leq \det A[S] \cdot \det A[T]$ .

The above three determinantal inequalities also hold for positive semidefinite matrices. (See Chapter 8.5.)

- [FGJ03] Let  $\alpha_1, \alpha_2, \beta_1$ , and  $\beta_2$  be subsets of  $\{1, 2, \dots, n\}$ , and let  $A$  be any TN matrix. Then

$$\det A[\alpha_1] \det A[\alpha_2] \leq \det A[\beta_1] \det A[\beta_2]$$

if and only if each index  $i$  has the same multiplicity in the multiset  $\alpha_1 \cup \alpha_2$  and the multiset  $\beta_1 \cup \beta_2$ , and  $\max(|\alpha_1 \cap L|, |\alpha_2 \cap L|) \geq \max(|\beta_1 \cap L|, |\beta_2 \cap L|)$ , for every contiguous (i.e.,  $d(L) = 0$ )  $L \subseteq \{1, 2, \dots, n\}$  (see [FGJ03] for other classes of principal-minor inequalities).

- [FJS00] Let  $A$  be an  $n \times n$  totally nonnegative matrix with  $\det A(\{1\}) \neq 0$ . Then  $A - xE_{11}$  is totally nonnegative for all  $x \in [0, \frac{\det A}{\det A(\{1\})}]$ .
- [FJ98] Let  $A$  be an  $n \times n$  TN matrix partitioned as follows

$$A = \begin{bmatrix} A_{11} & \mathbf{b} \\ \mathbf{c}^T & d \end{bmatrix},$$

where  $A_{11}$  is  $(n-1) \times (n-1)$ . Suppose that  $\text{rank}(A_{11}) = p$ . Then either  $\text{rank}([A_{11}, \mathbf{b}]) = p$  or  $\text{rank}[A_{11}^T, \mathbf{c}]^T = p$ . See [FJ98] for other types of row and column inclusion results for TN matrices.

- [CFJ01] Let  $T$  be an  $n \times n$  totally nonnegative tridiagonal matrix. Then the Hadamard product of  $T$  with any other TN matrix is again TN.

7. [CFJ01][Mar70b] The Hadamard product of any two  $n \times n$  tridiagonal totally nonnegative matrices is again totally nonnegative.

8. [CFJ01] Let  $A = \begin{bmatrix} a & b & c \\ d & e & f \\ g & h & i \end{bmatrix}$  be a  $3 \times 3$  totally nonnegative matrix. Then  $A$  has the property that  $A \circ B$  is TN for all  $B$  TN if and only if

$$\begin{aligned} aei + gbh &\geq afh + dbi, \\ aei + dch &\geq afh + dbi. \end{aligned}$$

9. [CFJ01] Let  $A$  be an  $n \times n$  totally nonnegative matrix with the property that  $A \circ B$  is TN for all  $B$  TN, and suppose  $B$  is any  $n \times n$  totally nonnegative matrix. Then

$$\det(A \circ B) \geq \det B \prod_{i=1}^n a_{ii}.$$

10. [Ste91] Let  $A = [a_{ij}] \in \mathbb{R}^{n \times n}$ , and let  $S_n$  denote the symmetric group on  $n$  symbols. If  $\chi$  is an irreducible character of  $S_n$ , then the corresponding matrix function

$$[a_{ij}] \mapsto \sum_{\omega \in S_n} \chi(\omega) \prod_{i=1}^n a_{i,\omega(i)}$$

is called an *immanant*. For example, if  $\chi$  is the trivial character  $\chi(\omega) = 1$ , then the corresponding immanant is the permanent and, if  $\chi$  is  $\text{sgn}(\omega)$ , then the immanant is the determinant. Then every immanant of a totally nonnegative matrix is nonnegative.

11. [Gar96] If  $A, B, C \in \mathbb{R}^{n \times n}$ ,  $A \stackrel{*}{\leq} C \stackrel{*}{\leq} B$ , and  $A$  and  $B$  are TP, then  $\det C > 0$ .

12. [Gar96] If  $A, B, C \in \mathbb{R}^{n \times n}$ ,  $A \stackrel{*}{\leq} C \stackrel{*}{\leq} B$ , and  $A$  and  $B$  are TP, then  $C$  is TP.

### Examples:

1. Let

$$P_4 = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 2 & 3 & 4 \\ 1 & 3 & 6 & 10 \\ 1 & 4 & 10 & 20 \end{bmatrix} \quad \text{and} \quad \text{let } \mathbf{x} = \begin{bmatrix} 1 \\ -2 \\ -5 \\ 4 \end{bmatrix}.$$

Then  $V^-(\mathbf{x}) = 2$  and  $P_4 \mathbf{x} = [-2, -2, 5, 23]^T$ , so  $V^+(P_4 \mathbf{x}) = 1$ . Hence, Schoenberg's variation diminishing property (Fact 1 of section 21.5) holds in this case.

2. Let

$$H = \begin{bmatrix} 1 & 1 & 0 & 0 \\ 1 & 1 & 1 & 0 \\ 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \end{bmatrix} \quad \text{and} \quad \text{let } \mathbf{x} = \begin{bmatrix} 1 \\ -1 \\ -1 \\ 1 \end{bmatrix}.$$

Then  $V^-(\mathbf{x}) = 2$  and  $H\mathbf{x} = [0, -1, 0, 0]^T$ , so  $V^+(H\mathbf{x}) = 3$ . Hence, Schoenberg's variation diminishing property (Fact 1 of section 21.5) does not hold in general for TN matrices.

3. If  $0 < A < B$  and  $A, B \in \mathbb{R}^{n \times n}$  are TP, then not all matrices in the interval between  $A$  and  $B$  need be TP. Let

$$A = \begin{bmatrix} 2 & 1 \\ 1 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} 4 & 5 \\ 5 & 7 \end{bmatrix}.$$

Then  $A, B$  are TP and

$$C = \begin{bmatrix} 3 & 4 \\ 4 & 5 \end{bmatrix}$$

satisfies  $A < C < B$ , and  $C$  is not TP.

4. If TP is replaced by TN, then Fact 12 no longer holds. For example,

$$\begin{bmatrix} 2 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 1 \end{bmatrix} \stackrel{*}{\leq} \begin{bmatrix} 3 & 0 & 4 \\ 0 & 0 & 0 \\ 4 & 0 & 5 \end{bmatrix} \stackrel{*}{\leq} \begin{bmatrix} 4 & 0 & 5 \\ 0 & 0 & 0 \\ 5 & 0 & 7 \end{bmatrix};$$

however, both end matrices are TN while the middle matrix is not.

5. A polynomial  $f(x)$  is *stable* if all the zeros of  $f(x)$  have negative real parts, which is equivalent to the the Routh–Hurwitz matrix (Example 4 of Section 21.1) formed from  $f$  being totally nonnegative [Asn70]. Suppose  $f(x) = \sum_{i=0}^n a_i x^i$  and  $g(x) = \sum_{i=0}^m b_i x^i$  are two polynomials of degree  $n$  and  $m$ , respectively. Then the *Hadamard product of  $f$  and  $g$*  is the polynomial  $(f \circ g)(x) = \sum_{i=0}^k a_i b_i x^i$ , where  $k = \min(m, n)$ . In [GW96a], it is proved that the Hadamard product of stable polynomials is stable. Hence, the Hadamard product of two totally nonnegative Routh–Hurwitz matrices is in turn a totally nonnegative matrix ([GW96a]). See also [GW96b] for a list of other subclasses of TN matrices that are closed under Hadamard multiplication.

6. Let  $A = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}$  and let  $B = A^T$ . Then  $A$  and  $B$  are TN,  $A \circ B = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 1 & 1 \\ 0 & 1 & 1 \end{bmatrix}$ , and

$\det(A \circ B) = -1 < 0$ . Thus,  $A \circ B$  is not TN.

7. (Polya matrix) Let  $q \in (0, 1)$ . The  $n \times n$  Polya matrix  $Q$  has its  $(i, j)^{th}$  entry equal to  $q^{-2ij}$ . Then  $Q$  is totally positive for all  $n$  (see [Whi52]). In fact,  $Q$  is diagonally equivalent to a TP Vandermonde matrix. Suppose  $Q$  represents the  $3 \times 3$  Polya matrix. Then  $Q$  satisfies that  $Q \circ A$  is TN for all  $A$  TN whenever  $q \in (0, \sqrt{1/\mu})$ , where  $\mu = \frac{1+\sqrt{5}}{2}$  (the golden mean).
8. The bidiagonal factorization (21.2) from Fact 5 of section 21.2 for TN matrices was used in [Loe55] to show that for each nonsingular  $n \times n$  TN matrix  $A$  there is a piece-wise continuous family of matrices  $\Omega(t)$  of a special form such that the unique solution of the initial value problem

$$\frac{dA(t)}{dt} = \Omega(t)A(t), \quad A(0) = I \tag{21.5}$$

has  $A(1) = A$ . Let  $A(t) = [a_{ij}(t)]$  be a differentiable matrix-valued function of  $t$  such that  $A(t)$  is nonsingular and TN for all  $t \in [0, 1]$ , and  $A(0) = I$ . Then

$$\Omega \equiv \left( \frac{dA(t)}{dt} \right)_{t=0} \tag{21.6}$$

is called an *infinitesimal element* of the semigroup of nonsingular TN matrices. By (21.2) every nonsingular TN matrix can be obtained from the solution of the initial value problem (21.5) in which all  $\Omega(t)$  are infinitesimal elements.

9. If the main diagonal entries of a TP matrix are all ones, then it is not difficult to observe that as you move away from the diagonal there is a “drop off” effect in the entries of this matrix. Craven and

Csordas [CC98] have worked out an enticing sufficient “drop off” condition for a matrix to be TP. If  $A = [a_{ij}]$  is an  $n \times n$  matrix with positive entries and satisfies

$$a_{ij}a_{i+1,j+1} \geq c_0 a_{i,j+1} a_{i+1,j},$$

where  $c_0 = 4.07959562349\dots$ , then  $A$  is TP. This condition is particularly appealing for both Hankel and Toeplitz matrices. Recall that a Hankel matrix is an  $(n+1) \times (n+1)$  matrix of the form

$$\begin{bmatrix} a_0 & a_1 & \cdots & a_n \\ a_1 & a_2 & \cdots & a_{n+1} \\ \vdots & \vdots & \cdots & \vdots \\ a_n & a_{n+1} & \cdots & a_{2n} \end{bmatrix}.$$

So, if the positive sequence  $\{a_i\}$  satisfies  $a_{k-1}a_{k+1} \geq c_0 a_k^2$ , then the corresponding Hankel matrix is TP. An  $(n+1) \times (n+1)$  Toeplitz matrix is of the form

$$\begin{bmatrix} a_0 & a_1 & a_2 & \cdots & a_n \\ a_{-1} & a_0 & a_1 & \cdots & a_{n-1} \\ a_{-2} & a_{-1} & a_0 & \cdots & a_{n-2} \\ \vdots & \vdots & \vdots & \cdots & \vdots \\ a_{-n} & a_{-(n-1)} & a_{-(n-2)} & \cdots & a_0 \end{bmatrix}.$$

Hence, if the positive sequence  $\{a_i\}$  satisfies  $a_k^2 \geq c_0 a_{k-1} a_{k+1}$ , then the corresponding Toeplitz matrix is TP.

10. A sequence  $a_0, a_1, \dots$  of real numbers is called *totally positive* if the two-way infinite matrix given by

$$\begin{bmatrix} a_0 & 0 & 0 & \cdots \\ a_1 & a_0 & 0 & \cdots \\ a_2 & a_1 & a_0 & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{bmatrix}$$

is TP. As usual, an infinite matrix is TP all of its minors are positive. Notice that the above matrix is a Toeplitz matrix. Studying the functions that generate totally positive sequences was a difficult and important step in the area of totally positive matrices;  $f(x)$  generates the sequence  $a_0, a_1, \dots$  if  $f(x) = a_0 + a_1x + a_2x^2 + \dots$ . In Aissen et al. [ASW52] (see also [Edr52]), it was shown that the above two-way infinite Toeplitz matrix is TP (i.e., the corresponding sequence is totally positive) if and only if the generating function  $f(x)$  for the sequence  $a_0, a_1, \dots$  has the form

$$f(x) = e^{\gamma x} \frac{\prod_{v=1}^{\infty} (1 + \alpha_v x)}{\prod_{v=1}^{\infty} (1 - \beta_v x)},$$

where  $\gamma, \alpha_v, \beta_v \geq 0$ , and  $\sum \alpha_v$  and  $\sum \beta_v$  are convergent.

Linear preservers are linear maps on linear spaces of matrices that leave certain subsets, properties, relations, functions, etc., invariant. Linear preserver problems ask what is the general form of such maps. Describing the structure of such maps often gives a deeper understanding of the matrix sets, functions, or relations under the consideration. Some of the linear preserver problems are motivated by applications (system theory, quantum mechanics, etc.).

### 22.1 Basic Concepts

---

#### Definitions:

Let  $\mathcal{V}$  be a linear subspace of  $F^{m \times n}$ . Let  $f$  be a (scalar-valued, vector-valued, or set-valued) function on  $\mathcal{V}$ ,  $\mathcal{M}$  a subset of  $\mathcal{V}$ , and  $\sim$  a relation defined on  $\mathcal{V}$ .

A linear map  $\phi : \mathcal{V} \rightarrow \mathcal{V}$  is called a **linear preserver of function**  $f$  if  $f(\phi(A)) = f(A)$  for every  $A \in \mathcal{V}$ .

A linear map  $\phi : \mathcal{V} \rightarrow \mathcal{V}$  **preserves**  $\mathcal{M}$  if  $\phi(\mathcal{M}) \subseteq \mathcal{M}$ .

The map  $\phi$  **strongly preserves**  $\mathcal{M}$  if  $\phi(\mathcal{M}) = \mathcal{M}$ .

A linear map  $\phi : \mathcal{V} \rightarrow \mathcal{V}$  **preserves the relation**  $\sim$  if  $\phi(A) \sim \phi(B)$  whenever  $A \sim B$ ,  $A, B \in \mathcal{V}$ .

If for every pair  $A, B \in \mathcal{V}$  we have  $\phi(A) \sim \phi(B)$  if and only if  $A \sim B$ , then  $\phi$  **strongly preserves the relation**  $\sim$ .

#### Facts:

1. If linear maps  $\phi : \mathcal{V} \rightarrow \mathcal{V}$  and  $\psi : \mathcal{V} \rightarrow \mathcal{V}$  both preserve  $\mathcal{M}$ , then  $\phi\psi : \mathcal{V} \rightarrow \mathcal{V}$  preserves  $\mathcal{M}$ . Consequently, the set of all linear transformations on  $\mathcal{V}$  preserving  $\mathcal{M}$  is a multiplicative semigroup.
2. The set of all bijective linear transformations strongly preserving  $\mathcal{M}$  is a multiplicative group.
3. [BLL92, p. 41] Let  $\mathcal{M} \subseteq \mathcal{V}$  be an algebraic subset and  $\phi : \mathcal{V} \rightarrow \mathcal{V}$  a bijective linear map satisfying  $\phi(\mathcal{M}) \subseteq \mathcal{M}$ . Then  $\phi$  strongly preserves  $\mathcal{M}$ .

**Examples:**

1. Let  $R \in F^{m \times m}$  and  $S \in F^{n \times n}$ . The linear map  $\phi: F^{m \times n} \rightarrow F^{m \times n}$  defined by  $\phi(A) = RAS$ ,  $A \in F^{m \times n}$ , preserves the set of all matrices of rank at most one. In general, such a map does not preserve this set strongly.
2. If  $R$  and  $S$  in the previous example are invertible, then  $\phi$  is a bijective linear map strongly preserving matrices of rank one. In fact, such a map  $\phi$  strongly preserves matrices of rank  $k$ ,  $k = 1, \dots, \min\{m, n\}$ .
3. If  $m = n$  and  $R, S \in F^{n \times n}$ , then the linear map  $A \mapsto RA^T S$ ,  $A \in F^{n \times n}$ , preserves matrices of rank at most one. If both  $R$  and  $S$  are invertible, then  $\phi$  strongly preserves the set of all matrices of rank  $k$ ,  $1 \leq k \leq n$ .
4. Assume that  $m = n$ . Let  $R \in F^{n \times n}$  be an invertible matrix,  $c$  a nonzero scalar, and  $f: F^{n \times n} \rightarrow F$  a linear functional. Then both maps  $A \mapsto cRAR^{-1} + f(A)I$ ,  $A \in F^{n \times n}$ , and  $A \mapsto cRA^T R^{-1} + f(A)I$ ,  $A \in F^{n \times n}$ , strongly preserve commutativity; that is, if  $\phi: F^{n \times n} \rightarrow F^{n \times n}$  is any of these two maps, then for every pair  $A, B \in F^{n \times n}$  we have  $\phi(A)\phi(B) = \phi(B)\phi(A)$  if and only if  $AB = BA$ .
5. Let  $\|\cdot\|$  be any norm on  $\mathbb{C}^{m \times n}$ . A linear map  $\phi: \mathbb{C}^{m \times n} \rightarrow \mathbb{C}^{m \times n}$  is called an isometry if  $\|\phi(A)\| = \|A\|$ ,  $A \in \mathbb{C}^{m \times n}$ . Thus, isometries are linear preservers of norm functions.
6. Let  $1 \leq k < \min\{m, n\}$ . A matrix  $A \in F^{m \times n}$  is of rank at most  $k$  if the determinant of every  $(k+1) \times (k+1)$  submatrix of  $A$  is zero. Thus, the set of all  $m \times n$  matrices of rank at most  $k$  is an algebraic subset of  $F^{m \times n}$ .
7. The set of all nilpotent  $n \times n$  matrices is an algebraic subset of  $F^{n \times n}$ . More generally, given a polynomial  $p \in F[X]$ , the set of all matrices  $A \in F^{n \times n}$  satisfying  $p(A) = 0$  is an algebraic set. Hence, bijective linear maps on  $F^{n \times n}$  preserving idempotent matrices, nilpotents, involutions, etc. preserve these sets strongly.

## 22.2 Standard Forms

---

**Definitions:**

Let  $\mathcal{V}$  be a linear subspace of  $F^{m \times n}$  and let  $P$  be a preserving property which makes sense for linear maps acting on  $\mathcal{V}$  ( $P$  may be the property of preserving a certain subset of  $\mathcal{V}$  or the property of preserving a certain relation on  $\mathcal{V}$  or the property of preserving a certain function defined on  $\mathcal{V}$ ). A **linear preserver problem** corresponding to the property  $P$  is the problem of characterizing all linear (bijective) maps on  $\mathcal{V}$  satisfying this property. Very often, linear preservers have the standard forms (see the next section). Occasionally, there are interesting exceptional cases especially in low dimensions (see later examples).

Let  $R \in F^{m \times m}$  and  $S \in F^{n \times n}$  be invertible matrices. A map  $\phi: F^{m \times n} \rightarrow F^{m \times n}$  is called an  $(R, S)$ -**standard map** if either  $\phi(A) = RAS$ ,  $A \in F^{m \times n}$ , or  $m = n$  and  $\phi(A) = RA^T S$ ,  $A \in F^{n \times n}$ . In many cases we assume that  $R$  and  $S$  satisfy some additional assumptions.

Let  $R \in F^{n \times n}$  be an invertible matrix,  $c$  a nonzero scalar, and  $f: F^{n \times n} \rightarrow F$  a linear functional. A map  $\phi: F^{n \times n} \rightarrow F^{n \times n}$  is called an  $(R, c, f)$ -**standard map** if either  $\phi(A) = cRAR^{-1} + f(A)I$ ,  $A \in F^{n \times n}$ , or  $\phi(A) = cRA^T R^{-1} + f(A)I$ ,  $A \in F^{n \times n}$ .

When we consider linear preservers on proper subspaces  $\mathcal{V} \subset F^{m \times n}$ , we usually have to modify the notion of standard maps. Let us consider the case when  $\mathcal{V} = \mathcal{T}_n \subset F^{n \times n}$  is the subalgebra of all upper triangular matrices. The **flip map**  $A \mapsto A^f$ ,  $A \in \mathcal{T}_n$ , is defined as the transposition over the antidiagonal; that is,  $A^f = GA^T G$ , where  $G = E_{1n} + E_{2,n-1} + \dots + E_{n1}$  (see Example 1). Standard maps on  $\mathcal{T}_n$  are maps of the form

$$A \mapsto RAS, \quad A \in \mathcal{T}_n,$$

$$A \mapsto RA^f S, \quad A \in \mathcal{T}_n,$$

$$A \mapsto cRAR^{-1} + f(A)I, \quad A \in \mathcal{T}_n,$$

and

$$A \mapsto cRA^fR^{-1} + f(A)I, \quad A \in \mathcal{T}_n,$$

where  $R$  and  $S$  are invertible upper triangular matrices,  $c$  is a nonzero scalar, and  $f$  is a linear functional on  $\mathcal{T}_n$ .

**Facts:**

1. Every  $(R, S)$ -standard map is bijective. It strongly preserves matrices of rank  $k, k = 1, \dots, \min\{m, n\}$ . Every  $(R, c, f)$ -standard map is either bijective, or its kernel is the one-dimensional subspace consisting of all scalar matrices.
2. Let  $U \in \mathbb{C}^{m \times m}$  and  $V \in \mathbb{C}^{n \times n}$  be unitary matrices. Then a  $(U, V)$ -standard map preserves singular values and, hence, all functions of singular values including unitarily invariant norms.
3. Let  $R \in \mathbb{C}^{n \times n}$  be an invertible matrix. Then an  $(R, R^{-1})$ -standard map on  $\mathbb{C}^{n \times n}$  preserves spectrum, idempotents, nilpotents, similarity, zero products, etc.
4. If  $U \in \mathbb{C}^{n \times n}$  is a unitary matrix, then a  $(U, U^*)$ -standard map defined on  $\mathbb{C}^{n \times n}$  strongly preserves the set of all orthogonal idempotents, the set of all normal matrices, numerical range, etc.
5. If  $A, B \in \mathcal{T}_n$ , then  $(AB)^f = B^f A^f$ .

**Examples:**

- 1.

$$\begin{bmatrix} a & b & c & d \\ 0 & e & f & g \\ 0 & 0 & h & i \\ 0 & 0 & 0 & j \end{bmatrix}^f = \begin{bmatrix} j & i & g & d \\ 0 & h & f & c \\ 0 & 0 & e & b \\ 0 & 0 & 0 & a \end{bmatrix}.$$

2. A map  $\phi : \mathbb{C}^{2 \times 2} \rightarrow \mathbb{C}^{2 \times 2}$  given by

$$\phi \left( \begin{bmatrix} a & b \\ c & d \end{bmatrix} \right) = \begin{bmatrix} a & -b \\ c & d \end{bmatrix}$$

is a bijective linear map that strongly preserves commutativity but is not of a standard form. More generally, any bijective linear map  $\phi : \mathbb{C}^{2 \times 2} \rightarrow \mathbb{C}^{2 \times 2}$  satisfying  $\phi(I) = I$  strongly preserves commutativity [Kun99]. In higher dimensions there are no nonstandard bijective linear maps preserving commutativity [BLL92, p. 76].

3. Let  $\mathcal{W} \subset \mathbb{C}^{n \times n}$  be any linear subspace of matrices with the property that  $AB = BA$  for every pair  $A, B \in \mathcal{W}$ . Assume that  $\phi : \mathbb{C}^{n \times n} \rightarrow \mathbb{C}^{n \times n}$  is a linear map whose range is contained in  $\mathcal{W}$ . Then  $\phi$  is a nonstandard map preserving commutativity. If  $n > 1$ , then it does not preserve commutativity strongly. A map  $\phi : \mathbb{C}^{2 \times 2} \rightarrow \mathbb{C}^{2 \times 2}$  defined by

$$\phi \left( \begin{bmatrix} a & b \\ c & d \end{bmatrix} \right) = \begin{bmatrix} a & b \\ -b & a \end{bmatrix}$$

is a concrete example of such map.

4. A map  $\phi : \mathbb{R}^{4 \times 4} \rightarrow \mathbb{R}^{4 \times 4}$  given by

$$\phi \left( \begin{bmatrix} a & b & c & d \\ * & * & * & * \\ * & * & * & * \\ * & * & * & * \end{bmatrix} \right) = \begin{bmatrix} a & b & c & d \\ -b & a & -d & c \\ -c & d & a & -b \\ -d & -c & b & a \end{bmatrix}$$

preserves the real orthogonal group, that is,  $\phi(O)$  is an orthogonal matrix for every orthogonal matrix  $O \in \mathbb{R}^{4 \times 4}$ . Note that the right-hand side of the above equation is the standard matrix representation of the quaternion  $a + bi + cj + dk$ . Similar constructions with matrix representations of complex and Cayley numbers give nonstandard linear preservers of real orthogonal group on  $\mathbb{R}^{2 \times 2}$  and  $\mathbb{R}^{8 \times 8}$ . If  $\phi: \mathbb{R}^{n \times n} \rightarrow \mathbb{R}^{n \times n}$  is a linear preserver of orthogonal group and  $n \notin \{2, 4, 8\}$ , then  $\phi$  is a  $(U, V)$ -standard map with  $U$  and  $V$  being orthogonal matrices [LP01, p. 601].

5. A linear map  $\phi$  acting on  $4 \times 4$  upper triangular matrices given by

$$\begin{bmatrix} a & b & c & d \\ 0 & e & f & g \\ 0 & 0 & h & i \\ 0 & 0 & 0 & j \end{bmatrix} \mapsto \begin{bmatrix} e & f & g & b \\ 0 & j & i & c \\ 0 & 0 & h & d \\ 0 & 0 & 0 & a \end{bmatrix}$$

is a nonstandard bijective linear map strongly preserving the set of invertible matrices. All that is important in this example is that  $A$  and  $\phi(A)$  have the same diagonal entries up to a permutation.

## 22.3 Standard Linear Preserver Problems

### Definitions:

Linear preserver problems ask what is the general form of (bijective) linear maps on matrix spaces having a certain preserving property. When the general form of linear preservers under the consideration is one of the standard forms, we speak of a **standard linear preserver problem**. The following list of some most important standard linear preserver results is far from being complete. Many more results can be found in the survey [BLL92].

### Facts:

- [BLL92, Theorem 2.2], [LT92, Prop. 3] Let  $m, n$  be positive integers and  $\phi: \mathbb{C}^{m \times n} \rightarrow \mathbb{C}^{m \times n}$  a linear map. Assume that one of the following two conditions is satisfied:
  - Let  $k$  be a positive integer,  $k \leq \min\{m, n\}$ , and assume that  $\text{rank } \phi(A) = k$  whenever  $\text{rank } A = k$ .
  - $\phi$  is invertible and  $\text{rank } \phi(A) = \text{rank } \phi(B)$  whenever  $\text{rank } A = \text{rank } B$ .
 Then  $\phi$  is an  $(R, S)$ -standard map for some invertible matrices  $R \in \mathbb{C}^{m \times m}$  and  $S \in \mathbb{C}^{n \times n}$ .
- [BLL92, p. 9] Let  $F$  be a field with more than three elements,  $k$  a positive integer,  $k \leq \min\{m, n\}$ , and  $\phi: F^{m \times n} \rightarrow F^{m \times n}$  an invertible linear map such that  $\text{rank } \phi(A) = k$  whenever  $\text{rank } A = k$ . Then  $\phi$  is an  $(R, S)$ -standard map for some invertible matrices  $R \in F^{m \times m}$  and  $S \in F^{n \times n}$ .
- [BLL92, Theorem 2.6] Let  $\phi: F^{m \times n} \rightarrow F^{p \times q}$  be a linear map such that  $\text{rank } \phi(A) \leq 1$  whenever  $\text{rank } A = 1$ . Then either
  - $\phi(A) = RAS$  for some  $R \in F^{p \times m}$  and some  $S \in F^{n \times q}$  or
  - $\phi(A) = RA^T S$  for some  $R \in F^{p \times n}$  and some  $S \in F^{m \times q}$  or
  - The range of  $\phi$  is contained in the set of all matrices of rank at most one.
- [BLL92, p. 10] Let  $F$  be an infinite field with characteristic  $\neq 2$ ,  $\mathcal{S}_n$  the space of all  $n \times n$  symmetric matrices over  $F$ , and let  $k$  be an integer,  $1 \leq k \leq n$ . If  $\phi: \mathcal{S}_n \rightarrow \mathcal{S}_n$  is an invertible linear rank  $k$  preserver, then  $\phi(A) = cRAR^T$  for every  $A \in \mathcal{S}$ . Here,  $c$  is a nonzero scalar and  $R$  an invertible  $n \times n$  matrix.
- [BLL92, Theorem 2.9] Let  $F$  be a field with characteristic  $\neq 2$ . Assume that  $F$  has more than three elements. Let  $\phi: \mathcal{S}_n \rightarrow \mathcal{S}_m$  be a linear map such that  $\text{rank } \phi(A) \leq 1$  whenever  $\text{rank } A = 1$ . Then either

- (a) There exist an  $m \times n$  matrix  $R$  and a scalar  $c$  such that  $\phi(A) = cRAR^T$  or
  - (b) The range of  $\phi$  is contained in a linear span of some rank one  $m \times m$  symmetric matrix.
6. [BLL92, Theorem 2.7, Theorem 2.8, p. 25] Let  $\phi$  be a real linear map acting on the real linear space  $\mathcal{H}_n$  of all  $n \times n$  Hermitian complex matrices. Let  $\pi, \nu, \delta$  be nonnegative integers with  $\pi + \nu + \delta = n$  and denote by  $G(\pi, \nu, \delta)$  the set of all  $A \in \mathcal{H}_n$  with inertia  $\text{in}(A) = (\pi, \nu, \delta)$ . Assume that one of the following is satisfied:
- $n \geq 3, k < n, \phi$  is invertible, and  $\text{rank } \phi(A) \leq k$  whenever  $\text{rank } A = k$ .
  - $n \geq 2$ , the range of  $\phi$  is not one-dimensional, and  $\text{rank } \phi(A) = 1$  whenever  $\text{rank } A = 1$ .
  - The triple  $(\pi, \nu, \delta)$  does not belong to the set  $\{(n, 0, 0), (0, n, 0), (0, 0, n)\}$ ,  $\phi$  is bijective, and  $\phi(G(\pi, \nu, \delta)) \subseteq G(\pi, \nu, \delta)$ .

Then there exist an invertible  $n \times n$  complex matrix  $R$  and a constant  $c \in \{-1, 1\}$  such that either

- (a)  $\phi(A) = cRAR^*$  for every  $A \in \mathcal{H}_n$  or
- (b)  $\phi(A) = cRA^T R^*$  for every  $A \in \mathcal{H}_n$ .

Of course, if the third of the above conditions is satisfied, then the possibility  $c = -1$  can occur only when  $\pi = \nu$ .

7. [BLL92, p. 76] Let  $n \geq 3$  and let  $\phi: F^{n \times n} \rightarrow F^{n \times n}$  be an invertible linear map such that  $\phi(A)\phi(B) = \phi(B)\phi(A)$  whenever  $A$  and  $B$  commute. Then  $\phi$  is an  $(R, c, f)$ -standard map for some invertible  $R \in F^{n \times n}$ , some nonzero scalar  $c$ , and some linear functional  $f: F^{n \times n} \rightarrow F$ .
8. [LP01, Theorem 2.3] Let  $\phi: \mathbb{C}^{n \times n} \rightarrow \mathbb{C}^{n \times n}$  be a linear similarity preserving map. Then either
- (a)  $\phi$  is an  $(R, c, f)$ -standard map or
  - (b)  $\phi(A) = (\text{tr } A)B, A \in \mathbb{C}^{n \times n}$ .

Here,  $B, R \in \mathbb{C}^{n \times n}$  and  $R$  is invertible,  $c$  is a nonzero complex number, and  $f: \mathbb{C}^{n \times n} \rightarrow \mathbb{C}$  is a functional of the form  $f(A) = b \text{tr } A, A \in \mathbb{C}^{n \times n}$ , for some  $b \in \mathbb{C}$ .

9. [BLL92, p. 77] Let  $\phi$  be a real-linear unitary similarity preserving map on  $\mathcal{H}_n$ . Then either
- (a)  $\phi(A) = (\text{tr } A)B, A \in \mathcal{H}_n$  or
  - (b)  $\phi(A) = cUAU^* + b(\text{tr } A)I, A \in \mathcal{H}_n$  or
  - (c)  $\phi(A) = cUA^T U^* + b(\text{tr } A)I, A \in \mathcal{H}_n$ .

Here,  $B$  is a Hermitian matrix,  $U$  is a unitary matrix, and  $b, c$  are real constants.

10. [BLL92, Theorem 4.7.6] Let  $n > 2$  and let  $F$  be an algebraically closed field of characteristic zero. Let  $p$  be a polynomial of degree  $n$  with at least two distinct roots. Let us write  $p$  as  $p(x) = x^k q(x)$  with  $k \geq 0$  and  $q(0) \neq 0$ . Assume that  $\phi: F^{n \times n} \rightarrow F^{n \times n}$  is an invertible linear map preserving the set of all matrices annihilated by  $p$ . Then either
- (a)  $\phi(A) = cRAR^{-1}, A \in F^{n \times n}$  or
  - (b)  $\phi(A) = cRA^T R^{-1}, A \in F^{n \times n}$ .

Here,  $R$  is an invertible matrix and  $c$  is a constant permuting the roots of  $q$ ; that is,  $q(c\lambda) = 0$  for each  $\lambda \in F$  satisfying  $q(\lambda) = 0$ .

11. [BLL92, p. 48] Let  $sI_n \subset F^{n \times n}$  be the linear space of all trace zero matrices and  $\phi: sI_n \rightarrow sI_n$  an invertible linear map preserving the set of all nilpotent matrices. Then there exist an invertible matrix  $R \in F^{n \times n}$  and a nonzero scalar  $c$  such that either
- (a)  $\phi(A) = cRAR^{-1}, A \in sI_n$  or
  - (b)  $\phi(A) = cRA^T R^{-1}, A \in sI_n$ .

When considering linear preservers of nilpotent matrices one should observe first that the linear span of all nilpotent matrices is  $sI_n$  and, therefore, it is natural to confine maps under consideration to this subspace of codimension one.

12. [GLS00, pp. 76, 78] Let  $F$  be an algebraically closed field of characteristic 0,  $m, n$  positive integers, and  $\phi: F^{n \times n} \rightarrow F^{m \times m}$  a linear transformation. If  $\phi$  is nonzero and maps idempotent matrices to idempotent matrices, then  $m \geq n$  and there exist an invertible matrix  $R \in F^{m \times m}$  and nonnegative integers  $k_1, k_2$  such that  $1 \leq k_1 + k_2$ ,  $(k_1 + k_2)n \leq m$  and

$$\phi(A) = R(A \oplus \dots \oplus A \oplus A^T \oplus \dots \oplus A^T \oplus 0)R^{-1}$$

for every  $A \in F^{n \times n}$ . In the above block diagonal direct sum the matrix  $A$  appears  $k_1$  times,  $A^T$  appears  $k_2$  times, and 0 is the zero matrix of the appropriate size (possibly absent). If  $p \in F[X]$  is a polynomial of degree  $> 1$  with simple zeros (each zero has multiplicity one),  $\phi$  is unital and maps every  $A \in F^{n \times n}$  satisfying  $p(A) = 0$  into some  $m \times m$  matrix annihilated by  $p$ , then  $\phi$  is of the above described form with  $(k_1 + k_2)n = m$ .

13. [BLL92, Theorem 4.6.2] Let  $\phi: \mathbb{C}^{n \times n} \rightarrow \mathbb{C}^{n \times n}$  be a linear map preserving the unitary group. Then  $\phi$  is a  $(U, V)$ -standard map for some unitary matrices  $U, V \in \mathbb{C}^{n \times n}$ .
14. [KH92] Let  $\phi: \mathbb{C}^{n \times n} \rightarrow \mathbb{C}^{n \times n}$  be a linear map preserving normal matrices. Then either
- $\phi(A) = cUAU^* + f(A)I$ ,  $A \in \mathbb{C}^{n \times n}$  or
  - $\phi(A) = cUA^tU^* + f(A)I$ ,  $A \in \mathbb{C}^{n \times n}$  or
  - the range of  $\phi$  is contained in the set of normal matrices.

Here,  $U$  is a unitary matrix,  $c$  is a nonzero scalar, and  $f$  is a linear functional on  $\mathbb{C}^{n \times n}$ .

15. [LP01, p. 595] Let  $\|\cdot\|$  be a unitarily invariant norm on  $\mathbb{C}^{m \times n}$  that is not a multiple of the Frobenius norm defined by  $\|A\| = \sqrt{\text{tr}(AA^*)}$ . The group of linear preservers of  $\|\cdot\|$  on  $\mathbb{C}^{m \times n}$  is the group of all  $(U, V)$ -standard maps, where  $U \in \mathbb{C}^{m \times m}$  and  $V \in \mathbb{C}^{n \times n}$  are unitary matrices. Of course, if  $\|\cdot\|$  is a multiple of the Frobenius norm, then the group of linear preservers of  $\|\cdot\|$  on  $\mathbb{C}^{m \times n}$  is the group of all unitary operators, i.e., those linear operators  $\phi: \mathbb{C}^{m \times n} \rightarrow \mathbb{C}^{m \times n}$  that preserve the usual inner product  $\langle A, B \rangle = \text{tr}(AB^*)$  on  $\mathbb{C}^{m \times n}$ .
16. [BLL92, p. 63–64] Let  $\phi: \mathbb{C}^{n \times n} \rightarrow \mathbb{C}^{n \times n}$  be a linear map preserving the numerical radius. Then either
- $\phi(A) = cUAU^*$ ,  $A \in \mathbb{C}^{n \times n}$  or
  - $\phi(A) = cUA^tU^*$ ,  $A \in \mathbb{C}^{n \times n}$ .

Here,  $U$  is a unitary matrix and  $c$  a complex constant with  $|c| = 1$ .

17. [BLL92, Theorem 4.3.1] Let  $n > 2$  and let  $\phi: F^{n \times n} \rightarrow F^{n \times n}$  be a linear map preserving the permanent. Then  $\phi$  is an  $(R, S)$ -standard map, where  $R$  and  $S$  are each a product of a diagonal and a permutation matrix, and the product of the two diagonal matrices has determinant one.
18. [CL98] Let  $\phi: \mathcal{T}_n \rightarrow \mathcal{T}_n$  be a linear rank one preserver. Then either

- (a) The range of  $\phi$  is the space of all matrices of the form

$$\begin{bmatrix} * & * & \dots & * \\ 0 & 0 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 0 \end{bmatrix}$$

or

- (b) The range of  $\phi$  is the space of all matrices of the form

$$\begin{bmatrix} 0 & 0 & \dots & 0 & * \\ 0 & 0 & \dots & 0 & * \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & 0 & * \end{bmatrix}$$

or

- (c)  $\phi(A) = RAS$  for some invertible  $R, S \in \mathcal{T}_n$  or
- (d)  $\phi(A) = RA^f S$  for some invertible  $R, S \in \mathcal{T}_n$ .

**Examples:**

1. Let  $n \geq 2$ . Then the linear map  $\phi : \mathcal{T}_n \rightarrow \mathcal{T}_n$  defined by

$$\phi \left( \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ 0 & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & a_{nn} \end{bmatrix} \right) = \begin{bmatrix} a_{11} + a_{22} + \dots + a_{nn} & a_{12} + a_{23} + \dots + a_{n-1,n} & \dots & a_{1n} \\ 0 & 0 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 0 \end{bmatrix}$$

is an example of a singular preserver of rank one.

2. The most important example of a nonstandard linear preserver problem is the problem of characterizing linear maps on  $n \times n$  real or complex matrices preserving the set of positive semidefinite matrices. Let  $R_1, \dots, R_r, S_1, \dots, S_k$  be  $n \times n$  matrices. Then the linear map  $\phi$  given by  $\phi(A) = R_1 A R_1^* + \dots + R_r A R_r^* + S_1 A^T S_1^* + \dots + S_k A^T S_k^*$  is a linear preserver of positive semidefinite matrices. Such a map is called decomposable. In general it cannot be reduced to a single congruence or a single congruence composed with the transposition. Moreover, there exist linear maps on the space of  $n \times n$  matrices preserving positive semidefinite matrices that are not decomposable. There is no general structural result for such maps.

## 22.4 Additive, Multiplicative, and Nonlinear Preservers

---

**Definitions:**

A map  $\phi : F^{m \times n} \rightarrow F^{m \times n}$  is **additive** if  $\phi(A + B) = \phi(A) + \phi(B)$ ,  $A, B \in F^{m \times n}$ . An additive map  $\phi : F^{m \times n} \rightarrow F^{m \times n}$  having a certain preserving property is called an **additive preserver**.

A map  $\phi : F^{n \times n} \rightarrow F^{n \times n}$  is **multiplicative** if  $\phi(AB) = \phi(A)\phi(B)$ ,  $A, B \in F^{n \times n}$ . A multiplicative map  $\phi : F^{n \times n} \rightarrow F^{n \times n}$  having a certain preserving property is called a **multiplicative preserver**.

Two matrices  $A, B \in F^{m \times n}$  are said to be **adjacent** if  $\text{rank}(A - B) = 1$ .

A map  $\phi : F^{n \times n} \rightarrow F^{n \times n}$  is called a **local similarity** if for every  $A \in F^{n \times n}$  there exists an invertible  $R_A \in F^{n \times n}$  such that  $\phi(A) = R_A A R_A^{-1}$ .

Let  $f : F \rightarrow F$  be an automorphism of the field  $F$ . A map  $\phi : F^{n \times n} \rightarrow F^{n \times n}$  defined by  $\phi([a_{ij}]) = [f(a_{ij})]$  is called a **ring automorphism of  $F^{n \times n}$  induced by  $f$** .

**Facts:**

1. [BS00] Let  $n \geq 2$  and assume that  $\phi : F^{n \times n} \rightarrow F^{n \times n}$  is a surjective additive map preserving rank one matrices. Then there exist a pair of invertible matrices  $R, S \in F^{n \times n}$  and an automorphism  $f$  of the field  $F$  such that  $\phi$  is a composition of an  $(R, S)$ -standard map and a ring automorphism of  $F^{n \times n}$  induced by  $f$ .
2. [GLR03] Let  $SL(n, \mathbb{C})$  denote the group of all  $n \times n$  complex matrices  $A$  such that  $\det A = 1$ . A multiplicative map  $\phi : SL(n, \mathbb{C}) \rightarrow \mathbb{C}^{n \times n}$  satisfies  $\rho(\phi(A)) = \rho(A)$  for every  $A \in SL(n, \mathbb{C})$  if and only if there exists  $S \in SL(n, \mathbb{C})$  such that either

- (a)  $\phi(A) = SAS^{-1}$ ,  $A \in SL(n, \mathbb{C})$  or  
 (b)  $\phi(A) = S\overline{A}S^{-1}$ ,  $A \in SL(n, \mathbb{C})$ .

Here,  $\overline{A}$  denotes the matrix obtained from  $A$  by applying the complex conjugation entrywise.

3. [PS98] Let  $n \geq 3$  and let  $\phi: \mathbb{C}^{n \times n} \rightarrow \mathbb{C}^{n \times n}$  be a continuous mapping. Then  $\phi$  preserves spectrum, commutativity, and rank one matrices (no linearity, additivity, or multiplicativity is assumed) if and only if there exists an invertible matrix  $R \in \mathbb{C}^{n \times n}$  such that  $\phi$  is an  $(R, R^{-1})$ -standard map.
4. [BR00] Let  $\phi: \mathbb{C}^{n \times n} \rightarrow \mathbb{C}^{n \times n}$  be a spectrum preserving  $C^1$ -diffeomorphism (again, we do not assume that  $\phi$  is additive or multiplicative). Then  $\phi$  is a local similarity.
5. [HHW04] Let  $n \geq 2$ . Then  $\phi: \mathcal{H}_n \rightarrow \mathcal{H}_n$  is a bijective map such that  $\phi(A)$  and  $\phi(B)$  are adjacent for every adjacent pair  $A, B \in \mathcal{H}_n$  if and only if there exist a nonzero real number  $c$ , an invertible  $R \in \mathbb{C}^{n \times n}$ , and  $S \in \mathcal{H}_n$  such that either
- (a)  $\phi(A) = cRAR^* + S$ ,  $A \in \mathcal{H}_n$  or  
 (b)  $\phi(A) = cR\overline{A}R^* + S$ ,  $A \in \mathcal{H}_n$ .
6. [Mol01] Let  $n \geq 2$  be an integer and  $\phi: \mathcal{H}_n \rightarrow \mathcal{H}_n$  a bijective map such that  $\phi(A) \leq \phi(B)$  if and only if  $A \leq B$ ,  $A, B \in \mathcal{H}_n$  (here,  $A \leq B$  if and only if  $B - A$  is a positive semidefinite matrix). Then there exist an invertible  $R \in \mathbb{C}^{n \times n}$  and  $S \in \mathcal{H}_n$  such that either
- (a)  $\phi(A) = RAR^* + S$ ,  $A \in \mathcal{H}_n$  or  
 (b)  $\phi(A) = R\overline{A}R^* + S$ ,  $A \in \mathcal{H}_n$ .

This result has an infinite-dimensional analog important in quantum mechanics. In the language of quantum mechanics, the relation  $A \leq B$  means that the expected value of the bounded observable  $A$  in any state is less than or equal to the expected value of  $B$  in the same state.

### Examples:

- We define a mapping  $\phi: \mathbb{C}^{n \times n} \rightarrow \mathbb{C}^{n \times n}$  in the following way. For a diagonal matrix  $A$  with distinct diagonal entries, we define  $\phi(A)$  to be the diagonal matrix obtained from  $A$  by interchanging the first two diagonal elements. Otherwise, let  $\phi(A)$  be equal to  $A$ . Clearly,  $\phi$  is a bijective mapping preserving spectrum, rank, and commutativity in both directions. This shows that the continuity assumption is indispensable in Fact 3 above.
- Let  $\phi: \mathbb{C}^{n \times n} \rightarrow \mathbb{C}^{n \times n}$  be a map defined by  $\phi(0) = E_{12}$ ,  $\phi(E_{12}) = 0$ , and  $\phi(A) = A$  for all  $A \in \mathbb{C}^{n \times n} \setminus \{0, E_{12}\}$ . Then  $\phi$  is a bijective spectrum preserving map that is not a local similarity. More generally, we can decompose  $\mathbb{C}^{n \times n}$  into the disjoint union of the classes of matrices having the same spectrum and then any bijection leaving each of these classes invariant preserves spectrum. Thus, the assumption on differentiability is essential in Fact 4 above.

23.1	Certain Integral Domains .....	23-1
23.2	Equivalence of Matrices .....	23-4
23.3	Linear Equations over Bezout Domains .....	23-8
23.4	Strict Equivalence of Pencils .....	23-9
	References .....	23-10

In this chapter, we present some results on matrices over integral domains, which extend the well-known results for matrices over the fields discussed in Chapter 1 of this book. The general theory of linear algebra over commutative rings is extensively studied in the book [McD84]. It is mostly intended for readers with a thorough training in ring theory. The aim of this chapter is to give a brief survey of notions and facts about matrices over classical domains that come up in applications. Namely over the ring of integers, the ring of polynomials over the field, the ring of analytic functions in one variable on an open connected set, and germs of analytic functions in one variable at the origin. The last section of this chapter is devoted to the notion of strict equivalence of pencils.

Most of the results in this chapter are well known to the experts. A few new results are taken from the book in progress [Frixx], which are mostly contained in the preprint [Fri81].

### 23.1 Certain Integral Domains

---

#### Definitions:

A commutative ring without zero divisors and containing identity 1 is an **integral domain** and denoted by  $\mathbb{D}$ .

The **quotient field**  $F$  of a given integral domain  $\mathbb{D}$  is formed by the set of equivalence classes of all quotients  $\frac{a}{b}, b \neq 0$ , where  $\frac{a}{b} \equiv \frac{c}{d}$  if and only if  $ad = bc$ , such that

$$\frac{a}{b} + \frac{c}{d} = \frac{ad + bc}{bd}, \quad \frac{a}{b} \frac{c}{d} = \frac{ac}{bd}, \quad b, d \neq 0.$$

For  $\mathbf{x} = [x_1, \dots, x_n]^T \in \mathbb{D}^n, \alpha = [\alpha_1, \dots, \alpha_n]^T \in \mathbb{Z}_+^n$  we define  $\mathbf{x}^\alpha = x_1^{\alpha_1} \cdots x_n^{\alpha_n}$  and  $|\alpha| = \sum_{i=1}^n |\alpha_i|$ .

$\mathbb{D}[\mathbf{x}] = \mathbb{D}[x_1, \dots, x_n]$  is the ring of all **polynomials**  $p(\mathbf{x}) = p(x_1, \dots, x_n)$  in  $n$  variables with coefficients in  $\mathbb{D}$ :

$$p(\mathbf{x}) = \sum_{|\alpha| \leq m} a_\alpha \mathbf{x}^\alpha.$$

The **total degree**, or simply the **degree** of  $p(x) \neq 0$ , denoted by  $\deg p$ , is the maximum  $m \in \mathbb{Z}_+$  such that there exists  $a_\alpha \neq 0$  such that  $|\alpha| = m$ . ( $\deg 0 = -\infty$ .)

A polynomial  $p$  is **homogeneous** if  $a_\alpha = 0$  for all  $|\alpha| < \deg p$ .

A polynomial  $p(x) = \sum_{i=0}^n a_i x^i \in \mathbb{D}[x]$  is **monic** if  $a_n = 1$ .

$F(x)$  denotes the quotient field of  $F[x]$ , and is the **field of rational functions** over  $F$  in  $n$  variables.

Let  $\Omega \subset \mathbb{C}^n$  be a nonempty path-connected set. Then  $H(\Omega)$  denotes the ring of analytic functions  $f(z)$ , such that for each  $\zeta \in \Omega$  there exists an open neighborhood  $O(\zeta, f)$  of  $\zeta$  such that  $f$  is analytic on  $O(\zeta, f)$ . The addition and the product of functions are given by the standard identities:  $(f + g)(\zeta) = f(\zeta) + g(\zeta)$ ,  $(fg)(\zeta) = f(\zeta)g(\zeta)$ . If  $\Omega$  is an open set, we assume that  $f$  is defined only on  $\Omega$ . If  $\Omega$  consists of one point  $\zeta$ , then  $H_\zeta$  stands for  $H(\{\zeta\})$ .

Denote by  $\mathcal{M}(\Omega), \mathcal{M}_\zeta$  the quotient fields of  $H(\Omega), H_\zeta$  respectively.

For  $a, d \in \mathbb{D}$ ,  $d$  **divides**  $a$  (or  $d$  is a **divisor** of  $a$ ), denoted by  $d|a$ , if  $a = db$  for some  $b \in \mathbb{D}$ .

$a \in \mathbb{D}$  is **unit** if  $a|1$ .

$a, b \in \mathbb{D}$  are **associates**, denoted by  $a \equiv b$ , if  $a|b$  and  $b|a$ . Denote  $\{\{a\}\} = \{b \in \mathbb{D} : b \equiv a\}$ .

The associates of  $a \in \mathbb{D}$  and the units are called **improper** divisors of  $a$ .

$a \in \mathbb{D}$  is **irreducible** if it is not a unit and every divisor of  $a$  is improper.

A nonzero, nonunit element  $p \in \mathbb{D}$  is **prime** if for any  $a, b \in \mathbb{D}$ ,  $p|ab$  implies  $p|a$  or  $p|b$ .

Let  $a_1, \dots, a_n \in \mathbb{D}$ . Assume first that not all of  $a_1, \dots, a_n$  are equal to zero. An element  $d \in \mathbb{D}$  is a **greatest common divisor** (g.c.d) of  $a_1, \dots, a_n$  if  $d|a_i$  for  $i = 1, \dots, n$ , and for any  $d'$  such that  $d'|a_i, i = 1, \dots, n$ ,  $d'|d$ . Denote by  $(a_1, \dots, a_n)$  any g.c.d. of  $a_1, \dots, a_n$ . Then  $\{\{(a_1, \dots, a_n)\}\}$  is the equivalence class of all g.c.d. of  $a_1, \dots, a_n$ . For  $a_1 = \dots = a_n = 0$ , we define 0 to be the g.c.d. of  $a_1, \dots, a_n$ , i.e.  $(a_1, \dots, a_n) = 0$ .

$a_1, \dots, a_n \in \mathbb{D}$  are **coprime** if  $\{\{(a_1, \dots, a_n)\}\} = \{\{1\}\}$ .

$I \subseteq \mathbb{D}$  is an **ideal** if for any  $a, b \in I$  and  $p, q \in \mathbb{D}$  the element  $pa + qb$  belongs to  $I$ .

An ideal  $I \neq \mathbb{D}$  is **prime** if  $ab \in I$  implies that either  $a$  or  $b$  is in  $I$ .

An ideal  $I \neq \mathbb{D}$  is **maximal** if the only ideals that contain  $I$  are  $I$  and  $\mathbb{D}$ .

An ideal  $I$  is **finitely generated** if there exists  $k$  elements (**generators**)  $p_1, \dots, p_k \in I$  such that any  $i \in I$  is of the form  $i = a_1 p_1 + \dots + a_k p_k$  for some  $a_1, \dots, a_k \in \mathbb{D}$ .

An ideal is **principal** ideal if it is generated by one element  $p$ .

$\mathbb{D}$  is a **greatest common divisor domain** (GCDD), denoted by  $\mathbb{D}_g$ , if any two elements in  $\mathbb{D}$  have a g.c.d.

$\mathbb{D}$  is a **unique factorization domain** (UFD), denoted by  $\mathbb{D}_u$ , if any nonzero, nonunit element  $a$  can be factored as a product of irreducible elements  $a = p_1 \cdots p_r$ , and this factorization is unique within order and unit factors.

$\mathbb{D}$  is a **principal ideal domain** (PID), denoted  $\mathbb{D}_p$ , if any ideal of  $\mathbb{D}$  is principal.

$\mathbb{D}$  is a **Euclidean domain** (ED), denoted  $\mathbb{D}_e$ , if there exists a function  $d : \mathbb{D} \setminus \{0\} \rightarrow \mathbb{Z}_+$  such that:

$$\text{for all } a, b \in \mathbb{D}, ab \neq 0, \quad d(a) \leq d(ab);$$

$$\text{for any } a, b \in \mathbb{D}, ab \neq 0, \text{ there exists } t, r \in \mathbb{D} \text{ such that}$$

$$a = tb + r, \text{ where either } r = 0 \text{ or } d(r) < d(b).$$

It is convenient to define  $d(0) = \infty$ . Let  $a_1, a_2 \in \mathbb{D}_e$  and assume that  $\infty > d(a_1) \geq d(a_2)$ . **Euclid's algorithm** consists of a sequence  $a_1, \dots, a_{k+1}$ , where  $(a_1 \dots a_k) \neq 0$ , which is defined recursively as follows:

$$a_i = t_i a_{i+1} + a_{i+2}, \quad a_{i+2} = 0 \text{ or } d(a_{i+2}) < d(a_{i+1}) \quad \text{for } i = 1, \dots, k-1.$$

[Hel43], [Kap49] A GCDD  $\mathbb{D}$  is an **elementary divisor domain** (EDD), denoted by  $\mathbb{D}_{ed}$ , if for any three elements  $a, b, c \in \mathbb{D}$  there exists  $p, q, x, y \in \mathbb{D}$  such that  $(a, b, c) = (px)a + (py)b + (qy)c$ .

A GCDD  $\mathbb{D}$  is a **Bezout domain** (BD), denoted by  $\mathbb{D}_b$ , if for any two elements  $a, b \in \mathbb{D}$   $(a, b) = pa + qb$ , for some  $p, q \in \mathbb{D}$ .

$p(x) = \sum_{i=0}^m a_i x^{m-i} \in \mathbb{Z}[x], a_0 \neq 0, m \geq 1$  is **primitive** if 1 is a g.c.d. of  $a_0, \dots, a_m$ .

For  $m \in \mathbb{N}$ , the set of integers modulo  $m$  is denoted by  $\mathbb{Z}_m$ .

**Facts:**

Most of the facts about domains can be found in [ZS58] and [DF04]. More special results and references on the elementary divisor domains and rings are in [McD84]. The standard results on the domains of analytic functions can be found in [GR65]. More special results on analytic functions in one complex variable are in [Rud74].

1. Any integral domain satisfies *cancellation laws*: if  $ab = ac$  or  $ba = ca$  and  $a \neq 0$ , then  $b = c$ .
2. An integral domain such that any nonzero element is unit is a field  $F$ , and any field is an integral domain in which any nonzero element is unit.
3. A finite integral domain is a field.
4.  $\mathbb{D}[\mathbf{x}]$  is an integral domain.
5.  $H(\Omega)$  is an integral domain.
6. Any prime element in  $\mathbb{D}$  is irreducible.
7. In a UFD, any irreducible element is prime. This is not true in all integral domains.
8. Let  $\mathbb{D}$  be a UFD. Then  $\mathbb{D}[x]$  is a UFD. Hence,  $\mathbb{D}[\mathbf{x}]$  is a UFD.
9. Let  $a_1, a_2 \in \mathbb{D}_e$  and assume that  $\infty > d(a_1) \geq d(a_2)$ . Then Euclid's algorithm terminates in a finite number of steps, i.e., there exists  $k \geq 3$  such that  $a_1 \neq 0, \dots, a_k \neq 0$  and  $a_{k+1} = 0$ . Hence,  $a_k = (a_1, a_2)$ .
10. An ED is a PID.
11. A PID is an EDD.
12. A PID is a UFD.
13. An EDD is a BD.
14. A BD is a GCDD.
15. A UFD is a GCDD.
16. The converses of Facts 10, 11, 12, 14, 15 are false (see Facts 28, 27, 21, 22).
17. [DF04, Chap. 8] An integral domain that is both a BD and a UFD is a PID.
18. An integral domain is a Bezout domain if and only if any finitely generated ideal is principal.
19.  $\mathbb{Z}$  is an ED with  $d(a) = |a|$ .
20. Let  $p, q \in \mathbb{Z}[x]$  be primitive polynomials. Then  $pq$  is primitive.
21.  $F[x]$  is an ED with  $d(p) =$  the degree of a nonzero polynomial. Hence,  $F[x_1, \dots, x_n]$  is a UFD. But  $F[x_1, \dots, x_n]$  is not a PID for  $n \geq 2$ .
22.  $\mathbb{Z}[x_1, \dots, x_m]$ ,  $F[x_1, \dots, x_n]$ , and  $H(\Omega)$  (for a connected set  $\Omega \subset \mathbb{C}^n$ ) are GCDDs, but for  $m \geq 1$  and  $n \geq 2$  these domains are not BDs.
23. [Frixx] (See Example 17 below.) Let  $\Omega \subset \mathbb{C}$  be an open connected set. Then for  $a, b \in H(\Omega)$  there exists  $p \in H(\Omega)$  such that  $(a, b) = pa + b$ .
24.  $H_\zeta$ ,  $\zeta \in \mathbb{C}$ , is a UFD.
25. If  $\Omega \subset \mathbb{C}^n$  is a connected open set, then  $H(\Omega)$  is not a UFD. (For  $n = 1$  there is no prime factorization of an analytic function  $f \in H(\Omega)$  with an infinite countable number of zeros.)
26. Let  $\Omega \subset \mathbb{C}$  be a compact connected set. Then  $H(\Omega)$  is an ED. Here,  $d(a)$  is the number of zeros of a nonzero function  $a \in H(\Omega)$  counted with their multiplicities.
27. [Frixx] If  $\Omega \subset \mathbb{C}$  is an open connected set, then  $H(\Omega)$  is an EDD. (See Example 17.) As  $H(\Omega)$  is not a UFD, it follows that  $H(\Omega)$  is not a PID. (Contrary to [McD84, Exc. II.E.10 (b), p. 144].)
28. [DF04, Chap. 8]  $\mathbb{Z}[(1 + \sqrt{-19})/2]$  is a PID that is not an ED.

**Examples:**

1.  $\{1, -1\}$  is the set of units in  $\mathbb{Z}$ . A g.c.d. of  $a_1, \dots, a_k \in \mathbb{Z}$  is **uniquely normalized** by the condition  $(a_1, \dots, a_k) \geq 0$ .
2. A positive integer  $p \in \mathbb{Z}$  is irreducible if and only if  $p$  is prime.
3.  $\mathbb{Z}_m$  is an integral domain and, hence, a field with  $m$  elements if and only if  $p$  is a prime.
4.  $\mathbb{Z} \supset I$  is a prime ideal if and only if all elements of  $I$  are divisible by some prime  $p$ .

5.  $\{1, -1\}$  is the set of units in  $\mathbb{Z}[x]$ . A g.c.d. of  $p_1, \dots, p_k \in \mathbb{Z}[x]$ , is **uniquely normalized** by the condition  $(p_1, \dots, p_k) = \sum_{i=0}^m a_i x^{m-i}$  and  $a_0 > 0$ .
6. Any prime element in  $p(x) \in \mathbb{Z}[x]$ ,  $\deg p \geq 1$ , is a primitive polynomial.
7. Let  $p(x) = 2x+3, q(x) = 5x-3 \in \mathbb{Z}[x]$ . Clearly  $p, q$  are primitive polynomials and  $(p(x), q(x)) = 1$ . However, 1 cannot be expressed as  $1 = a(x)p(x) + b(x)q(x)$ , where  $a(x), b(x) \in \mathbb{Z}[x]$ . Indeed, if this was possible, then  $1 = a(0)p(0) + b(0)q(0) = 3(a(0) - b(0))$ , which is impossible for  $a(0), b(0) \in \mathbb{Z}$ . Hence,  $\mathbb{Z}[x]$  is not BD.
8. The field of quotients of  $\mathbb{Z}$  is the field of rational numbers  $\mathbb{Q}$ .
9. Let  $p(x), q(x) \in \mathbb{Z}[x]$  be two nonzero polynomials. Let  $(p(x), q(x))$  be the g.c.d. of  $p, q$  in  $\mathbb{Z}[x]$ . Use the fact that  $p(x), q(x) \in \mathbb{Q}[x]$  to deduce that there exists a positive integer  $m$  and  $a(x), b(x) \in \mathbb{Z}[x]$  such that  $a(x)p(x) + b(x)q(x) = m(p(x), q(x))$ . Furthermore, if  $c(x)p(x) + d(x)q(x) = l(p(x), q(x))$  for some  $c(x), d(x) \in \mathbb{Z}[x]$  and  $0 \neq l \in \mathbb{Z}$ , then  $m|l$ .
10. The set of real numbers  $\mathbb{R}$  and the set of complex numbers  $\mathbb{C}$  are fields.
11. A g.c.d. of  $a_1, \dots, a_k \in F[x]$  is **uniquely normalized** by the condition  $(p_1, \dots, p_k)$  is a monic polynomial.
12. A linear polynomial in  $\mathbb{D}[x]$  is irreducible.
13. Let  $\Omega \subset \mathbb{C}$  be a connected set. Then each irreducible element of  $H(\Omega)$  is an associate of  $z - \zeta$  for some  $\zeta \in \Omega$ .
14. For  $\zeta \in \mathbb{C} \setminus H_\zeta$ , every irreducible element is of the form  $a(z - \zeta)$  for some  $0 \neq a \in \mathbb{C}$ . A g.c.d. of  $a_1, \dots, a_k \in H_\zeta$  is **uniquely normalized** by the condition  $(a_1, \dots, a_k) = (z - \zeta)^m$  for some nonnegative integer  $m$ .
15. In  $H(\Omega)$ , the set of functions which vanishes on a prescribed set  $U \subseteq \Omega$ , i.e.,

$$I(U) := \{f \in H(\Omega) : f(\zeta) = 0, \zeta \in U\},$$

is an ideal.

16. Let  $\Omega$  be an open connected set in  $\mathbb{C}$ . [Rud74, Theorems 15.11, 15.13] implies the following:
  - $I(U) \neq \{0\}$  if and only if  $U$  is a countable set, with no accumulation points in  $\Omega$ .
  - Let  $U$  be a countable subset of  $\Omega$  with no accumulation points in  $\Omega$ . Assume that for each  $\zeta \in U$  one is given a nonnegative integer  $m(\zeta)$  and  $m(\zeta) + 1$  complex numbers  $w_{0,\zeta}, \dots, w_{m(\zeta),\zeta}$ . Then there exists  $f \in H(\Omega)$  such that  $f^{(n)}(\zeta) = n!w_{n,\zeta}$ ,  $n = 0, \dots, m(\zeta)$ , for all  $\zeta \in U$ . Furthermore, if all  $w_{n,\zeta} = 0$ , then there exists  $g \in H(\Omega)$  such that all zeros of  $g$  are in  $U$  and  $g$  has a zero of order  $m(\zeta) + 1$  at each  $\zeta \in U$ .
  - Let  $a, b \in H(\Omega), ab \neq 0$ . Then there exists  $f \in H(\Omega)$  such that  $a = cf, b = df$ , where  $c, d \in H(\Omega)$  and  $c, d$  do not have a common zero in  $\Omega$ .
  - Let  $c, d \in H(\Omega)$  and assume that  $c, d$  do not have a common zero in  $\Omega$ . Let  $U$  be the zero set of  $c$  in  $\Omega$ , and denote by  $m(\zeta) \geq 1$  the multiplicity of the zero  $\zeta \in U$  of  $c$ . Then there exists  $g \in H(\Omega)$  such that  $(e^g)^{(n)}(\zeta) = d^{(n)}(\zeta)$  for  $n = 0, \dots, m(\zeta)$ , for all  $\zeta \in U$ . Hence,  $p = \frac{e^g - d}{c} \in H(\Omega)$  and  $e^g = pc + d$  is a unit in  $H(\Omega)$ .
  - For  $a, b \in H(\Omega)$  there exists  $p \in H(\Omega)$  such  $(a, b) = pa + b$ .
  - For  $a, b, c \in H(\Omega)$  one has  $(a, b, c) = p(a, b) + c = p(xa + b) + c$ . Hence,  $H(\Omega)$  is EDD.
17. Let  $I \subset \mathbb{C}[x, y]$  be the ideal given by given by the condition  $p(0, 0) = 0$ . Then  $I$  is generated by  $x$  and  $y$ , and  $(x, y) = 1$ .  $I$  is not principal and  $\mathbb{C}[x, y]$  is not BD.
18.  $\mathbb{D}[x, y]$  is not BD.
19.  $\mathbb{Z}[\sqrt{-5}]$  is an integral domain that is not a GCDD, since  $2 + 2\sqrt{-5}$  and  $6$  have no greatest common divisor. This can be seen by using the norm  $N(a + b\sqrt{-5}) = a^2 + 5b^2$ .

## 23.2 Equivalence of Matrices

In this section, we introduce matrices over an integral domain. Since any domain  $\mathbb{D}$  can be viewed as a subset of its quotient field  $F$ , the notion of determinant, minor, rank, and adjugate in Chapters 1, 2, and 4 can be applied to these matrices. It is an interesting problem to determine whether one given matrix can

be transformed to another by left multiplication, right multiplication, or multiplication on both sides, using only matrices invertible with the domain. These are equivalence relations and the problem is to characterize left (row) equivalence classes, right (columns) equivalence classes, and equivalence classes in  $\mathbb{D}^{m \times n}$ . For BD, the left equivalence classes are characterized by their Hermite normal form, which are attributed to Hermite. For EDD, the equivalence classes are characterized by their Smith normal form.

**Definitions:**

For a set  $S$ , denote by  $S^{m \times n}$  the set of all  $m \times n$  matrices  $A = [a_{ij}]_{i=1, j=1}^{i=m, j=n}$ , where each  $a_{ij} \in S$ .

For positive integers  $p \leq q$ , denote by  $Q_{p,q}$  the set of all subsets  $\{i_1, \dots, i_p\} \subset \{1, 2, \dots, q\}$  of cardinality  $p$ , where we assume that  $1 \leq i_1 < \dots < i_p \leq q$ .

$U \in \mathbb{D}^{n \times n}$  is  **$\mathbb{D}$ -invertible (unimodular)**, if there exists  $V \in \mathbb{D}^{n \times n}$  such that  $UV = VU = I_n$ .

$\mathbf{GL}(n, \mathbb{D})$  denotes the group of  $\mathbb{D}$ -invertible matrices in  $\mathbb{D}^{n \times n}$ .

Let  $A, B \in \mathbb{D}^{m \times n}$ . Then  $A$  and  $B$  are **column equivalent**, **row equivalent**, and **equivalent** if the following conditions hold respectively:

$$\begin{aligned} B &= AP \quad \text{for some } P \in \mathbf{GL}(n, \mathbb{D}) \quad (A \sim_c B), \\ B &= QA \quad \text{for some } Q \in \mathbf{GL}(m, \mathbb{D}) \quad (A \sim_r B), \\ B &= QAP \quad \text{for some } P \in \mathbf{GL}(n, \mathbb{D}), Q \in \mathbf{GL}(m, \mathbb{D}) \quad (A \sim B). \end{aligned}$$

For  $A \in \mathbb{D}_g^{m \times n}$ , let

$$\begin{aligned} \mu(\alpha, A) &= \text{g.c.d. } \{\det A[\alpha, \theta], \theta \in Q_{k,m}\}, \quad \alpha \in Q_{k,m}, \\ \nu(\beta, A) &= \text{g.c.d. } \{\det A[\phi, \beta], \phi \in Q_{k,m}\}, \quad \beta \in Q_{k,m}, \\ \delta_k(A) &= \text{g.c.d. } \{\det A[\phi, \theta], \phi \in Q_{k,m}, \theta \in Q_{k,n}\}. \end{aligned}$$

$\delta_k(A)$  is the  $k$ -th **determinant invariant** of  $A$ .

For  $A \in \mathbb{D}_g^{m \times n}$ ,

$$\begin{aligned} i_j(A) &= \frac{\delta_j(A)}{\delta_{j-1}(A)}, \quad j = 1, \dots, \text{rank } A, \quad (\delta_0(A) = 1), \\ i_j(A) &= 0 \quad \text{for } \text{rank } A < j \leq \min(m, n), \end{aligned}$$

are called the **invariant factors** of  $A$ .  $i_j(A)$  is a **trivial factor** if  $i_j(A)$  is unit in  $\mathbb{D}_g$ . We adopt the **normalization**  $i_j(A) = 1$  for any trivial factor of  $A$ . For  $\mathbb{D} = \mathbb{Z}, \mathbb{Z}[x], F[x]$ , we adopt the normalizations given in the previous section in the Examples 1, 6, and 12, respectively.

Assume that  $\mathbb{D}[x]$  is a GCDD. Then the invariant factors of  $A \in \mathbb{D}[x]^{m \times n}$  are also called **invariant polynomials**.

$D = [d_{ij}] \in \mathbb{D}^{m \times n}$  is a **diagonal matrix** if  $d_{ij} = 0$  for all  $i \neq j$ . The entries  $d_{11}, \dots, d_{\ell\ell}$ ,  $\ell = \min(m, n)$ , are called the **diagonal entries** of  $D$ .  $D$  is denoted as  $D = \text{diag}(d_{11}, \dots, d_{\ell\ell}) \in \mathbb{D}^{m \times n}$ .

Denote by  $\Pi_n \subset \mathbf{GL}(n, \mathbb{D})$  the group of  $n \times n$  permutation matrices.

An  $\mathbb{D}$ -invertible matrix  $U \in \mathbf{GL}(n, \mathbb{D})$  is **simple** if there exists  $P, Q \in \Pi_n$  such that  $U = P \begin{bmatrix} V & 0 \\ 0 & I_{n-2} \end{bmatrix} Q$ ,

where  $V = \begin{bmatrix} \alpha & \beta \\ \gamma & \delta \end{bmatrix} \in \mathbf{GL}(2, \mathbb{D})$ , i.e.,  $\alpha\delta - \beta\gamma$  is  $\mathbb{D}$ -invertible.

$U$  is **elementary** if  $U$  is of the above form and  $V = \begin{bmatrix} \alpha & 0 \\ \gamma & \delta \end{bmatrix} \in \mathbf{GL}(2, \mathbb{D})$ , i.e.,  $\alpha, \delta$  are invertible.

For  $A \in \mathbb{D}^{m \times n}$ , the following row (column) operations are **elementary row operations**:

- (a) Interchange any two rows (columns) of  $A$ .
- (b) Multiply row (column)  $i$  by an invertible element  $a$ .
- (c) Add to row (column)  $j$   $b$  times row (column)  $i$  ( $i \neq j$ ).

For  $A \in \mathbb{D}^{m \times n}$ , the following row (column) operations are **simple row operations**:

- (d) Replace row (column)  $i$  by  $a$  times row (column)  $i$  plus  $b$  times row (column)  $j$ , and row (column)  $j$  by  $c$  times row (column)  $i$  plus  $d$  times row (column)  $j$ , where  $i \neq j$  and  $ad - bc$  is invertible in  $\mathbb{D}$ .

$B = [b_{ij}] \in \mathbb{D}^{m \times n}$  is in **Hermite normal** form if the following conditions hold. Let  $r = \text{rank } B$ . First, the  $i$ -th row of  $B$  is a nonzero row if and only if  $i \leq r$ . Second, let  $b_{i n_i}$  be the first nonzero entry in the  $i$ -th row for  $i = 1, \dots, r$ . Then  $1 \leq n_1 < n_2 < \dots < n_r \leq n$ .

$B \in \mathbb{D}_g^{m \times n}$  is in **Smith normal** form if  $B$  is a diagonal matrix  $B = \text{diag}(b_1, \dots, b_r, 0, \dots, 0)$ ,  $b_i \neq 0$ , for  $i = 1, \dots, r$  and  $b_{i-1} | b_i$  for  $i = 2, \dots, r$ .

### Facts:

Most of the results of this section can be found in [McD84]. Some special results of this section are given in [Fri81] and [Frixx]. For information about equivalence over fields, see Chapter 1 and Chapter 2.

1. The cardinality of  $Q_{p,q}$  is  $\binom{q}{p}$ .
2. If  $U$  is  $\mathbb{D}$ -invertible then  $\det U$  is a unit in  $\mathbb{D}$ . Conversely, if  $\det U$  is a unit then  $U$  is  $\mathbb{D}$ -invertible, and its inverse  $U^{-1}$  is given by  $U^{-1} = (\det U)^{-1} \text{adj } U$ .
3. For  $A \in \mathbb{D}^{m \times n}$ , the rank of  $A$  is the maximal size of the nonvanishing minor. (The rank of zero matrix is 0.)
4. Column equivalence, row equivalence, and equivalence of matrices are equivalence relations in  $\mathbb{D}^{m \times n}$ .
5. For any  $A, B \in \mathbb{D}^{m \times n}$ , one has  $A \sim_r B \iff A^T \sim_c B^T$ . Hence, it is enough to consider the row equivalence relation.
6. For  $A, B \in \mathbb{D}_g^{m \times n}$ , the Cauchy–Binet formula (Chapter 4) yields

$$\begin{aligned} \mu(\alpha, A) &\equiv \mu(\alpha, B) \quad \text{for all } \alpha \in Q_{k,m} \quad \text{if } A \sim_c B, \\ \nu(\beta, A) &\equiv \nu(\beta, B) \quad \text{for all } \beta \in Q_{k,n} \quad \text{if } A \sim_r B, \\ \delta_k(A) &\equiv \delta_k(B) \quad \text{if } A \sim B, \end{aligned}$$

for  $k = 1, \dots, \min(m, n)$ .

7. Any elementary matrix is a simple matrix, but not conversely.
8. The elementary row and column operations can be carried out by multiplications by  $A$  by suitable elementary matrices from the left and the right, respectively.
9. The simple row and column operations are carried out by multiplications by  $A$  by suitable simple matrices  $U$  from the left and right, respectively.
10. Let  $\mathbb{D}_b$  be a Bezout domain,  $A \in \mathbb{D}_b^{m \times n}$ ,  $\text{rank } A = r$ . Then  $A$  is row equivalent to  $B = [b_{ij}] \in \mathbb{D}_b^{m \times n}$ , in a Hermite normal form, which satisfies the following conditions.

Let  $b_{i n_i}$  be the first nonzero entry in the  $i$ -th row for  $i = 1, \dots, r$ . Then  $1 \leq n_1 < n_2 < \dots < n_r \leq n$  are uniquely determined and the elements  $b_{i n_i}$ ,  $i = 1, \dots, r$  are uniquely determined, up to units, by the conditions

$$\begin{aligned} \nu((n_1, \dots, n_i), A) &= b_{1 n_1} \cdots b_{i n_i}, \quad i = 1, \dots, r, \\ \nu(\alpha, A) &= 0, \quad \alpha \in Q_{i, n_i-1}, \quad i = 1, \dots, r. \end{aligned}$$

The elements  $b_{j n_i}$ ,  $j = 1, \dots, i-1$  are then successively uniquely determined up to the addition of arbitrary multiples of  $b_{i n_i}$ . The remaining elements  $b_{i k}$  are now uniquely determined. The  $\mathbb{D}$ -invertible matrix  $Q$ , such that  $B = QA$ , can be given by a finite product of simple matrices.

If  $b_{i n_i}$  in the Hermite normal form is invertible, we assume the normalization conditions  $b_{i n_i} = 1$  and  $b_{j n_i} = 0$  for  $i < j$ .

11. For Euclidean domains, we assume normalization conditions either  $b_{j n_i} = 0$  or  $d(b_{j n_i}) < d(b_{i n_i})$  for  $j < i$ . Then for any  $A \in \mathbb{D}_e^{m \times n}$ , in a Hermite normal form  $B = QA$ ,  $Q \in \mathbf{GL}_m(\mathbb{D}_e)$   $Q$  is a product of a finite elementary matrices.

12.  $U \in \mathbf{GL}(n, \mathbb{D}_e)$  is a finite product of elementary  $\mathbb{D}$ -invertible matrices.
13. For  $\mathbb{Z}$ , we assume the normalization  $b_{i_{n_i}} \geq 1$  and  $0 \leq b_{j_{n_i}} < b_{i_{n_i}}$  for  $j < i$ . For  $F[x]$ , we assume that  $b_{i_{n_i}}$  is a monic polynomial and  $\deg b_{j_{n_i}} < \deg b_{i_{n_i}}$  for  $j < i$ . Then for  $\mathbb{D}_e = \mathbb{Z}, F[x]$ , any  $A \in \mathbb{D}_e^{m \times n}$  has a unique Hermite normal form.
14.  $A, B \in \mathbb{D}_b$  are row equivalent if and only if  $A$  and  $B$  are row equivalent to the same Hermite normal form.
15.  $A \in F^{m \times n}$  can be brought to its unique Hermite normal form, called the *reduced row echelon form* (RREF),

$$b_{i_{n_i}} = 1, \quad b_{j_{n_i}} = 0, \quad j = 1, \dots, i - 1, \quad i = 1, \dots, r = \text{rank } A,$$

by a finite number of elementary row operations. Hence,  $A, B \in F^{m \times n}$  are row equivalent if and only if  $r = \text{rank } A = \text{rank } B$  and they have the same RREF. (See Chapter 1.)

16. For  $A \in \mathbb{D}_g^{m \times n}$  and  $1 \leq p < q \leq \min(m, n)$ ,  $\delta_p(A) | \delta_q(A)$ .
17. For  $A \in \mathbb{D}_g^{m \times n}$ ,  $i_{j-1}(A) | i_j(A)$  for  $j = 2, \dots, \text{rank } A$ .
18. Any  $0 \neq A \in \mathbb{D}_{ed}^{m \times n}$  is equivalent to its Smith normal form  $B = \text{diag}(i_1(A), \dots, i_r(A), 0, \dots, 0)$ , where  $r = \text{rank } A$  and  $i_1(A), \dots, i_r(A)$  are the invariant factors of  $A$ .
19.  $A, B \in \mathbb{D}_{ed}^{m \times n}$  are equivalent if and only if  $A$  and  $B$  have the same rank and the same invariant factors.

**Examples:**

1. Let  $A = \begin{bmatrix} 1 & a \\ 0 & 0 \end{bmatrix}, B = \begin{bmatrix} 1 & b \\ 0 & 0 \end{bmatrix} \in \mathbb{D}^{2 \times 2}$  be two Hermite normal forms. It is straightforward to show that  $A \sim_r B$  if and only if  $a = b$ . Assume that  $\mathbb{D}$  is a BD and let  $a \neq 0$ . Then  $\text{rank } A = 1, \nu((1), A) = 1, \{\nu((2), A)\} = \{a\}, \nu((1, 2), A) = 0$ . If  $\mathbb{D}$  has other units than 1, it follows that  $\nu(\beta, A)$  for all  $\beta \in Q_{k,2}, k = 1, 2$  do not determine the row equivalence class of  $A$ .

2. Let  $A = \begin{bmatrix} a & c \\ b & d \end{bmatrix} \in \mathbb{D}_b^{2 \times 2}$ . Then there exists  $u, v \in \mathbb{D}_b$  such that  $ua + vb = (a, b) = \nu((1), A)$ . If  $(a, b) \neq 0$ , then  $1 = (u, v)$ . If  $a = b = 0$ , choose  $u = 1, v = 0$ . Hence, there exists  $x, y \in \mathbb{D}_b$  such that  $yu - xv = 1$ . Thus  $V = \begin{bmatrix} u & v \\ x & y \end{bmatrix} \in \mathbf{GL}(2, \mathbb{D}_b)$  and  $VA = \begin{bmatrix} (a, b) & c' \\ b' & d' \end{bmatrix}$ . Clearly  $b' = xa + yb = (a, b)e$ . Hence,  $\begin{bmatrix} 1 & 0 \\ -e & 1 \end{bmatrix} VA = \begin{bmatrix} (a, b) & c' \\ 0 & f \end{bmatrix}$  is a Hermite normal form of  $A$ .

This construction is easily extended to obtain a Hermite normal form for any  $A \in \mathbb{D}_b^{m \times n}$ , using simple row operations.

3. Let  $A \in \mathbb{D}_e^{2 \times 2}$  as in the previous example. Assume that  $ab \neq 0$ . Change the two rows of  $A$  if needed to assume that  $d(a) \leq d(b)$ . Let  $a_1 = b, a_2 = a$  and do the first step of Euclid's algorithm:  $a_1 = t_1 a_2 + a_3$ , where  $a_3 = 0$  or  $d(a_3) < d(a_2)$ . Let  $V = \begin{bmatrix} 1 & 0 \\ -t_1 & 1 \end{bmatrix} \in \mathbf{GL}(2, \mathbb{D}_e)$  be an elementary matrix. Then  $A_1 = VA = \begin{bmatrix} a_2 & * \\ a_3 & * \end{bmatrix}$ . If  $a_3 = 0$ , then  $A_1$  has a Hermite normal form. If  $a_3 \neq 0$ , continue as above. Since Euclid's algorithm terminates after a finite number of steps, it follows that  $A$  can be put into Hermite normal form by a finite number of elementary row operations. This statement holds similarly in the case  $ab = 0$ . This construction is easily extended to obtain a Hermite normal form for any  $A \in \mathbb{D}_e^{m \times n}$  using elementary row operations.

4. Assume that  $\mathbb{D}$  is a BD and let  $A = \begin{bmatrix} a & b \\ 0 & c \end{bmatrix} \in \mathbb{D}^{2 \times 2}$ . Note that  $\delta_1(A) = (a, b, c)$ . If  $A$  is equivalent to a Smith normal form then there exists  $V, U \in \mathbf{GL}(2, \mathbb{D})$  such that  $VAU = \begin{bmatrix} (a, b, c) & * \\ * & * \end{bmatrix}$ .

Assume that  $V = \begin{bmatrix} p & q \\ \tilde{q} & \tilde{p} \end{bmatrix}, U = \begin{bmatrix} x & \tilde{y} \\ y & \tilde{x} \end{bmatrix}$ . Then there exist  $p, q, x, y \in \mathbb{D}$  such that  $(px)a + (py)b + (qy)c = (a, b, c)$ . Thus, if each  $A \in \mathbb{D}^{2 \times 2}$  is equivalent to Smith normal form in  $\mathbb{D}^{2 \times 2}$ , then it follows that  $\mathbb{D}$  is an EDD.

Conversely, suppose that  $\mathbb{D}$  is an EDD. Then  $\mathbb{D}$  is also a BD. Let  $A \in \mathbb{D}^{2 \times 2}$ . First, bring  $A$  to an upper triangular Hermite normal form using simple row operations:  $A_1 = WA = \begin{bmatrix} a & b \\ 0 & c \end{bmatrix}, W \in \mathbf{GL}(2, \mathbb{D})$ . Note that  $\delta_1(A) = \delta_1(A_1) = (a, b, c)$ . Since  $\mathbb{D}$  is an EDD, there exist  $p, q, x, y \in \mathbb{D}$  such that  $(px)a + (py)b + (qy)c = (a, b, c)$ . If  $(a, b, c) \neq (0, 0, 0)$ , then  $(p, q) = (x, y) = 1$ . Otherwise  $A = A_1 = 0$  and we are done. Hence, there exist  $\tilde{p}, \tilde{q}, \tilde{x}, \tilde{y}$  such that  $p\tilde{p} - q\tilde{q} = x\tilde{x} - y\tilde{y} = 1$ . Let  $V = \begin{bmatrix} p & q \\ \tilde{q} & \tilde{p} \end{bmatrix}, U = \begin{bmatrix} x & \tilde{y} \\ y & \tilde{x} \end{bmatrix}$ . Thus,  $G = VA_1U = \begin{bmatrix} \delta_1(A) & g_{12} \\ g_{21} & g_{22} \end{bmatrix}$ . Since  $\delta_1(G) = \delta_1(A)$ , we deduce that  $\delta_1(A)$  divides  $g_{12}$  and  $g_{21}$ . Apply appropriate elementary row and column operations to deduce that  $A$  is equivalent to a diagonal matrix  $C = \text{diag}(i_1(A), d_2)$ . As  $\delta_2(C) = i_1(A)d_2 = \delta_2(A)$ , we see that  $C$  has Smith normal form.

These arguments are easily extended to obtain a Smith normal form for any  $A \in \mathbb{D}_{ed}^{m \times n}$ , using simple row and column operations.

5. The converse of Fact 6 is false, as can be seen by considering

$$A = \begin{bmatrix} 2 & 2 \\ x & x \end{bmatrix}, B = \begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix} \in \mathbb{Z}[x]^{2 \times 2}. \mu(\{1\}, A) = \mu(\{1\}, B) = 1, \mu(\{2\}, A) = \mu(\{2\}, B) = 1, \mu(\{1, 2\}, A) = \mu(\{1, 2\}, B) = 0, \text{ but there does not exist a } \mathbb{D}\text{-invertible } P \text{ such that } PA = B.$$

6. Let  $\mathbb{D}$  be an integral domain and assume that  $p(x) = x^m + \sum_{i=1}^m a_i x^{m-i} \in \mathbb{D}[x]$  is a monic polynomial of degree  $m \geq 2$ . Let  $C(p) \in \mathbb{D}^{m \times m}$  be the companion matrix (see Chapter 4). Then  $\det(xI_m - C(p)) = p(x)$ . Assume that  $\mathbb{D}[x]$  is a GCDD. Let  $C(p)(x) = xI_m - C(p) \in \mathbb{D}[x]^{m \times m}$ . By deleting the last column and first row, we obtain a triangular  $(m-1) \times (m-1)$  submatrix with  $-1$ s on the diagonal, so it follows that  $\delta_i(C(p)(x)) = 1$  for  $i = 1, \dots, m-1$ . Hence, the invariant factors of  $C(p)(x)$  are  $i_1(C(p)(x)) = \dots = i_{m-1}(C(p)(x)) = 1$  and  $i_m(C(p)(x)) = p(x)$ . If  $\mathbb{D}$  is a field, then  $C(p)(x)$  is equivalent over  $\mathbb{D}[x]$  to  $\text{diag}(1, \dots, 1, p(x))$ .

## 23.3 Linear Equations over Bezout Domains

### Definitions:

$\mathbf{M}$  is a  $\mathbb{D}$ -**module** if  $\mathbf{M}$  is an additive group with respect to the operation  $+$  and  $\mathbf{M}$  admits a multiplication by a **scalar**  $a \in \mathbb{D}$ , i.e., there exists a mapping  $\mathbb{D} \times \mathbf{M} \rightarrow \mathbf{M}$  which satisfies the standard distribution properties and  $1\mathbf{v} = \mathbf{v}$  for all  $\mathbf{v} \in \mathbf{M}$  (the latter requirement sometimes results in the module being called unital). (For a field  $F$ , a module  $\mathbf{M}$  is a vector space over  $F$ .)

$\mathbf{M}$  is **finitely generated** if there exist  $\mathbf{v}_1, \dots, \mathbf{v}_n \in \mathbf{M}$  so that every  $\mathbf{v} \in \mathbf{M}$  is a **linear combination** of  $\mathbf{v}_1, \dots, \mathbf{v}_n$ , over  $\mathbb{D}$ , i.e.,  $\mathbf{v} = a_1\mathbf{v}_1 + \dots + a_n\mathbf{v}_n$  for some  $a_1, \dots, a_n \in \mathbb{D}$ .  $\mathbf{v}_1, \dots, \mathbf{v}_n$  is a **basis** of  $\mathbf{M}$  if every  $\mathbf{v}$  can be written as a unique linear combination of  $\mathbf{v}_1, \dots, \mathbf{v}_n$ .  $\dim \mathbf{M} = n$  means that  $\mathbf{M}$  has a basis of  $n$  elements.

$\mathbf{N} \subseteq \mathbf{M}$  is a  $\mathbb{D}$ -**submodule** of  $\mathbf{M}$  if  $\mathbf{N}$  is closed under the addition and multiplication by scalars.

$\mathbb{D}^n (= \mathbb{D}^{n \times 1})$  is a  $\mathbb{D}$ -module. It has a **standard basis**  $\mathbf{e}_i$  for  $i = 1, \dots, n$ , where  $\mathbf{e}_i$  is the  $i$ -th column of the identity matrix  $I_n$ .

For any  $A \in \mathbb{D}^{m \times n}$ , the **range** of  $A$ , denoted by  $\text{range}(A)$ , is the set of all linear combinations of the columns of  $A$ .

The **kernel** of  $A$ , denoted by  $\ker(A)$ , is the set of all solutions to the homogeneous equation  $Ax = \mathbf{0}$ .

Consider a system of  $m$  linear equations in  $n$  unknowns:

$\sum_{j=1}^n a_{ij}x_j = b_j, \quad i = 1, \dots, m$ , where  $a_{ij}, b_i \in \mathbb{D}$  for  $i = 1, \dots, m, j = 1, \dots, n$ . In matrix notation this system is  $\mathbf{Ax} = \mathbf{b}$ , where  $A = [a_{ij}] \in \mathbb{D}^{m \times n}$ ,  $\mathbf{x} = [x_1, \dots, x_n]^T \in \mathbb{D}^n$ ,  $\mathbf{b} = [b_1, \dots, b_m]^T \in \mathbb{D}^m$ .  $A$  and  $[A, \mathbf{b}] \in \mathbb{D}^{m \times (n+1)}$  are called the **coefficient** matrix and the **augmented** matrix, respectively.

Let  $A \in H_0^{m \times n}$ . Then  $A = A(z) = [a_{ij}(z)]_{i,j=1}^{m,n}$  and  $A(z)$  has the McLaurin expansion  $A(z) = \sum_{k=0}^{\infty} A_k z^k$ , where  $A_k \in \mathbb{C}^{m \times n}, k = 0, \dots$ . Here, each  $a_{ij}(z)$  has convergent McLaurin series for  $|z| < R(A)$  for some  $R(A) > 0$ .

The invariant factors of  $A$  are called the **local invariant polynomials** of  $A$ , which are normalized to be of the form  $i_k(A) = z^{i_k}$  for  $0 \leq i_1 \leq i_2 \leq \dots \leq i_r$ , where  $r = \text{rank } A$ .

The integer  $i_r$  is the **index** of  $A$  and is denoted by  $\eta = \eta(A)$ . For a nonnegative integer  $p$ , denote by  $\mathcal{K}_p = \mathcal{K}_p(A)$  the number of local invariant polynomials of  $A$  whose degree is equal to  $p$ .

**Facts:**

For modules, see [ZS58], [DF04], and [McD84]. The solvability of linear systems over EDD can be traced to [Hel43] and [Kap49]. The results for BD can be found in [Fri81] and [Frixx]. The results for  $H_0$  are given in [Fri80]. The general theory of solvability of the systems of equations over commutative rings is discussed in [McD84, Exc. I.G.7–I.G.8]. (See Chapter 1 for information about solvability over fields.)

1. The system  $\mathbf{Ax} = \mathbf{b}$  is solvable over a Bezout domain  $\mathbb{D}_b$  if and only if  $r = \text{rank } A = \text{rank } [A, \mathbf{b}]$  and  $\delta_r(A) = \delta_r([A, \mathbf{b}])$ , which is equivalent to the statement that  $A$  and  $[A, \mathbf{b}]$  have the same set of invariant factors, up to invertible elements. For a field  $F$ , this result reduces to the equality  $\text{rank } A = \text{rank } [A, \mathbf{b}]$ .
2. For  $A \in \mathbb{D}_b^{m \times n}$ ,  $\text{range } A$  and  $\ker A$  are modules in  $\mathbb{D}_b^m$  and  $\mathbb{D}_b^n$  having finite bases with  $\text{rank } A$  and null  $A$  elements, respectively. Moreover, the basis of  $\ker A$  can be completed to a basis of  $\mathbb{D}_b^n$ .
3. For  $A, B \in H_0^{m \times n}$ , let  $C(z) = A(z) + z^{k+1}B(z)$ , where  $k$  is a nonnegative integer. Then  $A$  and  $C$  have the same local invariant polynomials up to degree  $k$ . Moreover, if  $k$  is equal to the index of  $A$ , and  $A$  and  $C$  have the same rank, then  $A$  is equivalent to  $C$ .
4. Consider a system of linear equations over  $H_0$   $A(z)\mathbf{u}(z) = \mathbf{b}(z)$ , where  $A(z) \in H_0^{m \times n}$  and  $\mathbf{b}(z) = \sum_{k=0}^{\infty} \mathbf{b}_k z^k \in H_0^m, \mathbf{b}_k \in \mathbb{C}^m, k = 0, \dots$ . Look for the power series solution  $\mathbf{u}(z) = \sum_{k=0}^{\infty} \mathbf{u}_k z^k$ , where  $\mathbf{u}_k \in \mathbb{C}^n, k = 0, \dots$ . Then  $\sum_{j=0}^k A_{k-j} \mathbf{u}_j = \mathbf{b}_k$ , for  $k = 0, \dots$ . This system is solvable for  $k = 0, \dots, q \in \mathbb{Z}_+$  if and only if  $A(z)$  and  $[A(z), \mathbf{b}(z)]$  have the same local invariant polynomials up to degree  $q$ .
5. Suppose that  $A(z)\mathbf{u}(z) = \mathbf{b}(z)$  is solvable over  $H_0$ . Let  $q = \eta(A)$  and suppose that  $\mathbf{u}_0, \dots, \mathbf{u}_q$  satisfies the system of equations, given in the previous fact, for  $k = 0, \dots, q$ . Then there exists a solution  $\mathbf{u}(z) \in H_0^n$  satisfying  $\mathbf{u}(0) = \mathbf{u}_0$ .
6. Let  $q \in \mathbb{Z}_+$  and  $\mathbf{W}_q \subset \mathbb{C}^n$  be the subspace of all vectors  $\mathbf{w}_0$  such that  $\mathbf{w}_0, \dots, \mathbf{w}_q$  is a solution to the homogenous system  $\sum_{j=0}^k A_{k-j} \mathbf{w}_j = 0$ , for  $k = 0, \dots, q$ . Then  $\dim \mathbf{W}_q = n - \sum_{j=0}^q \mathcal{K}_j(A)$ . In particular, for  $\eta = \eta(A)$  and any  $\mathbf{w}_0 \in \mathbf{W}_\eta$  there exists  $\mathbf{w}(z) \in H_0^n$  such that  $A(z)\mathbf{w}(z) = \mathbf{0}$ ,  $\mathbf{w}(0) = \mathbf{w}_0$ .

## 23.4 Strict Equivalence of Pencils

**Definitions:**

A matrix  $A(x) \in \mathbb{D}[x]^{m \times n}$  is a **pencil** if  $A(x) = A_0 + xA_1, A_0, A_1 \in \mathbb{D}^{m \times n}$ .

A pencil  $A(x)$  is **regular** if  $m = n$  and  $\det A(x)$  is not the zero polynomial. Otherwise  $A(x)$  is a **singular** pencil.

Associate with a pencil  $A(x) = A_0 + xA_1 \in \mathbb{D}[x]^{m \times n}$  the **homogeneous** pencil  $A(x_0, x_1) = x_0A_0 + x_1A_1 \in \mathbb{D}[x_0, x_1]^{m \times n}$ .

Two pencils  $A(x), B(x) \in \mathbb{D}[x]^{m \times n}$  are **strictly** equivalent, denoted by  $A(x) \stackrel{\sim}{\sim} B(x)$ , if  $B(x) = QA(x)P$  for some  $P \in \mathbf{GL}_n(\mathbb{D}), Q \in \mathbf{GL}_m(\mathbb{D})$ . Similarly, two homogeneous pencils  $A(x_0, x_1), B(x_0, x_1)$

$\in \mathbb{D}[x_0, x_1]^{m \times n}$  are **strictly** equivalent, denoted by  $A(x_0, x_1) \stackrel{s}{\sim} B(x_0, x_1)$ , if  $B(x_0, x_1) = QA(x_0, x_1)P$  for some  $P \in \mathbf{GL}_n(\mathbb{D})$ ,  $Q \in \mathbf{GL}_m(\mathbb{D})$ .

For a UFD  $\mathbb{D}_u$  let  $\delta_k(x_0, x_1)$ ,  $i_k(x_0, x_1)$  be the invariant determinants and factors of  $A(x_0, x_1)$ , respectively, for  $k = 1, \dots, \text{rank } A(x_0, x_1)$ . They are called **homogeneous** determinants and the invariant **homogeneous** polynomials (factors), respectively, of  $A(x_0, x_1)$ . (Sometimes,  $\delta_k(x_0, x_1)$ ,  $i_k(x_0, x_1)$ ,  $k = 1, \dots, \text{rank } A(x_0, x_1)$  are called the homogeneous determinants and the invariant homogeneous polynomials  $A(x)$ .)

Let  $A(x) \in F[x]^{m \times n}$  and consider the module  $\mathbf{M} \subset F[x]^n$  of all solutions of  $A(x)\mathbf{w}(x) = 0$ . The set of all solutions  $\mathbf{w}(x)$  is an  $F[x]$ -module  $\mathbf{M}$  with a finite basis  $\mathbf{w}_1(x), \dots, \mathbf{w}_s(x)$ , where  $s = n - \text{rank } A(x)$ . Choose a basis  $\mathbf{w}_1(x), \dots, \mathbf{w}_s(x)$  in  $\mathbf{M}$  such that  $\mathbf{w}_k(x) \in \mathbf{M}$  has the lowest degree among all  $\mathbf{w}(x) \in \mathbf{M}$ , which are linearly independent over  $F[x]$  of  $\mathbf{w}_1, \dots, \mathbf{w}_{k-1}(x)$  for  $k = 1, \dots, s$ . Then the **column indices**  $\alpha_1 \leq \alpha_2 \leq \dots \leq \alpha_s$  of  $A(x)$  are given as  $\alpha_k = \deg \mathbf{w}_k(x)$ ,  $k = 1, \dots, s$ . The **row indices**  $0 \leq \beta_1 \leq \beta_2 \leq \dots \leq \beta_t$ ,  $t = m - \text{rank } A(x)$ , of  $A(x)$ , are the column indices of  $A(x)^T$ .

### Facts:

The notion of strict equivalence of  $n \times n$  regular pencils over the fields goes back to K. Weierstrass [Wei67]. The notion of strict similarity of  $m \times n$  matrices over the fields is due to L. Kronecker [Kro90]. Most of the details can be found in [Gan59]. Some special results are proven in [Frixx]. For information about matrix pencils over fields see Section 43.1.

1. Let  $A_0, A_1, B_0, B_1 \in \mathbb{D}^{m \times n}$ . Then  $A_0 + xA_1 \stackrel{s}{\sim} B_0 + xB_1 \iff x_0A_0 + x_1A_1 \stackrel{s}{\sim} B_0x_0 + B_1x_1$ .
2. Let  $A_0, A_1 \in \mathbb{D}_u$ . Then the invariant determinants and the invariant polynomials  $\delta_k(x_0, x_1)$ ,  $i_k(x_0, x_1)$ ,  $k = 1, \dots, \text{rank } x_0A_0 + x_1A_1$ , of  $x_0A_0 + x_1A_1$  are homogeneous polynomials. Moreover, if  $\delta_k(x)$  and  $i_k(x)$  are the invariant determinants and factors of the pencil  $A_0 + xA_1$  for  $k = 1, \dots, \text{rank } A_0 + xA_1$ , then  $\delta_k(x) = \delta_k(1, x)$ ,  $i_k(x) = i_k(1, x)$ , for  $k = 1, \dots, \text{rank } A_0 + xA_1$ .
3. [Wei67] Let  $A_0 + xA_1 \in F[x]^{n \times n}$  be a regular pencil. Then a pencil  $B_0 + xB_1 \in F[x]^{n \times n}$  is strictly equivalent to  $A_0 + xA_1$  if and only if  $A_0 + xA_1$  and  $B_0 + xB_1$  have the same invariant polynomials over  $F[x]$ .
4. [Frixx] Let  $A_0 + xA_1, B_0 + xB_1 \in \mathbb{D}[x]^{n \times n}$ . Assume that  $A_1, B_1 \in \mathbf{GL}_n(\mathbb{D})$ . Then  $A_0 + xA_1 \stackrel{s}{\sim} B_0 + xB_1 \iff A_0 + xA_1 \sim B_0 + xB_1$ .
5. [Gan59] The column (row) indices are independent of a particular allowed choice of a basis  $\mathbf{w}_1(x), \dots, \mathbf{w}_s(x)$ .
6. For singular pencils the invariant homogeneous polynomials alone do not determine the class of strictly equivalent pencils.
7. [Kro90], [Gan59] The pencils  $A(x), B(x) \in F[x]^{m \times n}$  are strictly equivalent if and only if they have the same invariant homogeneous polynomials and the same row and column indices.

24.1	Similarity of Matrices .....	24-1
24.2	Simultaneous Similarity of Matrices .....	24-5
24.3	Property $L$ .....	24-6
24.4	Simultaneous Similarity Classification I .....	24-7
24.5	Simultaneous Similarity Classification II .....	24-10
	References .....	24-12

This chapter uses the notations, definitions, and facts given in Chapter 23. The aim of this chapter is to acquaint the reader with two difficult problems in matrix theory:

1. Similarity of matrices over integral domains, which are not fields.
2. Simultaneous similarity of tuples of matrices over  $\mathbb{C}$ .

Problem 1 is notoriously difficult. We show that for the local ring  $H_0$  this problem reduces to a Problem 2 for certain kind of matrices. We then discuss certain special cases of Problem 2 as simultaneous similarity of tuples of matrices to upper triangular and diagonal matrices. The  $L$ -property of pairs of matrices, which is discussed next, is closely related to simultaneous similarity of pair of matrices to a diagonal pair. The rest of the chapter is devoted to a “solution” of the Problem 2, by the author, in terms of basic notions of algebraic geometry.

### 24.1 Similarity of Matrices

---

The classical result of K. Weierstrass [Wei67] states that the similarity class of  $A \in F^{n \times n}$  is determined by the invariant factors of  $-A + xI_n$  over  $F[x]$ . (See Chapter 6 and Chapter 23.) For a given  $A, B \in F^{n \times n}$ , one can easily determine if  $A$  and  $B$  are similar, by considering *only* the ranks of three specific matrices associated with  $A, B$  [GB77]. It is well known that it is a difficult problem to determine if  $A, B \in \mathbb{D}^{n \times n}$  are  $\mathbb{D}$ -similar for most integral domains that are not fields. The emphasis of this chapter is the similarity over the local field  $H_0$ . The subject of similarity of matrices over  $H_0$  arises naturally in theory linear differential equations having singularity with respect to a parameter. It was studied by Wasow in [Was63], [Was77], and [Was78].

#### Definitions:

For  $E \in \mathbb{D}^{m \times n}, G \in \mathbb{D}^{p \times q}$  extend the definition of the **tensor** or **Kronecker** product  $E \otimes G \in \mathbb{D}^{mp \times nq}$  of  $E$  with  $G$  to the domain  $\mathbb{D}$  in the obvious way. (See Section 10.4.)

$A, B \in \mathbb{D}^{m \times m}$  are called **similar**, denoted by  $A \approx B$  if  $B = QAQ^{-1}$ , for some  $Q \in GL_m(\mathbb{D})$ .

Let  $A, B \in H(\Omega)^{n \times n}$ . Then  $A$  and  $B$  are called **analytically similar**, denoted as  $A \stackrel{a}{\approx} B$ , if  $A$  and  $B$  are similar over  $H(\Omega)$ .

$A$  and  $B$  are called **locally similar** if for any  $\zeta \in \Omega$ , the restrictions  $A_\zeta, B_\zeta$  of  $A, B$  to the local rings  $H_\zeta$ , respectively, are similar over  $H_\zeta$ .

$A, B$  are called **point-wise similar** if  $A(\zeta), B(\zeta)$  are similar matrices in  $\mathbb{C}^{n \times n}$  for each  $\zeta \in \Omega$ .

$A, B$  are called **rationally similar**, denoted as  $A \stackrel{r}{\approx} B$ , if  $A, B$  are similar over the quotient field  $\mathcal{M}(\Omega)$  of  $H(\Omega)$ .

Let  $A, B \in H_0^{n \times n}$ :

$$A(x) = \sum_{k=0}^{\infty} A_k x^k, \quad |x| < R(A), \quad B(x) = \sum_{k=0}^{\infty} B_k x^k, \quad |x| < R(B).$$

Then  $\eta(A, B)$  and  $\mathcal{K}_p(A, B)$  are the index and the number of local invariant polynomials of degree  $p$  of the matrix  $I_n \otimes A(x) - B(x)^T \otimes I_n$ , respectively, for  $p = 0, 1, \dots$ .

$\lambda(x)$  is called an **algebraic function** if there exists a monic polynomial  $p(\lambda, x) = \lambda^n + \sum_{i=1}^n q_i(x) \lambda^{n-i} \in (\mathbb{C}[x])[\lambda]$  of  $\lambda$ -degree  $n \geq 1$  such that  $p(\lambda(x), x) = 0$  identically. Then  $\lambda(x)$  is a multivalued function on  $\mathbb{C}$ , which has  $n$  **branches**. At each point  $\zeta \in \mathbb{C}$  each branch  $\lambda_j(x)$  of  $\lambda(x)$  has **Puiseux** expansion:  $\lambda_j(x) = \sum_{i=0}^{\infty} b_{ji}(\zeta)(x - \zeta)^{\frac{i}{m}}$ , which converges for  $|x - \zeta| < R(\zeta)$ , and some integer  $m$  depending on  $p(x)$ .  $\sum_{i=0}^m b_{ji}(\zeta)(x - \zeta)^{\frac{i}{m}}$  is called the **linear part** of  $\lambda_j(x)$  at  $\zeta$ . Two distinct branches  $\lambda_j(x)$  and  $\lambda_k(x)$  are called **tangent** at  $\zeta \in \mathbb{C}$  if the linear parts of  $\lambda_j(x)$  and  $\lambda_k(x)$  coincide at  $\zeta$ . Each branch  $\lambda_j(x)$  has Puiseux expansion around  $\infty$ :  $\lambda_j(x) = x^l \sum_{i=0}^{\infty} c_{ji} x^{-\frac{i}{m}}$ , which converges for  $|x| > R$ . Here,  $l$  is the smallest nonnegative integer such that  $c_{j0} \neq 0$  at least for some branch  $\lambda_j$ .  $x^l \sum_{i=0}^m c_{ji} x^{-\frac{i}{m}}$  is called the **principal part** of  $\lambda_j(x)$  at  $\infty$ . Two distinct branches  $\lambda_j(x)$  and  $\lambda_k(x)$  are called **tangent** at  $\infty$  if the principal parts of  $\lambda_j(x)$  and  $\lambda_k(x)$  coincide at  $\infty$ .

**Facts:**

The standard results on the tensor products can be found in Chapter 10 or Chapter 13 or in [MM64]. Most of the results of this section related to the analytic similarity over  $H_0$  are taken from [Fri80].

1. The similarity relation is an equivalence relation on  $\mathbb{D}^{m \times m}$ .
2.  $A \approx B \iff A(x) = -A + xI \stackrel{s}{\sim} B(x) = -B + xI$ .
3. Let  $A, B \in F^{n \times n}$ . Then  $A$  and  $B$  are similar if and only if the pencils  $-A + xI$  and  $-B + xI$  have the same invariant polynomials over  $F[x]$ .
4. If  $E = [e_{ij}] \in \mathbb{D}^{m \times n}, G \in \mathbb{D}^{p \times q}$ , then  $E \otimes G$  can be viewed as the  $m \times n$  block matrix  $[e_{ij}G]_{i,j=1}^{m,n}$ . Alternatively,  $E \otimes G$  can be identified with the linear transformation

$$L(E, G) : \mathbb{D}^{q \times n} \rightarrow \mathbb{D}^{p \times m}, \quad X \rightarrow GXE^T.$$

5.  $(E \otimes G)(U \otimes V) = EU \otimes GV$  whenever the products  $EU$  and  $GV$  are defined. Also  $(E \otimes G)^T = E^T \otimes G^T$  (cf. §2.5.4).
6. For  $A, B \in \mathbb{D}^{n \times n}$ , if  $A$  is similar to  $B$ , then

$$I_n \otimes A - A^T \otimes I_n \sim I_n \otimes A - B^T \otimes I_n \sim I_n \otimes B - B^T \otimes I_n.$$

7. [Gur80] There are examples over Euclidean domains for which the reverse of the implication in Fact 6 does not hold.
8. [GB77] For  $\mathbb{D} = F$ , the reverse of the implication in Fact 6 holds.
9. [Fri80] Let  $A \in F^{m \times m}, B \in F^{n \times n}$ . Then

$$\text{null}(I_n \otimes A - B^T \otimes I_m) \leq \frac{1}{2}(\text{null}(I_m \otimes A - A^T \otimes I_m) + \text{null}(I_n \otimes B - B^T \otimes I_n)).$$

Equality holds if and only if  $m = n$  and  $A$  and  $B$  are similar.

10. Let  $A \in F^{n \times n}$  and assume that  $p_1(x), \dots, p_k(x) \in F[x]$  are the nontrivial normalized invariant polynomials of  $-A + xI$ , where  $p_1(x)|p_2(x)|\dots|p_k(x)$  and  $p_1(x)p_2(x)\dots p_k(x) = \det(xI - A)$ . Then  $A \approx C(p_1) \oplus C(p_2) \oplus \dots \oplus C(p_k)$  and  $C(p_1) \oplus C(p_2) \oplus \dots \oplus C(p_k)$  is called the *rational canonical form* of  $A$  (cf. Chapter 6.6).
11. For  $A, B \in H(\Omega)^{n \times n}$ , analytic similarity implies local similarity, local similarity implies point-wise similarity, and point-wise similarity implies rational similarity.
12. For  $n = 1$ , all the four concepts in Fact 11 are equivalent. For  $n \geq 2$ , local similarity, point-wise similarity, and rational similarity, are distinct (see Example 2).
13. The equivalence of the three matrices in Fact 6 over  $H(\Omega)$  implies the point-wise similarity of  $A$  and  $B$ .
14. Let  $A, B \in H_0^{n \times n}$ . Then  $A$  and  $B$  are analytically similar over  $H_0$  if and only if  $A$  and  $B$  are rationally similar over  $H_0$  and there exists  $\eta(A, A) + 1$  matrices  $T_0, \dots, T_\eta \in \mathbb{C}^{n \times n}$  ( $\eta = \eta(A, A)$ ), such that  $\det T_0 \neq 0$  and

$$\sum_{i=0}^k A_i T_{k-i} - T_{k-i} B_i = 0, \quad k = 0, \dots, \eta(A, A).$$

15. Suppose that the characteristic polynomial of  $A(x)$  splits over  $H_0$ :

$$\det(\lambda I - A(x)) = \prod_{i=1}^n (\lambda - \lambda_i(x)), \quad \lambda_i(x) \in H_0, \quad i = 1, \dots, n.$$

Then  $A(x)$  is analytically similar to

$$C(x) = \bigoplus_{i=1}^{\ell} C_i(x), \quad C_i(x) \in H_0^{n_i \times n_i},$$

$$(\alpha_i I_{n_i} - C_i(0))^{n_i} = 0, \quad \alpha_i = \lambda_{n_i}(0), \quad \alpha_i \neq \alpha_j \quad \text{for } i \neq j, \quad i, j = 1, \dots, \ell.$$

16. Assume that the characteristic polynomial of  $A(x) \in H_0$  splits in  $H_0$ . Then  $A(x)$  is analytically similar to a block diagonal matrix  $C(x)$  of the form Fact 15 such that each  $C_i(x)$  is an upper triangular matrix whose off-diagonal entries are polynomials in  $x$ . Moreover, the degree of each polynomial entry above the diagonal in the matrix  $C_i(x)$  does not exceed  $\eta(C_i, C_i)$  for  $i = 1, \dots, \ell$ .
17. Let  $P(x)$  and  $Q(x)$  be matrices of the form

$$P(x) = \bigoplus_{i=1}^p P_i(x), \quad P_i(x) \in H_0^{m_i \times m_i},$$

$$(\alpha_i I_{m_i} - P_i(0))^{m_i} = 0, \quad \alpha_i \neq \alpha_j \quad \text{for } i \neq j, \quad i, j = 1, \dots, p,$$

$$Q(x) = \bigoplus_{j=1}^q Q_j(x), \quad Q_j(x) \in H_0^{n_j \times n_j},$$

$$(\beta_j I_{n_j} - Q_j(0))^{n_j} = 0, \quad \beta_i \neq \beta_j \quad \text{for } i \neq j, \quad i, j = 1, \dots, q.$$

Assume furthermore that

$$\alpha_i = \beta_i, \quad i = 1, \dots, t, \quad \alpha_j \neq \beta_j, \quad j = t + 1, \dots, p, \quad j = t + 1, \dots, q, \quad 0 \leq t \leq \min(p, q).$$

Then the nonconstant local invariant polynomials of  $I \otimes P(x) - Q(x)^T \otimes I$  are the nonconstant local invariant polynomials of  $I \otimes P_i(x) - Q_i(x)^T \otimes I$  for  $i = 1, \dots, t$ :

$$\mathcal{K}_p(P, Q) = \sum_{i=1}^t \mathcal{K}_p(P_i, Q_i), \quad p = 1, \dots, .$$

In particular, if  $C(x)$  is of the form in Fact 15, then

$$\eta(C, C) = \max_{1 \leq i \leq \ell} \eta(C_i, C_i).$$

18.  $A(x) \stackrel{a}{\approx} B(x) \iff A(y^m) \stackrel{a}{\approx} B(y^m)$  for any  $2 \leq m \in \mathbb{N}$ .
19. [GR65] (*Weierstrass preparation theorem*) For any monic polynomial  $p(\lambda, x) = \lambda^n + \sum_{i=1}^n a_i(x)\lambda^{n-i} \in H_0[\lambda]$  there exists  $m \in \mathbb{N}$  such that  $p(\lambda, y^m)$  splits over  $H_0$ .
20. For a given rational canonical form  $A(x) \in H_0^{2 \times 2}$  there are at most a countable number of analytic similarity classes. (See Example 3.)
21. For a given rational canonical form  $A(x) \in H_0^{n \times n}$ , where  $n \geq 3$ , there may exist a family of distinct similarity classes corresponding to a finite dimensional variety. (See Example 4.)
22. Let  $A(x) \in H_0^{n \times n}$  and assume that the characteristic polynomial of  $A(x)$  splits in  $H_0$  as in Fact 15. Let  $B(x) = \text{diag}(\lambda_1(x), \dots, \lambda_n(x))$ . Then  $A(x)$  and  $B(x)$  are not analytically similar if and only if there exists a nonnegative integer  $p$  such that

$$\begin{aligned} \mathcal{K}_p(A, A) + \mathcal{K}_p(B, B) &< 2\mathcal{K}_p(A, B), \\ \mathcal{K}_j(A, A) + \mathcal{K}_j(B, B) &= 2\mathcal{K}_j(A, B), \quad j = 0, \dots, p-1, \quad \text{if } p \geq 1. \end{aligned}$$

In particular,  $A(x) \stackrel{a}{\approx} B(x)$  if and only if the three matrices given in Fact 6 are equivalent over  $H_0$ .

23. [Fri78] Let  $A(x) \in \mathbb{C}[x]^{n \times n}$ . Then each eigenvalue  $\lambda(x)$  of  $A(x)$  is an algebraic function. Assume that  $A(\zeta)$  is diagonalizable for some  $\zeta \in \mathbb{C}$ . Then the linear part of each branch of  $\lambda_j(x)$  is linear at  $\zeta$ , i.e., is of the form  $\alpha + \beta x$  for some  $\alpha, \beta \in \mathbb{C}$ .
24. Let  $A(x) \in \mathbb{C}[x]^{n \times n}$  be of the form  $A(x) = \sum_{k=0}^{\ell} A_k x^k$ , where  $A_k \in \mathbb{C}^{n \times n}$  for  $k = 0, \dots, \ell$  and  $\ell \geq 1, A_{\ell} \neq 0$ . Then one of the following conditions imply that  $A(x) = S(x)B(x)S^{-1}(x)$ , where  $S(x) \in \text{GL}(n, \mathbb{C}[x])$  and  $B(x) \in \mathbb{C}[x]^{n \times n}$  is a diagonal matrix of the form  $\bigoplus_{i=1}^m \lambda_i(x) I_{k_i}$ , where  $k_1, \dots, k_m \geq 1$ . Furthermore,  $\lambda_1(x), \dots, \lambda_m(x)$  are  $m$  distinct polynomials satisfying the following conditions:
  - (a)  $\deg \lambda_1 = \ell \geq \deg \lambda_i(x), i = 2, \dots, m-1$ .
  - (b) The polynomial  $\lambda_i(x) - \lambda_j(x)$  has only simple roots in  $\mathbb{C}$  for  $i \neq j$ . ( $\lambda_i(\zeta) = \lambda_j(\zeta) \implies \lambda'_i(\zeta) \neq \lambda'_j(\zeta)$ ).
    - i. The characteristic polynomial of  $A(x)$  splits in  $\mathbb{C}[x]$ , i.e., all the eigenvalues of  $A(x)$  are polynomials.  $A(x)$  is point-wise diagonalizable in  $\mathbb{C}$  and no two distinct eigenvalues are tangent at any  $\zeta \in \mathbb{C}$ .
    - ii.  $A(x)$  is point-wise diagonalizable in  $\mathbb{C}$  and  $A_{\ell}$  is diagonalizable. No two distinct eigenvalues are tangent at any point  $\zeta \in \mathbb{C} \cup \{\infty\}$ . Then  $A(x)$  is strictly similar to  $B(x)$ , i.e.,  $S(x)$  can be chosen in  $\text{GL}(n, \mathbb{C})$ . Furthermore,  $\lambda_1(x), \dots, \lambda_m(x)$  satisfy the additional condition:
      - (c) For  $i \neq j$ , either  $\frac{d^{\ell} \lambda_i}{d^{\ell} x}(0) \neq \frac{d^{\ell} \lambda_j}{d^{\ell} x}(0)$  or  $\frac{d^{\ell} \lambda_i}{d^{\ell} x}(0) = \frac{d^{\ell} \lambda_j}{d^{\ell} x}(0)$  and  $\frac{d^{\ell-1} \lambda_i}{d^{\ell-1} x}(0) \neq \frac{d^{\ell-1} \lambda_j}{d^{\ell-1} x}(0)$ .

**Examples:**

1. Let

$$A = \begin{bmatrix} 1 & 0 \\ 0 & 5 \end{bmatrix}, \quad B = \begin{bmatrix} 1 & 1 \\ 0 & 5 \end{bmatrix} \in \mathbb{Z}^{2 \times 2}.$$

Then  $A(x)$  and  $B(x)$  have the same invariant polynomials over  $\mathbb{Z}[x]$  and  $A$  and  $B$  are not similar over  $\mathbb{Z}$ .

2. Let

$$A(z) = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}, \quad D(z) = \begin{bmatrix} z & 0 \\ 0 & 1 \end{bmatrix}.$$

Then  $zA(z) = D(z)A(z)D(z)^{-1}$ , i.e.,  $A(z), zA(z)$  are rationally similar. Clearly  $A(z)$  and  $zA(z)$  are not point-wise similar for any  $\Omega$  containing 0. Now  $zA(z), z^2A(z)$  are point-wise similar in  $\mathbb{C}$ , but they are not locally similar on  $H_0$ .

3. Let  $A(x) \in H_0^{2 \times 2}$  and assume that  $\det(\lambda I - A(x)) = (\lambda - \lambda_1(x))(\lambda - \lambda_2(x))$ . Then  $A(x)$  is analytically similar either to a diagonal matrix or to

$$B(x) = \begin{bmatrix} \lambda_1(x) & x^k \\ 0 & \lambda_2(x) \end{bmatrix}, \quad k = 0, \dots, p \ (p \geq 0).$$

Furthermore, if  $A(x) \stackrel{a}{\approx} B(x)$ , then  $\eta(A, A) = k$ .

4. Let  $A(x) \in H_0^{3 \times 3}$ . Assume that

$$A(x) \stackrel{r}{\approx} C(p), \quad p(\lambda, x) = \lambda(\lambda - x^{2m})(\lambda - x^{4m}), \quad m \geq 1.$$

Then  $A(x)$  is analytically similar to a matrix

$$B(x, a) = \begin{bmatrix} 0 & x^{k_1} & a(x) \\ 0 & x^{2m} & x^{k_2} \\ 0 & 0 & x^{4m} \end{bmatrix}, \quad 0 \leq k_1, k_2 \leq \infty \ (x^\infty = 0),$$

where  $a(x)$  is a polynomial of degree  $4m - 1$  at most. Furthermore,  $B(x, a) \stackrel{a}{\approx} B(x, b)$  if and only if

- (a) If  $a(0) \neq 1$ , then  $b - a$  is divisible by  $x^m$ .
- (b) If  $a(0) = 1$  and  $\frac{d^i a}{dx^i} = 0, i = 1, \dots, k - 1, \frac{d^k a}{dx^k} \neq 0$  for  $1 \leq k < m$ , then  $b - a$  is divisible by  $x^{m+k}$ .
- (c) If  $a(0) = 1$  and  $\frac{d^i a}{dx^i} = 0, i = 1, \dots, m$ , then  $b - a$  is divisible by  $x^{2m}$ .

Then for  $k_1 = k_2 = m$  and  $a(0) \in \mathbb{C} \setminus \{1\}$ , we can assume that  $a(x)$  is a polynomial of degree less than  $m$ . Furthermore, the similarity classes of  $A(x)$  are uniquely determined by such  $a(x)$ . These similarity classes are parameterized by  $\mathbb{C} \setminus \{1\} \times \mathbb{C}^{m-1}$  (the Taylor coefficients of  $a(x)$ ).

## 24.2 Simultaneous Similarity of Matrices

In this section, we introduce the notion of simultaneous similarity of matrices over a domain  $\mathbb{D}$ . The problem of simultaneous similarity of matrices over a field  $F$ , i.e., to describe the similarity class of a given  $m \ (\geq 2)$  tuple of matrices or to decide when a given two tuples of matrices are simultaneously similar, is in general a hard problem, which will be discussed in the next sections. There are some cases where this problem has a relatively simple solution. As shown below, the problem of analytic similarity of  $A(x), B(x) \in H_0^{n \times n}$  reduces to the problem of simultaneously similarity of certain 2-tuples of matrices.

### Definitions:

For  $A_0, \dots, A_\ell \in \mathbb{D}^{n \times n}$  denote by  $\mathcal{A}(A_0, \dots, A_\ell) \subset \mathbb{D}^{n \times n}$  the minimal algebra in  $\mathbb{D}^{n \times n}$  containing  $I_n$  and  $A_0, \dots, A_\ell$ . Thus, every matrix  $G \in \mathcal{A}(A_0, \dots, A_\ell)$  is a noncommutative polynomial in  $A_0, \dots, A_\ell$ .

For  $l \geq 1, (A_0, A_1, \dots, A_\ell), (B_0, \dots, B_\ell) \in (\mathbb{D}^{n \times n})^{\ell+1}$  are called **simultaneously similar**, denoted by  $(A_0, A_1, \dots, A_\ell) \approx (B_0, \dots, B_\ell)$ , if there exists  $P \in GL(n, \mathbb{D})$  such that  $B_i = P A_i P^{-1}, i = 0, \dots, \ell$ , i.e.,  $(B_0, B_1, \dots, B_\ell) = P(A_0, A_1, \dots, A_\ell)P^{-1}$ .

Associate with  $(A_0, A_1, \dots, A_\ell), (B_0, \dots, B_\ell) \in (\mathbb{D}^{n \times n})^{\ell+1}$  the matrix polynomials  $A(x) = \sum_{i=0}^\ell A_i x^i, B(x) = \sum_{i=0}^\ell B_i x^i \in \mathbb{D}[x]^{n \times n}$ .  $A(x)$  and  $B(x)$  are called **strictly similar** ( $A \stackrel{s}{\approx} B$ ) if there exists  $P \in GL(n, \mathbb{D})$  such that  $B(x) = P A(x) P^{-1}$ .

### Facts:

1.  $A \stackrel{s}{\approx} B \iff (A_0, A_1, \dots, A_\ell) \approx (B_0, \dots, B_\ell)$ .
2.  $(A_0, \dots, A_\ell) \in (\mathbb{C}^{n \times n})^{\ell+1}$  is simultaneously similar to a diagonal tuple  $(B_0, \dots, B_\ell) \in (\mathbb{C}^{n \times n})^{\ell+1}$ , i.e., each  $B_i$  is a diagonal matrix if and only if  $A_0, \dots, A_\ell$  are  $\ell + 1$  commuting diagonalizable matrices:  $A_i A_j = A_j A_i$  for  $i, j = 0, \dots, \ell$ .

3. If  $A_0, \dots, A_\ell \in \mathbb{C}^{n \times n}$  commute, then  $(A_0, \dots, A_\ell)$  is simultaneously similar to an upper triangular tuple  $(B_0, \dots, B_\ell)$ .
4. Let  $l \in \mathbb{N}$ ,  $(A_0, \dots, A_l), (B_0, \dots, B_l) \in (\mathbb{C}^{n \times n})^{l+1}$ , and  $U = [U_{ij}]_{i,j=1}^{l+1}, V = [V_{ij}]_{i,j=1}^{l+1}, W = [W_{ij}]_{i,j=1}^{l+1} \in \mathbb{C}^{(l+1) \times (l+1)}$ ,  $U_{ij}, V_{ij}, W_{ij} \in \mathbb{C}^{n \times n}, i, j = 1, \dots, l+1$  be block upper triangular matrices with the following block entries:

$$U_{ij} = A_{j-i}, \quad V_{ij} = B_{j-i}, \quad W_{ij} = \delta_{(i+1)j} I_n, \quad i = 1, \dots, l+1, j = i, \dots, l+1.$$

Then the system in Fact 14 of section 24.1 is solvable with  $T_0 \in \text{GL}(n, \mathbb{C})$  if and only for  $l = \kappa(A, A)$  the pairs  $(U, W)$  and  $(V, W)$  are simultaneously similar.

5. For  $A_0, \dots, A_\ell \in (\mathbb{C}^{n \times n})^{\ell+1}$  TFAE:
  - $(A_0, \dots, A_\ell)$  is simultaneously similar to an upper triangular tuple  $(B_0, \dots, B_\ell) \in (\mathbb{C}^{n \times n})^{\ell+1}$ .
  - For any  $0 \leq i < j \leq \ell$  and  $M \in \mathcal{A}(A_0, \dots, A_\ell)$ , the matrix  $(A_i A_j - A_j A_i)M$  is nilpotent.
6. Let  $\mathcal{X}_0 = \mathcal{A}(A_0, \dots, A_\ell) \subseteq F^{n \times n}$  and define recursively

$$\mathcal{X}_k = \sum_{0 \leq i < j \leq \ell} (A_i A_j - A_j A_i) \mathcal{X}_{k-1} \subseteq F^{n \times n}, \quad k = 1, \dots$$

Then  $(A_0, \dots, A_\ell)$  is simultaneously similar to an upper triangular tuple if and only if the following two conditions hold:

- $A_i \mathcal{X}_k \subseteq \mathcal{X}_k, \quad i = 0, \dots, \ell, k = 0, \dots$
- There exists  $q \geq 1$  such that  $\mathcal{X}_q = \{0\}$  and  $\mathcal{X}_k$  is a strict subspace of  $\mathcal{X}_{k-1}$  for  $k = 1, \dots, q$ .

**Examples:**

1. This example illustrates the construction of the matrices  $U$  and  $W$  in Fact 4. Let  $A_0 = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}$ ,

$$A_1 = \begin{bmatrix} 5 & 6 \\ 7 & 8 \end{bmatrix}, \text{ and } A_2 = \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix}. \text{ Then}$$

$$U = \begin{bmatrix} 1 & 2 & 5 & 6 & 1 & -1 \\ 3 & 4 & 7 & 8 & -1 & 1 \\ 0 & 0 & 1 & 2 & 5 & 6 \\ 0 & 0 & 3 & 4 & 7 & 8 \\ 0 & 0 & 0 & 0 & 1 & 2 \\ 0 & 0 & 0 & 0 & 3 & 4 \end{bmatrix} \quad \text{and} \quad W = \begin{bmatrix} 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}.$$

### 24.3 Property L

Property *L* was introduced and studied in [MT52] and [MT55]. In this section, we consider only square pencils  $A(x) = A_0 + A_1 x \in \mathbb{C}[x]^{n \times n}, A(x_0, x_1) \in \mathbb{C}[x_0, x_1]^{n \times n}$ , where  $A_1 \neq 0$ .

**Definitions:**

A pencil  $A(x) \in \mathbb{C}[x]^{n \times n}$  has **property L** if all the eigenvalues of  $A(x_0, x_1)$  are linear functions. That is,  $\lambda_i(x_0, x_1) = \alpha_i x_0 + \beta_i x_1$  is an eigenvalue of  $A(x_0, x_1)$  of multiplicity  $n_i$  for  $i = 1, \dots, m$ , where

$$n = \sum_{i=1}^m n_i, \quad (\alpha_i, \beta_i) \neq (\alpha_j, \beta_j), \quad \text{for } 1 \leq i < j \leq m.$$

A pencil  $A(x) = A_0 + A_1 x$  is **Hermitian** if  $A^0, A^1$  are Hermitian.

**Facts:**

Most of the results of this section can be found in [MF80], [Fri81], and [Frixx].

1. For a pencil  $A(x) = A_0 + xA_1 \in \mathbb{C}[x]^{n \times n}$  TFAE:
  - $A(x)$  has property  $L$ .
  - The eigenvalues of  $A(x)$  are polynomials of degree 1 at most.
  - The characteristic polynomial of  $A(x)$  splits into linear factors over  $\mathbb{C}[x]$ .
  - There is an ordering of the eigenvalues of  $A_0$  and  $A_1$ ,  $\alpha_1, \dots, \alpha_n$  and  $\beta_1, \dots, \beta_n$ , respectively, such that the eigenvalues of  $A_0x_0 + A_1x_1$  are  $\alpha_1x_0 + \beta_1x_1, \dots, \alpha_nx_0 + \beta_nx_1$ .
2. A pencil in  $A(x)$  has property  $L$  if one of the following conditions hold:
  - $A(x)$  is similar over  $\mathbb{C}(x)$  to an upper triangular matrix  $U(x) \in \mathbb{C}(x)^{n \times n}$ .
  - $A(x)$  is strictly similar to an upper triangular pencil  $U(x) = U_0 + U_1x$ .
  - $A(x)$  is similar over  $\mathbb{C}[x]$  to a diagonal matrix  $B(x) \in \mathbb{C}[x]^{n \times n}$ .
  - $A(x)$  is strictly similar to diagonal pencil.
3. If a pencil  $A(x_0, x_1)$  has property  $L$ , then any two distinct eigenvalues are not tangent at any point of  $\mathbb{C} \cup \infty$ .
4. Assume that  $A(x)$  is point-wise diagonalizable on  $\mathbb{C}$ . Then  $A(x)$  has property  $L$ . Furthermore,  $A(x)$  is similar over  $\mathbb{C}[x]$  to a diagonal pencil  $B(x) = B_0 + B_1x$ . Suppose furthermore that  $A_1$  is diagonalizable, i.e.,  $A(x_0, x_1)$  is point-wise diagonalizable on  $\mathbb{C}^2$ . Then  $A(x)$  is strictly similar to a diagonal pencil  $B(x)$ , i.e.,  $A_0$  and  $A_1$  are commuting diagonalizable matrices.
5. Let  $A(x) = A_0 + A_1x \in \mathbb{C}[x]^{n \times n}$  such that  $A_1$  and  $A_2$  are diagonalizable and  $A_0A_1 \neq A_1A_0$ . Then exactly one of the following conditions hold:
  - $A(x)$  is not diagonalizable exactly at the points  $\zeta_1, \dots, \zeta_p$ , where  $1 \leq p \leq n(n-1)$ .
  - For  $n \geq 3$ ,  $A(x) \in \mathbb{C}[x]^{n \times n}$  is diagonalizable exactly at the points  $\zeta_1 = 0, \dots, \zeta_q$  for some  $q \geq 1$ .  
(We do not know if this condition is satisfied for some pencil.)
6. Let  $A(x) = A_0 + A_1x$  be a Hermitian pencil satisfying  $A_0A_1 \neq A_1A_0$ . Then there exists  $2q$  distinct complex points  $\zeta_1, \bar{\zeta}_1, \dots, \zeta_q, \bar{\zeta}_q \in \mathbb{C} \setminus \mathbb{R}$ ,  $1 \leq q \leq \frac{n(n-1)}{2}$  such that  $A(x)$  is not diagonalizable if and only if  $x \in \{\zeta_1, \bar{\zeta}_1, \dots, \zeta_q, \bar{\zeta}_q\}$ .

**Examples:**

1. This example illustrates the case  $n = 2$  of Fact 5. Let

$$A_0 = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix} \quad \text{and} \quad A_1 = \begin{bmatrix} 1 & 3 \\ -3 & 1 \end{bmatrix}, \quad \text{so} \quad A(x) = \begin{bmatrix} x+1 & 3x \\ -3x & x+2 \end{bmatrix}.$$

For  $\zeta \in \mathbb{C}$ , the only possible way  $A(\zeta)$  can fail to be diagonalizable is if  $A(\zeta)$  has repeated eigenvalues. The eigenvalues of  $A(\zeta)$  are  $\frac{1}{2} \left( 2\zeta - \sqrt{1 - 36\zeta^2} + 3 \right)$  and  $\frac{1}{2} \left( 2\zeta + \sqrt{1 - 36\zeta^2} + 3 \right)$ , so the only values of  $\zeta$  at which it is possible that  $A(\zeta)$  is not diagonalizable are  $\zeta = \pm \frac{1}{6}$ , and in fact  $A(\pm \frac{1}{6})$  is not diagonalizable.

## 24.4 Simultaneous Similarity Classification I

---

This section outlines the setting for the classification of conjugacy classes of  $l + 1$  tuples  $(A_0, A_1, \dots, A_l) \in (\mathbb{C}^{n \times n})^{l+1}$  under the simultaneous similarity. This classification depends on certain standard notions in algebraic geometry that are explained briefly in this section. A detailed solution to the classification of conjugacy classes of  $l + 1$  tuples is outlined in the next section.

**Definitions:**

$\mathcal{X} \subset \mathbb{C}^N$  is called an **affine algebraic variety** (called here a **variety**) if it is the zero set of a finite number of polynomial equations in  $\mathbb{C}^N$ .

$\mathcal{X}$  is irreducible if  $\mathcal{X}$  does not decompose in a nontrivial way to a union of two varieties.

If  $\mathcal{X}$  is a finite nontrivial union of irreducible varieties, these irreducible varieties are called the **irreducible** components of  $\mathcal{X}$ .

$x \in \mathcal{X}$  is called a **regular (smooth)** point of irreducible  $\mathcal{X}$  if in the neighborhood of this point  $\mathcal{X}$  is a complex manifold of a fixed dimension  $d$ , which is called the **dimension** of  $\mathcal{X}$  and is denoted by  $\dim \mathcal{X}$ .  $\emptyset$  is an irreducible variety of dimension  $-1$ .

For a reducible variety  $\mathcal{Y} \subset \mathbb{C}^N$ , the **dimension** of  $\mathcal{Y}$ , denoted by  $\dim \mathcal{Y}$ , is the maximum dimension of its irreducible components.

The set of singular (nonsmooth) points of  $\mathcal{X}$  is denoted by  $\mathcal{X}_s$ .

A set  $\mathcal{Z}$  is a **quasi-irreducible** variety if there exists a nonempty irreducible variety  $\mathcal{X}$  and a strict subvariety  $\mathcal{Y} \subset \mathcal{X}$  such that  $\mathcal{Z} = \mathcal{X} \setminus \mathcal{Y}$ . The dimension of  $\mathcal{Z}$ , denoted by  $\dim \mathcal{Z}$ , is defined to be equal to the dimension of  $\mathcal{X}$ .

A quasi-irreducible variety  $\mathcal{Z}$  is **regular** if  $\mathcal{Z} \subset \mathcal{X} \setminus \mathcal{X}_s$ .

A **stratification** of  $\mathbb{C}^N$  is a decomposition of  $\mathbb{C}^N$  to a finite disjoint union of  $\mathcal{X}_1, \dots, \mathcal{X}_p$  of regular quasi-irreducible varieties such that  $\text{Cl}(\mathcal{X}_i) \setminus \mathcal{X}_i = \cup_{j \in \mathcal{A}_i} \mathcal{X}_j$  for some  $\mathcal{A}_i \subset \{1, \dots, p\}$  for  $i = 1, \dots, p$ . ( $\text{Cl}(\mathcal{X}_i) = \mathcal{X}_i \iff \mathcal{A}_i = \emptyset$ .)

Denote by  $\mathbb{C}[\mathbb{C}^N]$  the ring of polynomial in  $N$  variables with coefficients in  $\mathbb{C}$ .

Denote by  $\mathcal{W}_{n,l+1,r+1}$  the finite dimensional vector space of multilinear polynomials in  $(l+1)n^2$  variables of degree at most  $r+1$ . That is, the degree of each variable in any polynomial is at most 1.  $N(n,l,r) := \dim \mathcal{W}_{n,l+1,r+1}$ .  $\mathcal{W}_{n,l+1,r+1}$  has a standard basis  $\mathbf{e}_1, \dots, \mathbf{e}_{N(n,l,r)}$  in  $\mathcal{W}_{n,l+1,r+1}$  consisting of monomials in  $(l+1)n^2$  variables of degree  $r+1$  at most, arranged in a lexicographical order.

Let  $\mathcal{X} \subset \mathbb{C}^N$  be a quasi-irreducible variety. Denote by  $\mathbb{C}[\mathcal{X}]$  the restriction of all polynomials  $f(x) \in \mathbb{C}[\mathbb{C}^N]$  to  $\mathcal{X}$ , where  $f, g \in \mathbb{C}[\mathbb{C}^N]$  are identified if  $f - g$  vanishes on  $\mathcal{X}$ . Let  $\mathbb{C}(\mathcal{X})$  denote the quotient field of  $\mathbb{C}[\mathcal{X}]$ .

A rational function  $h \in \mathbb{C}(\mathcal{X})$  is **regular** if  $h$  is defined everywhere in  $\mathcal{X}$ . A regular rational function on  $\mathcal{X}$  is an analytic function.

Denote by  $\mathbf{A}$  the  $l+1$  tuple  $(A_0, \dots, A_l) \in (\mathbb{C}^{n \times n})^{l+1}$ . The group  $\text{GL}(n, \mathbb{C})$  acts by conjugation on  $(\mathbb{C}^{n \times n})^{l+1}$ :  $TAT^{-1} = (TA_0T^{-1}, \dots, TA_lT^{-1})$  for any  $\mathbf{A} \in (\mathbb{C}^{n \times n})^{l+1}$  and  $T \in \text{GL}(n, \mathbb{C})$ .

Let  $\text{orb}(\mathbf{A}) := \{TAT^{-1} : T \in \text{GL}(n, \mathbb{C})\}$  be the **orbit** of  $\mathbf{A}$  (under the action of  $\text{GL}(n, \mathbb{C})$ ).

Let  $\mathcal{X} \subset (\mathbb{C}^{n \times n})^{l+1}$  be a quasi-irreducible variety.  $\mathcal{X}$  is called **invariant** (under the action of  $\text{GL}(n, \mathbb{C})$ ) if  $T\mathcal{X}T^{-1} = \mathcal{X}$  for all  $T \in \text{GL}(n, \mathbb{C})$ .

Assume that  $\mathcal{X}$  is an invariant quasi-irreducible variety. A rational function  $h \in \mathbb{C}(\mathcal{X})$  is called **invariant** if  $h$  is the same value on any two points of a given orbit in  $\mathcal{X}$ , where  $h$  is defined. Denote by  $\mathbb{C}[\mathcal{X}]^{\text{inv}} \subseteq \mathbb{C}[\mathcal{X}]$  and  $\mathbb{C}(\mathcal{X})^{\text{inv}} \subseteq \mathbb{C}(\mathcal{X})$  the subdomain of invariant polynomials and subfield of invariant functions, respectively.

**Facts:**

For general background, consult for example [Sha77]. More specific details are given in [Fri83], [Fri85], and [Fri86].

1. An intersection of a finite or infinite number of varieties is a variety, which can be an empty set.
2. A finite union of varieties in  $\mathbb{C}^N$  is a variety.
3. Every variety  $\mathcal{X}$  is a finite nontrivial union of irreducible varieties.
4. Let  $\mathcal{X} \subset \mathbb{C}^N$  be an irreducible variety. Then  $\mathcal{X}$  is path-wise connected.
5.  $\mathcal{X}_s$  is a proper subvariety of the variety  $\mathcal{X}$  and  $\dim \mathcal{X}_s < \dim \mathcal{X}$ .
6.  $\dim \mathbb{C}^N = N$  and  $(\mathbb{C}^N)_s = \emptyset$ . For any  $\mathbf{z} \in \mathbb{C}^N$ , the set  $\{\mathbf{z}\}$  is an irreducible variety of dimension 0.
7. A quasi-irreducible variety  $\mathcal{Z} = \mathcal{X} \setminus \mathcal{Y}$  is path-wise connected and its closure, denoted by  $\text{Cl}(\mathcal{Z})$ , is equal to  $\mathcal{X}$ .  $\text{Cl}(\mathcal{Z}) \setminus \mathcal{Z}$  is a variety of dimension strictly less than the dimension of  $\mathcal{Z}$ .

8. The set of all regular points of an irreducible variety  $\mathcal{X}$ , denoted by  $\mathcal{X}_r := \mathcal{X} \setminus \mathcal{X}_s$ , is a quasi-irreducible variety. Moreover,  $\mathcal{X}_r$  is a path-wise connected complex manifold of complex dimension  $\dim \mathcal{X}$ .
9.  $N(n, l, r) := \dim \mathcal{W}_{n, l+1, r+1} = \sum_{i=0}^{r+1} \binom{(l+1)n^2}{i}$ .
10. For an irreducible  $\mathcal{X}$ ,  $\mathbb{C}[\mathcal{X}]$  is an integral domain.
11. For a quasi-irreducible  $\mathcal{X}$ ,  $\mathbb{C}[\mathcal{X}]$ ,  $\mathbb{C}(\mathcal{X})$  can be identified with  $\mathbb{C}[\text{Cl}(\mathcal{X})]$ ,  $\mathbb{C}(\text{Cl}(\mathcal{X}))$ , respectively.
12. For  $\mathbf{A} \in (\mathbb{C}^{n \times n})^{l+1}$ ,  $\text{orb}(\mathbf{A})$  is a quasi-irreducible variety in  $(\mathbb{C}^{n \times n})^{l+1}$ .
13. Let  $\mathcal{X} \subset (\mathbb{C}^{n \times n})^{l+1}$  be a quasi-irreducible variety.  $\mathcal{X}$  is invariant if  $\mathbf{A} \in \mathcal{X} \iff \text{orb}(\mathbf{A}) \subseteq \mathcal{X}$ .
14. Let  $\mathcal{X}$  be an invariant quasi-irreducible variety. The quotient field of  $\mathbb{C}[\mathcal{X}]^{\text{inv}}$  is a subfield of  $\mathbb{C}(\mathcal{X})^{\text{inv}}$ , and in some interesting cases the quotient field of  $\mathbb{C}[\mathcal{X}]^{\text{inv}}$  is a strict subfield of  $\mathbb{C}(\mathcal{X})^{\text{inv}}$ .
15. Assume that  $\mathcal{X} \subset (\mathbb{C}^{n \times n})^{l+1}$  is an invariant quasi-irreducible variety. Then  $\mathbb{C}[\mathcal{X}]^{\text{inv}}$  and  $\mathbb{C}(\mathcal{X})^{\text{inv}}$  are finitely invariant generated. That is, there exists  $f_1, \dots, f_i \in \mathbb{C}[\mathcal{X}]^{\text{inv}}$  and  $g_1, \dots, g_j \in \mathbb{C}(\mathcal{X})^{\text{inv}}$  such that any polynomial in  $\mathbb{C}[\mathcal{X}]^{\text{inv}}$  is a polynomial in  $f_1, \dots, f_i$ , and any rational function in  $\mathbb{C}(\mathcal{X})^{\text{inv}}$  is a rational function in  $g_1, \dots, g_j$ .
16. (**Classification Theorem**) Let  $n \geq 2$  and  $l \geq 0$  be fixed integers. Then there exists a stratification  $\cup_{i=1}^p \mathcal{X}_i$  of  $(\mathbb{C}^{n \times n})^{l+1}$  with the following properties. For each  $\mathcal{X}_i$  there exist  $m_i$  regular rational functions  $g_{1,i}, \dots, g_{m_i,i} \in \mathbb{C}(\mathcal{X}_i)^{\text{inv}}$  such that the values of  $g_{j,i}$  for  $j = 1, \dots, m_i$  on any orbit in  $\mathcal{X}_i$  determines this orbit uniquely.  
The rational functions  $g_{1,i}, \dots, g_{m_i,i}$  are the generators of  $\mathbb{C}(\mathcal{X}_i)^{\text{inv}}$  for  $i = 1, \dots, p$ .

**Examples:**

1. Let  $\mathcal{S}$  be an irreducible variety of scalar matrices  $\mathcal{S} := \{A \in \mathbb{C}^{2 \times 2} : A = \frac{\text{tr} A}{2} I_2\}$  and  $\mathcal{X} := \mathbb{C}^{2 \times 2} \setminus \mathcal{S}$  be a quasi-irreducible variety. Then  $\dim \mathcal{X} = 4$ ,  $\dim \mathcal{S} = 1$ , and  $\mathbb{C}^{2 \times 2} = \mathcal{X} \cup \mathcal{S}$  is a stratification of  $\mathbb{C}^{2 \times 2}$ .
2. Let  $\mathcal{U} \subset (\mathbb{C}^{2 \times 2})^2$  be the set of all pairs  $(A, B) \in (\mathbb{C}^{2 \times 2})^2$ , which are simultaneously similar to a pair of upper triangular matrices. Then  $\mathcal{U}$  is a variety given by the zero of the following polynomial:

$$\mathcal{U} := \{(A, B) \in (\mathbb{C}^{2 \times 2})^2 : (2 \text{tr} A^2 - (\text{tr} A)^2)(2 \text{tr} B^2 - (\text{tr} B)^2) - (2 \text{tr} AB - \text{tr} A \text{tr} B)^2 = 0\}.$$

Let  $\mathcal{C} \subset \mathcal{U}$  be the variety of commuting matrices:

$$\mathcal{C} := \{(A, B) \in (\mathbb{C}^{2 \times 2})^2 : AB - BA = 0\}.$$

Let  $\mathcal{V}$  be the variety given by the zeros of the following three polynomials:

$$\mathcal{V} := \{(A, B) \in (\mathbb{C}^{2 \times 2})^2 : 2 \text{tr} A^2 - (\text{tr} A)^2 = 2 \text{tr} B^2 - (\text{tr} B)^2 = 2 \text{tr} AB - \text{tr} A \text{tr} B = 0\}.$$

Then  $\mathcal{V}$  is the variety of all pairs  $(A, B)$ , which are simultaneously similar to a pair of the form  $\left( \begin{bmatrix} \lambda & \alpha \\ 0 & \lambda \end{bmatrix}, \begin{bmatrix} \mu & \beta \\ 0 & \mu \end{bmatrix} \right)$ . Hence,  $\mathcal{V} \subset \mathcal{C}$ . Let  $\mathcal{W} := \{A \in (\mathbb{C}^{2 \times 2}) : 2 \text{tr} A^2 - (\text{tr} A)^2 = 0\}$  and  $\mathcal{S} \subset \mathcal{W}$  be defined as in the previous example. Define the following quasi-irreducible varieties in  $(\mathbb{C}^{2 \times 2})^2$ :

$$\begin{aligned} \mathcal{X}_1 &:= (\mathbb{C}^{2 \times 2})^2 \setminus \mathcal{U}, \mathcal{X}_2 := \mathcal{U} \setminus \mathcal{C}, \mathcal{X}_3 = \mathcal{C} \setminus \mathcal{V}, \mathcal{X}_4 := \mathcal{V} \setminus (\mathcal{S} \times \mathcal{W} \cup \mathcal{W} \times \mathcal{S}), \\ \mathcal{X}_5 &:= \mathcal{S} \times (\mathcal{W} \setminus \mathcal{S}), \mathcal{X}_6 := (\mathcal{W} \setminus \mathcal{S}) \times \mathcal{S}, \mathcal{X}_7 = \mathcal{S} \times \mathcal{S}. \end{aligned}$$

Then

$$\begin{aligned} \dim \mathcal{X}_1 &= 8, \dim \mathcal{X}_2 = 7, \dim \mathcal{X}_3 = 6, \dim \mathcal{X}_4 = 5, \\ \dim \mathcal{X}_5 &= \dim \mathcal{X}_6 = 4, \dim \mathcal{X}_7 = 2, \end{aligned}$$

and  $\cup_{i=1}^7 \mathcal{X}_i$  is a stratification of  $(\mathbb{C}^{2 \times 2})^2$ .

3. In the classical case of similarity classes in  $\mathbb{C}^{n \times n}$ , i.e.,  $l = 0$ , it is possible to choose a fixed set of polynomial invariant functions as  $g_j(A) = \text{tr}(A^j)$  for  $j = 1, \dots, n$ . However, we still have to stratify  $\mathbb{C}^{n \times n}$  to  $\cup_{i=1}^p \mathcal{X}_i$ , where each  $A \in \mathcal{X}_i$  has some specific Jordan structures.

4. Consider the stratification  $\mathbb{C}^{2 \times 2} = \mathcal{X} \cup \mathcal{S}$  as in Example 1. Clearly  $\mathcal{X}$  and  $\mathcal{S}$  are invariant under the action of  $\text{GL}(2, \mathbb{C})$ . The invariant functions  $\text{tr } A, \text{tr } A^2$  determine uniquely  $\text{orb}(A)$  on  $\mathcal{X}$ . The Jordan canonical form of any  $A$  in  $\mathcal{X}$  is either consists of two distinct Jordan blocks of order 1 or one Jordan block of order 2. The invariant function  $\text{tr } A$  determines  $\text{orb}(A)$  for any  $A \in \mathcal{S}$ . It is possible to refine the stratification of  $\mathbb{C}^{2 \times 2}$  to three invariant components  $\mathbb{C}^{2 \times 2} \setminus \mathcal{W}, \mathcal{W} \setminus \mathcal{S}, \mathcal{S}$ , where  $\mathcal{W}$  is defined in Example 2. Each component contains only matrices with one kind of Jordan block. On the first component,  $\text{tr } A, \text{tr } A^2$  determine the orbit, and on the second and third component,  $\text{tr } A$  determines the orbit.
5. To see the fundamental difference between similarity ( $l = 0$ ) and simultaneous similarity  $l \geq 1$ , it is suffice to consider Example 2. Observe first that the stratification of  $(\mathbb{C}^{2 \times 2})^2 = \cup_{i=1}^7 \mathcal{X}_i$  is invariant under the action of  $\text{GL}(2, \mathbb{C})$ . On  $\mathcal{X}_1$  the five invariant polynomials  $\text{tr } A, \text{tr } A^2, \text{tr } B, \text{tr } B^2, \text{tr } AB$ , which are algebraically independent, determine uniquely any orbit in  $\mathcal{X}_1$ .

Let  $(A = [a_{ij}], B = [b_{ij}]) \in \mathcal{X}_2$ . Then  $A$  and  $B$  have a unique one-dimensional common eigenspace corresponding to the eigenvalues  $\lambda_1, \mu_1$  of  $A, B$ , respectively. Assume that  $a_{12}b_{21} - a_{21}b_{12} \neq 0$ . Define

$$\lambda_1 = \alpha(A, B) := \frac{(b_{11} - b_{22})a_{12}a_{21} + a_{22}a_{12}b_{21} - a_{11}a_{21}b_{12}}{a_{12}b_{21} - a_{21}b_{12}},$$

$$\mu_1 = \alpha(B, A).$$

Then  $\text{tr } A, \text{tr } B, \alpha(A, B), \alpha(B, A)$  are regular, algebraically independent, rational invariant functions on  $\mathcal{X}_2$ , whose values determine  $\text{orb}(A, B)$ .  $\text{Cl}(\text{orb}(A, B))$  contains an orbit generated by two diagonal matrices  $\text{diag}(\lambda_1, \lambda_2)$  and  $\text{diag}(\mu_1, \mu_2)$ . Hence,  $\mathbb{C}[\mathcal{X}_2]^{\text{inv}}$  is generated by the five invariant polynomials  $\text{tr } A, \text{tr } A^2, \text{tr } B, \text{tr } B^2, \text{tr } AB$ , which are algebraically dependent. Their values coincide exactly on two distinct orbits in  $\mathcal{X}_2$ . On  $\mathcal{X}_3$  the above invariant polynomials separate the orbits.

Any  $(A = [a_{ij}], B = [b_{ij}]) \in \mathcal{X}_4$  is simultaneously similar a unique pair of the form  $\left( \begin{bmatrix} \lambda & 1 \\ 0 & \lambda \end{bmatrix}, \begin{bmatrix} \mu & t \\ 0 & \mu \end{bmatrix} \right)$ .

Then  $t = \gamma(A, B) := \frac{b_{12}}{a_{12}}$ . Thus,  $\text{tr } A, \text{tr } B, \gamma(A, B)$  are three algebraically independent regular rational invariant functions on  $\mathcal{X}_4$ , whose values determine a unique orbit in  $\mathcal{X}_4$ . Clearly  $(\lambda I_2, \mu I_2) \in \text{Cl}(X_4)$ . Then  $\mathbb{C}[\mathcal{X}_4]^{\text{inv}}$  is generated by  $\text{tr } A, \text{tr } B$ . The values of  $\text{tr } A = 2\lambda, \text{tr } B = 2\mu$  correspond to a complex line of orbits in  $\mathcal{X}_4$ . Hence, the classification problem of simultaneous similarity classes in  $\mathcal{X}_4$  or  $\mathcal{V}$  is a *wild* problem.

On  $\mathcal{X}_5, \mathcal{X}_6, \mathcal{X}_7$ , the algebraically independent functions  $\text{tr } A, \text{tr } B$  determine the orbit in each of the stratum.

## 24.5 Simultaneous Similarity Classification II

In this section, we give an invariant stratification of  $(\mathbb{C}^{n \times n})^{l+1}$ , for  $l \geq 1$ , under the action of  $\text{GL}(n, \mathbb{C})$  and describe a set of invariant regular rational functions on each stratum, which separate the orbits up to a finite number. We assume the nontrivial case  $n > 1$ . It is conjectured that the continuous invariants of the given orbit determine uniquely the orbit on each stratum given in the Classification Theorem.

Classification of simultaneous similarity classes of matrices is a known *wild* problem [GP69]. For another approach to classification of simultaneous similarity classes of matrices using *Belitskii* reduction see [Ser00]. See other applications of these techniques to classifications of linear systems [Fri85] and to canonical forms [Fri86].

### Definitions:

For  $\mathbf{A} = (A_0, \dots, A_l), \mathbf{B} = (B_0, \dots, B_l) \in (\mathbb{C}^{n \times n})^{l+1}$  let  $L(\mathbf{B}, \mathbf{A}) : \mathbb{C}^{n \times n} \rightarrow (\mathbb{C}^{n \times n})^{l+1}$  be the linear operator given by  $U \mapsto (B_0U - UA_0, \dots, B_lU - UA_l)$ . Then  $L(\mathbf{B}, \mathbf{A})$  is represented by the  $(l+1)n^2 \times n^2$  matrix  $(I_n \otimes B_0^T - A_0 \otimes I_n, \dots, I_n \otimes B_l^T - A_l \otimes I_n)^T$ , where  $U \mapsto (I_n \otimes B_0^T - A_0 \otimes I_n, \dots, I_n \otimes B_l^T - A_l \otimes I_n)^T U$ . Let  $L(\mathbf{A}) := L(\mathbf{A}, \mathbf{A})$ . The dimension of  $\text{orb}(\mathbf{A})$  is denoted by  $\dim \text{orb}(\mathbf{A})$ .

Let  $\mathcal{S}_n := \{A \in \mathbb{C}^{n \times n} : A = \frac{\text{tr } A}{n} I_n\}$  be the variety of scalar matrices. Let

$$\mathcal{M}_{n,l+1,r} := \{\mathbf{A} \in (\mathbb{C}^{n \times n})^{l+1} : \text{rank } L(\mathbf{A}) = r\}, \quad r = 0, 1, \dots, n^2 - 1.$$

**Facts:**

Most of the results in this section are given in [Fri83].

1. For  $\mathbf{A} = (A_0, \dots, A_l) \in (\mathbb{C}^{n \times n})^{l+1}$ ,  $\dim \text{orb } (\mathbf{A})$  is equal to the rank of  $L(\mathbf{A})$ .
2. Since any  $U \in \mathcal{S}_n$  commutes with any  $B \in \mathbb{C}^{n \times n}$  it follows that  $\ker L(\mathbf{A}) \supset \mathcal{S}_n$ . Hence,  $\text{rank } L(\mathbf{A}) \leq n^2 - 1$ .
3.  $\mathcal{M}_{n,l+1,n^2-1}$  is a invariant quasi-irreducible variety of dimension  $(l+1)n^2$ , i.e.,  $\text{Cl}(\mathcal{M}_{n,l+1,n^2-1}) = (\mathbb{C}^{n \times n})^{l+1}$ . The sets  $\mathcal{M}_{n,l+1,r}, r = n^2 - 2, \dots, 0$  have the decomposition to invariant quasi-irreducible varieties, each of dimension strictly less than  $(l+1)n^2$ .
4. Let  $r \in [0, n^2 - 1]$ ,  $\mathbf{A} \in \mathcal{M}_{n,l+1,r}$ , and  $\mathbf{B} = T\mathbf{A}T^{-1}$ . Then  $L(\mathbf{B}, \mathbf{A}) = \text{diag}(I_n \otimes T, \dots, I_n \otimes T)L(\mathbf{A})(I_n \otimes T^{-1})$ ,  $\text{rank } L(\mathbf{B}, \mathbf{A}) = r$  and  $\det L(\mathbf{B}, \mathbf{A})[\alpha, \beta] = 0$  for any  $\alpha \in \mathbb{Q}_{r+1, (l+1)n^2}, \beta \in \mathbb{Q}_{r+1, n^2}$ . (See Chapter 23.2)
5. Let  $\mathbf{X} = (X_0, \dots, X_l) \in (\mathbb{C}^{n \times n})^{l+1}$  with the indeterminate entries  $X_k = [x_{k,ij}]$  for  $k = 0, \dots, l$ . Each  $\det L(\mathbf{X}, \mathbf{A})[\alpha, \beta], \alpha \in \mathbb{Q}_{r+1, (l+1)n^2}, \beta \in \mathbb{Q}_{r+1, n^2}$  is a vector in  $\mathcal{W}_{n,l+1,r+1}$ , i.e., it is a multilinear polynomial in  $(l+1)n^2$  variables of degree  $r+1$  at most. We identify  $\det L(\mathbf{X}, \mathbf{A})[\alpha, \beta], \alpha \in \mathbb{Q}_{r+1, (l+1)n^2}, \beta \in \mathbb{Q}_{r+1, n^2}$  with the **row** vector  $\mathbf{a}(\mathbf{A}, \alpha, \beta) \in \mathbb{C}^{N(n,l,r)}$  given by its coefficients in the basis  $\mathbf{e}_1, \dots, \mathbf{e}_{N(n,l,r)}$ . The number of these vectors is  $M(n, l, r) := \binom{(l+1)n^2}{r+1} \binom{n^2}{r+1}$ . Let  $R(\mathbf{A}) \in \mathbb{C}^{M(n,l,r)N(n,l,r) \times M(n,l,r)N(n,l,r)}$  be the matrix with the rows  $\mathbf{a}(\mathbf{A}, \alpha, \beta)$ , where the pairs  $(\alpha, \beta) \in \mathbb{Q}_{r+1, (l+1)n^2} \times \mathbb{Q}_{r+1, n^2}$  are listed in a lexicographical order.
6. All points on the orb  $(\mathbf{A})$  satisfy the following polynomial equations in  $\mathbb{C}[(\mathbb{C}^{n \times n})^{l+1}]$ :

$$\begin{aligned} \det L(\mathbf{X}, \mathbf{A})[\alpha, \beta] &= 0, \\ \text{for all } \alpha \in \mathbb{Q}_{r+1, (l+1)n^2}, \beta \in \mathbb{Q}_{r+1, n^2}. \end{aligned} \tag{24.1}$$

Thus, the matrix  $R(\mathbf{A})$  determines the above variety.

7. If  $\mathbf{B} = T\mathbf{A}T^{-1}$ , then  $R(\mathbf{A})$  is row equivalent to  $R(\mathbf{B})$ . To each orb  $(\mathbf{A})$  we can associate a unique reduced row echelon form  $F(\mathbf{A}) \in \mathbb{C}^{M(n,l,r)N(n,l,r) \times M(n,l,r)N(n,l,r)}$  of  $R(\mathbf{A})$ .  $\varrho(\mathbf{A}) := \text{rank } R(\mathbf{A})$  is the number of linearly independent polynomials given in (24.1). Let  $\mathcal{I}(\mathbf{A}) = \{(1, j_1), \dots, (\varrho(\mathbf{A}), j_{\varrho(\mathbf{A})})\} \subset \{1, \dots, \varrho(\mathbf{A})\} \times \{1, \dots, N(n, l, r)\}$  be the location of the pivots in the  $M(n, l, r) \times N(n, l, r)$  matrix  $F(\mathbf{A}) = [f_{ij}(\mathbf{A})]$ . That is,  $1 \leq j_1 < \dots < j_{\varrho(\mathbf{A})} \leq N(n, l, r)$ ,  $f_{j_i, i}(\mathbf{A}) = 1$  for  $i = 1, \dots, \varrho(\mathbf{A})$  and  $f_{ij} = 0$  unless  $j \geq i$  and  $i \in [1, \varrho(\mathbf{A})]$ . The nontrivial entries  $f_{ij}(\mathbf{A})$  for  $j > i$  are rational functions in the entries of the  $l+1$  tuple  $\mathbf{A}$ . Thus,  $F(\mathbf{B}) = F(\mathbf{A})$  for  $\mathbf{B} \in \text{orb } (\mathbf{A})$ . The numbers  $r(\mathbf{A}) := \text{rank } L(\mathbf{A}), \varrho(\mathbf{A})$  and the set  $\mathcal{I}(\mathbf{A})$  are called the **discrete** invariants of orb  $(\mathbf{A})$ . The rational functions  $f_{ij}(\mathbf{A}), i = 1, \dots, \varrho(\mathbf{A}), j = i+1, \dots, N(n, l, r)$  are called the **continuous** invariants of orb  $(\mathbf{A})$ .
8. (*Classification Theorem for Simultaneous Similarity*) Let  $l \geq 1, n \geq 2$  be integers. Fix an integer  $r \in [0, n^2 - 1]$  and let  $M(n, l, r), N(n, l, r)$  be the integers defined as above. Let  $0 \leq \varrho \leq \min(M(n, l, r), N(n, l, r))$  and the set  $\mathcal{I} = \{(1, j_1), \dots, (\varrho, j_{\varrho})\} \subset \{1, \dots, \varrho\} \times \{1, \dots, N(n, l, r)\}, 1 \leq j_1 < \dots < j_{\varrho} \leq N(n, l, r)$  be given. Let  $\mathcal{M}_{n,l+1,r}(\varrho, \mathcal{I})$  be the set of all  $\mathbf{A} \in (\mathbb{C}^{n \times n})^{l+1}$  such that  $\text{rank } L(\mathbf{A}) = r, \varrho(\mathbf{A}) = \varrho$ , and  $\mathcal{I}(\mathbf{A}) = \mathcal{I}$ . Then  $\mathcal{M}_{n,l+1,r}(\varrho, \mathcal{I})$  is invariant quasi-irreducible variety under the action of  $\text{GL}(n, \mathbb{C})$ . Suppose that  $\mathcal{M}_{n,l+1,r}(\varrho, \mathcal{I}) \neq \emptyset$ . Recall that for each  $\mathbf{A} \in \mathcal{M}_{n,l+1,r}(\varrho, \mathcal{I})$  the continuous invariants of  $\mathbf{A}$ , which correspond to the entries  $f_{ij}(\mathbf{A}), i = 1, \dots, \varrho, j = i+1, \dots, N(n, l, r)$  of the reduced row echelon form of  $R(\mathbf{A})$ , are regular rational invariant functions on  $\mathcal{M}_{n,l+1,r}(\varrho, \mathcal{I})$ . Then the values of the continuous invariants determine a finite number of orbits in  $\mathcal{M}_{n,l+1,r}(\varrho, \mathcal{I})$ .

The quasi-irreducible variety  $\mathcal{M}_{n,l+1,r}(\varrho, \mathcal{I})$  decomposes uniquely as a finite union of invariant regular quasi-irreducible varieties. The union of all these decompositions of  $\mathcal{M}_{n,l+1,r}(\varrho, \mathcal{I})$  for all possible values  $r, \varrho$ , and the sets  $\mathcal{I}$  gives rise to an invariant stratification of  $(\mathbb{C}^{n \times n})^{l+1}$ .

Max-plus algebra has been discovered more or less independently by several schools, in relation with various mathematical fields. This chapter is limited to finite dimensional linear algebra. For more information, the reader may consult the books [CG79], [Zim81], [CKR84], [BCOQ92], [KM97], [GM02], and [HOvdW06]. The collections of articles [MS92], [Gun98], and [LM05] give a good idea of current developments.

### 25.1 Preliminaries

---

#### Definitions:

The **max-plus semiring**  $\mathbb{R}_{\max}$  is the set  $\mathbb{R} \cup \{-\infty\}$ , equipped with the **addition**  $(a, b) \mapsto \max(a, b)$  and the **multiplication**  $(a, b) \mapsto a + b$ . The identity element for the addition, **zero**, is  $-\infty$ , and the identity element for the multiplication, **unit**, is 0. To illuminate the linear algebraic nature of the results, the generic notations  $\oplus$ ,  $\sum$ ,  $\otimes$  (or concatenation),  $\mathbf{0}$  and  $\mathbf{1}$  are used for the addition, the sum, the multiplication, the zero, and the unit of  $\mathbb{R}_{\max}$ , respectively, so that when  $a, b$  belong to  $\mathbb{R}_{\max}$ ,  $a \oplus b$  will mean  $\max(a, b)$ ,  $a \otimes b$  or  $ab$  will mean the usual sum  $a + b$ . We use blackboard (double struck) fonts to denote the max-plus operations (compare “ $\oplus$ ” with “ $+$ ”).

The **min-plus semiring**  $\mathbb{R}_{\min}$  is the set  $\mathbb{R} \cup \{+\infty\}$  equipped with the addition  $(a, b) \mapsto \min(a, b)$  and the multiplication  $(a, b) \mapsto a + b$ . The zero is  $+\infty$ , the unit 0. The name **tropical** is now also used essentially as a synonym of min-plus. Properly speaking, it refers to the **tropical semiring**, which is the subsemiring of  $\mathbb{R}_{\min}$  consisting of the elements in  $\mathbb{N} \cup \{+\infty\}$ .

The **completed max-plus semiring**  $\overline{\mathbb{R}}_{\max}$  is the set  $\mathbb{R} \cup \{\pm\infty\}$  equipped with the addition  $(a, b) \mapsto \max(a, b)$  and the multiplication  $(a, b) \mapsto a + b$ , with the convention that  $-\infty + (+\infty) = +\infty + (-\infty) = -\infty$ . The **completed min-plus semiring**,  $\overline{\mathbb{R}}_{\min}$ , is defined in a dual way.

Many classical algebraic definitions have max-plus analogues. For instance,  $\mathbb{R}_{\max}^n$  is the set of  $n$ -dimensional **vectors** and  $\mathbb{R}_{\max}^{n \times p}$  is the set of  $n \times p$  **matrices** with entries in  $\mathbb{R}_{\max}$ . They are equipped with the vector and matrix operations, defined and denoted in the usual way. The  $n \times p$  **zero matrix**,  $\mathbf{0}_{np}$  or  $\mathbf{0}$ , has all its entries equal to  $\mathbf{0}$ . The  $n \times n$  **identity matrix**,  $I_n$  or  $I$ , has diagonal entries equal to  $\mathbf{1}$ , and

nondiagonal entries equal to  $\mathbf{0}$ . Given a matrix  $A = (A_{ij}) \in \mathbb{R}_{\max}^{n \times p}$ , we denote by  $A_i$  and  $A_j$  the  $i$ -th row and the  $j$ -th column of  $A$ . We also denote by  $A$  the linear map  $\mathbb{R}_{\max}^p \rightarrow \mathbb{R}_{\max}^n$  sending a vector  $x$  to  $Ax$ . **Semimodules** and **subsemimodules** over the semiring  $\mathbb{R}_{\max}$  are defined as the analogues of modules and submodules over rings. A subset  $F$  of a semimodule  $M$  over  $\mathbb{R}_{\max}$  **spans**  $M$ , or is a **spanning family** of  $M$ , if every element  $\mathbf{x}$  of  $M$  can be expressed as a finite linear combination of the elements of  $F$ , meaning that  $\mathbf{x} = \sum_{\mathbf{f} \in F} \lambda_{\mathbf{f}} \mathbf{f}$ , where  $(\lambda_{\mathbf{f}})_{\mathbf{f} \in F}$  is a family of elements of  $\mathbb{R}_{\max}$  such that  $\lambda_{\mathbf{f}} = \mathbf{0}$  for all but finitely many  $\mathbf{f} \in F$ . A semimodule is **finitely generated** if it has a finite spanning family.

The sets  $\mathbb{R}_{\max}$  and  $\overline{\mathbb{R}}_{\max}$  are ordered by the usual order of  $\mathbb{R} \cup \{\pm\infty\}$ . Vectors and matrices over  $\overline{\mathbb{R}}_{\max}$  are ordered with the product ordering. The supremum and the infimum operations are denoted by  $\vee$  and  $\wedge$ , respectively. Moreover, the sum of the elements of an arbitrary set  $X$  of scalars, vectors, or matrices with entries in  $\overline{\mathbb{R}}_{\max}$  is by definition the supremum of  $X$ .

If  $A \in \overline{\mathbb{R}}_{\max}^{n \times n}$ , the **Kleene star** of  $A$  is the matrix  $A^* = I \# A \# A^2 \# \dots$ .

The **digraph**  $\Gamma(A)$  associated to an  $n \times n$  matrix  $A$  with entries in  $\overline{\mathbb{R}}_{\max}$  consists of the vertices  $1, \dots, n$ , with an arc from vertex  $i$  to vertex  $j$  when  $A_{ij} \neq \mathbf{0}$ . The **weight** of a walk  $W$  given by  $(i_1, i_2), \dots, (i_{k-1}, i_k)$  is  $|W|_A := A_{i_1 i_2} \cdots A_{i_{k-1} i_k}$ , and its **length** is  $|W| := k - 1$ . The matrix  $A$  is **irreducible** if  $\Gamma(A)$  is strongly connected.

### Facts:

1. When  $A \in \overline{\mathbb{R}}_{\max}^{n \times n}$ , the weight of a walk  $W = ((i_1, i_2), \dots, (i_{k-1}, i_k))$  in  $\Gamma(A)$  is given by the usual sum  $|W|_A = A_{i_1 i_2} + \dots + A_{i_{k-1} i_k}$ , and  $A_{ij}^*$  gives the maximal weight  $|W|_A$  of a walk from vertex  $i$  to vertex  $j$ . One can also define the matrix  $A^*$  when  $A \in \overline{\mathbb{R}}_{\min}^{n \times n}$ . Then,  $A_{ij}^*$  is the minimal weight of a walk from vertex  $i$  to vertex  $j$ . Computing  $A^*$  is the same as the all pairs' shortest path problem.
2. [CG79], [BCOQ92, Th. 3.20] If  $A \in \overline{\mathbb{R}}_{\max}^{n \times n}$  and the weights of the cycles of  $\Gamma(A)$  do not exceed  $\mathbb{1}$ , then  $A^* = I \# A \# \dots \# A^{n-1}$ .
3. [BCOQ92, Th. 4.75 and Rk. 80] If  $A \in \overline{\mathbb{R}}_{\max}^{n \times n}$  and  $\mathbf{b} \in \overline{\mathbb{R}}_{\max}^n$ , then the smallest  $\mathbf{x} \in \overline{\mathbb{R}}_{\max}^n$  such that  $\mathbf{x} = A\mathbf{x} \# \mathbf{b}$  coincides with the smallest  $\mathbf{x} \in \overline{\mathbb{R}}_{\max}^n$  such that  $\mathbf{x} \geq A\mathbf{x} \# \mathbf{b}$ , and it is given by  $A^*\mathbf{b}$ .
4. [BCOQ92, Th. 3.17] When  $A \in \overline{\mathbb{R}}_{\max}^{n \times n}$ ,  $\mathbf{b} \in \overline{\mathbb{R}}_{\max}^n$ , and when all the cycles of  $\Gamma(A)$  have a weight strictly less than  $\mathbb{1}$ , then  $A^*\mathbf{b}$  is the unique solution  $\mathbf{x} \in \overline{\mathbb{R}}_{\max}^n$  of  $\mathbf{x} = A\mathbf{x} \# \mathbf{b}$ .
5. Let  $A \in \overline{\mathbb{R}}_{\max}^{n \times n}$  and  $\mathbf{b} \in \overline{\mathbb{R}}_{\max}^n$ . Construct the sequence:

$$\mathbf{x}_0 = \mathbf{b}, \mathbf{x}_1 = A\mathbf{x}_0 \# \mathbf{b}, \mathbf{x}_2 = A\mathbf{x}_1 \# \mathbf{b}, \dots$$

The sequence  $\mathbf{x}_k$  is nondecreasing. If all the cycles of  $\Gamma(A)$  have a weight less than or equal to  $\mathbb{1}$ , then,  $\mathbf{x}_{n-1} = \mathbf{x}_n = \dots = A^*\mathbf{b}$ . Otherwise,  $\mathbf{x}_{n-1} \neq \mathbf{x}_n$ . Computing the sequence  $\mathbf{x}_k$  to determine  $A^*\mathbf{b}$  is a special instance of label correcting shortest path algorithm [GP88].

6. [BCOQ92, Lemma 4.101] For all  $a \in \overline{\mathbb{R}}_{\max}^{n \times n}$ ,  $b \in \overline{\mathbb{R}}_{\max}^{n \times p}$ ,  $c \in \overline{\mathbb{R}}_{\max}^{p \times n}$ , and  $d \in \overline{\mathbb{R}}_{\max}^{p \times p}$ , we have

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix}^* = \begin{bmatrix} a^* \# a^*b(ca^*b \# d)^*ca^* & a^*b(ca^*b \# d)^* \\ (ca^*b \# d)^*ca^* & (ca^*b \# d)^* \end{bmatrix}.$$

This fact and the next one are special instances of well-known results of language theory [Eil74], concerning unambiguous rational identities. Both are valid in more general semirings.

7. [MY60] Let  $A \in \overline{\mathbb{R}}_{\max}^{n \times n}$ . Construct the sequence of matrices  $A^{(0)}, \dots, A^{(n)}$  such that  $A^{(0)} = A$  and

$$A_{ij}^{(k)} = A_{ij}^{(k-1)} \# A_{ik}^{(k-1)}(A_{kk}^{(k-1)})^*A_{kj}^{(k-1)},$$

for  $i, j = 1, \dots, n$  and  $k = 1, \dots, n$ . Then,  $A^{(n)} = A \# A^2 \# \dots$ .

**Example:**

1. Consider the matrix

$$A = \begin{bmatrix} 4 & 3 \\ 7 & -\infty \end{bmatrix}.$$

The digraph  $\Gamma(A)$  is

We have

$$A^2 = \begin{bmatrix} 10 & 7 \\ 11 & 10 \end{bmatrix}.$$

For instance,  $A_{11}^2 = A_{1.}A_{.1} = [4 \ 3][4 \ 7]^T = \max(4 + 4, 3 + 7) = 10$ . This gives the maximal weight of a walk of length 2 from vertex 1 to vertex 1, which is attained by the walk  $(1, 2), (2, 1)$ . Since there is one cycle with positive weight in  $\Gamma(A)$  (for instance, the cycle  $(1, 1)$  has weight 4), and since  $A$  is irreducible, the matrix  $A^*$  has all its entries equal to  $+\infty$ . To get a Kleene star with finite entries, consider the matrix

$$C = (-5)A = \begin{bmatrix} -1 & -2 \\ 2 & -\infty \end{bmatrix}.$$

The only cycles in  $\Gamma(A)$  are  $(1, 1)$  and  $(1, 2), (2, 1)$  (up to a cyclic conjugacy). They have weights  $-1$  and  $0$ . Applying Fact 2, we get

$$C^* = I \uplus C = \begin{bmatrix} 0 & -2 \\ 2 & 0 \end{bmatrix}.$$

**Applications:**

1. *Dynamic programming.* Consider a deterministic Markov decision process with a set of states  $\{1, \dots, n\}$  in which one player can move from state  $i$  to state  $j$ , receiving a payoff of  $A_{ij} \in \mathbb{R} \cup \{-\infty\}$ . To every state  $i$ , associate an initial payoff  $c_i \in \mathbb{R} \cup \{-\infty\}$  and a terminal payoff  $\mathbf{b}_i \in \mathbb{R} \cup \{-\infty\}$ . The value in horizon  $k$  is by definition the maximum of the sums of the payoffs (including the initial and terminal payoffs) corresponding to all the trajectories consisting exactly of  $k$  moves. It is given by  $\mathbf{c}A^k\mathbf{b}$ , where the product and the power are understood in the max-plus sense. The special case where the initial state is equal to some given  $m \in \{1, \dots, n\}$  (and where there is no initial payoff) can be modeled by taking  $\mathbf{c} := \mathbf{e}_m$ , the  $m$ -th max-plus basis vector (whose entries are all equal to  $\mathbf{0}$ , except the  $m$ -th entry, which is equal to  $\mathbf{1}$ ). The case where the final state is fixed can be represented in a dual way. Deterministic Markov decision problems (which are the same as shortest path problems) are ubiquitous in operations research, mathematical economics, and optimal control.
2. [BCOQ92] *Discrete event systems.* Consider a system in which certain repetitive events, denoted by  $1, \dots, n$ , occur. To every event  $i$  is associated a dater function  $x_i : \mathbb{Z} \rightarrow \mathbb{R}$ , where  $x_i(k)$  represents the date of the  $k$ -th occurrence of event  $i$ . Precedence constraints between the repetitive events are given by a set of arcs  $E \subset \{1, \dots, n\}^2$ , equipped with two valuations  $\nu : E \rightarrow \mathbb{N}$  and  $\tau : E \rightarrow \mathbb{R}$ . If  $(i, j) \in E$ , the  $k$ -th execution of event  $i$  cannot occur earlier than  $\tau_{ij}$  time units before the  $(k - \nu_{ij})$ -th execution of event  $j$ , so that  $x_i(k) \geq \max_{j: (i,j) \in E} \tau_{ij} + x_j(k - \nu_{ij})$ . This can be rewritten, using the max-plus notation, as

$$\mathbf{x}(k) \geq A_0\mathbf{x}(k) \uplus \dots \uplus A_{\bar{\nu}}\mathbf{x}(k - \bar{\nu}),$$

where  $\bar{v} := \max_{(i,j) \in E} v_{ij}$  and  $\mathbf{x}(k) \in \mathbb{R}_{\max}^n$  is the vector with entries  $x_i(k)$ . Often, the dates  $x_i(k)$  are only defined for positive  $k$ , then appropriate initial conditions must be incorporated in the model. One is particularly interested in the earliest dynamics, which, by Fact 3, is given by  $\mathbf{x}(k) = A_0^* A_1 \mathbf{x}(k-1) \# \cdots \# A_0^* A_{\bar{v}} \mathbf{x}(k-\bar{v})$ . The class of systems following dynamics of these forms is known in the Petri net literature as **timed event graphs**. It is used to model certain manufacturing systems [CDQV85], or transportation or communication networks [BCOQ92], [HOvdW06].

- N. Bacaër [Bac03] observed that max-plus algebra appears in a familiar problem, crop rotation. Suppose  $n$  different crops can be cultivated every year. Assume for simplicity that the income of the year is a deterministic function,  $(i, j) \mapsto A_{ij}$ , depending only on the crop  $i$  of the preceding year, and of the crop  $j$  of the current year (a slightly more complex model in which the income of the year depends on the crops of the two preceding years is needed to explain the historical variations of crop rotations [Bac03]). The income of a sequence  $i_1, \dots, i_k$  of crops can be written as  $\mathbf{c}_{i_1} A_{i_1 i_2} \cdots A_{i_{k-1} i_k}$ , where  $\mathbf{c}_{i_1}$  is the income of the first year. The maximal income in  $k$  years is given by  $\mathbf{c} A^{k-1} \mathbf{b}$ , where  $\mathbf{b} = (\mathbf{1}, \dots, \mathbf{1})$ . We next show an example.

Here, vertices 1, 2, and 3 represent fallow (no crop), wheat, and oats, respectively. (We put no arc from 1 to 1, setting  $A_{11} = -\infty$ , to disallow two successive years of fallow.) The numerical values have no pretension to realism; however, the income of a year of wheat is 11 after a year of fallow, this is greater than after a year of cereal (5 or 6, depending on whether wheat or oats was cultivated). An initial vector coherent with these data may be  $\mathbf{c} = [-\infty \ 11 \ 8]$ , meaning that the income of the first year is the same as the income after a year of fallow. We have  $\mathbf{c} A \mathbf{b} = 18$ , meaning that the optimal income in 2 years is 18. This corresponds to the optimal walk (2, 3), indicating that wheat and oats should be successively cultivated during these 2 years.

## 25.2 The Maximal Cycle Mean

### Definitions:

- The **maximal cycle mean**,  $\rho_{\max}(A)$ , of a matrix  $A \in \mathbb{R}_{\max}^{n \times n}$ , is the maximum of the weight-to-length ratio over all cycles  $c$  of  $\Gamma(A)$ , that is,

$$\rho_{\max}(A) = \max_{c \text{ cycle of } \Gamma(A)} \frac{|c|_A}{|c|} = \max_{k \geq 1} \max_{i_1, \dots, i_k} \frac{A_{i_1 i_2} + \cdots + A_{i_k i_1}}{k}. \tag{25.1}$$

- Denote by  $\mathbb{R}_+^{n \times n}$  the set of real  $n \times n$  matrices with nonnegative entries. For  $A \in \mathbb{R}_+^{n \times n}$  and  $p > 0$ ,  $A^{(p)}$  is by definition the matrix such that  $(A^{(p)})_{ij} = (A_{ij})^p$ , and

$$\rho_p(A) := (\rho(A^{(p)}))^{1/p},$$

where  $\rho$  denotes the (usual) spectral radius. We also define  $\rho_\infty(A) = \lim_{p \rightarrow +\infty} \rho_p(A)$ .

### Facts:

- [CG79], [Gau92, Ch. IV], [BSvdD95] *Max-plus Collatz–Wielandt formula, I*. Let  $A \in \mathbb{R}_{\max}^{n \times n}$  and  $\lambda \in \mathbb{R}$ . The following assertions are equivalent: (i) There exists  $\mathbf{u} \in \mathbb{R}^n$  such that  $A \mathbf{u} \leq \lambda \mathbf{u}$ ; (ii)  $\rho_{\max}(A) \leq \lambda$ . It follows that

$$\rho_{\max}(A) = \inf_{\mathbf{u} \in \mathbb{R}^n} \max_{1 \leq i \leq n} (A \mathbf{u})_i / \mathbf{u}_i$$

(the product  $\mathbf{A}\mathbf{u}$  and the division by  $\mathbf{u}_i$  should be understood in the max-plus sense). If  $\rho_{\max}(A) > \mathbf{0}$ , then this infimum is attained by some  $\mathbf{u} \in \mathbb{R}^n$ . If in addition  $A$  is irreducible, then Assertion (i) is equivalent to the following: (i') there exists  $\mathbf{u} \in \mathbb{R}_{\max}^n \setminus \{\mathbf{0}\}$  such that  $\mathbf{A}\mathbf{u} \leq \lambda\mathbf{u}$ .

2. [Gau92, Ch. IV], [BSvdD95] *Max-plus Collatz–Wielandt formula, II*. Let  $\lambda \in \mathbb{R}_{\max}$ . The following assertions are equivalent: (i) There exists  $\mathbf{u} \in \mathbb{R}_{\max}^n \setminus \{\mathbf{0}\}$  such that  $\mathbf{A}\mathbf{u} \geq \lambda\mathbf{u}$ ; (ii)  $\rho_{\max}(A) \geq \lambda$ . It follows that

$$\rho_{\max}(A) = \max_{\mathbf{u} \in \mathbb{R}_{\max}^n \setminus \{\mathbf{0}\}} \min_{\substack{1 \leq i \leq n \\ \mathbf{u}_i \neq \mathbf{0}}} (\mathbf{A}\mathbf{u})_i / \mathbf{u}_i.$$

3. [Fri86] For  $A \in \mathbb{R}_+^{n \times n}$ , we have  $\rho_{\infty}(A) = \exp(\rho_{\max}(\log(A)))$ , where  $\log$  is interpreted entrywise.
4. [KO85] For all  $A \in \mathbb{R}_+^{n \times n}$ , and  $1 \leq q \leq p \leq \infty$ , we have  $\rho_p(A) \leq \rho_q(A)$ .
5. For all  $A, B \in \mathbb{R}_+^{n \times n}$ , we have

$$\rho(A \circ B) \leq \rho_p(A)\rho_q(B) \quad \text{for all } p, q \in [1, \infty] \quad \text{such that } \frac{1}{p} + \frac{1}{q} = 1.$$

This follows from the classical Kingman's inequality [Kin61], which states that the map  $\log \circ \rho \circ \exp$  is convex (exp is interpreted entrywise). We have in particular  $\rho(A \circ B) \leq \rho_{\infty}(A)\rho(B)$ .

6. [Fri86] For all  $A \in \mathbb{R}_+^{n \times n}$ , we have

$$\rho_{\infty}(A) \leq \rho(A) \leq \rho_{\infty}(A)\rho(\hat{A}) \leq \rho_{\infty}(A)n,$$

where  $\hat{A}$  is the pattern matrix of  $A$ , that is,  $\hat{A}_{ij} = 1$  if  $A_{ij} \neq 0$  and  $\hat{A}_{ij} = 0$  if  $A_{ij} = 0$ .

7. [Bap98], [EvdD99] For all  $A \in \mathbb{R}_+^{n \times n}$ , we have  $\lim_{k \rightarrow \infty} (\rho_{\infty}(A^k))^{1/k} = \rho(A)$ .
8. [CG79] *Computing  $\rho_{\max}(A)$  by linear programming*. For  $A \in \mathbb{R}_{\max}^{n \times n}$ ,  $\rho_{\max}(A)$  is the value of the linear program

$$\inf \lambda \text{ s.t. } \exists \mathbf{u} \in \mathbb{R}^n, \quad \forall (i, j) \in E, \quad A_{ij} + \mathbf{u}_j \leq \lambda + \mathbf{u}_i,$$

where  $E = \{(i, j) \mid 1 \leq i, j \leq n, A_{ij} \neq \mathbf{0}\}$  is the set of arcs of  $\Gamma(A)$ .

9. *Dual linear program to compute  $\rho_{\max}(A)$* . Let  $\mathcal{C}$  denote the set of nonnegative vectors  $x = (x_{ij})_{(i,j) \in E}$  such that

$$\forall 1 \leq i \leq n, \quad \sum_{1 \leq k \leq n, (k,i) \in E} x_{ki} = \sum_{1 \leq j \leq n, (i,j) \in E} x_{ij}, \quad \text{and} \quad \sum_{(i,j) \in E} x_{ij} = 1.$$

To every cycle  $c$  of  $\Gamma(A)$  corresponds bijectively the extreme point of the polytope  $\mathcal{C}$  that is given by  $x_{ij} = 1/|c|$  if  $(i, j)$  belongs to  $c$ , and  $x_{ij} = 0$  otherwise. Moreover,  $\rho_{\max}(A) = \sup\{\sum_{(i,j) \in E} A_{ij}x_{ij} \mid x \in \mathcal{C}\}$ .

10. [Kar78] *Karp's formula*. If  $A \in \mathbb{R}_{\max}^{n \times n}$  is irreducible, then, for all  $1 \leq i \leq n$ ,

$$\rho_{\max}(A) = \max_{\substack{1 \leq j \leq n \\ A_{ij}^n \neq \mathbf{0}}} \min_{1 \leq k \leq n} \frac{(A^n)_{ij} - (A^{n-k})_{ij}}{k}. \tag{25.2}$$

To evaluate the right-hand side expression, compute the sequence  $\mathbf{u}^0 = \mathbf{e}_i, \mathbf{u}^1 = \mathbf{u}^0 A, \mathbf{u}^n = \mathbf{u}^{n-1} A$ , so that  $\mathbf{u}^k = A_i^k$  for all  $0 \leq k \leq n$ . This takes a time  $O(nm)$ , where  $m$  is the number of arcs of  $\Gamma(A)$ . One can avoid storing the vectors  $\mathbf{u}^0, \dots, \mathbf{u}^n$ , at the price of recomputing the sequence  $\mathbf{u}^0, \dots, \mathbf{u}^{n-1}$  once  $\mathbf{u}^n$  is known. The time and space complexity of Karp's algorithm are  $O(nm)$  and  $O(n)$ , respectively. The policy iteration algorithm of [CTCG<sup>+</sup>98] seems experimentally more efficient than Karp's algorithm. Other algorithms are given in particular in [CGL96], [BO93], and [EvdD99]. A comparison of maximal cycle mean algorithms appears in [DGI98]. When the entries of  $A$  take only two finite values, the maximal cycle mean of  $A$  can be computed in linear time [CGB95]. The Karp and policy iteration algorithms, as well as the general max-plus operations

(full and sparse matrix products, matrix residuation, etc.) are implemented in the **Maxplus toolbox** of **Scilab**, freely available in the contributed section of the Web site [www.scilab.org](http://www.scilab.org).

**Example:**

1. For the matrix  $A$  in Application 3 of section 25.1, we have  $\rho_{\max}(A) = \max(5, 4, (2 + 11)/2, (2 + 8)/2, (7 + 6)/2, (11 + 7 + 2)/3, (8 + 6 + 2)/3) = 20/3$ , which gives the maximal reward per year. This is attained by the cycle  $(1, 2), (2, 3), (3, 1)$ , corresponding to the rotation of crops: fallow, wheat, oats.

## 25.3 The Max-Plus Eigenproblem

The results of this section and of the next one constitute max-plus spectral theory. Early and fundamental contributions are due to Cuninghame–Green (see [CG79]), Vorobyev [Vor67], Romanovskii [Rom67], Gondran and Minoux [GM77], and Cohen, Dubois, Quadrat, and Viot [CDQV83]. General presentations are included in [CG79], [BCOQ92], and [GM02]. The infinite dimensional max-plus spectral theory (which is not covered here) has been developed particularly after Maslov, in relation with Hamilton–Jacobi partial differential equations; see [MS92] and [KM97]. See also [MPN02], [AGW05], and [Fat06] for recent developments.

In this section and the next two,  $A$  denotes a matrix in  $\mathbb{R}_{\max}^{n \times n}$ .

**Definitions:**

An **eigenvector** of  $A$  is a vector  $\mathbf{u} \in \mathbb{R}_{\max}^n \setminus \{\mathbf{0}\}$  such that  $A\mathbf{u} = \lambda\mathbf{u}$ , for some scalar  $\lambda \in \mathbb{R}_{\max}$ , which is called the **(geometric) eigenvalue** corresponding to  $\mathbf{u}$ . With the notation of classical algebra, the equation  $A\mathbf{u} = \lambda\mathbf{u}$  can be rewritten as

$$\max_{1 \leq j \leq n} A_{ij} + \mathbf{u}_j = \lambda + \mathbf{u}_i, \quad \forall 1 \leq i \leq n.$$

If  $\lambda$  is an eigenvalue of  $A$ , the set of vectors  $\mathbf{u} \in \mathbb{R}_{\max}^n$  such that  $A\mathbf{u} = \lambda\mathbf{u}$  is the **eigenspace** of  $A$  for the eigenvalue  $\lambda$ .

The **saturation digraph** with respect to  $\mathbf{u} \in \mathbb{R}_{\max}^n$ ,  $\text{Sat}(A, \mathbf{u})$ , is the digraph with vertices  $1, \dots, n$  and an arc from vertex  $i$  to vertex  $j$  when  $A_{ij}\mathbf{u}_j = (A\mathbf{u})_i$ .

A cycle  $c = (i_1, i_2), \dots, (i_k, i_1)$  that attains the maximum in (25.1) is called **critical**. The **critical digraph** is the union of the critical cycles. The **critical vertices** are the vertices of the critical digraph.

The **normalized matrix** is  $\tilde{A} = \rho_{\max}(A)^{-1}A$  (when  $\rho_{\max}(A) \neq \mathbf{0}$ ).

For a digraph  $\Gamma$ , vertex  $i$  **has access** to a vertex  $j$  if there is a walk from  $i$  to  $j$  in  $\Gamma$ . The **(access equivalent) classes** of  $\Gamma$  are the equivalence classes of the set of its vertices for the relation “ $i$  has access to  $j$  and  $j$  has access to  $i$ .” A class  $C$  **has access** to a class  $C'$  if some vertex of  $C$  has access to some vertex of  $C'$ . A class is **final** if it has access only to itself.

The **classes** of a matrix  $A$  are the classes of  $\Gamma(A)$ , and the **critical classes** of  $A$  are the classes of the critical digraph of  $A$ . A class  $C$  of  $A$  is **basic** if  $\rho_{\max}(A[C, C]) = \rho_{\max}(A)$ .

**Facts:**

The proof of most of the following facts can be found in particular in [CG79] or [BCOQ92, Sec. 3.7]; we give specific references when needed.

1. For any matrix  $A$ ,  $\rho_{\max}(A)$  is an eigenvalue of  $A$ , and any eigenvalue of  $A$  is less than or equal to  $\rho_{\max}(A)$ .
2. An eigenvalue of  $A$  associated with an eigenvector in  $\mathbb{R}^n$  must be equal to  $\rho_{\max}(A)$ .
3. [ES75] *Max-plus diagonal scaling*. Assume that  $\mathbf{u} \in \mathbb{R}^n$  is an eigenvector of  $A$ . Then the matrix  $B$  such that  $B_{ij} = \mathbf{u}_i^{-1}A_{ij}\mathbf{u}_j$  has all its entries less than or equal to  $\rho_{\max}(A)$ , and the maximum of every of its rows is equal to  $\rho_{\max}(A)$ .
4. If  $A$  is irreducible, then  $\rho_{\max}(A) > \mathbf{0}$  and it is the only eigenvalue of  $A$ . *From now on, we assume that  $\Gamma(A)$  has at least one cycle, so that  $\rho_{\max}(A) > \mathbf{0}$ .*

5. For all critical vertices  $i$  of  $A$ , the column  $\tilde{A}_i^*$  is an eigenvector of  $A$  for the eigenvalue  $\rho_{\max}(A)$ . Moreover, if  $i$  and  $j$  belong to the same critical class of  $A$ , then  $\tilde{A}_i^* = \tilde{A}_j^* \tilde{A}_{ji}^*$ .
6. *Eigenspace for the eigenvalue  $\rho_{\max}(A)$ .* Let  $C_1, \dots, C_s$  denote the critical classes of  $A$ , and let us choose arbitrarily one vertex  $i_t \in C_t$ , for every  $t = 1, \dots, s$ . Then, the columns  $\tilde{A}_{i_t}^*, t = 1, \dots, s$  span the eigenspace of  $A$  for the eigenvalue  $\rho_{\max}(A)$ . Moreover, any spanning family of this eigenspace contains some scalar multiple of every column  $\tilde{A}_{i_t}^*, t = 1, \dots, s$ .
7. Let  $C$  denote the set of critical vertices, and let  $T = \{1, \dots, n\} \setminus C$ . The following facts are proved in a more general setting in [AG03, Th. 3.4], with the exception of (b), which follows from Fact 4 of Section 25.1.
  - (a) The restriction  $\mathbf{v} \mapsto \mathbf{v}[C]$  is an isomorphism from the eigenspace of  $A$  for the eigenvalue  $\rho_{\max}(A)$  to the eigenspace of  $A[C, C]$  for the same eigenvalue.
  - (b) An eigenvector  $\mathbf{u}$  for the eigenvalue  $\rho_{\max}(A)$  is determined from its restriction  $\mathbf{u}[C]$  by  $\mathbf{u}[T] = (\tilde{A}[T, T])^* \tilde{A}[T, C] \mathbf{u}[C]$ .
  - (c) Moreover,  $\rho_{\max}(A)$  is the only eigenvalue of  $A[C, C]$  and the eigenspace of  $A[C, C]$  is stable by infimum and by convex combination in the usual sense.
8. *Complementary slackness.* If  $\mathbf{u} \in \mathbb{R}_{\max}^n$  is such that  $A\mathbf{u} \leq \rho_{\max}(A)\mathbf{u}$ , then  $(A\mathbf{u})_i = \rho_{\max}(A)\mathbf{u}_i$ , for all critical vertices  $i$ .
9. *Critical digraph vs. saturation digraph.* Let  $\mathbf{u} \in \mathbb{R}^n$  be such that  $A\mathbf{u} \leq \rho_{\max}(A)\mathbf{u}$ . Then, the union of the cycles of  $\text{Sat}(A, \mathbf{u})$  is equal to the critical digraph of  $A$ .
10. [CQD90], [Gau92, Ch. IV], [BSvdD95] *Spectrum of reducible matrices.* A scalar  $\lambda \neq \mathbf{0}$  is an eigenvalue of  $A$  if and only if there is at least one class  $C$  of  $A$  such that  $\rho_{\max}(A[C, C]) = \lambda$  and  $\rho_{\max}(A[C, C]) \geq \rho_{\max}(A[C', C'])$  for all classes  $C'$  that have access to  $C$ .
11. [CQD90], [BSvdD95] The matrix  $A$  has an eigenvector in  $\mathbb{R}^n$  if and only if all its final classes are basic.
12. [Gau92, Ch. IV] *Eigenspace for an eigenvalue  $\lambda$ .* Let  $C^1, \dots, C^m$  denote all the classes  $C$  of  $A$  such that  $\rho_{\max}(A[C, C]) = \lambda$  and  $\rho_{\max}(A[C', C']) \leq \lambda$  for all classes  $C'$  that have access to  $C$ . For every  $1 \leq k \leq m$ , let  $C_1^k, \dots, C_{s_k}^k$  denote the critical classes of the matrix  $A[C^k, C^k]$ . For all  $1 \leq k \leq m$  and  $1 \leq t \leq s_k$ , let us choose arbitrarily an element  $j_{k,t}$  in  $C_t^k$ . Then, the family of columns  $(\lambda^{-1}A)_{j_{k,t}}^*$ , indexed by all these  $k$  and  $t$ , spans the eigenspace of  $A$  for the eigenvalue  $\lambda$ , and any spanning family of this eigenspace contains a scalar multiple of every  $(\lambda^{-1}A)_{j_{k,t}}^*$ .
13. *Computing the eigenvectors.* Observe first that any vertex  $j$  that attains the maximum in Karp's formula (25.2) is critical. To compute one eigenvector for the eigenvalue  $\rho_{\max}(A)$ , it suffices to compute  $\tilde{A}_j^*$  for some critical vertex  $j$ . This is equivalent to a single source shortest path problem, which can be solved in  $O(nm)$  time and  $O(n)$  space. Alternatively, one may use the *policy iteration algorithm* of [CTCG<sup>+</sup>98] or the improvement in [EvdD99] of the *power algorithm* [BO93]. Once a particular eigenvector is known, the critical digraph can be computed from Fact 9 in  $O(m)$  additional time.

**Examples:**

1. For the matrix  $A$  in Application 3 of section 25.1, the only critical cycle is (1, 2), (2, 3), (3, 1) (up to a circular permutation of vertices). The critical digraph consists of the vertices and arcs of this cycle. By Fact 6, any eigenvector  $\mathbf{u}$  of  $A$  is proportional to  $\tilde{A}_1^* = [0 - 13/3 - 14/3]^T$  (or equivalently, to  $\tilde{A}_2^*$  or  $\tilde{A}_3^*$ ). Observe that an eigenvector yields a relative price information between the different states.
2. Consider the matrix and its associated digraph:

$$A = \begin{array}{c|ccc|ccc|c} \hline 0 & \cdot & 0 & \cdot & 7 & \cdot & \cdot & \cdot \\ \hline \cdot & \cdot & 3 & 0 & \cdot & \cdot & \cdot & \cdot \\ \hline \cdot & 1 & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \hline \cdot & 2 & \cdot & \cdot & \cdot & \cdot & \cdot & 10 \\ \hline \cdot & \cdot & \cdot & \cdot & 1 & 0 & \cdot & \cdot \\ \hline \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & 0 & \cdot \\ \hline \cdot & \cdot & \cdot & \cdot & -1 & 2 & \cdot & 23 \\ \hline \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & -3 \\ \hline \end{array}$$

(We use  $\cdot$  to represent the element  $-\infty$ .) The classes of  $A$  are  $C^1 = \{1\}$ ,  $C^2 = \{2, 3, 4\}$ ,  $C^3 = \{5, 6, 7\}$ , and  $C^4 = \{8\}$ . We have  $\rho_{\max}(A) = \rho_{\max}(A[C^2, C^2]) = 2$ ,  $\rho_{\max}(A[C^1, C^1]) = 0$ ,  $\rho_{\max}(A[C^3, C^3]) = 1$ , and  $\rho_{\max}(A[C^4, C^4]) = -3$ . The critical digraph is reduced to the critical cycle  $(2, 3)(3, 2)$ . By Fact 6, any eigenvector for the eigenvalue  $\rho_{\max}(A)$  is proportional to  $\tilde{A}_2^* = [-3 \ 0 \ -1 \ 0 \ -\infty \ -\infty \ -\infty \ -\infty]^T$ . By Fact 10, the other eigenvalues of  $A$  are 0 and 1. By Fact 12, any eigenvector for the eigenvalue 0 is proportional to  $A_{\cdot 1}^* = \mathbf{e}_1$ . Observe that the critical classes of  $A[C^3, C^3]$  are  $C_1^3 = \{5\}$  and  $C_2^3 = \{6, 7\}$ . Therefore, by Fact 12, any eigenvector for the eigenvalue 1 is a max-plus linear combination of  $(1^{-1}A)_{\cdot 5}^* = [6 \ -\infty \ -\infty \ -\infty \ 0 \ -3 \ -2 \ -\infty]^T$  and  $(1^{-1}A)_{\cdot 6}^* = [5 \ -\infty \ -\infty \ -\infty \ -1 \ 0 \ 1 \ -\infty]^T$ . The eigenvalues of  $A^T$  are 2, 1, and  $-3$ . So  $A$  and  $A^T$  have only two eigenvalues in common.

## 25.4 Asymptotics of Matrix Powers

### Definitions:

A sequence  $s_0, s_1, \dots$  of elements of  $\mathbb{R}_{\max}$  is **recognizable** if there exists a positive integer  $p$ , vectors  $\mathbf{b} \in \mathbb{R}_{\max}^{p \times 1}$  and  $\mathbf{c} \in \mathbb{R}_{\max}^{1 \times p}$ , and a matrix  $M \in \mathbb{R}_{\max}^{p \times p}$  such that  $s_k = \mathbf{c}M^k\mathbf{b}$ , for all nonnegative integers  $k$ .

A sequence  $s_0, s_1, \dots$  of elements of  $\mathbb{R}_{\max}$  is **ultimately geometric with rate**  $\lambda \in \mathbb{R}_{\max}$  if  $s_{k+1} = \lambda s_k$  for  $k$  large enough.

The **merge** of  $q$  sequences  $s^1, \dots, s^q$  is the sequence  $s$  such that  $s_{kq+i-1} = s_k^i$ , for all  $k \geq 0$  and  $1 \leq i \leq q$ .

### Facts:

- [Gun94], [CTGG99] If every row of the matrix  $A$  has at least one entry different from  $\mathbf{0}$ , then, for all  $1 \leq i \leq n$  and  $\mathbf{u} \in \mathbb{R}^n$ , the limit

$$\chi_i(A) = \lim_{k \rightarrow \infty} (A^k \mathbf{u})_i^{1/k}$$

exists and is independent of the choice of  $\mathbf{u}$ . The vector  $\chi(A) = (\chi_i(A))_{1 \leq i \leq n} \in \mathbb{R}^n$  is called the **cycle-time** of  $A$ . It is given by

$$\chi_i(A) = \max\{\rho_{\max}(A[C, C]) \mid C \text{ is a class of } A \text{ to which } i \text{ has access}\}.$$

In particular, if  $A$  is irreducible, then  $\chi_i(A) = \rho_{\max}(A)$  for all  $i = 1, \dots, n$ .

- The following constitutes the cyclicity theorem, due to Cohen, Dubois, Quadrat, and Viot [CDQV83]. See [BCOQ92] and [AGW05] for more accessible accounts.
  - If  $A$  is irreducible, there exists a positive integer  $\gamma$  such that  $A^{k+\gamma} = \rho_{\max}(A)^\gamma A^k$  for  $k$  large enough. The minimal value of  $\gamma$  is called the **cyclicity** of  $A$ .
  - Assume again that  $A$  is irreducible. Let  $C_1, \dots, C_s$  be the critical classes of  $A$ , and for  $i = 1, \dots, s$ , let  $\gamma_i$  denote the g.c.d. (greatest common divisor) of the lengths of the critical cycles of  $A$  belonging to  $C_i$ . Then, the cyclicity  $\gamma$  of  $A$  is the l.c.m. (least common multiple) of  $\gamma_1, \dots, \gamma_s$ .
  - Assume that  $\rho_{\max}(A) \neq \mathbf{0}$ . The **spectral projector** of  $A$  is the matrix  $P := \lim_{k \rightarrow \infty} \tilde{A}^k \tilde{A}^* = \lim_{k \rightarrow \infty} \tilde{A}^k \# \tilde{A}^{k+1} \# \dots$ . It is given by  $P = \sum_{i \in C} \tilde{A}_{\cdot i}^* \tilde{A}_{i \cdot}^*$ , where  $C$  denotes the set of critical vertices of  $A$ . When  $A$  is irreducible, the limit is attained in finite time. If, in addition,  $A$  has cyclicity one, then  $A^k = \rho_{\max}(A)^k P$  for  $k$  large enough.
- Assume that  $A$  is irreducible, and let  $m$  denote the number of arcs of its critical digraph. Then, the cyclicity of  $A$  can be computed in  $O(m)$  time from the critical digraph of  $A$ , using the algorithm of Denardo [Den77].

4. The smallest integer  $k$  such that  $A^{k+\gamma} = \rho_{\max}(A)^\gamma A^k$  is called the **coupling time**. It is estimated in [HA99], [BG01], [AGW05] (assuming again that  $A$  is irreducible).
5. [AGW05, Th. 7.5] *Turnpike theorem*. Define a walk of  $\Gamma(A)$  to be optimal if it has a maximal weight amongst all walks with the same ends and length. If  $A$  is irreducible, then the number of noncritical vertices of an optimal walk (counted with multiplicities) is bounded by a constant depending only on  $A$ .
6. [Mol88], [Gau94], [KB94], [DeS00] A sequence of elements of  $\mathbb{R}_{\max}$  is recognizable if and only if it is a merge of ultimately geometric sequences. In particular, for all  $1 \leq i, j \leq n$ , the sequence  $(A^k)_{ij}$  is a merge of ultimately geometric sequences.
7. [Sim78], [Has90], [Sim94], [Gau96] One can decide whether a finitely generated semigroup  $S$  of matrices with effective entries in  $\mathbb{R}_{\max}$  is finite. One can also decide whether the set of entries in a given position of the matrices of  $S$  is finite (limitedness problem). However [Kro94], whether this set contains a given entry is undecidable (even when the entries of the matrices belong to  $\mathbb{Z} \cup \{-\infty\}$ ).

**Example:**

1. For the matrix  $A$  in Application 3 of section 25.1, the cyclicity is 3, and the spectral projector is

$$P = \tilde{A}_{\cdot 1}^* \tilde{A}_{1 \cdot}^* = \begin{bmatrix} 0 \\ -13/3 \\ -14/3 \end{bmatrix} \begin{bmatrix} 0 & 13/3 & 14/3 \end{bmatrix}^T = \begin{bmatrix} 0 & 13/3 & 14/3 \\ -13/3 & 0 & 1/3 \\ -14/3 & -1/3 & 0 \end{bmatrix}.$$

2. For the matrix  $A$  in Example 2 of Section 25.3, the cycle-time is  $\chi(A) = [2 \ 2 \ 2 \ 2 \ 1 \ 1 \ 1 \ -3]^T$ . The cyclicity of  $A[C^2, C^2]$  is 2 because there is only one critical cycle, which has length 2. Let  $B := A[C^3, C^3]$ . The critical digraph of  $B$  has two strongly connected components consisting, respectively, of the cycles (5, 5) and (6, 7), (7, 6). So  $B$  has cyclicity l.c.m. (1, 2) = 2. The sequence  $s_k := (A^k)_{18}$  is such that  $s_{k+2} = s_k + 4$ , for  $k \geq 24$ , with  $s_{24} = s_{25} = 51$ . Hence,  $s_k$  is the merge of two ultimately geometric sequences, both with rate 4. To get an example where different rates appear, replace the entries  $A_{11}$  and  $A_{88}$  of  $A$  by  $-\infty$ . Then, the same sequence  $s_k$  is such that  $s_{k+2} = s_k + 4$ , for all even  $k \geq 24$ , and  $s_{k+2} = s_k + 2$ , for all odd  $k \geq 5$ , with  $s_5 = 31$  and  $s_{24} = 51$ .

## 25.5 The Max-Plus Permanent

---

**Definitions:**

The (max-plus) **permanent** of  $A$  is per  $A = \sum_{\sigma \in S_n} A_{1\sigma(1)} \cdots A_{n\sigma(n)}$ , or with the usual notation of classical algebra, per  $A = \max_{\sigma \in S_n} A_{1\sigma(1)} + \cdots + A_{n\sigma(n)}$ , which is the value of the optimal assignment problem with weights  $A_{ij}$ .

A **max-plus polynomial function**  $P$  is a map  $\mathbb{R}_{\max} \rightarrow \mathbb{R}_{\max}$  of the form  $P(x) = \sum_{i=0}^n p_i x^i$  with  $p_i \in \mathbb{R}_{\max}$ ,  $i = 0, \dots, n$ . If  $p_n \neq \mathbf{0}$ ,  $P$  is of **degree**  $n$ .

The **roots** of a nonzero max-plus polynomial function  $P$  are the points of nondifferentiability of  $P$ , together with the point  $\mathbf{0}$  when the derivative of  $P$  near  $-\infty$  is positive. The **multiplicity** of a root  $\alpha$  of  $P$  is defined as the variation of the derivative of  $P$  at the point  $\alpha$ ,  $P'(\alpha^+) - P'(\alpha^-)$ , when  $\alpha \neq \mathbf{0}$ , and as its derivative near  $-\infty$ ,  $P'(\mathbf{0}^+)$ , when  $\alpha = \mathbf{0}$ .

The (max-plus) **characteristic polynomial function** of  $A$  is the polynomial function  $P_A$  given by  $P_A(x) = \text{per}(A \# xI)$  for  $x \in \mathbb{R}_{\max}$ . The **algebraic eigenvalues** of  $A$  are the roots of  $P_A$ .

**Facts:**

1. [CGM80] Any nonzero max-plus polynomial function  $P$  can be factored uniquely as  $P(x) = a(x \# \alpha_1) \cdots (x \# \alpha_n)$ , where  $a \in \mathbb{R}$ ,  $n$  is the degree of  $P$ , and the  $\alpha_i$  are the roots of  $P$ , counted with multiplicities.

2. [CG83], [ABG04, Th. 4.6 and 4.7]. The greatest algebraic eigenvalue of  $A$  is equal to  $\rho_{\max}(A)$ . Its multiplicity is less than or equal to the number of critical vertices of  $A$ , with equality if and only if the critical vertices can be covered by disjoint critical cycles.
3. Any geometric eigenvalue of  $A$  is an algebraic eigenvalue of  $A$ . (This can be deduced from Fact 2 of this section, and Fact 10 of section 25.3.)
4. [Yoe61] If  $A \geq I$  and  $\text{per } A = \mathbb{1}$ , then  $A_{ij}^* = \text{per } A(j, i)$ , for all  $1 \leq i, j \leq n$ .
5. [But00] Assume that all the entries of  $A$  are different from  $\mathbf{0}$ . The following are equivalent: (i) there is a vector  $b \in \mathbb{R}^n$  that has a unique preimage by  $A$ ; (ii) there is only one permutation  $\sigma$  such that  $|\sigma|_A := A_{1\sigma(1)} \cdots A_{n\sigma(n)} = \text{per } A$ . Further characterizations can be found in [But00] and [DSS05].
6. [Bap95] *Alexandroff inequality over  $\mathbb{R}_{\max}$* . Construct the matrix  $B$  with columns  $A_{.1}, A_{.1}, A_{.3}, \dots, A_{.n}$  and the matrix  $C$  with columns  $A_{.2}, A_{.2}, A_{.3}, \dots, A_{.n}$ . Then  $(\text{per } A)^2 \geq (\text{per } B)(\text{per } C)$ , or with the notation of classical algebra,  $2 \times \text{per } A \geq \text{per } B + \text{per } C$ .
7. [BB03] The max-plus characteristic polynomial function of  $A$  can be computed by solving  $O(n)$  optimal assignment problems.

### Example:

1. For the matrix  $A$  in Example 2 of section 25.3, the characteristic polynomial of  $A$  is the product of the characteristic polynomials of the matrices  $A[C^i, C^i]$ , for  $i = 1, \dots, 4$ . Thus,  $P_A(x) = (x + 0)(x + 2)^2 x(x + 1)^3(x + (-3))$ , and so, the algebraic eigenvalues of  $A$  are  $-\infty, -3, 0, 1$ , and  $2$ , with respective multiplicities  $1, 1, 1, 3$ , and  $2$ .

## 25.6 Linear Inequalities and Projections

### Definitions:

If  $A \in \overline{\mathbb{R}}_{\max}^{n \times p}$ , the **range** of  $A$ , denoted  $\text{range } A$ , is  $\{Ax \mid x \in \overline{\mathbb{R}}_{\max}^p\} \subset \overline{\mathbb{R}}_{\max}^n$ . The **kernel** of  $A$ , denoted  $\ker A$ , is the set of **equivalence classes modulo  $A$** , which are the classes for the equivalence relation “ $x \sim y$  if  $Ax = Ay$ .”

The **support** of a vector  $b \in \overline{\mathbb{R}}_{\max}^n$  is  $\text{supp } b := \{i \in \{1, \dots, n\} \mid b_i \neq \mathbf{0}\}$ .

The **orthogonal congruence** of a subset  $U$  of  $\overline{\mathbb{R}}_{\max}^n$  is  $U^\perp := \{(x, y) \in \overline{\mathbb{R}}_{\max}^n \times \overline{\mathbb{R}}_{\max}^n \mid \mathbf{u} \cdot \mathbf{x} = \mathbf{u} \cdot \mathbf{y} \ \forall \mathbf{u} \in U\}$ , where “ $\cdot$ ” denotes the max-plus scalar product. The **orthogonal space** of a subset  $C$  of  $\overline{\mathbb{R}}_{\max}^n \times \overline{\mathbb{R}}_{\max}^n$  is  $C^\top := \{\mathbf{u} \in \overline{\mathbb{R}}_{\max}^n \mid \mathbf{u} \cdot \mathbf{x} = \mathbf{u} \cdot \mathbf{y} \ \forall (x, y) \in C\}$ .

### Facts:

1. For all  $a, b \in \overline{\mathbb{R}}_{\max}$ , the maximal  $c \in \overline{\mathbb{R}}_{\max}$  such that  $ac \leq b$ , denoted by  $a \setminus b$  (or  $b / a$ ), is given by  $a \setminus b = b - a$  if  $(a, b) \notin \{(-\infty, -\infty), (+\infty, +\infty)\}$ , and  $a \setminus b = +\infty$  otherwise.
2. [BCOQ92, Eq. 4.82] If  $A \in \overline{\mathbb{R}}_{\max}^{n \times p}$  and  $B \in \overline{\mathbb{R}}_{\max}^{n \times q}$ , then the inequation  $AX \leq B$  has a maximal solution  $X \in \overline{\mathbb{R}}_{\max}^{p \times q}$  given by the matrix  $A \setminus B$  defined by  $(A \setminus B)_{ij} = \bigwedge_{1 \leq k \leq n} A_{ki} \setminus B_{kj}$ . Similarly, for  $A \in \overline{\mathbb{R}}_{\max}^{n \times p}$  and  $C \in \overline{\mathbb{R}}_{\max}^{r \times p}$ , the maximal solution  $C / A \in \overline{\mathbb{R}}_{\max}^{r \times n}$  of  $XA \leq C$  exists and is given by  $(C / A)_{ij} = \bigwedge_{1 \leq k \leq p} C_{ik} / A_{jk}$ .
3. The equation  $AX = B$  has a solution if and only if  $A(A \setminus B) = B$ .
4. For  $A \in \overline{\mathbb{R}}_{\max}^{n \times p}$ , the map  $A^\sharp : \mathbf{y} \in \overline{\mathbb{R}}_{\min}^p \rightarrow A \setminus \mathbf{y} \in \overline{\mathbb{R}}_{\min}^n$  is linear. It is represented by the matrix  $-A^T$ .
5. [BCOQ92, Table 4.1] For matrices  $A, B, C$  with entries in  $\overline{\mathbb{R}}_{\max}$  and with appropriate dimensions, we have

$$\begin{aligned} A(A \setminus (AB)) &= AB, & A \setminus (A(A \setminus B)) &= A \setminus B, \\ (A + B) \setminus C &= (A \setminus C) \wedge (B \setminus C), & A \setminus (B \wedge C) &= (A \setminus B) \wedge (A \setminus C), \\ (AB) \setminus C &= B \setminus (A \setminus C), & A \setminus (B / C) &= (A \setminus B) / C. \end{aligned}$$

The first five identities have dual versions, with  $//$  instead of  $\backslash$ . Due to the last identity, we shall write  $A \backslash B // C$  instead of  $A \backslash (B // C)$ .

6. [CGQ97] Let  $A \in \overline{\mathbb{R}}_{\max}^{n \times p}$ ,  $B \in \overline{\mathbb{R}}_{\max}^{n \times q}$  and  $C \in \overline{\mathbb{R}}_{\max}^{r \times p}$ . We have  $\text{range } A \subset \text{range } B \iff A = B(B \backslash A)$ , and  $\text{ker } A \subset \text{ker } C \iff C = (C // A)A$ .
7. [CGQ96] Let  $A \in \overline{\mathbb{R}}_{\max}^{n \times p}$ . The map  $\Pi_A := A \circ A^\sharp$  is a projector on the range of  $A$ , meaning that  $(\Pi_A)^2 = \Pi_A$  and  $\text{range } \Pi_A = \text{range } A$ . Moreover,  $\Pi_A(x)$  is the greatest element of the range of  $A$ , which is less than or equal to  $x$ . Similarly, the map  $\Pi^A := A^\sharp \circ A$  is a projector on the range of  $A^\sharp$ , and  $\Pi^A(x)$  is the smallest element of the range of  $A^\sharp$  that is greater than or equal to  $x$ . Finally, every equivalence class modulo  $A$  meets the range of  $A^\sharp$  at a unique point.
8. [CGQ04], [DS04] For any  $A \in \overline{\mathbb{R}}_{\max}^{n \times p}$ , the map  $x \mapsto A(-x)$  is a bijection from  $\text{range}(A^T)$  to  $\text{range}(A)$ , with inverse map  $x \mapsto A^T(-x)$ .
9. [CGQ96], [CGQ97] *Projection onto a range parallel to a kernel.* Let  $B \in \overline{\mathbb{R}}_{\max}^{n \times p}$  and  $C \in \overline{\mathbb{R}}_{\max}^{q \times n}$ . For all  $x \in \overline{\mathbb{R}}_{\max}^n$ , there is a greatest  $\xi$  on the range of  $B$  such that  $C\xi \leq Cx$ . It is given by  $\Pi_B^C(x)$ , where  $\Pi_B^C := \Pi_B \circ \Pi^C$ . We have  $(\Pi_B^C)^2 = \Pi_B^C$ . Assume now that every equivalence class modulo  $C$  meets the range of  $B$  at a unique point. This is the case if and only if  $\text{range}(CB) = \text{range } C$  and  $\text{ker}(CB) = \text{ker } B$ . Then  $\Pi_B^C(x)$  is the unique element of the range of  $B$ , which is equivalent to  $x$  modulo  $C$ , the map  $\Pi_B^C$  is a linear projector on the range of  $B$ , and it is represented by the matrix  $(B // (CB))C$ , which is equal to  $B((CB) \backslash C)$ .
10. [CGQ97] *Regular matrices.* Let  $A \in \overline{\mathbb{R}}_{\max}^{n \times p}$ . The following assertions are equivalent: (i) there is a linear projector from  $\overline{\mathbb{R}}_{\max}^n$  to  $\text{range } A$ ; (ii)  $A = AXA$  for some  $X \in \overline{\mathbb{R}}_{\max}^{p \times n}$ ; (iii)  $A = A(A \backslash A // A)A$ .
11. [Vor67], [Zim76, Ch. 3] (See also [But94], [AGK05].) *Vorobyev–Zimmermann covering theorem.* Assume that  $A \in \overline{\mathbb{R}}_{\max}^{n \times p}$  and  $\mathbf{b} \in \overline{\mathbb{R}}_{\max}^n$ . For  $j \in \{1, \dots, p\}$ , let

$$S_j = \{i \in \{1, \dots, n\} \mid A_{ij} \neq \mathbf{0} \text{ and } A_{ij} \backslash \mathbf{b}_i = (A \backslash \mathbf{b})_j\}.$$

The equation  $A\mathbf{x} = \mathbf{b}$  has a solution if and only if  $\bigcup_{1 \leq j \leq p} S_j \supset \text{supp } \mathbf{b}$  or equivalently  $\bigcup_{j \in \text{supp}(A \backslash \mathbf{b})} S_j \supset \text{supp } \mathbf{b}$ . It has a unique solution if and only if  $\bigcup_{j \in \text{supp}(A \backslash \mathbf{b})} S_j \supset \text{supp } \mathbf{b}$  and  $\bigcup_{j \in J} S_j \not\supset \text{supp } \mathbf{b}$  for all strict subsets  $J$  of  $\text{supp}(A \backslash \mathbf{b})$ .

12. [Zim77], [SS92], [CGQ04], [CGQS05], [DS04] *Separation theorem.* Let  $A \in \overline{\mathbb{R}}_{\max}^{n \times p}$  and  $\mathbf{b} \in \overline{\mathbb{R}}_{\max}^n$ . If  $\mathbf{b} \notin \text{range } A$ , then there exists  $\mathbf{c}, \mathbf{d} \in \overline{\mathbb{R}}_{\max}^n$  such that the **halfspace**  $H := \{\mathbf{x} \in \overline{\mathbb{R}}_{\max}^n \mid \mathbf{c} \cdot \mathbf{x} \geq \mathbf{d} \cdot \mathbf{x}\}$  contains  $\text{range } A$  but not  $\mathbf{b}$ . We can take  $\mathbf{c} = -\mathbf{b}$  and  $\mathbf{d} = -\Pi_A(\mathbf{b})$ . Moreover, when  $A$  and  $\mathbf{b}$  have entries in  $\mathbb{R}_{\max}$ ,  $\mathbf{c}, \mathbf{d}$  can be chosen with entries in  $\mathbb{R}_{\max}$ .
13. [GP97] For any  $A \in \overline{\mathbb{R}}_{\max}^{n \times p}$ , we have  $(\text{range } A)^\perp = \text{range } A$ .
14. [LMS01], [CGQ04] A linear form defined on a finitely generated subsemimodule of  $\overline{\mathbb{R}}_{\max}^n$  can be extended to  $\overline{\mathbb{R}}_{\max}^n$ . This is a special case of a max-plus analogue of the Riesz representation theorem.
15. [BH84], [GP97] Let  $A, B \in \overline{\mathbb{R}}_{\max}^{n \times p}$ . The set of solutions  $\mathbf{x} \in \overline{\mathbb{R}}_{\max}^p$  of  $A\mathbf{x} = B\mathbf{x}$  is a finitely generated subsemimodule of  $\overline{\mathbb{R}}_{\max}^p$ .
16. [GP97], [Gau98] Let  $X, Y$  be finitely generated subsemimodules of  $\overline{\mathbb{R}}_{\max}^n$ ,  $A \in \overline{\mathbb{R}}_{\max}^{n \times p}$  and  $B \in \overline{\mathbb{R}}_{\max}^{r \times n}$ . Then  $X \cap Y$ ,  $X \sharp Y := \{\mathbf{x} \sharp \mathbf{y} \mid \mathbf{x} \in X, \mathbf{y} \in Y\}$ , and  $X - Y := \{\mathbf{z} \in \overline{\mathbb{R}}_{\max}^n \mid \exists \mathbf{x} \in X, \mathbf{y} \in Y, \mathbf{x} = \mathbf{y} \sharp \mathbf{z}\}$  are finitely generated subsemimodules of  $\overline{\mathbb{R}}_{\max}^n$ . Also,  $A^{-1}(X)$ ,  $B(X)$ , and  $X^\perp$  are finitely generated subsemimodules of  $\overline{\mathbb{R}}_{\max}^p$ ,  $\overline{\mathbb{R}}_{\max}^r$ , and  $\overline{\mathbb{R}}_{\max}^n \times \overline{\mathbb{R}}_{\max}^n$ , respectively. Similarly, if  $Z$  is a finitely generated subsemimodule of  $\overline{\mathbb{R}}_{\max}^n \times \overline{\mathbb{R}}_{\max}^n$ , then  $Z^\perp$  is a finitely generated subsemimodule of  $\overline{\mathbb{R}}_{\max}^n$ .
17. Facts 13 to 16 still hold if  $\overline{\mathbb{R}}_{\max}$  is replaced by  $\mathbb{R}_{\max}$ .
18. When  $A, B \in \overline{\mathbb{R}}_{\max}^{n \times p}$ , algorithms to find one solution of  $A\mathbf{x} = B\mathbf{x}$  are given in [WB98] or [CGB03]. One can also use the general algorithm of [GG98] to compute a finite fixed point of a min-max function, together with the observation that  $\mathbf{x}$  satisfies  $A\mathbf{x} = B\mathbf{x}$  if and only if  $\mathbf{x} = f(\mathbf{x})$ , where  $f(\mathbf{x}) = \mathbf{x} \wedge (A \backslash (B\mathbf{x})) \wedge (B \backslash (A\mathbf{x}))$ .

FIGURE 25.1 Projection of a point on a range.

**Examples:**

1. In order to illustrate Fact 11, consider

$$A = \begin{bmatrix} 0 & 0 & 0 & -\infty & 0.5 \\ 1 & -2 & 0 & 0 & 1.5 \\ 0 & 3 & 2 & 0 & 3 \end{bmatrix}, \quad \mathbf{b} = \begin{bmatrix} 3 \\ 0 \\ 0.5 \end{bmatrix}. \tag{25.3}$$

Let  $\bar{\mathbf{x}} := A \parallel \mathbf{b}$ . We have  $\bar{x}_1 = \min(-0 + 3, -1 + 0, -0 + 0.5) = -1$ , and so,  $S_1 = \{2\}$  because the minimum is attained only by the second term. Similarly,  $\bar{x}_2 = -2.5$ ,  $S_2 = \{3\}$ ,  $\bar{x}_3 = -1.5$ ,  $S_3 = \{3\}$ ,  $\bar{x}_4 = 0$ ,  $S_4 = \{2\}$ ,  $\bar{x}_5 = -2.5$ ,  $S_5 = \{3\}$ . Since  $\cup_{1 \leq j \leq 5} S_j = \{2, 3\} \not\subseteq \text{supp } \mathbf{b} = \{1, 2, 3\}$ , Fact 11 shows that the equation  $A\mathbf{x} = \mathbf{b}$  has no solution. This also follows from the fact that  $\Pi_A(\mathbf{b}) = A(A \parallel \mathbf{b}) = [-1 \ 0 \ 0.5]^T < \mathbf{b}$ .

2. The range of the previous matrix  $A$  is represented in Figure 25.1 (left). A nonzero vector  $\mathbf{x} \in \mathbb{R}_{\max}^3$  is represented by the point that is the barycenter with weights  $(\exp(\beta x_i))_{1 \leq i \leq 3}$  of the vertices of the simplex, where  $\beta > 0$  is a fixed scaling parameter. Every vertex of the simplex represents one basis vector  $\mathbf{e}_i$ . Proportional vectors are represented by the same point. The  $i$ -th column of  $A$ ,  $A_{\cdot i}$ , is represented by the point  $\mathbf{p}_i$  on the figure. Observe that the broken segment from  $\mathbf{p}_1$  to  $\mathbf{p}_2$ , which represents the semimodule generated by  $A_{\cdot 1}$  and  $A_{\cdot 2}$ , contains  $\mathbf{p}_5$ . Indeed,  $A_{\cdot 5} = 0.5A_{\cdot 1} \uplus A_{\cdot 2}$ . The range of  $A$  is represented by the closed region in dark grey and by the bold segments joining the points  $\mathbf{p}_1, \mathbf{p}_2, \mathbf{p}_4$  to it.

We next compute a half-space separating the point  $\mathbf{b}$  defined in (25.3) from range  $A$ . Recall that  $\Pi_A(\mathbf{b}) = [-1 \ 0 \ 0.5]^T$ . So, by Fact 12, a half-space containing range  $A$  and not  $\mathbf{b}$  is  $H := \{\mathbf{x} \in \mathbb{R}_{\max}^3 \mid (-3)\mathbf{x}_1 \uplus \mathbf{x}_2 \uplus (-0.5)\mathbf{x}_3 \geq 1\mathbf{x}_1 \uplus \mathbf{x}_2 \uplus (-0.5)\mathbf{x}_3\}$ . We also have  $H \cap \mathbb{R}_{\max}^3 = \{\mathbf{x} \in \mathbb{R}_{\max}^3 \mid \mathbf{x}_2 \uplus (-0.5)\mathbf{x}_3 \geq 1\mathbf{x}_1\}$ . The set of nonzero points of  $H \cap \mathbb{R}_{\max}^3$  is represented by the light gray region in Figure 25.1 (right).

## 25.7 Max-Plus Linear Independence and Rank

**Definitions:**

If  $M$  is a subsemimodule of  $\mathbb{R}_{\max}^n$ ,  $\mathbf{u} \in M$  is an **extremal generator** of  $M$ , or  $\mathbb{R}_{\max} \mathbf{u} := \{\lambda \cdot \mathbf{u} \mid \lambda \in \mathbb{R}_{\max}\}$  is an **extreme ray** of  $M$ , if  $\mathbf{u} \neq \mathbf{0}$  and if  $\mathbf{u} = \mathbf{v} \uplus \mathbf{w}$  with  $\mathbf{v}, \mathbf{w} \in M$  imply that  $\mathbf{u} = \mathbf{v}$  or  $\mathbf{u} = \mathbf{w}$ .

A family  $\mathbf{u}_1, \dots, \mathbf{u}_r$  of vectors of  $\mathbb{R}_{\max}^n$  is **linearly independent in the Gondran–Minoux sense** if for all disjoint subsets  $I$  and  $J$  of  $\{1, \dots, r\}$ , and all  $\lambda_i \in \mathbb{R}_{\max}$ ,  $i \in I \cup J$ , we have  $\sum_{i \in I} \lambda_i \cdot \mathbf{u}_i \neq \sum_{j \in J} \lambda_j \cdot \mathbf{u}_j$ , unless  $\lambda_i = \mathbf{0}$  for all  $i \in I \cup J$ .

For  $A \in \mathbb{R}_{\max}^{n \times n}$ , we define

$$\det^+ A := \sum_{\sigma \in S_n^+} A_{1\sigma(1)} \cdots A_{n\sigma(n)}, \quad \det^- A := \sum_{\sigma \in S_n^-} A_{1\sigma(1)} \cdots A_{n\sigma(n)},$$

where  $S_n^+$  and  $S_n^-$  are, respectively, the sets of even and odd permutations of  $\{1, \dots, n\}$ . The **bideterminant** [GM84] of  $A$  is  $(\det^+ A, \det^- A)$ .

For  $A \in \mathbb{R}_{\max}^{n \times p} \setminus \{\mathbf{0}\}$ , we define

- The **row rank** (resp. the **column rank**) of  $A$ , denoted  $\text{rk}_{\text{row}}(A)$  (resp.  $\text{rk}_{\text{col}}(A)$ ), as the number of extreme rays of range  $A^T$  (resp. range  $A$ ).
- The **Schein rank** of  $A$  as  $\text{rk}_{\text{Sch}}(A) := \min\{r \geq 1 \mid A = BC, \text{ with } B \in \mathbb{R}_{\max}^{n \times r}, C \in \mathbb{R}_{\max}^{r \times p}\}$ .
- The **strong rank** of  $A$ , denoted  $\text{rk}_{\text{st}}(A)$ , as the maximal  $r \geq 1$  such that there exists an  $r \times r$  submatrix  $B$  of  $A$  for which there is only one permutation  $\sigma$  such that  $|\sigma|_B = \text{per } B$ .
- The row (resp. column) **Gondran–Minoux rank** of  $A$ , denoted  $\text{rk}_{\text{GMr}}(A)$  (resp.  $\text{rk}_{\text{GMc}}$ ), as the maximal  $r \geq 1$  such that  $A$  has  $r$  linearly independent rows (resp. columns) in the Gondran–Minoux sense.
- The **symmetrized rank** of  $A$ , denoted  $\text{rk}_{\text{sym}}(A)$ , as the maximal  $r \geq 1$  such that  $A$  has an  $r \times r$  submatrix  $B$  such that  $\det^+ B \neq \det^- B$ .

(A new rank notion, **Kapranov rank**, which is not discussed here, has been recently studied [DSS05]. We also note that the Schein rank is called in this reference Barvinok rank.)

**Facts:**

1. [Hel88], [Mol88], [Wag91], [Gau98], [DS04] Let  $M$  be a finitely generated subsemimodule of  $\mathbb{R}_{\max}^n$ . A subset of vectors of  $M$  spans  $M$  if and only if it contains at least one nonzero element of every extreme ray of  $M$ .
2. [GM02] The columns of  $A \in \mathbb{R}_{\max}^{n \times n}$  are linearly independent in the Gondran–Minoux sense if and only if  $\det^+ A \neq \det^- A$ .
3. [Plu90], [BCOQ92, Th. 3.78]. *Max-plus Cramer’s formula.* Let  $A \in \mathbb{R}_{\max}^{n \times n}$ , and let  $\mathbf{b}^-, \mathbf{b}^+ \in \mathbb{R}_{\max}^n$ . Define the  $i$ -th positive Cramer’s determinant by

$$D_i^+ := \det^+(A_{.1} \dots A_{.i-1} \mathbf{b}^+ A_{.i+1} \dots A_{.n}) \# \det^-(A_{.1} \dots A_{.i-1} \mathbf{b}^- A_{.i+1} \dots A_{.n}),$$

and the  $i$ -th negative Cramer’s determinant,  $D_i^-$ , by exchanging  $\mathbf{b}^+$  and  $\mathbf{b}^-$  in the definition of  $D_i^+$ . Assume that  $\mathbf{x}^+, \mathbf{x}^- \in \mathbb{R}_{\max}^n$  have disjoint supports. Then  $A\mathbf{x}^+ \# \mathbf{b}^- = A\mathbf{x}^- \# \mathbf{b}^+$  implies that

$$(\det^+ A)\mathbf{x}_i^+ \# (\det^- A)\mathbf{x}_i^- \# D_i^- = (\det^- A)\mathbf{x}_i^+ \# (\det^+ A)\mathbf{x}_i^- \# D_i^+ \quad \forall 1 \leq i \leq n. \quad (25.4)$$

The converse implication holds, and the vectors  $\mathbf{x}^+$  and  $\mathbf{x}^-$  are uniquely determined by (25.4), if  $\det^+ A \neq \det^- A$ , and if  $D_i^+ \neq D_i^-$  or  $D_i^+ = D_i^- = \mathbf{0}$ , for all  $1 \leq i \leq n$ . This result is formulated in a simpler way in [Plu90], [BCOQ92] using the **symmetrization** of the max-plus semiring, which leads to more general results. We note that the converse implication relies on the following semiring analogue of the classical adjugate identity:  $A \text{adj}^+ A \# \det^- A I = A \text{adj}^- A \# \det^+ A I$ , where  $\text{adj}^\pm A := (\det^\pm A(j, i))_{1 \leq i, j \leq n}$ . This identity, as well as analogues of many other determinantal identities, can be obtained using the general method of [RS84]. See, for instance, [GBCG98], where the derivation of the Binet–Cauchy identity is detailed.

4. For  $A \in \mathbb{R}_{\max}^{n \times p}$ , we have

$$\text{rk}_{\text{st}}(A) \leq \text{rk}_{\text{sym}}(A) \leq \left\{ \begin{array}{l} \text{rk}_{\text{GMr}}(A) \\ \text{rk}_{\text{GMc}}(A) \end{array} \right\} \leq \text{rk}_{\text{Sch}}(A) \leq \left\{ \begin{array}{l} \text{rk}_{\text{row}}(A) \\ \text{rk}_{\text{col}}(A) \end{array} \right\}.$$

The second inequality follows from Fact 2, the third one from Facts 2 and 3. The other inequalities are immediate. Moreover, all these inequalities become equalities if  $A$  is regular [CGQ06].

### Examples:

1. The matrix  $A$  in Example 1 of section 25.6 has column rank 4: The extremal rays of range  $A$  are generated by the first four columns of  $A$ . All the other ranks of  $A$  are equal to 3.

Generalizations of the Perron–Frobenius theory of nonnegative matrices to linear operators leaving a cone invariant were first developed for operators on a Banach space by Krein and Rutman [KR48], Karlin [Kar59], and Schaefer [Sfr66], although there are early examples in finite dimensions, e.g., [Sch65] and [Bir67]. In this chapter, we describe a generalization that is sometimes called the geometric spectral theory of nonnegative linear operators in finite dimensions, which emerged in the late 1980s. Motivated by a search for geometric analogs of results in the previously developed combinatorial spectral theory of (reducible) nonnegative matrices (for reviews see [Sch86] and [Her99]), this area is a study of the Perron–Frobenius theory of a nonnegative matrix and its generalizations from the cone-theoretic viewpoint. The treatment is linear-algebraic and cone-theoretic (geometric) with the facial and duality concepts and occasionally certain elementary analytic tools playing the dominant role. The theory is particularly rich when the underlying cone is polyhedral (finitely generated) and it reduces to the nonnegative matrix case when the cone is simplicial.

### 26.1 Perron–Frobenius Theorem for Cones

---

We work with cones in a real vector space, as “cone” is a real concept. To deal with cones in  $\mathbb{C}^n$ , we can identify the latter space with  $\mathbb{R}^{2n}$ . For a discussion on the connection between the real and complex case of the spectral theory, see [TS94, Sect. 8].

#### Definitions:

A **proper cone**  $K$  in a finite-dimensional real vector space  $V$  is a closed, pointed, full convex cone, *viz.*

- $K + K \subseteq K$ , *viz.*  $\mathbf{x}, \mathbf{y} \in K \implies \mathbf{x} + \mathbf{y} \in K$ .
- $\mathbb{R}^+ K \subseteq K$ , *viz.*  $\mathbf{x} \in K, \alpha \in \mathbb{R}^+ \implies \alpha \mathbf{x} \in K$ .
- $K$  is closed in the usual topology of  $V$ .

- $K \cap (-K) = \{\mathbf{0}\}$ , viz.  $\mathbf{x}, -\mathbf{x} \in K \implies \mathbf{x} = \mathbf{0}$ .
- $\text{int}K \neq \emptyset$ , where  $\text{int}K$  is the interior of  $K$ .

Usually, the unqualified term **cone** is defined by the first two items in the above definition. However, in this chapter we call a proper cone simply a **cone**. We denote by  $K$  a cone in  $\mathbb{R}^n$ ,  $n \geq 2$ .

The vector  $\mathbf{x} \in \mathbb{R}^n$  is  **$K$ -nonnegative**, written  $\mathbf{x} \succeq^K \mathbf{0}$ , if  $\mathbf{x} \in K$ .

The vector  $\mathbf{x}$  is  **$K$ -semipositive**, written  $\mathbf{x} \succeq^K \mathbf{0}$ , if  $\mathbf{x} \succeq^K \mathbf{0}$  and  $\mathbf{x} \neq \mathbf{0}$ .

The vector  $\mathbf{x}$  is  **$K$ -positive**, written  $\mathbf{x} \succ^K \mathbf{0}$ , if  $\mathbf{x} \in \text{int}K$ .

For  $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$ , we write  $\mathbf{x} \succeq^K \mathbf{y}$  ( $\mathbf{x} \succ^K \mathbf{y}$ ,  $\mathbf{x} \succ^K \mathbf{y}$ ) if  $\mathbf{x} - \mathbf{y}$  is  $K$ -nonnegative ( $K$ -semipositive,  $K$ -positive).

The matrix  $A \in \mathbb{R}^{n \times n}$  is  **$K$ -nonnegative**, written  $A \succeq^K \mathbf{0}$ , if  $AK \subseteq K$ .

The matrix  $A$  is  **$K$ -semipositive**, written  $A \succeq^K \mathbf{0}$ , if  $A \succeq^K \mathbf{0}$  and  $A \neq \mathbf{0}$ .

The matrix  $A$  is  **$K$ -positive**, written  $A \succ^K \mathbf{0}$ , if  $A(K \setminus \{\mathbf{0}\}) \subseteq \text{int}K$ .

For  $A, B \in \mathbb{R}^{n \times n}$ ,  $A \succeq^K B$  ( $A \succ^K B$ ,  $A \succ^K B$ ) means  $A - B \succeq^K \mathbf{0}$  ( $A - B \succeq^K \mathbf{0}$ ,  $A - B \succ^K \mathbf{0}$ ).

A **face**  $F$  of a cone  $K \subseteq \mathbb{R}^n$  is a subset of  $K$ , which is a cone in the linear span of  $F$  such that  $\mathbf{x} \in F$ ,  $\mathbf{x} \succeq^K \mathbf{y} \succeq^K \mathbf{0} \implies \mathbf{y} \in F$ .

(In this chapter,  $F$  will always denote a face rather than a field, since the only fields involved are  $\mathbb{R}$  and  $\mathbb{C}$ .) Thus,  $F$  satisfies all definitions of a cone except that its interior may be empty.

A face  $F$  of  $K$  is a **trivial face** if  $F = \{\mathbf{0}\}$  or  $F = K$ .

For a subset  $S$  of a cone  $K$ , the intersection of all faces of  $K$  including  $S$  is called the **face of  $K$  generated by  $S$**  and is denoted by  $\Phi(S)$ . If  $S = \{\mathbf{x}\}$ , then  $\Phi(S)$  is written simply as  $\Phi(\mathbf{x})$ .

For faces  $F, G$  of  $K$ , their **meet** and **join** are given respectively by  $F \wedge G = F \cap G$  and  $F \vee G = \Phi(F \cup G)$ .

A vector  $\mathbf{x} \in K$  is an **extreme vector** if either  $\mathbf{x}$  is the zero vector or  $\mathbf{x}$  is nonzero and  $\Phi(\mathbf{x}) = \{\lambda \mathbf{x} : \lambda \geq 0\}$ ; in the latter case, the face  $\Phi(\mathbf{x})$  is called an **extreme ray**.

If  $P$  is  $K$ -nonnegative, then a face  $F$  of  $K$  is a  **$P$ -invariant face** if  $PF \subseteq F$ .

If  $P$  is  $K$ -nonnegative, then  $P$  is  **$K$ -irreducible** if the only  $P$ -invariant faces are the trivial faces.

If  $K$  is a cone in  $\mathbb{R}^n$ , then a cone, called the **dual cone** of  $K$ , is denoted and given by

$$K^* = \{\mathbf{y} \in \mathbb{R}^n : \mathbf{y}^T \mathbf{x} \geq 0 \text{ for all } \mathbf{x} \in K\}.$$

If  $A$  is an  $n \times n$  complex matrix and  $\mathbf{x}$  is a vector in  $\mathbb{C}^n$ , then the **local spectral radius of  $A$  at  $\mathbf{x}$**  is denoted and given by  $\rho_{\mathbf{x}}(A) = \limsup_{m \rightarrow \infty} \|A^m \mathbf{x}\|^{1/m}$ , where  $\|\cdot\|$  is any norm of  $\mathbb{C}^n$ . For  $A \in \mathbb{C}^{n \times n}$ , its spectral radius is denoted by  $\rho(A)$  (or  $\rho$ ) (cf. Section 4.3).

**Facts:**

Let  $K$  be a cone in  $\mathbb{R}^n$ .

1. The condition  $\text{int}K \neq \emptyset$  in the definition of a cone is equivalent to  $K - K = V$ , viz., for all  $\mathbf{z} \in V$  there exist  $\mathbf{x}, \mathbf{y} \in K$  such that  $\mathbf{z} = \mathbf{x} - \mathbf{y}$ .
2. A  $K$ -positive matrix is  $K$ -irreducible.
3. [Van68], [SV70] Let  $P$  be a  $K$ -nonnegative matrix. The following are equivalent:
  - (a)  $P$  is  $K$ -irreducible.
  - (b)  $\sum_{i=0}^{n-1} P^i \succ^K \mathbf{0}$ .
  - (c)  $(I + P)^{n-1} \succ^K \mathbf{0}$ .
  - (d) No eigenvector of  $P$  (for any eigenvalue) lies on the boundary of  $K$ .
4. (Generalization of Perron–Frobenius Theorem) [KR48], [BS75] Let  $P$  be a  $K$ -irreducible matrix with spectral radius  $\rho$ . Then
  - (a)  $\rho$  is positive and is a simple eigenvalue of  $P$ .
  - (b) There exists a (up to a scalar multiple) unique  $K$ -positive (right) eigenvector  $\mathbf{u}$  of  $P$  corresponding to  $\rho$ .
  - (c)  $\mathbf{u}$  is the only  $K$ -semipositive eigenvector for  $P$  (for any eigenvalue).
  - (d)  $K \cap (\rho I - P)\mathbb{R}^n = \{\mathbf{0}\}$ .

5. (Generalization of Perron–Frobenius Theorem) Let  $P$  be a  $K$ -nonnegative matrix with spectral radius  $\rho$ . Then
  - (a)  $\rho$  is an eigenvalue of  $P$ .
  - (b) There is a  $K$ -semipositive eigenvector of  $P$  corresponding to  $\rho$ .
6. If  $P, Q$  are  $K$ -nonnegative and  $Q \stackrel{K}{\leq} P$ , then  $\rho(Q) \leq \rho(P)$ . Further, if  $P$  is  $K$ -irreducible and  $Q \stackrel{K}{\lt} P$ , then  $\rho(Q) < \rho(P)$ .
7.  $P$  is  $K$ -nonnegative ( $K$ -irreducible) if and only if  $P^T$  is  $K^*$ -nonnegative ( $K^*$ -irreducible).
8. If  $A$  is an  $n \times n$  complex matrix and  $\mathbf{x}$  is a vector in  $\mathbf{C}^n$ , then the local spectral radius  $\rho_{\mathbf{x}}(A)$  of  $A$  at  $\mathbf{x}$  is equal to the spectral radius of the restriction of  $A$  to the  $A$ -cyclic subspace generated by  $\mathbf{x}$ , i.e.,  $\text{span}\{A^i \mathbf{x} : i = 0, 1, \dots\}$ . If  $\mathbf{x}$  is nonzero and  $\mathbf{x} = \mathbf{x}_1 + \dots + \mathbf{x}_k$  is the representation of  $\mathbf{x}$  as a sum of generalized eigenvectors of  $A$  corresponding, respectively, to distinct eigenvalues  $\lambda_1, \dots, \lambda_k$ , then  $\rho_{\mathbf{x}}(A)$  is also equal to  $\max_{1 \leq i \leq k} |\lambda_i|$ .
9. Barker and Schneider [BS75] developed Perron–Frobenius theory in the setting of a (possibly infinite-dimensional) vector space over a fully ordered field without topology. They introduced the concepts of irreducibility and strong irreducibility, and show that these two concepts are equivalent if the underlying cone has ascending chain condition on faces. See [ERS95] for the role of real closed-ordered fields in this theory.

**Examples:**

1. The nonnegative orthant  $(\mathbb{R}_0^+)^n$  in  $\mathbb{R}^n$  is a cone. Then  $\mathbf{x} \geq^K \mathbf{0}$  if and only if  $\mathbf{x} \geq \mathbf{0}$ , viz. the entries of  $\mathbf{x}$  are nonnegative, and  $F$  is a face of  $(\mathbb{R}_0^+)^n$  if and only if  $F$  is of the form  $F_J$  for some  $J \subseteq \{1, \dots, n\}$ , where

$$F_J = \{\mathbf{x} \in (\mathbb{R}_0^+)^n : x_i = 0, i \notin J\}.$$

Further,  $P \geq^K \mathbf{0}$  ( $P \succeq^K \mathbf{0}$ ,  $P >^K \mathbf{0}$ ,  $P$  is  $K$ -irreducible) if and only if  $P \geq \mathbf{0}$  ( $P \succeq \mathbf{0}$ ,  $P > \mathbf{0}$ ,  $P$  is irreducible) in the sense used for nonnegative matrices, cf. Chapter 9.

2. The nontrivial faces of the Lorentz (ice cream) cone  $K_n$  in  $\mathbb{R}^n$ , viz.

$$K_n = \{\mathbf{x} \in \mathbb{R}^n : (x_1^2 + \dots + x_{n-1}^2)^{1/2} \leq x_n\},$$

are precisely its extreme rays, each generated by a nonzero boundary vector, that is, one for which the equality holds above. The matrix

$$P = \begin{bmatrix} -1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

is  $K_3$ -irreducible [BP79, p. 22].

## 26.2 Collatz–Wielandt Sets and Distinguished Eigenvalues

Collatz–Wielandt sets were apparently first defined in [BS75]. However, they are so-called because they are closely related to Wielandt’s proof of the Perron–Frobenius theorem for irreducible nonnegative matrices, [Wie50], which employs an inequality found in Collatz [Col42]. See also [Sch96] for further remarks on Collatz–Wielandt sets and related max-min and min-max characterizations of the spectral radius of nonnegative matrices and their generalizations.

**Definitions:**

Let  $P$  be a  $K$ -nonnegative matrix.

The **Collatz–Wielandt sets** associated with  $P$  ([BS75], [TW89], [TS01], [TS03], and [Tam01]) are defined by

$$\begin{aligned}\Omega(P) &= \{\omega \geq 0 : \exists \mathbf{x} \in K \setminus \{\mathbf{0}\}, P\mathbf{x} \geq^K \omega\mathbf{x}\}, \\ \Omega_1(P) &= \{\omega \geq 0 : \exists \mathbf{x} \in \text{int } K, P\mathbf{x} \geq^K \omega\mathbf{x}\}, \\ \Sigma(P) &= \{\sigma \geq 0 : \exists \mathbf{x} \in K \setminus \{\mathbf{0}\}, P\mathbf{x} \leq^K \sigma\mathbf{x}\}, \\ \Sigma_1(P) &= \{\sigma \geq 0 : \exists \mathbf{x} \in \text{int } K, P\mathbf{x} \leq^K \sigma\mathbf{x}\}.\end{aligned}$$

For a  $K$ -nonnegative vector  $\mathbf{x}$ , the **lower and upper Collatz–Wielandt numbers** of  $\mathbf{x}$  with respect to  $P$  are defined by

$$\begin{aligned}r_P(\mathbf{x}) &= \sup \{\omega \geq 0 : P\mathbf{x} \geq^K \omega\mathbf{x}\}, \\ R_P(\mathbf{x}) &= \inf \{\sigma \geq 0 : P\mathbf{x} \leq^K \sigma\mathbf{x}\},\end{aligned}$$

where we write  $R_P(\mathbf{x}) = \infty$  if no  $\sigma$  exists such that  $P\mathbf{x} \leq^K \sigma\mathbf{x}$ .

A (nonnegative) eigenvalue of  $P$  is a **distinguished eigenvalue** for  $K$  if it has an associated  $K$ -semipositive eigenvector.

The **Perron space**  $N_\rho^k(P)$  (or  $N_\rho^k$ ) is the subspace consisting of all  $\mathbf{u} \in \mathbb{R}^n$  such that  $(P - \rho I)^k \mathbf{u} = \mathbf{0}$  for some positive integer  $k$ . (See Chapter 6.1 for a more general definition of  $N_\lambda^k(A)$ .)

If  $F$  is a  $P$ -invariant face of  $K$ , then the restriction of  $P$  to  $\text{span } F$  is written as  $P|F$ . The spectral radius of  $P|F$  is written as  $\rho[F]$ , and if  $\lambda$  is an eigenvalue of  $P|F$ , its index is written as  $\nu_\lambda[F]$ .

A cone  $K$  in  $\mathbb{R}^n$  is **polyhedral** if it is the set of linear combinations with nonnegative coefficients of vectors taken from a finite subset of  $\mathbb{R}^n$ , and is **simplicial** if the finite subset is linearly independent.

**Facts:**

Let  $P$  be a  $K$ -nonnegative matrix.

1. [TW89] A real number  $\lambda$  is a distinguished eigenvalue of  $P$  for  $K$  if and only if  $\lambda = \rho_{\mathbf{b}}(P)$  for some  $K$ -semipositive vector  $\mathbf{b}$ .
2. [Tam90] Consider the following conditions:
  - (a)  $\rho$  is the only distinguished eigenvalue of  $P$  for  $K$ .
  - (b)  $\mathbf{x} \geq^K \mathbf{0}$  and  $P\mathbf{x} \leq^K \rho\mathbf{x}$  imply that  $P\mathbf{x} = \rho\mathbf{x}$ .
  - (c) The Perron space of  $P^T$  contains a  $K^*$ -positive vector.
  - (d)  $\rho \in \Omega_1(P^T)$ .

Conditions (a), (b), and (c) are always equivalent and are implied by condition (d). When  $K$  is polyhedral, condition (d) is also an equivalent condition.

3. [Tam90] The following conditions are equivalent:
  - (a)  $\rho(P)$  is the only distinguished eigenvalue of  $P$  for  $K$  and the index of  $\rho(P)$  is one.
  - (b) For any vector  $\mathbf{x} \in \mathbb{R}^n$ ,  $P\mathbf{x} \leq^K \rho(P)\mathbf{x}$  implies that  $P\mathbf{x} = \rho(P)\mathbf{x}$ .
  - (c)  $K \cap (\rho I - P)\mathbb{R}^n = \{\mathbf{0}\}$ .
  - (d)  $P^T$  has a  $K^*$ -positive eigenvector (corresponding to  $\rho(P)$ ).
4. [TW89] The following statements all hold:
  - (a) [BS75] If  $P$  is  $K$ -irreducible, then
 
$$\sup \Omega(P) = \sup \Omega_1(P) = \inf \Sigma(P) = \inf \Sigma_1(P) = \rho(P).$$
  - (b)  $\sup \Omega(P) = \inf \Sigma_1(P) = \rho(P)$ .
  - (c)  $\inf \Sigma(P)$  is equal to the least distinguished eigenvalue of  $P$  for  $K$ .

- (d)  $\sup \Omega_1(P) = \inf \Sigma(P^T)$  and, hence, is equal to the least distinguished eigenvalue of  $P^T$  for  $K^*$ .
  - (e)  $\sup \Omega(P) \in \Omega(P)$  and  $\inf \Sigma(P) \in \Sigma(P)$ .
  - (f) When  $K$  is polyhedral, we have  $\sup \Omega_1(P) \in \Omega_1(P)$ . For general cones, we may have  $\sup \Omega_1(P) \notin \Omega_1(P)$ .
  - (g) [Tam90] When  $K$  is polyhedral,  $\rho(P) \in \Omega_1(P)$  if and only if  $\rho(A)$  is the only distinguished eigenvalue of  $P^T$  for  $K^*$ .
  - (h) [TS03]  $\rho(P) \in \Sigma_1(P)$  if and only if  $\Phi((N_\rho^1(P) \cap K) \cup C) = K$ , where  $C$  is the set  $\{\mathbf{x} \in K : \rho_{\mathbf{x}}(P) < \rho(P)\}$  and  $N_\rho^1(P)$  is the Perron eigenspace of  $P$ .
5. In the irreducible nonnegative matrix case, statement (b) of the preceding fact reduces to the well-known max-min and min-max characterizations of  $\rho(P)$  due to Wielandt. Schaefer [Sfr84] generalized the result to irreducible compact operators in  $L^p$ -spaces and more recently Friedland [Fri90], [Fri91] also extended the characterizations in the settings of a Banach space or a  $C^*$ -algebra.
  6. [TW89, Theorem 2.4(i)] For any  $\mathbf{x} \geq^K \mathbf{0}$ ,  $r_P(\mathbf{x}) \leq \rho_{\mathbf{x}}(P) \leq R_P(\mathbf{x})$ . (This fact extends the well-known inequality  $r_P(\mathbf{x}) \leq \rho(P) \leq R_P(\mathbf{x})$  in the nonnegative matrix case, due to Collatz [Col42] under the assumption that  $\mathbf{x}$  is a positive vector and due to Wielandt [Wie50] under the assumption that  $P$  is irreducible and  $\mathbf{x}$  is semipositive. For similar results concerning a nonnegative linear continuous operator in a Banach space, see [FN89].)
  7. A discussion on estimating  $\rho(P)$  or  $\rho_{\mathbf{x}}(P)$  by a convergent sequence of (lower or upper) Collatz–Wielandt numbers can be found in [TW89, Sect. 5] and [Tam01, Subsect. 3.1.4].
  8. [GKT95, Corollary 3.2] If  $K$  is strictly convex (i.e., each boundary vector is extreme), then  $P$  has at most two distinguished eigenvalues. This fact supports the statement that the spectral theory of nonnegative linear operators depends on the geometry of the underlying cone.

## 26.3 The Peripheral Spectrum, the Core, and the Perron–Schaefer Condition

In addition to using Collatz–Wielandt sets to study Perron–Frobenius theory, we may also approach this theory by considering the core (whose definition will be given below). This geometric approach started with the work of Pullman [Pul71], who succeeded in rederiving the Frobenius theorem for irreducible nonnegative matrices. Naturally, this approach was also taken up in geometric spectral theory. It was found that there are close connections between the core, the peripheral spectrum, the Perron–Schaefer condition, and the distinguished faces of a  $K$ -nonnegative linear operator. This led to a revival of interest in the Perron–Schaefer condition and associated conditions for the existence of a cone  $K$  such that a preassigned matrix is  $K$ -nonnegative. (See [Bir67], [Sfr66], [Van68], [Sch81].) The study has also led to the identification of necessary and equivalent conditions for a collection of Jordan blocks to correspond to the peripheral eigenvalues of a nonnegative matrix. (See [TS94] and [McD03].) The local Perron–Schaefer condition was identified in [TS01] and has played a role in the subsequent work. In the course of this investigation, methods were found for producing invariant cones for a matrix with the Perron–Schaefer condition, see [TS94], [Tam06]. These constructions may also be useful in the study of allied fields, such as linear dynamical systems. There invariant cones for matrices are often encountered. (See, for instance, [BNS89].)

### Definitions:

If  $P$  is  $K$ -nonnegative, then a nonzero  $P$ -invariant face  $F$  of  $K$  is a **distinguished face** (associated with  $\lambda$ ) if for every  $P$ -invariant face  $G$ , with  $G \subset F$ , we have  $\rho[G] < \rho[F]$  (and  $\rho[F] = \lambda$ ).

If  $\lambda$  is an eigenvalue of  $A \in \mathbb{C}^{n \times n}$ , then  $\ker(A - \lambda I)^k$  is denoted by  $N_\lambda^k(A)$  for  $k = 1, 2, \dots$ , the **index** of  $\lambda$  is denoted by  $v_A(\lambda)$  (or  $v_\lambda$  when  $A$  is clear), and the **generalized eigenspace** at  $\lambda$  is denoted by  $N_\lambda^v(A)$ . See Chapter 6.1 for more information.

Let  $A \in \mathbf{C}^{n \times n}$ .

The **order** of a generalized eigenvector  $\mathbf{x}$  for  $\lambda$  is the smallest positive integer  $k$  such that  $(A - \lambda I)^k \mathbf{x} = \mathbf{0}$ . The maximal order of all  $K$ -semipositive generalized eigenvectors in  $N_\lambda^n(A)$  is denoted by  $\text{ord}_\lambda$ .

The matrix  $A$  satisfies the **Perron–Schaefer condition** ([Sfr66], [Sch81]) if

- $\rho = \rho(A)$  is an eigenvalue of  $A$ .
- If  $\lambda$  is an eigenvalue of  $A$  and  $|\lambda| = \rho$ , then  $v_A(\lambda) \leq v_A(\rho)$ .

If  $K$  is a cone and  $P$  is  $K$ -nonnegative, then the set  $\bigcap_{i=0}^{\infty} P^i K$ , denoted by  $\text{core}_K(P)$ , is called the **core** of  $P$  relative to  $K$ .

An eigenvalue  $\lambda$  of  $A$  is called a **peripheral eigenvalue** if  $|\lambda| = \rho(A)$ . The peripheral eigenvalues of  $A$  constitute the **peripheral spectrum** of  $A$ .

Let  $\mathbf{x} \in \mathbf{C}^n$ . Then  $A$  satisfies the **local Perron–Schaefer condition at  $\mathbf{x}$**  if there is a generalized eigenvector  $\mathbf{y}$  of  $A$  corresponding to  $\rho_{\mathbf{x}}(A)$  that appears as a term in the representation of  $\mathbf{x}$  as a sum of generalized eigenvectors of  $A$ . Furthermore, the order of  $\mathbf{y}$  is equal to the maximum of the orders of the generalized eigenvectors that appear in the representation and correspond to eigenvalues with modulus  $\rho_{\mathbf{x}}(A)$ .

### Facts:

1. [Sfr66, Chap. V] Let  $K$  be a cone in  $\mathbb{R}^n$  and let  $P$  be a  $K$ -nonnegative matrix. Then  $P$  satisfies the Perron–Schaefer condition.
2. [Sch81] Let  $K$  be a cone in  $\mathbb{R}^n$  and let  $P$  be a  $K$ -nonnegative matrix with spectral radius  $\rho$ . Then  $P$  has at least  $m$  linearly independent  $K$ -semipositive eigenvectors corresponding to  $\rho$ , where  $m$  is the number of Jordan blocks in the Jordan form of  $P$  of maximal size that correspond to  $\rho$ .
3. [Van68] Let  $A \in \mathbb{R}^{n \times n}$ . Then there exists a cone  $K$  in  $\mathbb{R}^n$  such that  $A$  is  $K$ -nonnegative if and only if  $A$  satisfies the Perron–Schaefer condition.
4. [TS94] Let  $A \in \mathbb{R}^{n \times n}$  that satisfies the Perron–Schaefer condition. Let  $m$  be the number of Jordan blocks in the Jordan form of  $A$  of maximal size that correspond to  $\rho(A)$ . Then for each positive integer  $k$ ,  $m \leq k \leq \dim N_\rho^1(A)$ , there exists a cone  $K$  in  $\mathbb{R}^n$  such that  $A$  is  $K$ -nonnegative and  $\dim \text{span}(N_\rho^1(A) \cap K) = k$ .
5. Let  $A \in \mathbb{R}^{n \times n}$ . Let  $k$  be a nonnegative integer and let  $\omega_k(A)$  consist of all linear combinations with nonnegative coefficients of  $A^k, A^{k+1}, \dots$ . The closure of  $\omega_k(A)$  is a cone in its linear span if and only if  $A$  satisfies the Perron–Schaefer condition. (For this fact in the setting of complex matrices see [Sch81].)
6. Necessary and sufficient conditions involving  $\omega_k(A)$  so that  $A \in \mathbf{C}^{n \times n}$  has a positive (nonnegative) eigenvalue appear in [Sch81]. For the corresponding real versions, see [Tam06].
7. [Pul71], [TS94] If  $K$  is a cone and  $P$  is  $K$ -nonnegative, then  $\text{core}_K(P)$  is a cone in its linear span and  $P(\text{core}_K(P)) = \text{core}_K(P)$ . Furthermore,  $\text{core}_K(P)$  is polyhedral (or simplicial) whenever  $K$  is. So when  $\text{core}_K(P)$  is polyhedral,  $P$  permutes the extreme rays of  $\text{core}_K(P)$ .
8. For a  $K$ -nonnegative matrix  $P$ , a characterization of  $K$ -irreducibility (as well as  $K$ -primitivity) of  $P$  in terms of  $\text{core}_K(P)$ , which extends the corresponding result of Pullman for a nonnegative matrix, can be found in [TS94].
9. [Pul71] If  $P$  is an irreducible nonnegative matrix, then the permutation induced by  $P$  on the extreme rays of  $\text{core}_{(\mathbb{R}_0^+)^n}(P)$  is a single cycle of length equal to the number of distinct peripheral eigenvalues of  $P$ . (This fact can be regarded as a geometric characterization of the said quantity (cf. the known combinatorial characterization, see Fact 5(c) of Chapter 9.2), whereas part (b) of the next fact is its extension.)
10. [TS94, Theorem 3.14] For a  $K$ -nonnegative matrix  $P$ , if  $\text{core}_K(P)$  is a nonzero simplicial cone, then:
  - (a) There is a one-to-one correspondence between the set of distinguished faces associated with nonzero eigenvalues and the set of cycles of the permutation  $\tau_P$  induced by  $P$  on the extreme rays of  $\text{core}_K(P)$ .

- (b) If  $\sigma$  is a cycle of the induced permutation  $\tau_P$ , then the peripheral eigenvalues of the restriction of  $P$  to the linear span of the distinguished  $P$ -invariant face  $F$  corresponding to  $\sigma$  are simple and are exactly  $\rho[F]$  times all the  $d_\sigma$ th roots of unity, where  $d_\sigma$  is the length of the cycle  $\sigma$ .
11. [TS94] If  $P$  is  $K$ -nonnegative and  $\text{core}_K(P)$  is nonzero polyhedral, then:
    - (a)  $\text{core}_K(P)$  consists of all linear combinations with nonnegative coefficients of the distinguished eigenvectors of positive powers of  $P$  corresponding to nonzero distinguished eigenvalues.
    - (b)  $\text{core}_K(P)$  does not contain a generalized eigenvector of any positive powers of  $P$  other than eigenvectors.

This fact indicates that we cannot expect that the index of the spectral radius of a nonnegative linear operator can be determined from a knowledge of its core.

12. A complete description of the core of a nonnegative matrix (relative to the nonnegative orthant) can be found in [TS94, Theorem 4.2].
13. For  $A \in \mathbb{R}^{n \times n}$ , in order that there exists a cone  $K$  in  $\mathbb{R}^n$  such that  $AK = K$  and  $A$  has a  $K$ -positive eigenvector, it is necessary and sufficient that  $A$  is nonzero, diagonalizable, all eigenvalues of  $A$  are of the same modulus, and  $\rho(A)$  is an eigenvalue of  $A$ . For further equivalent conditions, see [TS94, Theorem 5.9].
14. For  $A \in \mathbb{R}^{n \times n}$ , an equivalent condition given in terms of the peripheral eigenvalues of  $A$  so that there exists a cone  $K$  in  $\mathbb{R}^n$  such that  $A$  is  $K$ -nonnegative and (a)  $K$  is polyhedral, or (b)  $\text{core}_K(A)$  is polyhedral (simplicial or a single ray) can be found in [TS94, Theorems 7.9, 7.8, 7.12, 7.10].
15. [TS94, Theorem 7.12] Let  $A \in \mathbb{R}^{n \times n}$  with  $\rho(A) > 0$  that satisfies the Perron–Schaefer condition. Let  $S$  denote the multiset of peripheral eigenvalues of  $A$  with maximal index (i.e.,  $\nu_A(\rho)$ ), the multiplicity of each element being equal to the number of corresponding blocks in the Jordan form of  $A$  of order  $\nu_A(\rho)$ . Let  $T$  be the multiset of peripheral eigenvalues of  $A$  for which there are corresponding blocks in the Jordan form of  $A$  of order less than  $\nu_A(\rho)$ , the multiplicity of each element being equal to the number of such corresponding blocks. The following conditions are equivalent:
  - (a) There exists a cone  $K$  in  $\mathbb{R}^n$  such that  $A$  is  $K$ -nonnegative and  $\text{core}_K(A)$  is simplicial.
  - (b) There exists a multisubset  $\tilde{T}$  of  $T$  such that  $S \cup \tilde{T}$  is the multiset union of certain complete sets of roots of unity multiplied by  $\rho(A)$ .
16. McDonald [McD03] refers to the condition (b) that appears in the preceding result as the **Tam–Schneider condition**. She also provides another condition, called the **extended Tam–Schneider condition**, which is necessary and sufficient for a collection of Jordan blocks to correspond to the peripheral spectrum of a nonnegative matrix.
17. [TS01] If  $P$  is  $K$ -nonnegative and  $\mathbf{x}$  is  $K$ -semipositive, then  $P$  satisfies the local Perron–Schaefer condition at  $\mathbf{x}$ .
18. [Tam06] Let  $A$  be an  $n \times n$  real matrix, and let  $\mathbf{x}$  be a given nonzero vector of  $\mathbb{R}^n$ . The following conditions are equivalent:
  - (a)  $A$  satisfies the local Perron–Schaefer condition at  $\mathbf{x}$ .
  - (b) The restriction of  $A$  to  $\text{span}\{A^i \mathbf{x} : i = 0, 1, \dots\}$  satisfies the Perron–Schaefer condition.
  - (c) For every (or, for some) nonnegative integer  $k$ , the closure of  $\omega_k(A, \mathbf{x})$ , where  $\omega_k(A, \mathbf{x})$  consists of all linear combinations with nonnegative coefficients of  $A^k \mathbf{x}, A^{k+1} \mathbf{x}, \dots$ , is a cone in its linear span.
  - (d) There is a cone  $C$  in a subspace of  $\mathbb{R}^n$  containing  $\mathbf{x}$  such that  $AC \subseteq C$ .
19. The local Perron–Schaefer condition has played a role in the work of [TS01], [TS03], and [Tam04]. Further work involving this condition and the cones  $\omega_k(A, \mathbf{x})$  (defined in the preceding fact) will appear in [Tam06].
20. One may apply results on the core of a nonnegative matrix to rederive simply many known results on the limiting behavior of Markov chains. An illustration can be found in [Tam01, Sec. 4.6].

## 26.4 Spectral Theory of $K$ -Reducible Matrices

In this section, we touch upon the geometric version of the extensive combinatorial spectral theory of reducible nonnegative matrices first found in [Fro12, Sect. 11] and continued in [Sch56]. Many subsequent developments are reviewed in [Sch86] and [Her99]. Results on the geometric spectral theory of reducible  $K$ -nonnegative matrices may be largely found in a series of papers by B.S. Tam, some jointly with Wu and H. Schneider ([TW89], [Tam90], [TS94], [TS01], [TS03], [Tam04]). For a review containing considerably more information than this section, see [Tam01].

In some studies, the underlying cone is lattice-ordered (for a definition and much information, see [Sfr74]) and, in some studies, the Frobenius form of a reducible nonnegative matrix is generalized; see the work by Jang and Victory [JV93] on positive eventually compact linear operators on Banach lattices. However in the geometric spectral theory the Frobenius normal form of a nonnegative reducible matrix is not generalized as the underlying cone need not be lattice-ordered. Invariant faces are considered instead of the classes that play an important role in combinatorial spectral theory of nonnegative matrices; in particular, distinguished faces and semidistinguished faces are used in place of distinguished classes and semidistinguished classes, respectively. (For definitions of the preceding terms, see [TS01].)

It turns out that the various results on a reducible nonnegative matrix are extended to a  $K$ -nonnegative matrix in different degrees of generality. In particular, the Frobenius–Victory theorem ([Fro12], [Vic85]) is extended to a  $K$ -nonnegative matrix on a general cone. The following are extended to a polyhedral cone: The Rothblum index theorem ([Rot75]), a characterization (in terms of the accessibility relation between basic classes) for the spectral radius to have geometric multiplicity 1, for the spectral radius to have index 1 ([Sch56]), and a majorization relation between the (spectral) height characteristic and the (combinatorial) level characteristic of a nonnegative matrix ([HS91b]). Various conditions are used to generalize the theorem on equivalent conditions for equality of the two characteristics ([Ris78], [HS89], [HS91a]). Even for polyhedral cones there is no complete generalization for the nonnegative-basis theorem, not to mention the preferred-basis theorem ([Rot75], [Ris78], [Sch86], [HS88]). There is a natural conjecture for the latter case ([Tam04]). The attempts to carry out the extensions have also led to the identification of important new concepts or tools. For instance, the useful concepts of semidistinguished faces and of spectral pairs of faces associated with a  $K$ -nonnegative matrix are introduced in [TS01] in proving the cone version of some of the combinatorial theorems referred to above. To achieve these ends certain elementary analytic tools are also brought in.

### Definitions:

Let  $P$  be a  $K$ -nonnegative matrix.

A nonzero  $P$ -invariant face  $F$  is a **semidistinguished face** if  $F$  contains in its relative interior a generalized eigenvector of  $P$  and if  $F$  is not the join of two  $P$ -invariant faces that are properly included in  $F$ .

A  **$K$ -semipositive Jordan chain** for  $P$  of length  $m$  (corresponding to  $\rho(P)$ ) is a sequence of  $m$   $K$ -semipositive vectors  $\mathbf{x}, (P - \rho(P)I)\mathbf{x}, \dots, (P - \rho(P)I)^{m-1}\mathbf{x}$  such that  $(P - \rho(P)I)^m\mathbf{x} = \mathbf{0}$ .

A basis for  $N_\rho^\nu(P)$  is called a  **$K$ -semipositive basis** if it consists of  $K$ -semipositive vectors.

A basis for  $N_\rho^\nu(P)$  is called a  **$K$ -semipositive Jordan basis** for  $P$  if it is composed of  $K$ -semipositive Jordan chains for  $P$ .

The set  $C(P, K) = \{\mathbf{x} \in K : (P - \rho(P)I)^i\mathbf{x} \in K \text{ for all positive integers } i\}$  is called the **spectral cone** of  $P$  (for  $K$  corresponding to  $\rho(P)$ ).

Denote  $v_\rho$  by  $\nu$ .

The **height characteristic** of  $P$  is the  $\nu$ -tuple  $\eta(P) = (\eta_1, \dots, \eta_\nu)$  given by:

$$\eta_k = \dim(N_\rho^k(P)) - \dim(N_\rho^{k-1}(P)).$$

The **level characteristic** of  $P$  is the  $\nu$ -tuple  $\lambda(P) = (\lambda_1, \dots, \lambda_\nu)$  given by:

$$\lambda_k = \dim \text{span}(N_\rho^k(P) \cap K) - \dim \text{span}(N_\rho^{k-1}(P) \cap K).$$

The **peak characteristic** of  $P$  is the  $\nu$ -tuple  $\xi(P) = (\xi_1, \dots, \xi_\nu)$  given by:

$$\xi_k = \dim(P - \rho(P)I)^{k-1}(N_\rho^k \cap K).$$

If  $A \in \mathbb{C}^{n \times n}$  and  $\mathbf{x}$  is a nonzero vector of  $\mathbb{C}^n$ , then the **order of  $\mathbf{x}$  relative to  $A$** , denoted by  $\text{ord}_A(\mathbf{x})$ , is defined to be the maximum of the orders of the generalized eigenvectors, each corresponding to an eigenvalue of modulus  $\rho_{\mathbf{x}}(A)$  that appear in the representation of  $\mathbf{x}$  as a sum of generalized eigenvectors of  $A$ .

The ordered pair  $(\rho_{\mathbf{x}}(A), \text{ord}_A(\mathbf{x}))$  is called the **spectral pair of  $\mathbf{x}$  relative to  $A$**  and is denoted by  $\text{sp}_A(\mathbf{x})$ . We also set  $\text{sp}_A(\mathbf{0}) = (0, 0)$  to take care of the zero vector  $\mathbf{0}$ .

We use  $\preceq$  to denote the lexicographic ordering between ordered pairs of real numbers, i.e.,  $(a, b) \preceq (c, d)$  if either  $a < c$ , or  $a = c$  and  $b \leq d$ . In case  $(a, b) \preceq (c, d)$  but  $(a, b) \neq (c, d)$ , we write  $(a, b) \prec (c, d)$ .

**Facts:**

1. If  $A \in \mathbb{C}^{n \times n}$  and  $\mathbf{x}$  is a vector of  $\mathbb{C}^n$ , then  $\text{ord}_A(\mathbf{x})$  is equal to the size of the largest Jordan block in the Jordan form of the restriction of  $A$  to the  $A$ -cyclic subspace generated by  $\mathbf{x}$  for a peripheral eigenvalue.  
Let  $P$  be a  $K$ -nonnegative matrix.
2. In the nonnegative matrix case, the present definition of the level characteristic of  $P$  is equivalent to the usual graph-theoretic definition; see [NS94, (3.2)] or [Tam04, Remark 2.2].
3. [TS01] For any  $\mathbf{x} \in K$ , the smallest  $P$ -invariant face containing  $\mathbf{x}$  is equal to  $\Phi(\hat{\mathbf{x}})$ , where  $\hat{\mathbf{x}} = (I + P)^{n-1}\mathbf{x}$ . Furthermore,  $\text{sp}_P(\mathbf{x}) = \text{sp}_P(\hat{\mathbf{x}})$ . In the nonnegative matrix case, the said face is also equal to  $F_J$ , where  $F_J$  is as defined in Example 1 of Section 26.1 and  $J$  is the union of all classes of  $P$  having access to  $\text{supp}(\mathbf{x}) = \{i : x_i > 0\}$ . (For definitions of classes and the accessibility relation, see Chapter 9.)
4. [TS01] For any face  $F$  of  $K$ ,  $P$ -invariant or not, the value of the spectral pair  $\text{sp}_P(\mathbf{x})$  is independent of the choice of  $\mathbf{x}$  from the relative interior of  $F$ . This common value, denoted by  $\text{sp}_A(F)$ , is referred to as the **spectral pair of  $F$  relative to  $A$** .
5. [TS01] For any faces  $F, G$  of  $K$ , we have
  - (a)  $\text{sp}_P(F) = \text{sp}_P(\hat{F})$ , where  $\hat{F}$  is the smallest  $P$ -invariant face of  $K$ , including  $F$ .
  - (b) If  $F \subseteq G$ , then  $\text{sp}_P(F) \preceq \text{sp}_P(G)$ . If  $F, G$  are  $P$ -invariant faces and  $F \subset G$ , then  $\text{sp}_P(F) \preceq \text{sp}_P(G)$ ; viz. either  $\rho[F] < \rho[G]$  or  $\rho[F] = \rho[G]$  and  $\nu_{\rho[F]}[F] \leq \nu_{\rho[G]}[G]$ .
6. [TS01] If  $K$  is a cone with the property that the dual cone of each of its faces is a facially exposed cone, for instance, when  $K$  is a polyhedral cone, a perfect cone, or equals  $P(n)$  (see [TS01] for definitions), then for any nonzero  $P$ -invariant face  $G$ ,  $G$  is semidistinguished if and only if  $\text{sp}_P(F) \prec \text{sp}_P(G)$  for all  $P$ -invariant faces  $F$  properly included in  $G$ .
7. [Tam04] (Cone version of the Frobenius–Victory theorem, [Fro12], [Vic85], [Sch86])
  - (a) For any real number  $\lambda$ ,  $\lambda$  is a distinguished eigenvalue of  $P$  if and only if  $\lambda = \rho[F]$  for some distinguished face  $F$  of  $K$ .
  - (b) If  $F$  is a distinguished face, then there is (up to multiples) a unique eigenvector  $\mathbf{x}$  of  $P$  corresponding to  $\rho[F]$  that lies in  $F$ . Furthermore,  $\mathbf{x}$  belongs to the relative interior of  $F$ .
  - (c) For each distinguished eigenvalue  $\lambda$  of  $P$ , the extreme vectors of the cone  $N_\lambda^1(P) \cap K$  are precisely all the distinguished eigenvectors of  $P$  that lie in the relative interior of certain distinguished faces of  $K$  associated with  $\lambda$ .
8. Let  $P$  be a nonnegative matrix. The Jordan form of  $P$  contains only one Jordan block corresponding to  $\rho(P)$  if and only if any two basic classes of  $P$  are comparable (with respect to the accessibility relation); all Jordan blocks corresponding to  $\rho(P)$  are of size 1 if and only if no two basic classes are comparable ([Schn56]). An extension of these results to a  $K$ -nonnegative matrix on a class of cones that contains all polyhedral cones can be found in [TS01, Theorems 7.2 and 7.1].

9. [Tam90, Theorem 7.5] If  $K$  is polyhedral, then:
- There is a  $K$ -semipositive Jordan chain for  $P$  of length  $\nu_\rho$ ; thus, there is a  $K$ -semipositive vector in  $N_\rho^\nu(P)$  of order  $\nu_\rho$ , viz.  $\text{ord}_\rho = \nu_\rho$ .
  - The Perron space  $N_\rho^\nu(P)$  has a basis consisting of  $K$ -semipositive vectors.

However, when  $K$  is nonpolyhedral, there need not exist a  $K$ -semipositive vector in  $N_\rho^\nu(P)$  of order  $\nu_\rho$ , viz.  $\text{ord}_\rho < \nu_\rho$ . For a general distinguished eigenvalue  $\lambda$ , we always have  $\text{ord}_\lambda \leq \nu_\lambda$ , no matter whether  $K$  is polyhedral or not.

10. Part (b) of the preceding fact is not yet a complete cone version of the nonnegative-basis theorem, as the latter theorem guarantees the existence of a basis for the Perron space that consists of semipositive vectors that satisfy certain combinatorial properties. For a conjecture on a cone version of the nonnegative-basis theorem, see [Tam04, Conj. 9.1].
11. [TS01, Theorem 5.1] (Cone version of the (combinatorial) generalization of the Rothblum index theorem, [Rot75], [HS88]).

Let  $K$  be a polyhedral cone. Let  $\lambda$  be a distinguished eigenvalue of  $P$  for  $K$ . Then there is a chain  $F_1 \subset F_2 \subset \dots \subset F_k$  of  $k = \text{ord}_\lambda$  distinct semidistinguished faces of  $K$  associated with  $\lambda$ , but there is no such chain with more than  $\text{ord}_\lambda$  members. When  $K$  is a general cone, the maximum cardinality of a chain of semidistinguished faces associated with a distinguished eigenvalue  $\lambda$  may be less than, equal to, or greater than  $\text{ord}_\lambda$ ; see [TS01, Ex. 5.3, 5.4, 5.5].

12. For  $K = (\mathbb{R}_0^+)^n$ , viz.  $P$  is a nonnegative matrix, characterizations of different types of  $P$ -invariant faces (in particular, the distinguished and semidistinguished faces) are given in [TS01] (in terms of the concept of an initial subset for  $P$ ; see [HS88] or [TS01] for definition of an initial subset).
13. [Tam04] The spectral cone  $C(P, K)$  is always invariant under  $P - \rho(P)I$  and satisfies:

$$N_\rho^1(P) \cap K \subseteq C(A, K) \subseteq N_\rho^\nu(P) \cap K.$$

If  $K$  is polyhedral, then  $C(A, K)$  is a polyhedral cone in  $N_\rho^\nu(P)$ .

14. (Generalization of corresponding results on nonnegative matrices, [NS94]) We always have  $\xi_k(P) \leq \eta_k(P)$  and  $\xi_k(P) \leq \lambda_k(P)$  for  $k = 1, \dots, \nu_\rho$ .
15. [Tam04, Theorem 5.9] Consider the following conditions:
- $\eta(P) = \lambda(P)$ .
  - $\eta(P) = \xi(P)$ .
  - For each  $k, k = 1, \dots, \nu_\rho$ ,  $N_\rho^k(P)$  contains a  $K$ -semipositive basis.
  - There exists a  $K$ -semipositive Jordan basis for  $P$ .
  - For each  $k, k = 1, \dots, \nu_\rho$ ,  $N_\rho^k(P)$  has a basis consisting of vectors taken from  $N_\rho^k(P) \cap C(P, K)$ .
  - For each  $k, k = 1, \dots, \nu_\rho$ , we have

$$\eta_k(P) = \dim(P - \rho(P)I)^{k-1} [N_\rho^k(P) \cap C(P, K)].$$

Conditions (a) to (c) are equivalent and so are conditions (d) to (f). Moreover, we always have (a)  $\implies$  (d), and when  $K$  is polyhedral, conditions (a) to (f) are all equivalent.

16. As shown in [Tam04], the level of a nonzero vector  $\mathbf{x} \in N_\rho^\nu(P)$  can be defined to be the smallest positive integer  $k$  such that  $\mathbf{x} \in \text{span}(N_\rho^k(P) \cap K)$ ; when there is no such  $k$  the level is taken to be  $\infty$ . Then the concepts of  $K$ -semipositive level basis, height-level basis, peak vector, etc., can be introduced and further conditions can be added to the list given in the preceding result.
17. [Tam04, Theorem 7.2] If  $K$  is polyhedral, then  $\lambda(P) \preceq \eta(P)$ .
18. Cone-theoretic proofs for the preferred-basis theorem for a nonnegative matrix and for a result about the nonnegativity structure of the principal components of a nonnegative matrix can be found in [Tam04].

## 26.5 Linear Equations over Cones

Given a  $K$ -nonnegative matrix  $P$  and a vector  $\mathbf{b} \in K$ , in this section we consider the solvability of following two linear equations over cones and some consequences:

$$(\lambda I - P)\mathbf{x} = \mathbf{b}, \quad \mathbf{x} \in K \tag{26.1}$$

and

$$(P - \lambda I)\mathbf{x} = \mathbf{b}, \quad \mathbf{x} \in K. \tag{26.2}$$

Equation (26.1) has been treated by several authors in finite-dimensional as well as infinite-dimensional settings, and several equivalent conditions for its solvability have been found. (See [TS03] for a detailed historical account.) The study of Equation (26.2) is relatively new. A treatment of the equation by graph-theoretic arguments for the special case when  $\lambda = \rho(P)$  and  $K = (\mathbb{R}_0^+)^n$  can be found in [TW89]. The general case is considered in [TS03]. It turns out that the solvability of Equation (26.2) is a more delicate problem. It depends on whether  $\lambda$  is greater than, equal to, or less than  $\rho_{\mathbf{b}}(P)$ .

### Facts:

Let  $P$  be a  $K$ -nonnegative matrix, let  $\mathbf{0} \neq \mathbf{b} \in K$ , and let  $\lambda$  be a given positive real number.

1. [TS03, Theorem 3.1] The following conditions are equivalent:
  - (a) Equation (26.1) is solvable.
  - (b)  $\rho_{\mathbf{b}}(P) < \lambda$ .
  - (c)  $\lim_{m \rightarrow \infty} \sum_{j=0}^m \lambda^{-j} P^j \mathbf{b}$  exists.
  - (d)  $\lim_{m \rightarrow \infty} (\lambda^{-1} P)^m \mathbf{b} = \mathbf{0}$ .
  - (e)  $\langle \mathbf{z}, \mathbf{b} \rangle = 0$  for each generalized eigenvector  $\mathbf{z}$  of  $P^T$  corresponding to an eigenvalue with modulus greater than or equal to  $\lambda$ .
  - (f)  $\langle \mathbf{z}, \mathbf{b} \rangle = 0$  for each generalized eigenvector  $\mathbf{z}$  of  $P^T$  corresponding to a distinguished eigenvalue of  $P$  for  $K$  that is greater than or equal to  $\lambda$ .
2. For a fixed  $\lambda$ , the set  $(\lambda I - P)K \cap K$ , which consists of precisely all vectors  $\mathbf{b} \in K$  for which Equation (26.1) has a solution, is equal to  $\{\mathbf{b} \in K : \rho_{\mathbf{b}}(P) < \lambda\}$  and is a face of  $K$ .
3. For a fixed  $\lambda$ , the set  $(P - \lambda I)K \cap K$ , which consists of precisely all vectors  $\mathbf{b} \in K$  for which Equation (26.2) has a solution, is, in general, not a face of  $K$ .
4. [TS03, Theorem 4.1] When  $\lambda > \rho_{\mathbf{b}}(P)$ , Equation (26.2) is solvable if and only if  $\lambda$  is a distinguished eigenvalue of  $P$  for  $K$  and  $\mathbf{b} \in \Phi(N_{\lambda}^1(P) \cap K)$ .
5. [TS03, Theorem 4.5] When  $\lambda = \rho_{\mathbf{b}}(P)$ , if Equation (26.2) is solvable, then  $\mathbf{b} \in (P - \rho_{\mathbf{b}}(P)I)\Phi(N_{\rho_{\mathbf{b}}(P)}^v(P) \cap K)$ .
6. [TS03, Theorem 4.19] Let  $r$  denote the largest real eigenvalue of  $P$  less than  $\rho(P)$ . (If no such eigenvalues exist, take  $r = -\infty$ .) Then for any  $\lambda$ ,  $r < \lambda < \rho(P)$ , we have

$$\Phi((P - \lambda I)K \cap K) = \Phi(N_{\rho}^v(P) \cap K).$$

Thus, a necessary condition for Equation (26.2) to have a solution is that  $\mathbf{b} \stackrel{K}{\leq} \mathbf{u}$  for some  $\mathbf{u} \in N_{\rho}^v(P) \cap K$ .

7. [TS03, Theorem 5.11] Consider the following conditions:
  - (a)  $\rho(P) \in \Sigma_1(P^T)$ .
  - (b)  $N_{\rho}^v(P) \cap K = N_{\rho}^1(P) \cap K$ , and  $P$  has no eigenvectors in  $\Phi(N_{\rho}^1(P) \cap K)$  corresponding to an eigenvalue other than  $\rho(P)$ .

(c)  $K \cap (P - \rho(P)I)K = \{\mathbf{0}\}$  (equivalently,  $\mathbf{x} \geq^K \mathbf{0}, P\mathbf{x} \geq^K \rho(P)\mathbf{x}$  imply that  $P\mathbf{x} = \rho(P)\mathbf{x}$ ). We always have (a)  $\implies$  (b)  $\implies$  (c). When  $K$  is polyhedral, conditions (a), (b), and (c) are equivalent. When  $K$  is nonpolyhedral, the missing implications do not hold.

## 26.6 Elementary Analytic Results

In geometric spectral theory, besides the linear-algebraic method and the cone-theoretic method, certain elementary analytic methods have also been called into play; for example, the use of Jordan form or the components of a matrix. This approach may have begun with the work of Birkhoff [Bir67] and it was followed by Vandergraft [Van68] and Schneider [Sch81]. Friedland and Schneider [FS80] and Rothblum [Rot81] have also studied the asymptotic behavior of the powers of a nonnegative matrix, or their variants, by elementary analytic methods. The papers [TS94] and [TS01] in the series also need a certain kind of analytic argument in their proofs; more specifically, they each make use of the  $K$ -nonnegativity of a certain matrix, either itself a component or a matrix defined in terms of the components of a given  $K$ -nonnegative matrix (see Facts 3 and 4 in this section). In [HNR90], Hartwig, Neumann, and Rose offer a (linear) algebraic-analytic approach to the Perron–Frobenius theory of a nonnegative matrix, one which utilizes the resolvent expansion, but does not involve the Frobenius normal form. Their approach is further developed by Neumann and Schneider ([NS92], [NS93], [NS94]). By employing the concept of spectral cone and combining the cone-theoretic methods developed in the earlier papers of the series with this algebraic-analytic method, Tam [Tam04] offers a unified treatment to reprove or extend (or partly extend) several well-known results in the combinatorial spectral theory of nonnegative matrices. The proofs given in [Tam04] rely on the fact that if  $K$  is a cone in  $\mathbb{R}^n$ , then the set  $\pi(K)$  that consists of all  $K$ -nonnegative matrices is a cone in the matrix space  $\mathbb{R}^{n \times n}$  and if, in addition,  $K$  is polyhedral, then so is  $\pi(K)$  ([Fen53, p. 22], [SV70], [Tam77]). See [Tam01, Sec. 6.5] and [Tam04, Sec. 9] for further remarks on the use of the cone  $\pi(K)$  in the study of the spectral properties of  $K$ -nonnegative matrices.

In this section, we collect a few elementary analytic results (whose proofs rely on the Jordan form), which have proved to be useful in the study of the geometric spectral theory. In particular, Facts 3, 4, and 5 identify members of  $\pi(K)$ . As such, they can be regarded as nice results, which are difficult to come by for the following reason: If  $K$  is nonsimplicial, then  $\pi(K)$  must contain matrices that are not nonnegative linear combinations of its rank-one members ([Tam77]). However, not much is known about such matrices ([Tam92]).

### Definitions:

Let  $P$  be a  $K$ -nonnegative matrix. Denote  $\nu_\rho$  by  $\nu$ .

The **principal eigenprojection** of  $P$ , denoted by  $Z_p^{(0)}$ , is the projection of  $\mathbb{C}^n$  onto the Perron space  $N_p^\nu$  along the direct sum of other generalized eigenspaces of  $P$ .

For  $k = 0, \dots, \nu$ , the  **$k$ th principal component of  $P$**  is given by

$$Z_p^{(k)} = (P - \rho(P))^k Z_p^{(0)}.$$

The  $k$ th component of  $P$  corresponding to an eigenvalue  $\lambda$  is defined in a similar way.

For  $k = 0, \dots, \rho$ , the  **$k$ th transform principal component of  $P$**  is given by:

$$J_p^{(k)}(\varepsilon) = Z_p^{(k)} + Z_p^{(k+1)}/\varepsilon + \dots + Z_p^{(\nu-1)}/\varepsilon^{\nu-k-1} \quad \text{for all } \varepsilon \in \mathbb{C} \setminus \{0\}.$$

### Facts:

Let  $P$  be a  $K$ -nonnegative matrix. Denote  $\nu_\rho$  by  $\nu$ .

- [Kar59], [Sch81]  $Z_p^{(\nu-1)}$  is  $K$ -nonnegative.
- [TS94, Theorem 4.19(i)] The sum of the  $\nu$ th components of  $P$  corresponding to its peripheral eigenvalues is  $K$ -nonnegative; it is the limit of a convergent subsequence of  $((\nu-1)!P^k/[\rho^{k-\nu+1}k^{\nu-1}])$ .

3. [Tam04, Theorem 3.6(i)] If  $K$  is a polyhedral cone, then for  $k = 0, \dots, \nu - 1$ ,  $J_P^{(k)}(\varepsilon)$  is  $K$ -nonnegative for all sufficiently small positive  $\varepsilon$ .

## 26.7 Splitting Theorems and Stability

Splitting theorems for matrices have played a large role in the study of convergence of iterations in numerical linear algebra; see [Var62]. Here we present a cone version of a splitting theorem which is proven in [Sch65] and applied to stability (inertia) theorems for matrices. A closely related result is generalized to operators on a partially ordered Banach space in [DH03] and [Dam04]. There it is used to describe stability properties of (stochastic) control systems and to derive non-local convergence results for Newton's method applied to nonlinear operator equation of Riccati type. We also discuss several kinds of positivity for operators involving a cone that are relevant to the applications mentioned.

For recent splitting theorems involving cones, see [SSA05]. For applications of theorems of the alternative for cones to the stability of matrices, see [CHS97]. Cones occur in many parts of stability theory; see, for instance, [Her98].

### Definitions:

Let  $K$  be a cone in  $\mathbb{R}^n$  and let  $A \in \mathbb{R}^{n \times n}$ .

$A$  is **positive stable** if  $\text{spec}(A) \subseteq \mathbb{C}^+$  viz. the spectrum of  $A$  is contained in the open right half-plane.

$A$  is  **$K$ -inverse nonnegative** if  $A$  is nonsingular and  $A^{-1}$  is  $K$ -nonnegative.

$A$  is  **$K$ -resolvent nonnegative** if there exists an  $\alpha_0 \in \mathbb{R}$  such that, for all  $\alpha > \alpha_0$ ,  $\alpha I - A$  is  $K$ -inverse nonnegative.

$A$  is **cross-positive** on  $K$  if for all  $\mathbf{x} \in K$ ,  $\mathbf{y} \in K^*$ ,  $\mathbf{y}^T \mathbf{x} = 0$  implies  $\mathbf{y}^T A \mathbf{x} \geq 0$ .

$A$  is a **Z-matrix** if all of its off-diagonal entries are nonpositive.

### Facts:

Let  $K$  be a cone in  $\mathbb{R}^n$ .

1.  $A$  is  $K$ -resolvent nonnegative if and only if  $A$  is cross-positive on  $K$ . Other equivalent conditions and also Perron-Frobenius type theorems for the class of cross-positive matrices can be found in [Els74], [SV70] or [BNS89].
2. When  $K$  is  $(\mathbb{R}_0^+)^n$ ,  $A$  is cross-positive on  $K$  if and only if  $-A$  is a Z-matrix.
3. [Sch65], [Sch97]. Let  $T = R - P$  where  $R, P \in \mathbb{R}^{n \times n}$  and suppose that  $P$  is  $K$ -nonnegative. If  $R$  satisfies  $R(\text{int}K) \supseteq \text{int}K$  or  $R(\text{int}K) \cap \text{int}K = \emptyset$ , then the following are equivalent:
  - (a)  $T$  is  $K$ -inverse nonnegative.
  - (b) For all  $\mathbf{y} >^K \mathbf{0}$  there exists (unique)  $\mathbf{x} >^K \mathbf{0}$  such that  $\mathbf{y} = T\mathbf{x}$ .
  - (c) There exists  $\mathbf{x} >^K \mathbf{0}$  such that  $T\mathbf{x} >^K \mathbf{0}$ .
  - (d) There exists  $\mathbf{x} \geq^K \mathbf{0}$  such that  $T\mathbf{x} >^K \mathbf{0}$ .
  - (e)  $R$  is  $K$ -inverse nonnegative and  $\rho(R^{-1}P) < 1$ .
4. Let  $T \in \mathbb{R}^{n \times n}$ . If  $-T$  is  $K$ -resolvent nonnegative, then  $T$  satisfies  $T(\text{int}K) \supseteq \text{int}K$  or  $T(\text{int}K) \cap \text{int}K = \emptyset$ . But the converse is false, see Example 1 below.
5. [DH03, Theorem 2.11], [Dam04, Theorem 3.2.10]. Let  $T, R, P$  be as given in Fact 3. If  $-R$  is  $K$ -resolvent nonnegative, then conditions (a)–(e) of Fact 3 are equivalent. Moreover, the following are additional equivalent conditions:
  - (f)  $T$  is positive stable.
  - (g)  $R$  is positive stable and  $\rho(R^{-1}P) < 1$ .
6. If  $K$  is  $(\mathbb{R}_0^+)^n$ ,  $R = \alpha I$  and  $P$  is a nonnegative matrix, then  $T = R - P$  is a Z-matrix. It satisfies the equivalent conditions (a)–(g) of Facts 3 and 5 if and only if it is an M-matrix [BP79, Chapter 6].

7. (Special case of Fact 5 with  $P = 0$ ). Let  $T \in \mathbb{R}^{n \times n}$ . If  $-T$  is  $K$ -resolvent nonnegative, then conditions (a)–(d) of Fact 3 and conditions (f) of Fact 5 are equivalent.
8. In [GT06] a matrix  $T$  is called a  $Z$ -transformation on  $K$  if  $-T$  is cross-positive on  $K$ . Many properties on  $Z$ -matrices, such as being a  $P$ -matrix, a  $Q$ -matrix (which has connection with the linear complementarity problem), an inverse-nonnegative matrix, a positive stable matrix, a diagonally stable matrix, etc., are extended to  $Z$ -transformations. For a  $Z$ -transformation, the equivalence of these properties is examined for various kinds of cones, particularly for symmetric cones in Euclidean Jordan algebras.
9. [Schn65], [Schn97]. (Special case of Fact 3 with  $K$  equal to the cone of positive semi-definite matrices in the real space of  $n \times n$  Hermitian matrices, and  $R(H) = AHA^*$ ,  $P(H) = \sum_{k=1}^s C_k H C_k^*$ ). Let  $A, C_k, k = 1, \dots, s$  be complex  $n \times n$  matrices which can be simultaneously upper triangularized by similarity. Then there exists a natural correspondence  $\alpha_i, \gamma_i^{(k)}$  of the eigenvalues of  $A, C_k, k = 1, \dots, s$ . For Hermitian  $H$ , let  $T(H) = AHA^* - \sum_{k=1}^s C_k H C_k^*$ . Then the following are equivalent:
  - (a)  $|\alpha_i|^2 - \sum_{k=1}^s |\gamma_i^{(k)}|^2 > 0, i = 1, \dots, n$ .
  - (b) For all positive definite  $G$  there exists a (unique) positive definite  $H$  such that  $T(H) = G$ .
  - (c) There exists a positive definite  $H$  such that  $T(H)$  is positive definite.
10. Gantmacher-Lyapunov [Gan59, Chapter XV] (Special case of Fact 9 with  $A$  replaced by  $A + I, s = 2, C_1 = A, C_2 = I$ , and special case of Fact 7 with  $K$  equal to the cone of positive semi-definite matrices in the real space of  $n \times n$  Hermitian matrices and  $T(H) = AH + HA^*$ ). Let  $A \in \mathbb{C}^{n \times n}$ . The following are equivalent:
  - (a) For all positive definite  $G$  there exists a (unique) positive definite  $H$  such that  $AH + HA^* = G$ .
  - (b) There exists a positive definite  $H$  such that  $AH + HA^*$  is positive definite.
  - (c)  $A$  is positive stable.
11. Stein [Ste52] (Special case of Fact 9 with  $A = I, s = 1, C_1 = C$ , and special case of Fact 7 with  $T(H) = H - CHC^*$ ). Let  $C \in \mathbb{C}^{n \times n}$ . The following are equivalent:
  - (a) There exists a positive definite  $H$  such that  $H - CHC^*$  is positive definite.
  - (b) The spectrum of  $C$  is contained in the open unit disk.

### Examples:

Let  $K = (\mathbb{R}_0^+)^2$  and take  $T = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$ . Then  $TK = K$  and so  $T(\text{int}K) \supseteq \text{int}K$ . Note that  $\langle T\mathbf{e}_1, \mathbf{e}_2 \rangle = 1 > 0$  whereas  $\langle \mathbf{e}_1, \mathbf{e}_2 \rangle = 0$ ; so  $-T$  is not cross-positive on  $K$  and hence not  $K$ -resolvent nonnegative. Since the eigenvalues of  $T$  are  $-1$  and  $1$ ,  $T$  is not positive stable. This example tells us that the converse of Fact 4 is false. It also shows that to the list of equivalent conditions of Fact 3 we cannot add condition (f) of Fact 5.

### 27.1 Combinatorial Structure and Invariants

---

The **combinatorial structure of a matrix** generally refers to the locations of the nonzero entries of a matrix, or it might be used to refer to the locations of the zero entries. To study and take advantage of the combinatorial structure of a matrix, graphs are used as models. Associated with a matrix are several graphs that represent the combinatorial structure of a matrix in various ways. The type of graph (undirected graph, bipartite graph, digraph) used depends on the kind of matrices (symmetric, rectangular, square) being studied ([BR91], [Bru92], [BS04]). Conversely, associated with a graph, bipartite graph, or digraph are matrices that allow one to consider it as an algebraic object. These matrices — their algebraic properties — can often be used to obtain combinatorial information about a graph that is not otherwise obtainable. These are two of three general aspects of **combinatorial matrix theory**. A third aspect concerns intrinsic combinatorial properties of matrices viewed simply as an array of numbers.

#### Definitions:

Let  $A = [a_{ij}]$  be an  $m \times n$  matrix.

A **strong combinatorial invariant** of  $A$  is a quantity or property that does not change when the rows and columns of  $A$  are permuted, that is, which is shared by all matrices of the form  $PAQ$ , where  $P$  is a permutation matrix of order  $m$  and  $Q$  is a permutation matrix of order  $n$ .

A less restrictive definition can be considered when  $A$  is a square matrix of order  $n$ .

A **weak combinatorial invariant** is a quantity or property that does not change when the rows and columns are simultaneously permuted, that is, which is shared by all matrices of the form  $PAP^T$  where  $P$  is a permutation matrix of order  $n$ .

The  $(0, 1)$ -matrix obtained from  $A$  by replacing each nonzero entry with a 1 is the **pattern** of  $A$ . (In those situations where the actual value of the nonzero entries is unimportant, one may replace a matrix with its pattern, that is, one may assume that  $A$  itself is a  $(0, 1)$ -matrix.)

A **line** of a matrix is a row or column.

A **zero line** is a line of all zeros.

The **term rank** of a  $(0, 1)$ -matrix  $A$  is the largest size  $\varrho(A)$  of a collection of 1s of  $A$  with no two 1s in the same line.

A **cover** of  $A$  is a collection of lines that contain all the 1s of  $A$ .

A **minimum cover** is a cover with the smallest number of lines. The number of lines in a minimum line cover of  $A$  is denoted by  $c(A)$ .

A **co-cover** of  $A$  is a collection of 1s of  $A$  such that each line of  $A$  contains at least one of the 1s.

A **minimum co-cover** is a co-cover with the smallest number of 1s. The number of 1s in a minimum co-cover is denoted by  $c^*(A)$ .

The quantity  $\varrho^*(A)$  is the **largest size of a zero submatrix** of  $A$ , that is, the maximum of  $r + s$  taken over all integers  $r$  and  $s$  with  $0 \leq r \leq m$  and  $0 \leq s \leq n$  such that  $A$  has an  $r \times s$  zero (possibly vacuous) submatrix.

### Facts:

The following facts are either elementary or can be found in Chapters 1 and 4 of [BR91].

1. These are strong combinatorial invariants:
  - (a) The number of rows (respectively, columns) of a matrix.
  - (b) The quantity  $\max\{r, s\}$  taken over all  $r \times s$  zero submatrices ( $0 \leq r, s$ ).
  - (c) The maximum value of  $r + s$  taken over all  $r \times s$  zero submatrices ( $0 \leq r, s$ ).
  - (d) The number of zeros (respectively, nonzeros) in a matrix.
  - (e) The number of zero rows (respectively, zero columns) of a matrix.
  - (f) The multiset of row sums (respectively, column sums) of a matrix.
  - (g) The rank of a matrix.
  - (h) The permanent (see Chapter 31) of a matrix.
  - (i) The singular values of a matrix.
2. These are weak combinatorial invariants:
  - (a) The largest order of a principal submatrix that is a zero matrix.
  - (b) The number of  $A$  zeros on the main diagonal of a matrix.
  - (c) The maximum value of  $p + q$  taken over all  $p \times q$  zero submatrices that do not meet the main diagonal.
  - (d) Whether or not for some integer  $r$  with  $1 \leq r \leq n$ , the matrix  $A$  of order  $n$  has an  $r \times n - r$  zero submatrix that does not meet the main diagonal of  $A$ .
  - (e) Whether or not  $A$  is a symmetric matrix.
  - (f) The trace  $\text{tr}(A)$  of a matrix  $A$ .
  - (g) The determinant  $\det A$  of a matrix  $A$ .
  - (h) The eigenvalues of a matrix.
  - (i) The multiset of elements on the main diagonal of a matrix.
3.  $\varrho(A)$ ,  $c(A)$ ,  $\varrho^*(A)$ , and  $c^*(A)$  are all strong combinatorial invariants.
4.  $\rho(A) = c(A)$ .
5. A matrix  $A$  has a co-cover if and only if it does not have any zero lines. If  $A$  does not have any zero lines, then  $\varrho^*(A) = c^*(A)$ .
6. If  $A$  is an  $m \times n$  matrix without zero lines, then  $\varrho(A) + \varrho^*(A) = c(A) + c^*(A) = m + n$ .

7.  $\text{rank}(A) \leq \varrho(A)$ .
8. Let  $A$  be an  $m \times n$  (0,1)-matrix. Then there are permutation matrices  $P$  and  $Q$  such that

$$PAQ = \begin{bmatrix} A_1 & X & Y & Z \\ O & A_2 & O & O \\ O & S & A_3 & O \\ O & T & O & O \end{bmatrix},$$

where  $A_1, A_2,$  and  $A_3$  are square, possibly vacuous, matrices with only 1s on their main diagonals, and  $\rho(A)$  is the sum of the orders of  $A_1, A_2,$  and  $A_3$ . The rows, respectively columns, of  $A$  that are in every minimum cover of  $A$  are the rows, respectively columns, that meet  $A_1,$  respectively  $A_2$ . These rows and columns together with either the rows that meet  $A_3$  or the columns that meet  $A_3$  form minimum covers of  $A$ .

**Examples:**

1. Let

$$A = \begin{bmatrix} \mathbf{1} & 1 & | & 1 & 1 & | & 1 & | & 1 & 1 \\ 0 & \mathbf{1} & | & 0 & 1 & | & 0 & | & 0 & 1 \\ \hline 0 & 0 & | & \mathbf{1} & 0 & | & 0 & | & 0 & 0 \\ 0 & 0 & | & 1 & \mathbf{1} & | & 0 & | & 0 & 0 \\ \hline 0 & 0 & | & 1 & 1 & | & \mathbf{1} & | & 0 & 0 \\ \hline 0 & 0 & | & 1 & 0 & | & 0 & | & 0 & 0 \\ 0 & 0 & | & 1 & 1 & | & 0 & | & 0 & 0 \end{bmatrix}.$$

Then  $\varrho(A) = c(A) = 5$  with the five 1s in different lines, and rows 1, 2, and 5 and columns 3 and 4 forming a cover. The matrix is partitioned in the form given in Fact 8.

## 27.2 Square Matrices and Strong Combinatorial Invariants

---

In this section, we consider the strong combinatorial structure of square matrices.

**Definitions:**

Let  $A$  be a (0, 1)-matrix of order  $n$ .

A collection of  $n$  nonzero entries in  $A$  no two on the same line is a **diagonal** of  $A$  (this term is also applied to nonnegative matrices).

The next definitions are concerned with the existence of certain zero submatrices in  $A$ .

$A$  is **partly decomposable** provided there exist positive integers  $p$  and  $q$  with  $p + q = n$  such that  $A$  has a  $p \times q$  zero submatrix. Equivalently, there are permutation matrices  $P$  and  $Q$  and an integer  $k$  with  $1 \leq k \leq n - 1$  such that

$$PAQ = \begin{bmatrix} B & C \\ O_{k,n-k} & D \end{bmatrix}.$$

$A$  is a **Hall matrix** provided there does not exist positive integers  $p$  and  $q$  with  $p + q > n$  such that  $A$  has a  $p \times q$  zero submatrix.

$A$  has **total support** provided  $A \neq O$  and each 1 of  $A$  is on a diagonal of  $A$ .

$A$  is **fully indecomposable** provided it is not partly decomposable.

$A$  is **nearly decomposable** provided it is fully indecomposable and each matrix obtained from  $A$  by replacing a 1 with a 0 is partly decomposable.

**Facts:**

Unless otherwise noted, the following facts can be found in Chapter 4 of [BR91].

1. [BS94] Each of the following properties is equivalent to the matrix  $A$  of order  $n$  being a Hall matrix:
  - (a)  $\rho(A) = n$ , that is,  $A$  has a diagonal (*Frobenius–König theorem*).
  - (b) For all nonempty subsets  $L$  of  $\{1, 2, \dots, n\}$ ,  $A[\{1, 2, \dots, n\}, L]$  has at least  $|L|$  nonzero rows.
  - (c) For all nonempty subsets  $K$  of  $\{1, 2, \dots, n\}$ ,  $A[K, \{1, 2, \dots, n\}]$  has at least  $|K|$  nonzero columns.
2. Each of the following properties is equivalent to the matrix  $A$  of order  $n$  being a fully indecomposable matrix:
  - (a)  $\rho(A) = n$  and the only minimum line covers are the set of all rows and the set of all columns.
  - (b) For all nonempty subsets  $L$  of  $\{1, 2, \dots, n\}$ ,  $A[\{1, 2, \dots, n\}, L]$  has at least  $|L| + 1$  nonzero rows.
  - (c) For all nonempty subsets  $K$  of  $\{1, 2, \dots, n\}$ ,  $A[K, \{1, 2, \dots, n\}]$  has at least  $|K| + 1$  nonzero columns.
  - (d) The term rank  $\rho(A(i, j))$  of the matrix  $A(i, j)$  obtained from  $A$  by deleting row  $i$  and column  $j$  equals  $n - 1$  for all  $i, j = 1, 2, \dots, n$ .
  - (e)  $A^{n-1}$  is a positive matrix.
  - (f) The determinant  $\det A \circ X$  of the Hadamard product of  $A$  with a matrix  $X = [x_{ij}]$  of distinct indeterminates over a field  $F$  is irreducible in the ring  $F[\{x_{ij} : 1 \leq i, j \leq n\}]$ .
3. Each of the following properties is equivalent to the matrix  $A$  of order  $n$  having total support:
  - (a)  $A \neq O$  and the term rank  $\rho(A(i, j))$  equals  $n - 1$  for all  $i, j = 1, 2, \dots, n$  with  $a_{ij} \neq 0$ .
  - (b) There are permutation matrices  $P$  and  $Q$  such that  $PAQ$  is a direct sum of fully indecomposable matrices.
4. (*Dulmage–Mendelsohn Decomposition theorem*) If the matrix  $A$  of order  $n$  has term rank equal to  $n$ , then there exist permutation matrices  $P$  and  $Q$  and an integer  $t \geq 1$  such that

$$PAQ = \begin{bmatrix} A_1 & A_{12} & \cdots & A_{1t} \\ O & A_2 & \cdots & A_{2t} \\ \vdots & \vdots & \ddots & \vdots \\ O & O & \cdots & A_t \end{bmatrix},$$

where  $A_1, A_2, \dots, A_t$  are square fully indecomposable matrices. The matrices  $A_1, A_2, \dots, A_t$  are called the **fully indecomposable components** of  $A$  and they are uniquely determined up to permutations of their rows and columns. The matrix  $A$  has total support if and only if  $A_{ij} = O$  for all  $i$  and  $j$  with  $i < j$ ;  $A$  is fully indecomposable if and only if  $t = 1$ .

5. (*Inductive structure of fully indecomposable matrices*) If  $A$  is a fully indecomposable matrix of order  $n$ , then there exist permutation matrices  $P$  and  $Q$  and an integer  $k \geq 2$  such that

$$PAQ = \begin{bmatrix} B_1 & O & \cdots & O & E_1 \\ E_2 & B_2 & \cdots & O & O \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ O & O & \cdots & B_{k-1} & O \\ O & O & \cdots & E_k & B_k \end{bmatrix},$$

where  $B_1, B_2, \dots, B_k$  are fully indecomposable and  $E_1, E_2, \dots, E_k$  each contain at least one nonzero entry. Conversely, a matrix of such a form is fully indecomposable.

6. (*Inductive structure of nearly decomposable matrices*) If  $A$  is a nearly decomposable  $(0, 1)$ -matrix, then there exist permutation matrices  $P$  and  $Q$  and an integer  $p$  with  $1 \leq p \leq n - 1$  such that

$$PAQ = \left[ \begin{array}{cccc|cc} 1 & 0 & 0 & \cdots & 0 & 0 \\ 1 & 1 & 0 & \cdots & 0 & 0 \\ 0 & 1 & 1 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 1 & 0 \\ 0 & 0 & 0 & \cdots & 1 & 1 \\ \hline & & & & F_2 & A' \end{array} \right],$$

where  $A'$  is a nearly decomposable matrix of order  $n - p$ , the matrix  $F_1$  has exactly one 1 and this 1 occur in its first row, and the matrix  $F_2$  has exactly one 1 and this 1 occurs in its last column. If  $n - p \geq 2$ , and the 1 in  $F_2$  is in its column  $j$  and the 1 in  $F_1$  is in its row  $i$ , then the  $(i, j)$  entry of  $A'$  is 0.

7. The number of nonzero entries in a nearly decomposable matrix  $A$  of order  $n \geq 3$  is between  $2n$  and  $3(n - 1)$ .

**Examples:**

1. Let

$$A_1 = \begin{bmatrix} 1 & 0 & 0 \\ 1 & 0 & 0 \\ 1 & 1 & 1 \end{bmatrix}, A_2 = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 1 & 0 \\ 1 & 1 & 1 \end{bmatrix}, A_3 = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, A_4 = \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 1 & 0 & 1 \end{bmatrix}.$$

Then  $A_1$  is partly decomposable and not a Hall matrix. The matrix  $A_2$  is a Hall matrix and is partly decomposable, but does not have total support. The matrix  $A_3$  has total support. The matrix  $A_4$  is nearly decomposable.

### 27.3 Square Matrices and Weak Combinatorial Invariants

In this section, we restrict our attention to the weak combinatorial structure of square matrices.

**Definitions:**

Let  $A$  be a matrix of order  $n$ .

$B$  is **permutation similar** to  $A$  if there exists a permutation matrix  $P$  such that  $B = P^T A P (= P^{-1} A P)$ .  $A$  is **reducible** provided  $n \geq 2$  and for some integer  $r$  with  $1 \leq r \leq n - 1$ , there exists an  $r \times (n - r)$  zero submatrix which does not meet the main diagonal of  $A$ , that is, provided there is a permutation matrix  $P$  and an integer  $r$  with  $1 \leq r \leq n - 1$  such that

$$PAP^T = \begin{bmatrix} B & C \\ O_{r,n-r} & D \end{bmatrix}.$$

$A$  is **irreducible** provided that  $A$  is not reducible.

$A$  is **completely reducible** provided there exists an integer  $k \geq 2$  and a permutation matrix  $P$  such that  $PAP^T = A_1 \oplus A_2 \oplus \cdots \oplus A_k$  where  $A_1, A_2, \dots, A_k$  are irreducible.

$A$  is **nearly reducible** provided  $A$  is irreducible and each matrix obtained from  $A$  by replacing a nonzero entry with a zero is reducible.

A **Frobenius normal form** of  $A$  is a block upper triangular matrix with irreducible diagonal blocks that is permutation similar to  $A$ ; the diagonal blocks are called the **irreducible components** of  $A$ . (cf. Fact 27.3.)

The following facts can be found in Chapter 3 of [BR91].

**Facts:**

1. (*Frobenius normal form*) There is a permutation matrix  $P$  and an integer  $r \geq 1$  such that

$$PAP^T = \begin{bmatrix} A_1 & A_{12} & \cdots & A_{1r} \\ O & A_2 & \cdots & A_{2r} \\ \vdots & \vdots & \ddots & \vdots \\ O & O & \cdots & A_r \end{bmatrix},$$

where  $A_1, A_2, \dots, A_r$  are square irreducible matrices. The matrices  $A_1, A_2, \dots, A_r$  are the **irreducible components** of  $A$  and they are uniquely determined up to simultaneous permutations of their rows and columns.

2. There exists a permutation matrix  $Q$  such that  $AQ$  is irreducible if and only if  $A$  has at least one nonzero element in each line.
3. If  $A$  does not have any zeros on its main diagonal, then  $A$  is irreducible if and only if  $A$  is fully indecomposable. The matrix  $A$  is fully indecomposable if and only if there is a permutation matrix  $Q$  such that  $AQ$  has no zeros on its main diagonal and  $AQ$  is irreducible.
4. (*Inductive structure of irreducible matrices*) Let  $A$  be an irreducible matrix of order  $n \geq 2$ . Then there exists a permutation matrix  $P$  and an integer  $m \geq 2$  such that

$$PAP^T = \begin{bmatrix} A_1 & O & \cdots & O & E_1 \\ E_2 & A_2 & \cdots & O & O \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ O & O & \cdots & A_{m-1} & O \\ O & O & \cdots & E_m & A_m \end{bmatrix},$$

where  $A_1, A_2, \dots, A_m$  are irreducible and  $E_1, E_2, \dots, E_m$  each have at least one nonzero entry.

5. (*Inductive structure of nearly reducible matrices*) If  $A$  is a nearly reducible  $(0, 1)$ -matrix, then there exist permutation matrix  $P$  and an integer  $m$  with  $1 \leq m \leq n - 1$  such that

$$PAP^T = \left[ \begin{array}{cccccc|c} 0 & 0 & 0 & \cdots & 0 & 0 & \\ 1 & 0 & 0 & \cdots & 0 & 0 & \\ 0 & 1 & 0 & \cdots & 0 & 0 & \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \\ 0 & 0 & 0 & \cdots & 1 & 0 & \\ \hline & & & & & & F_2 \\ & & & & & & A' \end{array} \right],$$

where  $A'$  is a nearly reducible matrix of order  $m$ , the matrix  $F_1$  has exactly one 1 and it occurs in the first row and column  $j$  of  $F_1$  with  $1 \leq j \leq m$ , and the matrix  $F_2$  has exactly one 1 and it occurs in the last column and row  $i$  of  $F_2$  where  $1 \leq i \leq m$ . The element in position  $(i, j)$  of  $A'$  is 0.

6. The number of nonzero entries in a nearly reducible matrix of order  $n \geq 2$  is between  $n$  and  $2(n - 1)$

**Examples:**

1. Let

$$A_1 = \begin{bmatrix} 1 & 0 & 0 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}, \quad A_2 = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 0 & 1 \end{bmatrix}, \quad A_3 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & 1 \end{bmatrix}, \quad A_4 = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix}.$$

Then  $A_1$  is reducible but not completely reducible, and  $A_2$  is irreducible. (Both  $A_1$  and  $A_2$  are partly decomposable.) The matrix  $A_3$  is completely reducible. The matrix  $A_4$  is nearly reducible.

## 27.4 The Class $\mathcal{A}(R, S)$ of (0,1)-Matrices

In the next definition, we introduce one of the most important and widely studied classes of (0, 1)-matrices (see Chapter 6 of [Rys63] and [Bru80]).

### Definitions:

Let  $A = [a_{ij}]$  be an  $m \times n$  matrix.

The **row sum vector** of  $A$  is  $R = (r_1, r_2, \dots, r_m)$ , where  $r_i = \sum_{j=1}^n a_{ij}$ , ( $i = 1, 2, \dots, m$ ).

The **column sum vector** of  $A$  is  $S = (s_1, s_2, \dots, s_n)$ , where  $s_j = \sum_{i=1}^m a_{ij}$ , ( $j = 1, 2, \dots, n$ ).

A real vector  $(c_1, c_2, \dots, c_n)$  is **monotone** provided  $c_1 \geq c_2 \geq \dots \geq c_n$ .

The **class of all  $m \times n$  (0, 1)-matrices with row sum vector  $R$  and column sum vector  $S$**  is denoted by  $\mathcal{A}(R, S)$ .

The class  $\mathcal{A}(R, S)$  is a **monotone class** provided  $R$  and  $S$  are both monotone vectors.

An **interchange** is a transformation on a (0, 1)-matrix that replaces a submatrix equal to the identity matrix  $I_2$  by the submatrix

$$L_2 = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$$

or vice versa.

If  $\theta(A)$  is any real numerical quantity associated with a matrix  $A$ , then the **extreme values** of  $\theta$  are  $\bar{\theta}(R, S)$  and  $\tilde{\theta}(R, S)$ , defined by

$$\bar{\theta}(R, S) = \max\{\theta(A) : A \in \mathcal{A}(R, S)\} \text{ and } \tilde{\theta}(R, S) = \min\{\theta(A) : A \in \mathcal{A}(R, S)\}.$$

Let  $T = [t_{kl}]$  be the  $(m + 1) \times (n + 1)$  matrix defined by

$$t_{kl} = kl - \sum_{j=1}^l s_j + \sum_{i=k+1}^m r_i, \quad (k = 0, 1, \dots, m; l = 0, 1, \dots, n).$$

The matrix  $T$  is the **structure matrix** of  $\mathcal{A}(R, S)$ .

### Facts:

The following facts can be found in Chapter 6 of [Rys63], [Bru80], Chapter 6 of [BR91], and Chapters 3 and 4 of [Bru06].

1. A class  $\mathcal{A}(R, S)$  can be transformed into a monotone class by row and column permutations.
2. Let  $U = (u_1, u_2, \dots, u_n)$  and  $V = (v_1, v_2, \dots, v_n)$  be monotone, nonnegative integral vectors.  $U \leq V$  if and only if  $V^* \leq U^*$ , and  $U^{**} = U$  or  $U$  extended with 0s.
3. (*Gale–Ryser theorem*)  $\mathcal{A}(R, S)$  is nonempty if and only if  $S \leq R^*$ .
4. Let the monotone class  $\mathcal{A}(R, S)$  be nonempty, and let  $A$  be a matrix in  $\mathcal{A}(R, S)$ . Let  $K = \{1, 2, \dots, k\}$  and  $L = \{1, 2, \dots, l\}$ . Then  $t_{kl}$  equals the number of 0s in the submatrix  $A[K, L]$  plus the number of 1s in the submatrix  $A(K, L)$ ; in particular, we have  $t_{kl} \geq 0$ .
5. (*Ford–Fulkerson theorem*) The monotone class  $\mathcal{A}(R, S)$  is nonempty if and only if its structure matrix  $T$  is a nonnegative matrix.
6. If  $A$  is in  $\mathcal{A}(R, S)$  and  $B$  results from  $A$  by an interchange, then  $B$  is in  $\mathcal{A}(R, S)$ . Each matrix in  $\mathcal{A}(R, S)$  can be transformed to every other matrix in  $\mathcal{A}(R, S)$  by a sequence of interchanges.
7. The maximum and minimum term rank of a nonempty monotone class  $\mathcal{A}(R, S)$  satisfy:

$$\bar{\rho}(R, S) = \min\{t_{kl} + k + l; k = 0, 1, \dots, m, l = 0, 1, \dots, n\},$$

$$\tilde{\rho}(R, S) = \min\{k + l : \phi_{kl} \geq t_{kl}, k = 0, 1, \dots, m, l = 0, 1, \dots, n\},$$

where

$$\phi_{kl} = \min\{t_{i_1, l+j_2} + t_{k+i_2, j_1} + (k - i_1)(l - j_1)\},$$

the minimum being taken over all integers  $i_1, i_2, j_1, j_2$  such that  $0 \leq i_1 \leq k \leq k + i_2 \leq m$  and  $0 \leq j_1 \leq l \leq l + j_2 \leq n$ .

8. Let  $\text{tr}(A)$  denote the trace of a matrix  $A$ . The maximum and minimum trace of a nonempty monotone class  $\mathcal{A}(R, S)$  satisfy:

$$\begin{aligned} \overline{\text{tr}}(R, S) &= \min\{t_{kl} + \max\{k, l\} : 0 \leq k \leq m, 0 \leq l \leq n\}, \\ \underline{\text{tr}}(R, S) &= \max\{\min\{k, l\} - t_{kl} : 0 \leq k \leq m, 0 \leq l \leq n\}. \end{aligned}$$

9. Let  $k$  and  $n$  be integers with  $0 \leq k \leq n$ , and let  $\mathcal{A}(n, k)$  denote the class  $\mathcal{A}(R, S)$ , where  $R = S = (k, k, \dots, k)$  ( $n$   $k$ 's). Let  $\bar{v}(n, k)$  and  $\underline{v}(n, k)$  denote the minimum and maximum rank, respectively, of matrices in  $\mathcal{A}(n, k)$ .

$$(a) \quad \bar{v}(n, k) = \begin{cases} 0, & \text{if } k = 0, \\ 1, & \text{if } k = n, \\ 3, & \text{if } k = 2 \text{ and } n = 4, \\ n, & \text{otherwise.} \end{cases}$$

(b)  $\bar{v}(n, k) = \bar{v}(n, n - k)$  if  $1 \leq k \leq n - 1$ .

(c)  $\bar{v}(n, k) \geq \lceil n/k \rceil$ , ( $1 \leq k \leq n - 1$ ), with equality if and only if  $k$  divides  $n$ .

(d)  $\bar{v}(n, k) \leq \lfloor n/k \rfloor + k$ , ( $1 \leq k \leq n$ ).

(e)  $\bar{v}(n, 2) = n/2$  if  $n$  is even, and  $(n + 3)/2$  if  $n$  is odd.

(f)  $\bar{v}(n, 3) = n/3$  if 3 divides  $n$  and  $\lfloor n/3 \rfloor + 3$  otherwise.

Additional properties of  $\mathcal{A}(R, S)$  can be found in [Bru80] and in Chapters 3 and 4 of [Bru06].

**Examples:**

- Let  $R = (7, 3, 2, 2, 1, 1)$  and  $S = (5, 5, 3, 1, 1, 1)$ . Then  $R^* = (6, 4, 2, 1, 1, 1)$ . Since  $5 + 5 + 3 > 6 + 4 + 2$ ,  $S \not\leq R^*$  and, by Fact 3,  $\mathcal{A}(R, S) = \emptyset$ .
- Let  $R = S = (2, 2, 2, 2, 2)$ . Then the matrices

$$A = \begin{bmatrix} 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 1 \\ 1 & 0 & 0 & 0 & 1 \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 \\ 0 & 0 & 1 & 1 & 0 \\ 1 & 0 & 0 & 0 & 1 \end{bmatrix}$$

are in  $\mathcal{A}(R, S)$ . Then  $A$  can be transformed to  $B$  by two interchanges:

$$\begin{bmatrix} 1 & \mathbf{1} & 0 & 0 & \mathbf{0} \\ 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 \\ 0 & \mathbf{0} & 0 & 1 & \mathbf{1} \\ 1 & 0 & 0 & 0 & 1 \end{bmatrix} \rightarrow \begin{bmatrix} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 1 & 0 & 0 \\ 0 & \mathbf{0} & \mathbf{1} & 1 & 0 \\ 0 & \mathbf{1} & \mathbf{0} & 1 & 0 \\ 1 & 0 & 0 & 0 & 1 \end{bmatrix} \rightarrow \begin{bmatrix} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 \\ 0 & 0 & 1 & 1 & 0 \\ 1 & 0 & 0 & 0 & 1 \end{bmatrix}.$$

## 27.5 The Class $\mathcal{T}(R)$ of Tournament Matrices

---

In the next definition, we introduce another important class of  $(0, 1)$ -matrices.

**Definitions:**

A  $(0, 1)$ -matrix  $A = [a_{ij}]$  of order  $n$  is a **tournament matrix** provided  $a_{ii} = 0$ , ( $1 \leq i \leq n$ ) and  $a_{ij} + a_{ji} = 1$ , ( $1 \leq i < j \leq n$ ), that is, provided  $A + A^T = J_n - I_n$ .

The digraph of a tournament matrix is called a **tournament**.

Thinking of  $n$  teams  $p_1, p_2, \dots, p_n$  playing in a **round-robin tournament**, we have that  $a_{ij} = 1$  signifies that team  $p_i$  beats team  $p_j$ .

The row sum vector  $R$  is also called the **score vector** of the tournament (matrix).

A **transitive tournament matrix** is one for which  $a_{ij} = a_{jk} = 1$  implies  $a_{ik} = 1$ .

The **class of all tournament matrices with score vector**  $R$  is denoted by  $\mathcal{T}(R)$ .

A  **$\delta$ -interchange** is a transformation on a tournament matrix that replaces a principal submatrix of order 3 equal to

$$\begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix} \text{ with } \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix}$$

or vice versa.

The following facts can be found in Chapters 2 and 5 of [Bru06].

**Facts:**

1. The row sum vector  $R = (r_1, r_2, \dots, r_n)$  and column sum vector  $S = (s_1, s_2, \dots, s_n)$  of a tournament matrix of order  $n$  satisfy  $r_i + s_i = n - 1$ , ( $1 \leq i \leq n$ ); in particular, the column sum vector is determined by the row sum vector.
2. If  $A$  is a tournament matrix and  $P$  is a permutation matrix, then  $PAP^T$  is a tournament matrix. Thus, one may assume without loss of generality that  $R$  is nondecreasing, that is,  $r_1 \leq r_2 \leq \dots \leq r_n$ , so that the teams are ordered from worst to best.
3. (*Landau's theorem*) If  $R = (r_1, r_2, \dots, r_n)$  is a nondecreasing, nonnegative integral vector, then  $\mathcal{T}(R)$  is nonempty if and only if

$$\sum_{i=1}^k r_i \geq \binom{k}{2}, \quad (1 \leq k \leq n)$$

with equality when  $k = n$ . (A binomial coefficient  $\binom{k}{s}$  is 0 if  $k < s$ .)

4. Let  $R = (r_1, r_2, \dots, r_n)$  be a nondecreasing nonnegative integral vector. The following are equivalent:
  - (a) There exists an irreducible matrix in  $\mathcal{T}(R)$ .
  - (b)  $\mathcal{T}(R)$  is nonempty and every matrix in  $\mathcal{T}(R)$  is irreducible.
  - (c)  $\sum_{i=1}^k r_i \geq \binom{k}{2}$ , ( $1 \leq k \leq n$ ) with equality if and only if  $k = n$ .
5. If  $A$  is in  $\mathcal{T}(R)$  and  $B$  results from  $A$  by a  $\delta$ -interchange, then  $B$  is in  $\mathcal{T}(R)$ . Each matrix in  $\mathcal{T}(R)$  can be transformed to every other matrix in  $\mathcal{T}(R)$  by a sequence of  $\delta$ -interchanges.
6. The rank, and so term rank, of a tournament matrix of order  $n$  is at least  $n - 1$ .
7. (*Strengthened Landau inequalities*) Let  $R = (r_1, r_2, \dots, r_n)$  be a nondecreasing nonnegative integral vector. Then  $\mathcal{T}(R)$  is nonempty if and only if

$$\sum_{i \in I} r_i \geq \frac{1}{2} \sum_{i \in I} (i - 1) + \frac{1}{2} \binom{|I|}{2}, \quad (I \subseteq \{1, 2, \dots, n\}),$$

with equality if  $I = \{1, 2, \dots, n\}$ .

8. Let  $R = (r_1, r_2, \dots, r_n)$  be a nondecreasing, nonnegative integral vector such that  $\mathcal{T}(R)$  is nonempty. Then there exists a tournament matrix  $A$  such that the principal submatrices made out of the even-indexed and odd-indexed, respectively, rows and columns are transitive tournament matrices, that is, a matrix  $A$  in  $\mathcal{T}(R)$  such that  $A[\{1, 3, 5, \dots\}]$  and  $A[\{2, 4, 6, \dots\}]$  are transitive tournament matrices.

**Examples:**

1. The following are tournament matrices:

$$A_1 = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix} \text{ and } A_2 = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 1 & 1 & 1 & 0 \end{bmatrix}.$$

The matrix  $A_2$  is a transitive tournament matrix.

2. Let  $R = (2, 2, 2, 2, 3, 4)$ . A tournament matrix in  $\mathcal{T}(R)$  satisfying Fact 7 is

$$\begin{bmatrix} 0 & 0 & 1 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 1 \\ 1 & 1 & 0 & 0 & 1 & 0 \\ 1 & 1 & 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 1 & 1 & 0 \end{bmatrix},$$

since the two submatrices

$$A[[1, 3, 5]] = \begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix} \text{ and } A[\{2, 4, 6\}] = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 1 & 1 & 0 \end{bmatrix}$$

are transitive tournament matrices.

## 27.6 Convex Polytopes of Doubly Stochastic Matrices

---

Doubly stochastic matrices (see Chapter 9.4) are widely studied because of their connection with probability theory, as every doubly stochastic matrix is the transition matrix of a Markov chain. The reader is referred to Chapter 28 for graph terminology.

**Definitions:**

Since a convex combination  $cA + (1 - c)B$  of two doubly stochastic matrices  $A$  and  $B$ , where  $0 \leq c \leq 1$ , is doubly stochastic, the set  $\Omega_n$  of doubly stochastic matrices of order  $n$  is a convex polytope in  $\mathbb{R}^{n^2}$ .  $\Omega_n$  is also called the **assignment polytope** because of its appearance in the classical assignment problem.

If  $A$  is a  $(0, 1)$ -matrix of order  $n$ , then  $\mathcal{F}(A)$  is the convex polytope of all doubly stochastic matrices whose patterns  $P$  satisfy  $P \leq A$  (entrywise), that is, that have 0s at least wherever  $A$  has 0s.

The **dimension** of a convex polytope  $\mathcal{P}$  is the smallest dimension of an affine space containing it and is denoted by  $\dim \mathcal{P}$ .

The **graph**  $G(\mathcal{P})$  of a convex polytope  $\mathcal{P}$  has the extreme points of  $\mathcal{P}$  as its vertices and the pairs of extreme points of one-dimensional faces of  $\mathcal{P}$  as its edges.

The **chromatic index** of a graph is the smallest integer  $t$  such that the edges can be partitioned into sets  $E_1, E_2, \dots, E_t$  such that no two edges in the same  $E_i$  meet.

A **scaling** of a matrix  $A$  is a matrix of the form  $D_1 A D_2$ , where  $D_1$  and  $D_2$  are diagonal matrices with positive diagonal entries.

If  $D_1 = D_2$ , then the scaling  $D_1 A D_2$  is a **symmetric scaling**.

Let  $A = [a_{ij}]$  have order  $n$ . A **diagonal product** of  $A$  is the product of the entries on a diagonal of  $A$ , that is,  $a_{1j_1} a_{2j_2} \cdots a_{nj_n}$  where  $j_1, j_2, \dots, j_n$  is a permutation of  $\{1, 2, \dots, n\}$ .

The following facts can be found in Chapter 9 of [Bru06].

**Facts:**

1. (*Birkhoff's theorem*) The extreme points of  $\Omega_n$  are the permutation matrices of order  $n$ . Thus, each doubly stochastic matrix is a convex combination of permutation matrices.
2. The patterns of matrices in  $\Omega_n$  are precisely the  $(0, 1)$ -matrices of order  $n$  with total support.
3. The faces of  $\Omega_n$  are the sets  $\mathcal{F}(A)$ , where  $A$  is a  $(0, 1)$ -matrix of order  $n$  with total support.  $\Omega_n$  is a face of itself with  $\Omega_n = \mathcal{F}(J_n)$ . The dimension of  $\mathcal{F}(A)$  satisfies

$$\dim \mathcal{F}(A) = t - 2n + k,$$

where  $t$  is the number of 1s of  $A$  and  $k$  is the number of fully indecomposable components of  $A$ . The number of extreme points of  $\mathcal{F}(A)$  (this number is the permanent  $\text{per}(A)$  of  $A$ ), is at least  $t - 2n + k + 1$ . If  $A$  is fully indecomposable and  $\dim \mathcal{F}(A) = d$ , then  $\mathcal{F}(A)$  has at most  $2^{d-1} + 1$  extreme points. In general,  $\mathcal{F}(A)$  has at most  $2^d$  extreme points.

4. The graph  $G(\Omega_n)$  has the following properties:

(a) The number of vertices of  $G(\Omega_n)$  is  $n!$ .

(b) The degree of each vertex of  $G(\Omega_n)$  is

$$d_n = \sum_{k=2}^n \binom{n}{k} (k-1)!$$

(c)  $G(\Omega_n)$  is connected and its diameter equals 1 if  $n = 1, 2$ , and 3, and equals 2 if  $n \geq 4$ .

(d)  $G(\Omega_n)$  has a Hamilton cycle.

(e) The chromatic index of  $G(\Omega_n)$  equals  $d_n$ .

5. (*Hardy, Littlewood, Pólya theorem*) Let  $U = (u_1, u_2, \dots, u_n)$  and  $V = (v_1, v_2, \dots, v_n)$  be monotone, nonnegative integral vectors. Then  $U \leq V$  if and only if there is a doubly stochastic matrix  $A$  such that  $U = VA$ .
6. The set  $\Upsilon_n$  of symmetric doubly stochastic matrices of order  $n$  is a subpolytope of  $\Omega_n$  whose extreme points are those matrices  $A$  such that there is a permutation matrix  $P$  for which  $PAP^T$  is a direct sum of matrices each of which is either the identity matrix  $I_1$  of order 1, the matrix  $\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$ , or an odd order matrix of the type:

$$\begin{bmatrix} 0 & 1/2 & 0 & 0 & \cdots & 0 & 1/2 \\ 1/2 & 0 & 1/2 & 0 & \cdots & 0 & 0 \\ 0 & 1/2 & 0 & 1/2 & \cdots & 0 & 0 \\ 0 & 0 & 1/2 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & 0 & 1/2 \\ 1/2 & 0 & 0 & 0 & \cdots & 1/2 & 0 \end{bmatrix}.$$

7. Let  $A$  be a nonnegative matrix. Then there is a scaling  $B = D_1AD_2$  of  $A$  that is doubly stochastic if and only if  $A$  has total support. If  $A$  is fully indecomposable, then the doubly stochastic matrix  $B$  is unique and the diagonal matrices  $D_1$  and  $D_2$  are unique up to reciprocal scalar factors.
8. Let  $A$  be a nonnegative symmetric matrix with no zero lines. Then there is a symmetric scaling  $B = DAD$  such that  $B$  is doubly stochastic if and only if  $A$  has total support. If  $A$  is fully indecomposable, then the doubly stochastic matrix  $B$  and the diagonal matrix  $D$  are unique.
9. Distinct doubly stochastic matrices of order  $n$  do not have proportional diagonal products; that is, if  $A = [a_{ij}]$  and  $B = [b_{ij}]$  are doubly stochastic matrices of order  $n$  with  $A \neq B$ , there does not exist a constant  $c$  such that  $a_{1j_1}a_{2j_2} \cdots a_{nj_n} = cb_{1j_1}b_{2j_2} \cdots b_{nj_n}$  for all permutations  $j_1, j_2, \dots, j_n$  of  $\{1, 2, \dots, n\}$ .

The subpolytopes of  $\Omega_n$  consisting of (i) the convex combinations of the  $n! - 1$  nonidentity permutation matrices of order  $n$  and (ii) the permutation matrices corresponding to the even permutations of order  $n$  have been studied (see [Bru06]).

Polytopes of matrices more general than  $\Omega_n$  have also been studied, for instance, the nonnegative generalizations of  $\mathcal{A}(R, S)$  consisting of all nonnegative matrices with a given row sum vector  $R$  and a given column sum vector  $S$  (see Chapter 8 of [Bru06]).

### Examples:

1.  $\Omega_2$  consists of all matrices of the form

$$\begin{bmatrix} a & 1-a \\ 1-a & a \end{bmatrix}, \quad (0 \leq a \leq 1).$$

All permutation matrices are doubly stochastic.

2. The matrix

$$\begin{bmatrix} 1/2 & 1/4 & 1/4 \\ 1/6 & 1/3 & 1/2 \\ 1/3 & 5/12 & 1/4 \end{bmatrix}$$

is a doubly stochastic matrix of order 3.

3. If

$$A = \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix},$$

then

$$\begin{bmatrix} 1/2 & 1/2 & 0 \\ 0 & 1/2 & 1/2 \\ 1/2 & 0 & 1/2 \end{bmatrix}$$

is in  $\mathcal{F}(A)$ .

The first two sections of this chapter “Matrices and Graphs” give a short introduction to graph theory. Unfortunately much graph theoretic terminology is not standard, so we had to choose. We allow, for example, graphs to have multiple edges and loops, and call a graph simple if it has none of these. On the other hand, we assume that graphs are finite.

For all nontrivial facts, references are given, sometimes to the original source, but often to text books or survey papers. A recent global reference for this chapter is [BW04]. (This book was not available to the author when this chapter was written, so it is not referred to in the text below.)

### 28.1 Graphs: Basic Notions

---

#### Definitions:

A **graph**  $G = (V, E)$  consists of a finite set  $V = \{v_1, \dots, v_n\}$  of **vertices** and a finite multiset  $E$  of **edges**, where each edge is a pair  $\{v_i, v_j\}$  of vertices (not necessarily distinct). If  $v_i = v_j$ , the edge is called a **loop**. A vertex  $v_i$  of an edge is called an **endpoint** of the edge.

The **order** of graph  $G$  is the number of vertices of  $G$ .

A **simple graph** is a graph with no loops where each edge has multiplicity at most one.

Two graphs  $(V, E)$  and  $(V', E')$  are **isomorphic** whenever there exist bijections  $\phi : V \rightarrow V'$  and  $\psi : E \rightarrow E'$ , such that  $v \in V$  is an endpoint of  $e \in E$  if and only if  $\phi(v)$  is an endpoint of  $\psi(e)$ .

A **walk of length  $\ell$**  in a graph is an alternating sequence  $(v_{i_0}, e_{i_1}, v_{i_1}, e_{i_2}, \dots, e_{i_\ell}, v_{i_\ell})$  of vertices and edges (not necessarily distinct), such that  $v_{i_{j-1}}$  and  $v_{i_j}$  are endpoints of  $e_{i_j}$  for  $j = 1, \dots, \ell$ .

A **path of length  $\ell$**  in a graph is a walk of length  $\ell$  with all vertices distinct.

A **cycle of length  $\ell$**  in a graph is a walk  $(v_{i_0}, e_{i_1}, v_{i_1}, e_{i_2}, \dots, e_{i_\ell}, v_{i_\ell})$  with  $v_{i_0} = v_{i_\ell}$ ,  $\ell \neq 0$ , and  $v_{i_1}, \dots, v_{i_\ell}$  all distinct.

A **Hamilton cycle** in a graph is a cycle that includes all vertices.

A graph  $(V, E)$  is **connected** if  $V \neq \emptyset$  and there exists a walk between any two distinct vertices of  $V$ .

The **distance** between two vertices  $v_i$  and  $v_j$  of a graph  $G$  (denoted by  $d_G(v_i, v_j)$  or  $d(v_i, v_j)$ ) is the length of a shortest path between  $v_i$  and  $v_j$ . ( $d(v_i, v_j) = 0$  if  $i = j$ , and  $d(v_i, v_j)$  is infinite if there is no path between  $v_i$  and  $v_j$ .)

The **diameter** of a connected graph  $G$  is the largest distance that occurs between two vertices of  $G$ .

A **tree** is a connected graph with no cycles.

A **forest** is a graph with no cycles.

A graph  $(V', E')$  is a **subgraph** of a graph  $(V, E)$  if  $V' \subseteq V$  and  $E' \subseteq E$ . If  $E'$  contains all edges from  $E$  with endpoints in  $V'$ ,  $(V', E')$  is an **induced** subgraph of  $(V, E)$ .

A **spanning subgraph** of a connected graph  $(V, E)$  is a subgraph  $(V', E')$  with  $V' = V$ , which is connected.

A **spanning tree** of a connected graph  $(V, E)$  is a spanning subgraph, which is a tree.

A **connected component** of a graph  $(V, E)$  is an induced subgraph  $(V', E')$ , which is connected and such that there exists no edge in  $E$  with one endpoint in  $V'$  and one outside  $V'$ . A connected component with one vertex and no edge is called an **isolated vertex**.

Two graphs  $(V, E)$  and  $(V', E')$  are **disjoint** if  $V$  and  $V'$  are disjoint sets.

Two vertices  $u$  and  $v$  are **adjacent** if there exists an edge with endpoints  $u$  and  $v$ . A vertex adjacent to  $v$  is called a **neighbor** of  $v$ .

The **degree** or **valency** of a vertex  $v$  of a graph  $G$  (denoted by  $\delta_G(v)$  or  $\delta(v)$ ) is the number of times that  $v$  occurs as an endpoint of an edge (that is, the number of edges containing  $v$ , where loops count as 2).

A graph  $(V, E)$  is **bipartite** if the vertex set  $V$  admits a partition into two parts, such that no edge of  $E$  has both endpoints in one part (thus, there are no loops). More information on bipartite graphs is given in Chapter 30.

A simple graph  $(V, E)$  is **complete** if  $E$  consists of all unordered pairs from  $V$ . The (isomorphism class of the) complete graph on  $n$  vertices is denoted by  $K_n$ .

A graph  $(V, E)$  is **empty** if  $E = \emptyset$ . If also  $V = \emptyset$ , it is called the **null graph**.

A bipartite simple graph  $(V, E)$  with nonempty parts  $V_1$  and  $V_2$  is **complete bipartite** if  $E$  consists of all unordered pairs from  $V$  with one vertex in  $V_1$  and one in  $V_2$ . The (isomorphism class of the) complete bipartite graph is denoted by  $K_{n_1, n_2}$ , where  $n_1 = |V_1|$  and  $n_2 = |V_2|$ .

The (isomorphism class of the) simple graph that consists only of vertices and edges of a path of length  $\ell$  is called **the path of length  $\ell$** , and denoted by  $P_{\ell+1}$ .

The (isomorphism class of the) simple graph that consists only of vertices and edges of a cycle of length  $\ell$  is called **the cycle of length  $\ell$** , and denoted by  $C_\ell$ .

The **complement** of a simple graph  $G = (V, E)$  is the simple graph  $\overline{G} = (V, \overline{E})$ , where  $\overline{E}$  consists of all unordered pairs from  $V$  that are not in  $E$ .

The **union**  $G \cup G'$  of two graphs  $G = (V, E)$  and  $G' = (V', E')$  is the graph with vertex set  $V \cup V'$ , and edge (multi)set  $E \cup E'$ .

The **intersection**  $G \cap G'$  of two graphs  $G = (V, E)$  and  $G' = (V', E')$  is the graph with vertex set  $V \cap V'$ , and edge (multi)set  $E \cap E'$ .

The **join**  $G + G'$  of two disjoint graphs  $G = (V, E)$  and  $G' = (V', E')$  is the union of  $G \cup G'$  and the complete bipartite graph with vertex set  $V \cup V'$  and partition  $\{V, V'\}$ .

The **(strong) product**  $G \cdot G'$  of two simple graphs  $G = (V, E)$  and  $G' = (V', E')$  is the simple graph with vertex set  $V \times V'$ , where two distinct vertices are adjacent whenever in both coordinate places the vertices are adjacent or equal in the corresponding graph. The strong product of  $\ell$  copies of a graph  $G$  is denoted by  $G^\ell$ .

### Facts:

The facts below are elementary results that can be found in almost every introduction to graph theory, such as [Har69] or [Wes01].

1. For any graph, the sum of its degrees equals twice the number of edges; therefore, the number of vertices with odd degree is even.
2. For any simple graph, at least two vertices have the same degree.
3. A graph  $G$  is bipartite if and only if  $G$  has no cycles of odd length.
4. A tree with  $n$  vertices has  $n - 1$  edges.

FIGURE 28.1 Three graphs. (Vertices are represented by points and an edge is represented by a line segment between the endpoints, or a loop.)

5. A graph is a tree if and only if there is a unique path between any two vertices.
6. A graph  $G$  is connected if and only if  $G$  cannot be expressed as the union of two or more mutually disjoint connected graphs.

**Examples:**

1. Consider the complete bipartite graph  $K_{3,3} = (V_1 \cup V_2, E)$  with parts  $V_1 = \{v_1, v_2, v_3\}$  and  $V_2 = \{v_4, v_5, v_6\}$ . Then

$$v_1, \{v_1, v_5\}, v_5, \{v_5, v_2\}, v_2, \{v_2, v_6\}, v_6, \{v_6, v_3\}, v_3$$

is a path of length 4 between  $v_1$  and  $v_3$ ,

$$v_1, \{v_1, v_5\}, v_5, \{v_5, v_2\}, v_2, \{v_2, v_5\}, v_5, \{v_5, v_3\}, v_3$$

is a walk of length 4, which is not a path, and

$$v_1, \{v_1, v_5\}, v_5, \{v_5, v_2\}, v_2, \{v_2, v_6\}, v_6, \{v_6, v_1\}, v_1$$

is a cycle of length 4.

2. Graphs  $G_1$  and  $G_2$  in Figure 28.1 are simple, but  $G_3$  is not.
3. Graphs  $G_1$  and  $G_2$  are bipartite, but  $G_3$  is not.
4. Graph  $G_1$  is a tree. Its diameter equals 4.
5. Graph  $G_2$  is not connected; it is the union of two disjoint graphs, a path  $P_3$  and a cycle  $C_4$ . The complement  $\overline{G_2}$  is connected and can be expressed as the join of  $\overline{P_3}$  and  $\overline{C_4}$ .
6. Graph  $G_3$  contains three kinds of cycles, cycles of length 3 (corresponding to the two triangles), cycles of length 2 (corresponding to the pair of multiple edges), and one of length 1 (corresponding to the loop).

## 28.2 Special Graphs

A graph  $G$  is **regular** (or  **$k$ -regular**) if every vertex of  $G$  has the same degree (equal to  $k$ ).

A graph  $G$  is **walk-regular** if for every vertex  $v$  the number of walks from  $v$  to  $v$  of length  $\ell$  depends only on  $\ell$  (not on  $v$ ).

A simple graph  $G$  is **strongly regular** with parameters  $(n, k, \lambda, \mu)$  whenever  $G$  has  $n$  vertices and

- $G$  is  $k$ -regular with  $1 \leq k \leq n - 2$ .
- Every two adjacent vertices of  $G$  have exactly  $\lambda$  common neighbors.
- Every two distinct nonadjacent vertices of  $G$  have exactly  $\mu$  common neighbors.

An **embedding** of a graph in  $\mathbb{R}^n$  consists of a representation of the vertices by distinct points in  $\mathbb{R}^n$ , and a representation of the edges by curve segments between the endpoints, such that a curve segment

intersects another segment or itself only in an endpoint. (A curve segment between  $\mathbf{x}$  and  $\mathbf{y}$  is the range of a continuous map  $\phi$  from  $[0, 1]$  to  $\mathbb{R}^n$  with  $\phi(0) = \mathbf{x}$  and  $\phi(1) = \mathbf{y}$ .)

A graph is **planar** if it admits an embedding in  $\mathbb{R}^2$ .

A graph is **outerplanar** if it admits an embedding in  $\mathbb{R}^2$ , such that the vertices are represented by points on the unit circle, and the representations of the edges are contained in the unit disc.

A graph  $G$  is **linklessly embeddable** if it admits an embedding in  $\mathbb{R}^3$ , such that no two disjoint cycles of  $G$  are linked. (Two disjoint Jordan curves in  $\mathbb{R}^3$  are linked if there is no topological 2-sphere in  $\mathbb{R}^3$  separating them.)

**Deletion of an edge**  $e$  from a graph  $G = (V, E)$  is the operation that deletes  $e$  from  $E$  and results in the subgraph  $G - e = (V, E \setminus \{e\})$  of  $G$ .

**Deletion of a vertex**  $v$  from a graph  $G = (V, E)$  is the operation that deletes  $v$  from  $V$  and all edges with endpoint  $v$  from  $E$ . The resulting subgraph of  $G$  is denoted by  $G - v$ .

**Contraction** of an edge  $e$  of a graph  $(V, E)$  is the operation that merges the endpoints of  $e$  in  $V$ , and deletes  $e$  from  $E$ .

A **minor** of a graph  $G$  is any graph that can be obtained from  $G$  by a sequence of edge deletions, vertex deletions, and contractions.

Let  $G$  be a simple graph. The **line graph**  $L(G)$  of  $G$  has the edges of  $G$  as vertices, and vertices of  $L(G)$  are adjacent if the corresponding edges of  $G$  have an endpoint in common.

The **cocktail party graph**  $CP(a)$  is the graph obtained by deleting  $a$  disjoint edges from the complete graph  $K_{2a}$ . (Note that  $CP(0)$  is the null graph.)

Let  $G$  be a simple graph with vertex set  $\{v_1, \dots, v_n\}$ , and let  $a_1, \dots, a_n$  be nonnegative integers. The **generalized line graph**  $L(G; a_1, \dots, a_n)$  consists of the disjoint union of the line graph  $L(G)$  and the cocktail party graphs  $CP(a_1), \dots, CP(a_n)$ , together with all edges joining a vertex  $\{v_i, v_j\}$  of  $L(G)$  with each vertex of  $CP(a_i)$  and  $CP(a_j)$ .

### Facts:

If no reference is given, the fact is trivial or a classical result that can be found in almost every introduction to graph theory, such as [Har69] or [Wes01].

1. [God93, p. 81] A strongly regular graph is walk-regular.
2. A walk-regular graph is regular.
3. The complement of a strongly regular graph with parameters  $(n, k, \lambda, \mu)$  is strongly regular with parameters  $(n, n - k - 1, n - 2k + \mu - 2, n - 2k + \lambda)$ .
4. Every graph can be embedded in  $\mathbb{R}^3$ .
5. [RS04] (Robertson, Seymour) For every graph property  $\mathcal{P}$  that is closed under taking minors, there exists a finite list of graphs such that a graph  $G$  has property  $\mathcal{P}$  if and only if no graph from the list is a minor of  $G$ .
6. The graph properties: planar, outerplanar, and linklessly embeddable are closed under taking minors.
7. (Kuratowski, Wagner) A graph  $G$  is planar if and only if no minor of  $G$  is isomorphic to  $K_5$  or  $K_{3,3}$ .
8. [CRS04, p. 8] A regular generalized line graph is a line graph or a cocktail party graph.
9. (Whitney) The line graphs of two connected nonisomorphic graphs  $G$  and  $G'$  are nonisomorphic, unless  $\{G, G'\} = \{K_3, K_{1,3}\}$ .

### Examples:

1. Graph  $G_3$  of Figure 28.1 is regular of degree 3.
2. The complete graph  $K_n$  is walk-regular and regular of degree  $n - 1$ .
3. The complete bipartite graph  $K_{k,k}$  is regular of degree  $k$ , walk-regular and strongly regular with parameters  $(2k, k, 0, k)$ .
4. Examples of outerplanar graphs are all trees,  $C_n$ , and  $\overline{P_5}$ .
5. Examples of graphs that are planar, but not outerplanar are:  $K_4$ ,  $CP(3)$ ,  $\overline{C_6}$ , and  $K_{2,n-2}$  for  $n \geq 5$ .

6. Examples of graphs that are not planar, but linklessly embeddable are:  $K_5$ , and  $K_{3,n-3}$  for  $n \geq 6$ .
7. The Petersen graph (Figure 28.2) and  $K_n$  for  $n \geq 6$  are not linklessly embeddable.
8. The complete graph  $K_5$  can be obtained from the Petersen graph by contraction with respect to five mutually disjoint edges. Therefore,  $K_5$  is a minor of the Petersen graph.
9. The cycle  $C_5$  is a subgraph of the Petersen graph and, therefore, the Petersen graph has every cycle  $C_\ell$  with  $\ell \leq 9$  as a minor.
10. Figure 28.3 gives a simple graph  $G$ , the line graph  $L(G)$ , and the generalized line graph  $L(G; 2, 1, 0, 0, 0)$  (the vertices of  $G$  are ordered from left to right).
11. For  $n \geq 4$  and  $k \geq 2$  the line graphs  $L(K_n)$  and  $L(K_{k,k})$  and their complements are strongly regular. The complement of  $L(K_5)$  is the Petersen graph.

FIGURE 28.2 The Petersen graph.

### 28.3 The Adjacency Matrix and Its Eigenvalues

**Definitions:**

The **adjacency matrix**  $\mathcal{A}_G$  of a graph  $G$  with vertex set  $\{v_1, \dots, v_n\}$  is the symmetric  $n \times n$  matrix, whose  $(i, j)$ th entry is equal to the number of edges between  $v_i$  and  $v_j$ .

The **eigenvalues** of a graph  $G$  are the eigenvalues of its adjacency matrix.

The **spectrum**  $\sigma(G)$  of a graph  $G$  is the multiset of eigenvalues (that is, the eigenvalues with their multiplicities).

Two graphs are **cospectral** whenever they have the same spectrum.

A graph  $G$  is **determined by its spectrum** if every graph cospectral with  $G$  is isomorphic to  $G$ .

The **characteristic polynomial**  $p_G(x)$  of a graph  $G$  is the characteristic polynomial of its adjacency matrix  $\mathcal{A}_G$ , that is,  $p_G(x) = \det(xI - \mathcal{A}_G)$ .

A **Hoffman polynomial** of a graph  $G$  is a polynomial  $h(x)$  of minimum degree such that  $h(\mathcal{A}_G) = J$ .

The **main angles** of a graph  $G$  are the cosines of the angles between the eigenspaces of  $\mathcal{A}_G$  and the all-ones vector  $\mathbf{1}$ .

**Facts:**

If no reference is given, the fact is trivial or a standard result in algebraic graph theory that can be found in the classical books [Big74] and [CDS80].

1. If  $\mathcal{A}_G$  is the adjacency matrix of a simple graph  $G$ , then  $J - I - \mathcal{A}_G$  is the adjacency matrix of the complement of  $G$ .
2. If  $\mathcal{A}_G$  and  $\mathcal{A}_{G'}$  are adjacency matrices of simple graphs  $G$  and  $G'$ , respectively, then  $((\mathcal{A}_G + I) \otimes (\mathcal{A}_{G'} + I)) - I$  is the adjacency matrix of the strong product  $G \cdot G'$ .
3. Isomorphic graphs are cospectral.

FIGURE 28.3 A graph with its line graph and a generalized line graph.

4. Let  $G$  be a graph with vertex set  $\{v_1, \dots, v_n\}$  and adjacency matrix  $\mathcal{A}_G$ . The number of walks of length  $\ell$  from  $v_i$  to  $v_j$  equals  $(\mathcal{A}_G^\ell)_{ij}$ , i.e., the  $i, j$ -entry of  $\mathcal{A}_G^\ell$ .
5. The eigenvalues of a graph are real numbers.
6. The adjacency matrix of a graph is diagonalizable.
7. If  $\lambda_1 \geq \dots \geq \lambda_n$  are the eigenvalues of a graph  $G$ , then  $|\lambda_i| \leq \lambda_1$ . If  $\lambda_1 = \lambda_2$ , then  $G$  is disconnected. If  $\lambda_1 = -\lambda_n$  and  $G$  is not empty, then at least one connected component of  $G$  is nonempty and bipartite.
8. [CDS80, p. 87] If  $\lambda_1 \geq \dots \geq \lambda_n$  are the eigenvalues of a graph  $G$ , then  $G$  is bipartite if and only if  $\lambda_i = -\lambda_{n+1-i}$  for  $i = 1, \dots, n$ . For more information on bipartite graphs see Chapter 30.
9. If  $G$  is a simple  $k$ -regular graph, then the largest eigenvalue of  $G$  equals  $k$ , and the multiplicity of  $k$  equals the number of connected components of  $G$ .
10. [CDS80, p. 94] If  $\lambda_1 \geq \dots \geq \lambda_n$  are the eigenvalues of a simple graph  $G$  with  $n$  vertices and  $m$  edges, then  $\sum_i \lambda_i^2 = 2m \leq n\lambda_1$ . Equality holds if and only if  $G$  is regular.
11. [CDS80, p. 95] A simple graph  $G$  has a Hoffman polynomial if and only if  $G$  is regular and connected.
12. [CRS97, p. 99] Suppose  $G$  is a simple graph with  $n$  vertices,  $r$  distinct eigenvalues  $\nu_1, \dots, \nu_r$ , and main angles  $\beta_1, \dots, \beta_r$ . Then the complement  $\overline{G}$  of  $G$  has characteristic polynomial

$$p_{\overline{G}}(x) = (-1)^n p_G(-x-1) \left( 1 - n \sum_{i=1}^r \beta_i^2 / (x+1+\nu_i) \right).$$

13. [CDS80, p. 103], [God93, p. 179] A connected simple regular graph is strongly regular if and only if it has exactly three distinct eigenvalues. The eigenvalues ( $\nu_1 > \nu_2 > \nu_3$ ) and parameters  $(n, k, \lambda, \mu)$  are related by  $\nu_1 = k$  and

$$\nu_2, \nu_3 = \frac{1}{2} \left( \lambda - \mu \pm \sqrt{(\mu - \lambda)^2 + 4(k - \mu)} \right).$$

14. [BR91, p. 150], [God93, p. 180] The multiplicities of the eigenvalues  $\nu_1, \nu_2$ , and  $\nu_3$  of a connected strongly regular graph with parameters  $(n, k, \lambda, \mu)$  are 1 and

$$\frac{1}{2} \left( n - 1 \pm \frac{(n-1)(\mu - \lambda) - 2k}{\sqrt{(\mu - \lambda)^2 + 4(k - \mu)}} \right) \quad (\text{respectively}).$$

15. [GR01, p. 190] A regular simple graph with at most four distinct eigenvalues is walk-regular.
16. [CRS97, p. 79] Cospectral walk-regular simple graphs have the same main angles.
17. [Sch73] Almost all trees are cospectral with another tree.
18. [DH03] The number of nonisomorphic simple graphs on  $n$  vertices, not determined by the spectrum, is asymptotically bounded from below by  $n^3 g_{n-1} (\frac{1}{24} - o(1))$ , where  $g_{n-1}$  denotes the number of nonisomorphic simple graphs on  $n-1$  vertices.
19. [DH03] The complete graph, the cycle, the path, the regular complete bipartite graph, and their complements are determined by their spectrum.
20. [DH03] Suppose  $G$  is a regular connected simple graph on  $n$  vertices, which is determined by its spectrum. Then also the complement  $\overline{G}$  of  $G$  is determined by its spectrum, and if  $n+1$  is not a square, also the line graph  $L(G)$  of  $G$  is determined by its spectrum.
21. [CRS04, p. 7] A simple graph  $G$  is a generalized line graph if and only if the adjacency matrix  $\mathcal{A}_G$  can be expressed as  $\mathcal{A}_G = C^T C - 2I$ , where  $C$  is an integral matrix with exactly two nonzero entries in each column. (It follows that the nonzero entries are  $\pm 1$ .)
22. [CRS04, p. 7] A generalized line graph has smallest eigenvalue at least  $-2$ .
23. [CRS04, p. 85] A connected simple graph with more than 36 vertices and smallest eigenvalue at least  $-2$  is a generalized line graph.
24. [CRS04, p. 90] There are precisely 187 connected regular simple graphs with smallest eigenvalue at least  $-2$  that are not a line graph or a cocktail party graph. Each of these graphs has smallest eigenvalue equal to  $-2$ , at most 28 vertices, and degree at most 16.

FIGURE 28.4 Two cospectral graphs with their adjacency matrices.

**Examples:**

1. Figure 28.4 gives a pair of nonisomorphic bipartite graphs with their adjacency matrices. Both matrices have spectrum  $\{2, 0^3, -2\}$  (exponents indicate multiplicities), so the graphs are cospectral.
2. The main angles of the two graphs of Figure 28.4 (with the given ordering of the eigenvalues) are  $2/\sqrt{5}, 1/\sqrt{5}, 0$  and  $3/\sqrt{10}, 0, 1/\sqrt{10}$ , respectively.
3. The spectrum of  $K_{n_1, n_2}$  is  $\{\sqrt{n_1 n_2}, 0^{n-2}, -\sqrt{n_1 n_2}\}$ .
4. By Fact 14, the multiplicities of the eigenvalues of any strongly regular graph with parameters  $(n, k, 1, 1)$  would be nonintegral, so no such graph can exist (this result is known as the Friendship theorem).
5. The Petersen graph has spectrum  $\{3, 1^5, -2^4\}$  and Hoffman polynomial  $(x - 1)(x + 2)$ . It is one of the 187 connected regular graphs with least eigenvalue  $-2$ , which is neither a line graph nor a cocktail party graph.
6. The eigenvalues of the path  $P_n$  are  $2 \cos \frac{i\pi}{n+1}$  ( $i = 1, \dots, n$ ).
7. The eigenvalues of the cycle  $C_n$  are  $2 \cos \frac{2i\pi}{n}$  ( $i = 1, \dots, n$ ).

## 28.4 Other Matrix Representations

**Definitions:**

Let  $G$  be a simple graph with adjacency matrix  $\mathcal{A}_G$ . Suppose  $D$  is the diagonal matrix with the degrees of  $G$  on the diagonal (with the same vertex ordering as in  $\mathcal{A}_G$ ). Then  $L_G = D - \mathcal{A}_G$  is the **Laplacian matrix** of  $G$  (often abbreviated to the **Laplacian**, and also known as **admittance matrix**), and the matrix  $|L_G| = D + \mathcal{A}_G$  is (sometimes) called the **signless Laplacian matrix**.

The **Laplacian eigenvalues** of a simple graph  $G$  are the eigenvalues of the Laplacian matrix  $L_G$ .

If  $\mu_1 \leq \mu_2 \leq \dots \leq \mu_n$  are the Laplacian eigenvalues of  $G$ , then  $\mu_2$  is called the **algebraic connectivity** of  $G$ . (See section 28.6 below.)

Let  $G$  be simple graph with vertex set  $\{v_1, \dots, v_n\}$ . A symmetric real matrix  $M = [m_{ij}]$  is called a **generalized Laplacian** of  $G$ , whenever  $m_{ij} < 0$  if  $v_i$  and  $v_j$  are adjacent, and  $m_{ij} = 0$  if  $v_i$  and  $v_j$  are nonadjacent and distinct (nothing is required for the diagonal entries of  $M$ ).

Let  $G$  be a graph without loops with vertex set  $\{v_1, \dots, v_n\}$  and edge set  $\{e_1, \dots, e_m\}$ . The **(vertex-edge) incidence matrix** of  $G$  is the  $n \times m$  matrix  $N_G$  defined by  $(N_G)_{ij} = 1$  if vertex  $v_i$  is an endpoint of edge  $e_j$  and  $(N_G)_{ij} = 0$  otherwise.

An **oriented (vertex-edge) incidence matrix** of  $G$  is a matrix  $N'_G$  obtained from  $N_G$  by replacing a 1 in each column by a  $-1$ , and thereby orienting each edge of  $G$ .

If  $\mathcal{A}_G$  is the adjacency matrix of a simple graph  $G$ , then  $S_G = J - I - 2\mathcal{A}_G$  is the **Seidel matrix** of  $G$ .

Let  $G$  be a simple graph with Seidel matrix  $S_G$ , and let  $I'$  be a diagonal matrix with  $\pm 1$  on the diagonal. Then the simple graph  $G'$  with Seidel matrix  $S_{G'} = I'S_G I'$  is **switching equivalent** to  $G$ . The graph operation that changes  $G$  into  $G'$  is called **Seidel switching**.

### Facts:

In all facts below,  $G$  is a simple graph. If no reference is given, the fact is trivial or a classical result that can be found in [BR91].

- Let  $G$  be a simple graph. The Laplacian matrix  $L_G$  and the signless Laplacian  $|L_G|$  are positive semidefinite.
- The nullity of  $L_G$  is equal to the number of connected components of  $G$ .
- The nullity of  $|L_G|$  is equal to the number of connected components of  $G$  that are bipartite.
- [DH03] The Laplacian and the signless Laplacian of a graph  $G$  have the same spectrum if and only if  $G$  is bipartite.
- (Matrix-tree theorem) Let  $G$  be a graph with Laplacian matrix  $L_G$ , and let  $c_G$  denote the number of spanning trees of  $G$ . Then  $\text{adj}(L_G) = c_G J$ .
- Suppose  $N_G$  is the incidence matrix of  $G$ . Then  $N_G N_G^T = |L_G|$  and  $N_G^T N_G - 2I = \mathcal{A}_{L(G)}$ .
- Suppose  $N'_G$  is an oriented incidence matrix of  $G$ . Then  $N'_G N_G'^T = L_G$ .
- If  $\mu_1 \leq \dots \leq \mu_n$  are the Laplacian eigenvalues of  $G$ , and  $\bar{\mu}_1 \leq \dots \leq \bar{\mu}_n$  are the Laplacian eigenvalues of  $\bar{G}$ , then  $\mu_1 = \bar{\mu}_1 = 0$  and  $\bar{\mu}_i = n - \mu_{n+2-i}$  for  $i = 2, \dots, n$ .
- [DH03] If  $\mu_1 \leq \dots \leq \mu_n$  are the Laplacian eigenvalues of a graph  $G$  with  $n$  vertices and  $m$  edges, then  $\sum_i \mu_i = 2m \leq \sqrt{n \sum_i \mu_i (\mu_i - 1)}$  with equality if and only if  $G$  is regular.
- [DH98] A connected graph  $G$  has at most three distinct Laplacian eigenvalues if and only if there exist integers  $\mu$  and  $\bar{\mu}$ , such that any two distinct nonadjacent vertices have exactly  $\mu$  common neighbors, and any two adjacent vertices have exactly  $\bar{\mu}$  common nonneighbors.
- If  $G$  is  $k$ -regular and  $\mathbf{v} \notin \text{span}\{\mathbf{1}\}$ , then the following are equivalent:
  - $\lambda$  is an eigenvalue of  $\mathcal{A}_G$  with eigenvector  $\mathbf{v}$ .
  - $k - \lambda$  is an eigenvalue of  $L_G$  with eigenvector  $\mathbf{v}$ .
  - $k + \lambda$  is an eigenvalue of  $|L_G|$  with eigenvector  $\mathbf{v}$ .
  - $-1 - 2\lambda$  is an eigenvalue of  $S_G$  with eigenvector  $\mathbf{v}$ .
- [DH03] Consider a simple graph  $G$  with  $n$  vertices and  $m$  edges. Let  $\nu_1 \leq \dots \leq \nu_n$  be the eigenvalues of  $|L_G|$ , the signless Laplacian of  $G$ . Let  $\lambda_1 \geq \dots \geq \lambda_m$  be the eigenvalues of  $L(G)$ , the line graph of  $G$ . Then  $\lambda_i = \nu_{n-i+1} - 2$  if  $1 \leq i \leq \min\{m, n\}$ , and  $\lambda_i = -2$  if  $\min\{m, n\} < i \leq m$ .
- [GR01, p. 298] Let  $G$  be a connected graph, let  $M$  be a generalized Laplacian of  $G$ , and let  $\mathbf{v}$  be an eigenvector for  $M$  corresponding to the second smallest eigenvalue of  $M$ . Then the subgraph of  $G$  induced by the vertices corresponding to the positive entries of  $\mathbf{v}$  is connected.
- The Seidel matrices of switching equivalent graphs have the same spectrum.

FIGURE 28.5 Graphs with cospectral Laplacian matrices.

FIGURE 28.6 Graphs with cospectral signless Laplacian matrices.

**Examples:**

1. The Laplacian eigenvalues of the Petersen graph are  $\{0, 2^5, 5^4\}$ .
2. The two graphs of Figure 28.5 are nonisomorphic, but the Laplacian matrices have the same spectrum. Both Laplacian matrices have  $12J$  as adjugate, so both have 12 spanning trees. They are not cospectral with respect to the adjacency matrix because one is bipartite and the other one is not.
3. Figure 28.6 gives two graphs with cospectral signless Laplacian matrices. They are not cospectral with respect to the adjacency matrix because one is bipartite and the other one is not. They also do not have cospectral Laplacian matrices because the numbers of components differ.
4. The eigenvalues of the Laplacian and the signless Laplacian matrix of the path  $P_n$  are  $2 + 2 \cos \frac{i\pi}{n}$  ( $i = 1, \dots, n$ ).
5. The complete bipartite graph  $K_{n_1, n_2}$  is Seidel switching equivalent to the empty graph on  $n = n_1 + n_2$  vertices. The Seidel matrices have the same spectrum, being  $\{n - 1, -1^{n-1}\}$ .

## 28.5 Graph Parameters

---

**Definitions:**

A subgraph  $G'$  on  $n'$  vertices of a simple graph  $G$  is a **clique** if  $G'$  is isomorphic to the complete graph  $K_{n'}$ . The largest value of  $n'$  for which a clique with  $n'$  vertices exists is called the **clique number** of  $G$  and is denoted by  $\omega(G)$ .

An induced subgraph  $G'$  on  $n'$  vertices of a graph  $G$  is a **coclique** or **independent set of vertices** if  $G'$  has no edges. The largest value of  $n'$  for which a coclique with  $n'$  vertices exists is called the **vertex independence number** of  $G$  and is denoted by  $\iota(G)$ . Note that the standard notation for the vertex independence number of  $G$  is  $\alpha(G)$ , but  $\iota(G)$  is used here due to conflict with the use of  $\alpha(G)$  to denote the algebraic connectivity of  $G$  in Chapter 36.

The **Shannon capacity**  $\Theta(G)$  of a simple graph  $G$  is defined by  $\Theta(G) = \sup_{\ell} \sqrt[\ell]{\iota(G^\ell)}$

A **vertex coloring** of a graph is a partition of the vertex set into cocliques. A coclique in such a partition is called a **color class**.

The **chromatic number**  $\chi(G)$  of a graph  $G$  is the smallest number of color classes of any vertex coloring of  $G$ . (The chromatic number is not defined if  $G$  has loops.)

For a simple graph  $G = (V, E)$ , the **conductance** or **isoperimetric number**  $\Phi(G)$  is defined to be the minimum value of  $\partial(V')/|V'|$  over any subset  $V' \subset V$  with  $|V'| \leq |V|/2$ , where  $\partial(V')$  equals the number of edges in  $E$  with one endpoint in  $V'$  and one endpoint outside  $V'$ .

An infinite family of graphs with constant degree and isoperimetric number bounded from below is called a family of **expanders**.

A symmetric real matrix  $M$  is said to satisfy the **Strong Arnold Hypothesis** provided there does not exist a symmetric nonzero matrix  $X$  with zero diagonal, such that  $MX = \mathbf{0}, M \circ X = \mathbf{0}$ .

The **Colin de Verdière parameter**  $\mu(G)$  of a simple graph  $G$  is the largest nullity of any generalized Laplacian  $M$  of  $G$  satisfying the following:

- $M$  has exactly one negative eigenvalue of multiplicity 1.
- The Strong Arnold Hypothesis.

Consider a simple graph  $G$  with vertex set  $\{v_1, \dots, v_n\}$ . The **Lovász parameter**  $\vartheta(G)$  is the minimum value of the largest eigenvalue  $\lambda_1(M)$  of any real symmetric  $n \times n$  matrix  $M = [m_{ij}]$ , which satisfies  $m_{ij} = 1$  if  $v_i$  and  $v_j$  are nonadjacent (including the diagonal).

Consider a simple graph  $G$  with vertex set  $\{v_1, \dots, v_n\}$ . The integer  $\eta(G)$  is defined to be the smallest rank of any  $n \times n$  matrix  $M$  (over any field), which satisfies  $m_{ii} \neq 0$  for  $i = 1, \dots, n$  and  $m_{ij} = 0$ , if  $v_i$  and  $v_j$  are distinct nonadjacent vertices.

### Facts:

In the facts below, all graphs are simple.

1. [Big74, p. 13] A connected graph with  $r$  distinct eigenvalues (for the adjacency, the Laplacian or the signless Laplacian matrix) has diameter at most  $r - 1$ .
2. [CDS80, pp. 90–91], [God93, p. 83] The chromatic number  $\chi(G)$  of a graph  $G$  with adjacency eigenvalues  $\lambda_1 \geq \dots \geq \lambda_n$  satisfies:  $1 - \lambda_1/\lambda_n \leq \chi(G) \leq 1 + \lambda_1$ .
3. [CDS80, p. 88] For a graph  $G$ , let  $m_+$  and  $m_-$  denote the number of nonnegative and nonpositive adjacency eigenvalues, respectively. Then  $\iota(G) \leq \min\{m_+, m_-\}$ .
4. [GR01, p. 204] If  $G$  is a  $k$ -regular graph with adjacency eigenvalues  $\lambda_1 \geq \dots \geq \lambda_n$ , then  $\omega(G) \leq \frac{n(\lambda_2+1)}{n-k+\lambda_2}$  and  $\iota(G) \leq \frac{-n\lambda_n}{k-\lambda_n}$ .
5. [Moh97] Suppose  $G$  is a graph with maximum degree  $\Delta$  and algebraic connectivity  $\mu_2$ . Then the isoperimetric number  $\Phi(G)$  satisfies  $\mu_2/2 \leq \Phi(G) \leq \sqrt{\mu_2(2\Delta - \mu_2)}$ .
6. [HLS99] The Colin de Verdière parameter  $\mu(G)$  is minor monotonic, that is, if  $H$  is a minor of  $G$ , then  $\mu(H) \leq \mu(G)$ .
7. [HLS99] If  $G$  has at least one edge, then  $\mu(G) = \max\{\mu(H) \mid H \text{ is a component of } G\}$ .
8. [HLS99] The Colin de Verdière parameter  $\mu(G)$  satisfies the following:
  - $\mu(G) \leq 1$  if and only if  $G$  is the disjoint union of paths.
  - $\mu(G) \leq 2$  if and only if  $G$  is outerplanar.
  - $\mu(G) \leq 3$  if and only if  $G$  is planar.
  - $\mu(G) \leq 4$  if and only if  $G$  is linklessly embeddable.
9. (Sandwich theorems)[Lov79], [Hae81] The parameters  $\vartheta(G)$  and  $\eta(G)$  satisfy:  $\iota(G) \leq \vartheta(G) \leq \chi(\overline{G})$  and  $\iota(G) \leq \eta(G) \leq \chi(\overline{G})$ .
10. [Lov79], [Hae81] The parameters  $\vartheta(G)$  and  $\eta(G)$  satisfy:  $\vartheta(G \cdot H) = \vartheta(G)\vartheta(H)$  and  $\eta(G \cdot H) \leq \eta(G)\eta(H)$ .
11. [Lov79], [Hae81] The Shannon capacity  $\Theta(G)$  of a graph  $G$  satisfies:  $\iota(G) \leq \Theta(G)$ ,  $\Theta(G) \leq \vartheta(G)$ , and  $\Theta(G) \leq \eta(G)$ .
12. [Lov79], [Hae81] If  $G$  is a  $k$ -regular graph with eigenvalues  $k = \lambda_1 \geq \dots \geq \lambda_n$ , then  $\vartheta(G) \leq -n\lambda_n/(k - \lambda_n)$ . Equality holds if  $G$  is strongly regular.
13. [Lov79] The Lovász parameter  $\vartheta(G)$  can also be defined as the maximum value of  $\text{tr}(MJ_n)$ , where  $M$  is any positive semidefinite  $n \times n$  matrix, satisfying  $\text{tr}(M) = 1$  and  $m_{ij} = 0$  if  $v_i$  and  $v_j$  are adjacent vertices in  $G$ .

### Examples:

1. Suppose  $G$  is the Petersen graph. Then  $\iota(G) = 4$ ,  $\vartheta(G) = 4$  (by Facts 9 and 12). Thus,  $\Theta(G) = 4$  (by Fact 11). Moreover,  $\chi(G) = 3$ ,  $\chi(\overline{G}) = 5$ ,  $\mu(G) = 5$  (take  $M = L_G - 2I$ ), and  $\eta(G) = 4$  (take  $M = \mathcal{A}_G + I$  over the field with two elements).
2. The isoperimetric number  $\Phi(G)$  of the Petersen graph equals 1. Indeed,  $\Phi(G) \geq 1$ , by Fact 5, and any pentagon gives  $\Phi(G) \leq 1$ .
3.  $\mu(K_n) = n - 1$  (take  $M = -J$ ).
4. If  $G$  is the empty graph with at least two vertices, then  $\mu(G) = 1$ . ( $M$  must be a diagonal matrix with exactly one negative entry, and the Strong Arnold Hypothesis forbids two or more diagonal entries to be 0.)

5. By Fact 12,  $\vartheta(C_5) = \sqrt{5}$ . If  $(v_1, \dots, v_5)$  are the vertices of  $C_5$ , cyclically ordered, then  $(v_1, v_1), (v_2, v_3), (v_3, v_5), (v_4, v_2), (v_5, v_4)$  is a coclique of size 5 in  $C_5 \cdot C_5$ . Thus,  $\iota(C_5 \cdot C_5) \geq 5$  and, therefore,  $\Theta(C_5) = \sqrt{5}$ .

## 28.6 Association Schemes

### Definitions:

A set of graphs  $G_0, \dots, G_d$  on a common vertex set  $V = \{v_1, \dots, v_n\}$  is an **association scheme** if the adjacency matrices  $A_0, \dots, A_d$  satisfy:

- $A_0 = I$ .
- $\sum_{i=0}^d A_i = J$ .
- $\text{span}\{A_0, \dots, A_d\}$  is closed under matrix multiplication.

The numbers  $p_{i,j}^k$  defined by  $A_i A_j = \sum_{k=0}^d p_{i,j}^k A_k$  are called the **intersection numbers** of the association scheme.

The (associative) algebra spanned by  $A_0, \dots, A_d$  is the **Bose–Mesner algebra** of the association scheme.

Consider a connected graph  $G_1 = (V, E_1)$  with diameter  $d$ . Define  $G_i = (V, E_i)$  to be the graph wherein two vertices are adjacent if their distance in  $G_1$  equals  $i$ . If  $G_0, \dots, G_d$  is an association scheme, then  $G_1$  is a **distance-regular graph**.

Let  $V'$  be a subset of the vertex set  $V$  of an association scheme. The **inner distribution**  $\mathbf{a} = [a_0, \dots, a_d]^T$  of  $V'$  is defined by  $a_i |V'| = \mathbf{c}^T A_i \mathbf{c}$ , where  $\mathbf{c}$  is the characteristic vector of  $V'$  (that is,  $c_i = 1$  if  $v_i \in V$  and  $c_i = 0$  otherwise).

### Facts:

Facts 1 to 7 below are standard results on association schemes that can be found in any of the following references: [BI84], [BCN89], [God93].

1. Suppose  $G_0, \dots, G_d$  is an association scheme. For any three integers  $i, j, k \in \{0, \dots, d\}$  and for any two vertices  $x$  and  $y$  adjacent in  $G_k$ , the number of vertices  $z$  adjacent to  $x$  in  $G_i$  and to  $y$  in  $G_j$  equals the intersection number  $p_{ij}^k$ . In particular,  $G_i$  is regular of degree  $k_i = p_{ii}^0$  ( $i \neq 0$ ).
2. The matrices of a Bose–Mesner algebra  $\mathcal{A}$  can be diagonalized simultaneously. In other words, there exists a nonsingular matrix  $S$  such that  $SAS^{-1}$  is a diagonal matrix for every  $A \in \mathcal{A}$ .
3. A Bose–Mesner algebra has a basis  $\{E_0 = \frac{1}{n}J, E_1, \dots, E_d\}$  of idempotents, that is,  $E_i E_j = \delta_{i,j} E_i$  ( $\delta_{i,j}$  is the Kronecker symbol).
4. The change-of-coordinates matrix  $P = [p_{ij}]$  defined by  $A_j = \sum_i p_{ij} E_i$  satisfies:
  - $p_{ij}$  is an eigenvalue of  $A_j$  with eigenspace  $\text{range}(E_i)$ .
  - $p_{i0} = 1, p_{0i} = k_i$  (the degree of  $G_i$  ( $i \neq 0$ )).
  - $nk_j(P^{-1})_{ji} = m_i p_{ij}$ , where  $m_i = \text{rank}(E_i)$  (the multiplicity of eigenvalue  $p_{ij}$ ).
5. (Krein condition) The Bose–Mesner algebra of an association scheme is closed under Hadamard multiplication. The numbers  $q_{i,j}^k$ , defined by  $E_i \circ E_j = \sum_k q_{i,j}^k E_k$ , are nonnegative.
6. (Absolute bound) The multiplicities  $m_0 = 1, m_1, \dots, m_d$  of an association scheme satisfy

$$\sum_{k:q_{i,j}^k > 0} m_k \leq m_i m_j \quad \text{and} \quad \sum_{k:q_{i,i}^k > 0} m_k \leq m_i(m_i + 1)/2.$$

7. A connected strongly regular graph is distance-regular with diameter two.
8. [BCN89, p. 55] Let  $V'$  be a subset of the vertex set  $V$  of an association scheme with change-of-coordinates matrix  $P$ . The inner distribution  $\mathbf{a}$  of  $V'$  satisfies  $\mathbf{a}^T P^{-1} \geq \mathbf{0}$ .

**Examples:**

1. The change-of-coordinates matrix  $P$  of a strongly regular graph with eigenvalues  $k$ ,  $\nu_2$ , and  $\nu_3$  is equal to

$$\begin{bmatrix} 1 & k & n - k - 1 \\ 1 & \nu_2 & -\nu_2 - 1 \\ 1 & \nu_3 & -\nu_3 - 1 \end{bmatrix}.$$

2. A strongly regular graph with parameters  $(28, 9, 0, 4)$  cannot exist, because it violates Facts 5 and 6.
3. The Hamming association scheme  $H(d, q)$  has vertex set  $V = Q^d$ , the set of all vectors with  $d$  entries from a finite set  $Q$  of size  $q$ . Two such vectors are adjacent in  $G_i$  if they differ in exactly  $i$  coordinate places. The graph  $G_1$  is distance-regular. The matrix  $P$  of a Hamming association scheme can be expressed in terms of Kravčuk polynomials, which gives

$$p_{ij} = \sum_{k=0}^j (-1)^k (q-1)^{j-k} \binom{i}{k} \binom{d-i}{j-k}.$$

4. An error correcting code with minimum distance  $\delta$  is a subset  $V'$  of the vertex set  $V$  of a Hamming association scheme, such that  $V'$  induces a coclique in  $G_1, \dots, G_{\delta-1}$ . If  $\mathbf{a}$  is the inner distribution of  $V'$ , then  $a_0 = 1$ ,  $a_1 = \dots = a_{\delta-1} = 0$ , and  $|V'| = \sum_i a_i$ . Therefore, by Fact 8, the linear programming problem “Maximize  $\sum_{i \geq \delta} a_i$ , subject to  $\mathbf{a}^T P^{-1} \geq 0$  (with  $a_0 = 1$  and  $a_1 = \dots = a_{\delta-1} = 0$ )” leads to an upper bound for the size of an error correcting code with given minimum distance. This bound is known as Delsarte’s Linear Programming Bound.
5. The Johnson association scheme  $J(d, \ell)$  has as vertex set  $V$  all subsets of size  $d$  of a set of size  $\ell$  ( $\ell \geq 2d$ ). Two vertices are adjacent in  $G_i$  if the intersection of the corresponding subsets has size  $d - i$ . The graph  $G_1$  is distance-regular. The matrix  $P$  of a Johnson association scheme can be expressed in terms of Eberlein polynomials, which gives:

$$p_{ij} = \sum_{k=0}^j (-1)^k \binom{i}{k} \binom{d-i}{j-k} \binom{\ell-d-i}{j-k}.$$

*Pacific Lutheran University*

Directed graphs, often called digraphs, have much in common with graphs, which were the subject of the previous chapter. While digraphs are of interest in their own right, and have been the subject of much research, this chapter focuses on those aspects of digraphs that are most useful to matrix theory. In particular, it will be seen that digraphs can be used to understand how the zero–nonzero structure of square matrices affects matrix products, determinants, inverses, and eigenstructure. Basic material on digraphs and their adjacency matrices can be found in many texts on graph theory, nonnegative matrix theory, or combinatorial matrix theory. For all aspects of digraphs, except their spectra, see [BG00]. Perhaps the most comprehensive single source for results, proofs, and references to original papers on the interplay between digraphs and matrices is [BR91, Chapters 3 and 9]. Readers preferring a matrix analytic rather than combinatorial approach to irreducibility, primitivity, and their consequences, should consult [BP94, Chapter 2].

### 29.1 Digraphs

---

#### Definitions:

A **directed graph**  $\Gamma = \Gamma(V, E)$  consists of a finite, nonempty set  $V$  of **vertices** (sometimes called **nodes**), together with a multiset  $E$  of elements of  $V \times V$ , whose elements are called **arcs** (sometimes called **edges**, **directed edges**, or **directed arcs**).

FIGURE 29.1

A **loop** is an arc of the form  $(v, v)$  for some vertex  $v$ .

If there is more than one arc  $(u, v)$  for some  $u$  and  $v$  in  $V$ , then  $\Gamma$  is called a **directed multigraph**.

If there is at most one arc  $(u, v)$  for each  $u$  and  $v$  in  $V$ , then  $\Gamma$  is called a **digraph**.

If the digraph  $\Gamma$  contains no loops, then  $\Gamma$  is called a **simple digraph**.

A **weighted digraph** is a digraph  $\Gamma$  with a **weight function**  $w : E \rightarrow \mathbf{F}$ , where the set  $\mathbf{F}$  is often the real or complex numbers.

A **subdigraph**  $\Gamma'$  of a digraph  $\Gamma$  is a digraph  $\Gamma' = \Gamma'(V', E')$  such that  $V' \subseteq V$  and  $E' \subseteq E$ .

A **proper subdigraph**  $\Gamma'$  of a digraph  $\Gamma$  is a subdigraph of  $\Gamma$  such that  $V' \subset V$  or  $E' \subset E$ .

If  $V'$  is a nonempty subset of  $V$ , then the **induced subdigraph of  $\Gamma$  induced by  $V'$**  is the digraph with vertex set  $V'$  whose arcs are those arcs in  $E$  that lie in  $V' \times V'$ .

A **walk** is a sequence of arcs  $(v_0, v_1), (v_1, v_2), \dots, (v_{k-1}, v_k)$ , where one or more vertices may be repeated.

The **length** of a walk is the number of arcs in the walk. (Note that some authors define the length to be the number of vertices rather than the number of arcs.)

A **simple walk** is a walk in which all vertices, except possibly  $v_0$  and  $v_k$ , are distinct. (Note that some authors use **path** to mean what we call a simple walk.)

A **cycle** is a simple walk for which  $v_0 = v_k$ . A cycle of length  $k$  is called a  **$k$ -cycle**.

A **generalized cycle** is either a cycle passing through all vertices in  $V$  or else a union of cycles such that every vertex in  $V$  lies on exactly one cycle.

Let  $\Gamma = \Gamma(V, E)$  be a digraph. The **undirected graph  $G$  associated with the digraph  $\Gamma$**  is the undirected graph with vertex set  $V$ , whose edge set is determined as follows: There is an edge between vertices  $u$  and  $v$  in  $G$  if and only if at least one of the arcs  $(u, v)$  and  $(v, u)$  is present in  $\Gamma$ .

The digraph  $\Gamma$  is **connected** if the associated undirected graph  $G$  is connected.

The digraph  $\Gamma$  is a **tree** if the associated undirected graph  $G$  is a tree.

The digraph  $\Gamma$  is a **doubly directed tree** if the associated undirected graph is a tree and if whenever  $(i, j)$  is an arc in  $\Gamma$ ,  $(j, i)$  is also an arc in  $\Gamma$ .

### Examples:

1. The key distinction between a graph on a vertex set  $V$  and a digraph on the same set is that for a graph we refer to the *edge between vertices  $u$  and  $v$* , whereas for a digraph, we have two arcs, the *arc from  $u$  to  $v$*  and the *arc from  $v$  to  $u$* . Thus, there is one connected, simple graph on two vertices,  $K_2$  (see Figure 29.1a), but there are three possible connected, simple digraphs on two vertices (see Figure 29.1b). Note that all graphs in Figure 29.1 are trees, and that the graph in Figure 29.1a is the undirected graph associated with each of the digraphs in Figure 29.1b. The third graph in Figure 29.1b is a doubly directed tree.

2. Let  $\Gamma$  be the digraph in Figure 29.2. Then  $(1,1)$ ,  $(1,1), (1,3), (3,1), (1,2)$  is a walk of length 5 from vertex 1 to vertex 2.  $(1, 2), (2, 3)$  is a simple walk of length 2.  $(1, 1)$  is a 1-cycle;  $(1, 3), (3, 1)$  is a 2-cycle; and  $(1, 2), (2, 3), (3, 1)$  is a 3-cycle.  $(1, 1), (2, 3), (3, 2)$  and  $(1, 2), (2, 3), (3, 1)$  are two generalized cycles. Not all digraphs contain generalized cycles; consider the digraph obtained by deleting the arc  $(2, 3)$  from  $\Gamma$ , for example. Unless we are emphasizing a particular vertex on a cycle, such as all cycles starting (and ending) at vertex  $v$ , we view cyclic permutations of a cycle as equivalent. That is, in Figure 29.2, we would speak of *the* 3-cycle, although technically  $(1, 2), (2, 3), (3, 1)$ ;  $(2, 3), (3, 1), (1, 2)$ ; and  $(3, 1), (1, 2), (2, 3)$  are distinct cycles.

FIGURE 29.2

## 29.2 The Adjacency Matrix of a Directed Graph and the Digraph of a Matrix

If  $\Gamma$  is a directed graph on  $n$  vertices, then there is a natural way that we can record the arc information for  $\Gamma$  in an  $n \times n$  matrix. Conversely, if  $A$  is an  $n \times n$  matrix, we can naturally associate a digraph  $\Gamma$  on  $n$  vertices with  $A$ .

### Definitions:

Let  $\Gamma$  be a digraph with vertex set  $V$ . Label the vertices in  $V$  as  $v_1, v_2, \dots, v_n$ . Once the vertices have been ordered, the **adjacency matrix** for  $\Gamma$ , denoted  $\mathcal{A}_\Gamma$ , is the  $0, 1$ -matrix whose entries  $a_{ij}$  satisfy:  $a_{ij} = 1$  if  $(v_i, v_j)$  is an arc in  $\Gamma$ , and  $a_{ij} = 0$  otherwise. When the set of vertex labels is  $\{1, 2, \dots, n\}$ , the default labeling of the vertices is  $v_i = i$  for  $1 \leq i \leq n$ .

Let  $A$  be an  $n \times n$  matrix. Let  $V$  be the set  $\{1, 2, \dots, n\}$ . Construct a digraph denoted  $\Gamma(A)$  on  $V$  as follows. For each  $i$  and  $j$  in  $V$ , let  $(i, j)$  be an arc in  $\Gamma$  exactly when  $a_{ij} \neq 0$ .  $\Gamma(A)$  is called the **digraph of the matrix**  $A$ . Commonly  $\Gamma$  is viewed as a weighted digraph with weight function  $w((i, j)) = a_{ij}$  for all  $(i, j)$  with  $a_{ij} \neq 0$ .

**Facts:** [BR91, Chap. 3]

1. If a digraph  $H$  is obtained from a digraph  $\Gamma$  by adding or removing an arc, then  $\mathcal{A}_H$  is obtained by changing the corresponding entry of  $\mathcal{A}_\Gamma$  to a 1 or a 0, respectively. If a digraph  $H$  is obtained from a digraph  $\Gamma$  by deleting the  $i^{\text{th}}$  vertex in the ordered set  $V$  and by deleting all arcs in  $E$  containing the  $i^{\text{th}}$  vertex, then  $\mathcal{A}_H = \mathcal{A}_\Gamma(i)$ . That is,  $\mathcal{A}_H$  is obtained by deleting row  $i$  and column  $i$  of  $\mathcal{A}_\Gamma$ .
2. Given one ordering of the vertices in  $V$ , any other ordering of those vertices is simply a permutation of the original ordering. Since the rows and columns of  $A = \mathcal{A}_\Gamma$  are labeled by the ordered vertices, reordering the vertices in  $\Gamma$  corresponds to simultaneously permuting the rows and columns of  $A$ . That is, if  $P$  is the permutation matrix corresponding to a permutation of the vertices of  $V$ , then the new adjacency matrix is  $PAP^T$ . Since  $P^T = P^{-1}$  for a permutation matrix, all algebraic properties preserved by similarity transformations are invariant under changes of the ordering of the vertices.
3. Let  $\Gamma$  be a digraph with vertex set  $V$ . The Jordan canonical form of an adjacency matrix for  $\Gamma$  is independent of the ordering applied to the vertices in  $V$ . Consequently, all adjacency matrices for  $\Gamma$  have the same rank, trace, determinant, minimum polynomial, characteristic polynomial, and spectrum.
4. If  $A$  is an  $n \times n$  matrix and if  $v_i = i$  for  $1 \leq i \leq n$ , then  $A$  and  $\mathcal{A}_{\Gamma(A)}$  have the same zero–nonzero pattern and, hence,  $\Gamma(A) = \Gamma(\mathcal{A}_{\Gamma(A)})$ .

**Examples:**

- For the digraph  $\Gamma$  given in Figure 29.3, if we order the vertices as  $v_i = i$  for  $i = 1, 2, \dots, 7$ , then

$$A = \mathcal{A}_\Gamma = \begin{bmatrix} 0 & 1 & 1 & 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}.$$

FIGURE 29.3

If we reorder the vertices in the digraph  $\Gamma$  given in Figure 29.3 so that  $v_1, v_2, \dots, v_7$  is the sequence 1, 2, 5, 4, 3, 6, 7, then the new adjacency matrix is

$$B = \mathcal{A}_\Gamma = \begin{bmatrix} 0 & 1 & 0 & 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}.$$

- If  $A$  is the  $3 \times 3$  matrix

$$A = \begin{bmatrix} 3 & -2 & 5 \\ 0 & 0 & -11 \\ 9 & -6 & 0 \end{bmatrix},$$

then  $\Gamma(A)$  is the digraph given in Figure 29.2. Up to permutation similarity,

$$\mathcal{A}_\Gamma = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix}.$$

### 29.3 Walk Products and Cycle Products

For a square matrix  $A$ ,  $a_{12}a_{23}$  is nonzero exactly when both  $a_{12}$  and  $a_{23}$  are nonzero. That is, exactly when both  $(1, 2)$  and  $(2, 3)$  are arcs in  $\Gamma(A)$ . Note also that  $a_{12}a_{23}$  is one summand in  $(A^2)_{13}$ . Consequently, there is a close connection between powers of a matrix  $A$  and walks in its digraph  $\Gamma(A)$ . In fact, the signs (complex arguments) of walk products play a fundamental role in the study of the matrix sign patterns for real matrices (matrix ray patterns for complex matrices). See Chapter 33 [LHE94] or [Stu03].

**Definitions:**

Let  $A$  be an  $n \times n$  matrix. Let  $W$  given by  $(v_0, v_1), (v_1, v_2), \dots, (v_{k-1}, v_k)$  be a walk in  $\Gamma(A)$ . The **walk product** for the walk  $W$  is

$$\prod_{j=1}^k a_{v_{j-1}, v_j},$$

and is often denoted by  $\prod_W a_{ij}$ . This product is a generic summand of the  $(v_0, v_k)$ -entry of  $A^k$ . If  $s_1, s_2, \dots, s_n$  are scalars,  $\prod_W s_i$  denotes the ordinary product of the  $s_i$  over the index set  $v_0, v_1, v_2, \dots, v_{k-1}, v_k$ .

If  $W$  is a cycle in the directed graph  $\Gamma(A)$ , then the walk product for  $W$  is called a **cycle product**.

Let  $A$  be an  $n \times n$  real or complex matrix. Define  $|A|$  to be the matrix obtained from  $A$  by replacing  $a_{ij}$  with  $|a_{ij}|$  for all  $i$  and  $j$ .

**Facts:**

1. Let  $A$  be a square matrix. The walk  $W$  given by  $(v_0, v_1), (v_1, v_2), \dots, (v_{k-1}, v_k)$  occurs in  $\Gamma(A)$  exactly when  $a_{v_0 v_1} a_{v_1 v_2} \cdots a_{v_{k-1} v_k}$  is nonzero.
2. [BR91, Sec. 3.4] [LHE94] Let  $A$  be a square matrix. For each positive integer  $k$ , and for all  $i$  and  $j$ , the  $(i, j)$ -entry of  $A^k$  is the sum of the walk products for all length  $k$  walks in  $\Gamma(A)$  from  $i$  to  $j$ . Further, there is a walk of length  $k$  from  $i$  to  $j$  in  $\Gamma(A)$  exactly when the  $(i, j)$ -entry of  $|A|^k$  is nonzero.
3. [BR91, Sec. 3.4] [LHE94] Let  $A$  be a square, real or complex matrix. For all positive integers  $k$ ,  $\Gamma(A^k)$  is a subdigraph of  $\Gamma(|A|^k)$ . Further,  $\Gamma(A^k)$  is a proper subgraph of  $\Gamma(|A|^k)$  exactly when additive cancellation occurs in summing products for length  $k$  walks from some  $i$  to some  $j$ .
4. [LHE94] Let  $A$  be a square, real matrix. The sign pattern of the  $k^{\text{th}}$  power of  $A$  is determined solely by the sign pattern of  $A$  when the signs of the entries in  $A$  are assigned so that for each ordered pair of vertices, all products of length  $k$  walks from the first vertex to the second have the same sign.
5. [FP69] Let  $A$  and  $B$  be irreducible, real matrices with  $\Gamma(A) = \Gamma(B)$ . There exists a nonsingular, real diagonal matrix  $D$  such that  $B = DAD^{-1}$  if and only if the cycle product for every cycle in  $\Gamma(A)$  equals the cycle product for the corresponding cycle in  $\Gamma(B)$ .
6. Let  $A$  be an irreducible, real matrix. There exists a nonsingular, real diagonal matrix  $D$  such that  $DAD^{-1}$  is nonnegative if and only if the cycle product for every cycle in  $\Gamma(A)$  is positive.

**Examples:**

1. If  $A = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$ , then  $(A^2)_{12} = a_{11}a_{12} + a_{12}a_{22} = (1)(1) + (1)(-1) = 0$ , whereas  $(|A|^2)_{12} = 2$ .
2. If  $A$  is the matrix in Example 2 of the previous section, then  $\Gamma(A)$  contains four cycles: the loop  $(1, 1)$ ; the two 2-cycles  $(1, 3), (3, 1)$  and  $(2, 3), (3, 2)$ ; and the 3-cycle  $(1, 2), (2, 3), (3, 1)$ . Each of these cycles has a positive cycle product and using  $D = \text{diag}(1, -1, 1)$ ,  $DAD^{-1}$  is nonnegative.

## 29.4 Generalized Cycle Products

If the matrix  $A$  is  $2 \times 2$ , then  $\det(A) = a_{11}a_{22} - a_{12}a_{21}$ . Assuming that the entries of  $A$  are nonzero, the two summands  $a_{11}a_{22}$  and  $a_{12}a_{21}$  are exactly the walk products for the two generalized cycles of  $\Gamma(A)$ . From Chapter 4.1, the determinant of an  $n \times n$  matrix  $A$  is the sum of all terms of the form  $(-1)^{\text{sign}(\sigma)} a_{1j_1} a_{2j_2} \cdots a_{nj_n}$ , where  $\sigma = (j_1, j_2, \dots, j_n)$  is a permutation of the ordered set  $\{1, 2, \dots, n\}$ . Such a summand is nonzero precisely when  $(1, j_1), (2, j_2), \dots, (n, j_n)$  are all arcs in  $\Gamma(A)$ . For this set of arcs, there is exactly one arc originating at each of the  $n$  vertices and exactly one arc terminating at each of the  $n$  vertices. Hence, the arcs correspond to a generalized cycle in  $\Gamma(A)$ . See [BR91, Sect. 9.1]. Since the eigenvalues of  $A$  are the roots of  $\det(\lambda I - A)$ , it follows that results connecting the cycle structure of a matrix to its determinant should play a key role in determining the spectrum of the matrix. For further results connecting determinants and generalized cycles, see [MOD89] or [BJ86]. Generalized cycles play a crucial role in the study of the nonsingularity of sign patterns. (See Chapter 33 or [Stu91]). In general, there are fewer results for the spectra of digraphs than for the spectra of graphs. There are generalizations of Geršgorin's Theorem for spectral inclusion regions for complex matrices that depend on directed cycles. (See Chapter 14.2 [Bru82] or [BR91, Sect. 3.6], or especially, [Var04]).

**Definitions:**

Let  $A$  be an  $n \times n$  matrix. Let  $\sigma = \begin{pmatrix} 1 & 2 & \cdots & n \\ j_1 & j_2 & \cdots & j_n \end{pmatrix}$  be a permutation of the ordered set  $\{1, 2, \dots, n\}$ .

When  $(i, j_i)$  is an arc in  $\Gamma(A)$  for each  $i$ , the cycle or vertex disjoint union of cycles with arcs  $(1, j_1), (2, j_2), \dots, (n, j_n)$  is called the **generalized cycle induced by  $\sigma$** .

The product of the cycle products for the cycle(s) comprising the generalized cycle induced by  $\sigma$  is called the **generalized cycle product** corresponding to  $\sigma$ .

**Facts:**

1. The entries in  $A$  that correspond to a generalized cycle are a diagonal of  $A$  and vice versa.
2. If  $\sigma$  is a permutation of the ordered set  $\{1, 2, \dots, n\}$ , then the nonzero entries of the  $n \times n$  permutation matrix  $P$  corresponding to  $\sigma$  are precisely the diagonal of  $P$  corresponding to the generalized cycle induced by  $\sigma$ .
3. [BR91, Sec. 9.1] Let  $A$  be an  $n \times n$  real or complex matrix. Then  $\det(A)$  is the sum over all permutations of the ordered set  $\{1, 2, \dots, n\}$  of all of the signed generalized cycle products for  $\Gamma(A)$  where the sign of a generalized cycle is determined as  $(-1)^{n-k}$ , where  $k$  is the number of disjoint cycles in the generalized cycle. If  $\Gamma(A)$  contains no generalized cycle, then  $A$  is singular. If  $\Gamma(A)$  contains at least one generalized cycle, then  $A$  is nonsingular unless additive cancellation occurs in the sum of the signed generalized cycle products.
4. [Cve75] [Har62] Let  $A$  be an  $n \times n$  real or complex matrix. The coefficient of  $x^{n-k}$  in  $\det(xI - A)$  is the sum over all induced subdigraphs  $H$  of  $\Gamma(A)$  on  $k$  vertices of the signed generalized cycle products for  $H$ .
5. [BP94, Chap. 3], [BR97, Sec. 1.8] Let  $A$  be an  $n \times n$  real or complex matrix. Let  $g$  be the greatest common divisor of the lengths of all cycles in  $\Gamma(A)$ . Then  $\det(xI - A) = x^k p(x^g)$  for some nonnegative integer  $k$  and some polynomial  $p(z)$  with  $p(0) \neq 0$ . Consequently, the spectrum of  $A$  is invariant under  $\frac{2\pi}{g}$  rotations of the complex plane. Further, if  $A$  is nonsingular, then  $g$  divides  $n$ , and  $\det(xI - A) = p(x^g)$  for some polynomial  $p(z)$  with  $p(0) = (-1)^n \det(A)$ .

**Examples:**

1. If  $A$  is the matrix in Example 2 of the previous section, then  $\Gamma(A)$  contains two generalized cycles — the loop  $(1, 1)$  together with the 2-cycle  $(2, 3), (3, 2)$ ; and the 3-cycle  $(1, 2), (2, 3), (3, 1)$ . The corresponding generalized cycle products are  $(3)(-11)(-6) = 198$  and  $(-2)(-11)(9) = 198$ , with corresponding signs  $-1$  and  $1$ , respectively. Thus,  $\det(A) = 0$  is a consequence of additive cancellation.
2. If  $A = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$ , then the only cycles in  $\Gamma(A)$  are loops, so  $g = 1$ . The spectrum of  $A$  is clearly invariant under  $\frac{2\pi}{g}$  rotations, but it is also invariant under rotations through the smaller angle of  $\pi$ .

## 29.5 Strongly Connected Digraphs and Irreducible Matrices

---

Irreducibility of a matrix, which can be defined in terms of permutation similarity (see Section 27.3), and which Frobenius defined as an algebraic property in his extension of Perron's work on the spectra of positive matrices, is equivalent to the digraph property of being strongly connected, defined in this section. Today, most discussions of the celebrated Perron–Frobenius Theorem (see Chapter 9) use digraph theoretic terminology.

**Definitions:**

Vertex  $u$  has access to vertex  $v$  in a digraph  $\Gamma$  if there exists a walk in  $\Gamma$  from  $u$  to  $v$ . By convention, every vertex has access to itself even if there is no walk from that vertex to itself.

If  $u$  and  $v$  are vertices in a digraph  $\Gamma$  such that  $u$  has access to  $v$ , and such that  $v$  has access to  $u$ , then  $u$  and  $v$  are **access equivalent** (or  $u$  and  $v$  **communicate**).

Access equivalence is an equivalence relation on the vertex set  $V$  of  $\Gamma$  that partitions  $V$  into **access equivalence classes**.

If  $V_1$  and  $V_2$  are nonempty, disjoint subsets of  $V$ , then  $V_1$  **has access to**  $V_2$  if some vertex in  $v_1$  in  $V_1$  has access in  $\Gamma$  to some vertex  $v_2$  in  $V_2$ .

For a digraph  $\Gamma$ , the subdigraphs induced by each of the access equivalence classes of  $V$  are the **strongly connected components** of  $\Gamma$ .

When all of the vertices of  $\Gamma$  lie in a single access equivalence class,  $\Gamma$  is **strongly connected**.

Let  $V_1, V_2, \dots, V_k$  be the access equivalence classes for some digraph  $\Gamma$ . Define a new digraph,  $R(\Gamma)$ , called the **reduced digraph** (also called the **condensation digraph**) for  $\Gamma$  as follows. Let  $W = \{1, 2, \dots, k\}$  be the vertex set for  $R(\Gamma)$ . If  $i, j \in W$  with  $i \neq j$ , then  $(i, j)$  is an arc in  $R(\Gamma)$  precisely when  $V_i$  has access to  $V_j$ .

**Facts:** [BR91, Chap. 3]

1. [BR91, Sec. 3.1] A digraph  $\Gamma$  is strongly connected if and only if there is a walk from each vertex in  $\Gamma$  to every other vertex in  $\Gamma$ .
2. The square matrix  $A$  is irreducible if and only if  $\Gamma(A)$  is strongly connected. A reducible matrix  $A$  is completely reducible if  $\Gamma(A)$  is a disjoint union of two or more strongly connected digraphs.
3. [BR91, Sec. 3.1] Suppose that  $V_1$  and  $V_2$  are distinct access equivalence classes for some digraph  $\Gamma$ . If any vertex in  $V_1$  has access to any vertex in  $V_2$ , then every vertex in  $V_1$  has access to every vertex in  $V_2$ . Further, exactly one of the following holds:  $V_1$  has access to  $V_2$ ,  $V_2$  has access to  $V_1$ , or neither has access to the other. Consequently, access induces a partial order on the access equivalence classes of vertices.
4. [BR91, Lemma 3.2.3] The access equivalence classes for a digraph  $\Gamma$  can be labelled as  $V_1, V_2, \dots, V_k$  so that whenever there is an arc from a vertex in  $V_i$  to a vertex in  $V_j$ ,  $i \leq j$ .
5. [Sch86] If  $\Gamma$  is a digraph, then  $R(\Gamma)$  is a simple digraph that contains no cycles. Further, the vertices in  $R(\Gamma)$  can always be labelled so that if  $(i, j)$  is an arc in  $R(\Gamma)$ , then  $i < j$ .
6. [BR91, Theorem 3.2.4] Suppose that  $\Gamma$  is not strongly connected. Then there exists at least one ordering of the vertices in  $V$  so that  $\mathcal{A}_\Gamma$  is block upper triangular, where the diagonal blocks of  $\mathcal{A}_\Gamma$  are the adjacency matrices of the strongly connected components of  $\Gamma$ .
7. [BR91, Theorem 3.2.4] Let  $A$  be a square matrix. Then  $A$  has a Frobenius normal form. (See Chapter 27.3.)
8. The Frobenius normal form of a square matrix  $A$  is not necessarily unique. The set of Frobenius normal forms for  $A$  is preserved by permutation similarities that correspond to permutations that reorder the vertices within the access equivalence classes of  $\Gamma(A)$ . If  $B$  is a Frobenius normal form for  $A$ , then all the arcs in  $R(\Gamma(B))$  satisfy  $(i, j)$  is an edge implies  $i < j$ . Let  $\sigma$  be any permutation of the vertices of  $R(\Gamma(B))$  such that  $(\sigma(i), \sigma(j))$  is an edge in  $R(\Gamma(B))$  implies  $\sigma(i) < \sigma(j)$ . Let  $B$  be block partitioned by the access equivalence classes of  $\Gamma(B)$ . Applying the permutation similarity corresponding to  $\sigma$  to the blocks of  $B$  produces a Frobenius normal form for  $A$ . All Frobenius normal forms for  $A$  are produced using combinations of the above two types of permutations.
9. [BR91, Sect. 3.1] [BP94, Chap. 3] Let  $A$  be an  $n \times n$  matrix for  $n \geq 2$ . The following are equivalent:
  - (a)  $A$  is irreducible.
  - (b)  $\Gamma(A)$  is strongly connected.
  - (c) For each  $i$  and  $j$ , there is a positive integer  $k$  such that  $(|A|^k)_{ij} > 0$ .
  - (d) There does not exist a permutation matrix  $P$  such that

$$PAP^T = \left[ \begin{array}{c|c} A_{11} & A_{12} \\ \hline \mathbf{0} & A_{22} \end{array} \right],$$

where  $A_{11}$  and  $A_{22}$  are square matrices.

10. Let  $A$  be a square matrix.  $A$  is completely reducible if and only if there exists a permutation matrix  $P$  such that  $PAP^T$  is a direct sum of at least two irreducible matrices.
11. All combinations of the following transformations preserve irreducibility, reducibility, and complete reducibility: Scalar multiplication by a nonzero scalar; transposition; permutation similarity; left or right multiplication by a nonsingular, diagonal matrix.
12. Complex conjugation preserves irreducibility, reducibility, and complete reducibility for square, complex matrices.

**Examples:**

1. In the digraph  $\Gamma$  in Figure 29.3, vertex 4 has access to itself and to vertices 3, 6, and 7, but not to any of vertices 1, 2, or 5. For  $\Gamma$ , the access equivalence classes are:  $V_1 = \{1, 2, 5\}$ ,  $V_2 = \{3, 6\}$ ,  $V_3 = \{4\}$ , and  $V_4 = \{7\}$ . The strongly connected components of  $\Gamma$  are given in Figure 29.4, and  $R(\Gamma)$  is given in Figure 29.5. If the access equivalence classes for  $\Gamma$  are relabeled so that  $V_2 = \{4\}$  and  $V_3 = \{3, 6\}$ , then the labels on vertices 2 and 3 switch in the reduced digraph given in Figure 29.5. With this labeling, if  $(i, j)$  is an arc in the reduced digraph, then  $i \leq j$ .
2. If  $A$  and  $B$  are the adjacency matrices of Example 1 of Section 29.2, then  $A(3, 4, 6, 7) = A[1, 2, 5]$  is the adjacency matrix for the largest strongly connected component of the digraph  $\Gamma$  in Figure 29.3 using the first ordering of  $V$ ; and using the second ordering of  $V$ ,  $B$  is block-triangular and the irreducible, diagonal blocks of  $B$  are the adjacency matrices for each of the four strongly connected components of  $\Gamma$ .  $B$  is a Frobenius normal form for  $A$ .
3. The matrix  $A$  in Example 2 of Section 29.2 is irreducible, hence, it is its own Frobenius normal form.

FIGURE 29.5

## 29.6 Primitive Digraphs and Primitive Matrices

Primitive matrices, defined in this section, are necessarily irreducible. Unlike irreducibility, primitivity depends not just on the matrix  $A$ , but also its powers, and, hence, on the signs of the entries of the original matrix. Consequently, most authors restrict discussions of primitivity to nonnegative matrices. Much work has been done on bounding the exponent of a primitive matrix; see [BR91, Sec. 3.5] or [BP94, Sec. 2.4]. One consequence of the fifth fact stated below is that powers of sparse matrices and inverses of sparse matrices can experience substantial fill-in.

**Definitions:**

A digraph  $\Gamma$  with at least two vertices is **primitive** if there is a positive integer  $k$  such that for every pair of vertices  $u$  and  $v$  (not necessarily distinct), there exists at least one walk of length  $k$  from  $u$  to  $v$ . A digraph on a single vertex is **primitive** if there is a loop on that vertex.

The **exponent** of a digraph  $\Gamma$  (sometimes called the **index of primitivity**) is the smallest value of  $k$  that works in the definition of primitivity.

A digraph  $\Gamma$  is **imprimitive** if it is not primitive. This includes the simple digraph on one vertex.

If  $A$  is a square, nonnegative matrix such that  $\Gamma(A)$  is primitive with exponent  $k$ , then  $A$  is called a **primitive matrix with exponent  $k$** .

### Facts:

1. A primitive digraph must be strongly connected, but not conversely.
2. A strongly connected digraph with at least one loop is primitive.
3. [BP94, Chap. 3] [BR91, Sections 3.2 and 3.4] Let  $\Gamma$  be a strongly connected digraph with at least two vertices. The following are equivalent:
  - (a)  $\Gamma$  is primitive.
  - (b) The greatest common divisor of the cycle lengths for  $\Gamma$  is 1 (i.e.,  $\Gamma$  is aperiodic, cf. Chapter 9.2).
  - (c) There is a smallest positive integer  $k$  such that for each  $t \geq k$  and each pair of vertices  $u$  and  $v$  in  $\Gamma$ , there is a walk of length  $t$  from  $u$  to  $v$ .
4. [BR91, Sect. 3.5] Let  $\Gamma$  be a primitive digraph with  $n \geq 2$  vertices and exponent  $k$ . Then
  - (a)  $k \leq (n - 1)^2 + 1$ .
  - (b) If  $s$  is the length of the shortest cycle in  $\Gamma$ , then  $k \leq n + s(n - 2)$ .
  - (c) If  $\Gamma$  has  $p \geq 1$  loops, then  $k \leq 2n - p - 1$ .
5. [BR91, Theorem 3.4.4] Let  $A$  be an  $n \times n$  nonnegative matrix with  $n \geq 2$ . The matrix  $A$  is primitive if and only if there exists a positive integer  $k$  such that  $A^k$  is positive. When such a positive integer  $k$  exists, the smallest such  $k$  is the exponent of  $A$ . Further, if  $A^k$  is positive, then  $A^h$  is positive for all integers  $h \geq k$ . A nonnegative matrix  $A$  with the property that some power of  $A$  is positive is also called **regular**. See Chapter 9 and Chapter 54 for more information about primitive matrices and their uses.
6. [BP94, Chap. 3] If  $A$  is an irreducible, nonnegative matrix with positive trace, then  $A$  is primitive.
7. [BP94, Chap. 6] Let  $A$  be a nonnegative, tridiagonal matrix with all entries on the first superdiagonal and on the first subdiagonal positive, and at least one entry on the main diagonal positive. Then  $A$  is primitive and, hence, some power of  $A$  is positive. Further, if  $s > \rho(A)$  where  $\rho(A)$  is the spectral radius of  $A$ , then the tridiagonal matrix  $sI - A$  is a nonsingular M-matrix with a positive inverse.

### Examples:

1. The digraph  $\Gamma$  in Figure 29.2 is primitive with exponent 3; the strongly connected digraph in Figure 29.1b is not primitive.
2. Let  $A_1 = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}$  and let  $A_2 = \begin{bmatrix} 1 & -1 \\ 1 & -1 \end{bmatrix}$ . Note that  $A_1 = |A_2|$ . Clearly,  $\Gamma(A_1) = \Gamma(A_2)$  is an irreducible, primitive digraph with exponent 1. For all positive integers  $k$ ,  $A_1^k$  is positive, so it makes sense to call  $A_1$  a primitive matrix. In contrast,  $A_2^k = \mathbf{0}$  for all integers  $k \geq 2$ .

## 29.7 Irreducible, Imprimitive Matrices and Cyclic Normal Form

---

While most authors restrict discussions of matrices with primitive digraphs to nonnegative matrices, many authors have exploited results for imprimitive digraphs to understand the structure of real and complex matrices with imprimitive digraphs.

**Definitions:**

Let  $A$  be an irreducible  $n \times n$  matrix with  $n \geq 2$  such that  $\Gamma(A)$  is imprimitive. The greatest common divisor  $g > 1$  of the lengths of all cycles in  $\Gamma(A)$  is called the **index of imprimitivity of  $A$**  (or **period of  $A$** ).

If there is a permutation matrix  $P$  such that

$$PAP^T = \begin{bmatrix} \mathbf{0} & A_1 & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & A_2 & \cdots & \mathbf{0} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \cdots & A_{g-1} \\ A_g & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} \end{bmatrix},$$

where each of the diagonal blocks is a square zero matrix, then the matrix  $PAP^T$  is called a **cyclic normal form** for  $A$ .

By convention, when  $A$  is primitive,  $A$  is said to be its own cyclic normal form.

**Facts:**

- [BP94, Sec. 2.2] [BR91, Sections 3.4] [Min88, Sec. 3.3–3.4] Let  $A$  be an irreducible matrix with index of imprimitivity  $g > 1$ . Then there exists a permutation matrix  $P$  such that  $PAP^T$  is a cyclic normal form for  $A$ . Further, the cyclic normal form is unique up to cyclic permutation of the blocks  $A_j$  and permutations within the partition sets of  $V$  of  $\Gamma(A)$  induced by the partitioning of  $PAP^T$ . Finally, if  $A$  is real or complex, then  $|A_1| |A_2| \cdots |A_g|$  is irreducible and nonzero.
- [BP94, Sec. 3.3] [BR91, Sec. 3.4] If  $A$  is an irreducible matrix with index of imprimitivity  $g > 1$ , and if there exists a permutation matrix  $P$  and a positive integer  $k$  such that

$$PAP^T = \begin{bmatrix} \mathbf{0} & A_1 & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & A_2 & \cdots & \mathbf{0} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \cdots & A_{k-1} \\ A_k & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} \end{bmatrix},$$

where each diagonal block is square zero matrix, then  $k$  divides  $g$ . Conversely, if  $A$  is real or complex, if  $PAP^T$  has the specified form for some positive integer  $k$ , if  $PAP^T$  has no zero rows and no zero columns, and if  $|A_1| |A_2| \cdots |A_k|$  is irreducible, then  $A$  is irreducible, and  $k$  divides  $g$ .

- [BR91, Sec. 3.4] Let  $A$  be an irreducible, nonnegative matrix with index of imprimitivity  $g > 1$ . Let  $m$  be a positive integer. Then  $A^m$  is irreducible if and only if  $m$  and  $g$  are relatively prime. If  $A^m$  is reducible, then it is completely reducible, and it is permutation similar to a direct sum of  $r$  irreducible matrices for some positive integer  $r$ . Further, either each of these summands is primitive (when  $g/r = 1$ ), or each of these summands has index of imprimitivity  $g/r > 1$ .
- [Min88, Sec. 3.4] Let  $A$  be an irreducible, nonnegative matrix in cyclic normal form with index of imprimitivity  $g > 1$ . Suppose that for  $1 \leq i \leq k-1$ ,  $A_i$  is  $n_i \times n_{i+1}$  and that  $A_g$  is  $n_g \times n_1$ . Let  $k = \min(n_1, n_2, \dots, n_g)$ . Then 0 is an eigenvalue for  $A$  with multiplicity at least  $n - gk$ ; and if  $A$  is nonsingular, then each  $n_i = n/g$ .
- [Min88, Sec. 3.4] If  $A$  is an irreducible, nonnegative matrix in cyclic normal form with index of imprimitivity  $g$ , then for  $j = 1, 2, \dots, g$ , reading the indices modulo  $g$ ,  $B_j = \prod_{i=j}^{j+g-1} A_i$  is irreducible. Further, all of the matrices  $B_j$  have the same nonzero eigenvalues. If the nonzero eigenvalues (not necessarily distinct) of  $B_1$  are  $\omega_1, \omega_2, \dots, \omega_m$  for some positive integer  $m$ , then the spectrum of  $A$  consists of 0 with multiplicity  $n - gm$  together with the complete set of  $g^{\text{th}}$  roots of each of the  $\omega_i$ .

6. Let  $A$  be a square matrix. Then  $A$  has a Frobenius normal form for which each irreducible, diagonal block is in cyclic normal form.
7. Let  $A$  be a square matrix. If  $A$  is reducible, then the spectrum of  $A$  (which is a multiset) is the union of the spectra of the irreducible, diagonal blocks of any Frobenius normal form for  $A$ .
8. Explicit, efficient algorithms for computing the index of imprimitivity and the cyclic normal form for an imprimitive matrix and for computing the Frobenius normal form for a matrix can be found in [BR91, Sec. 3.7].
9. All results stated here for block upper triangular forms have analogs for block lower triangular forms.

**Examples:**

1. If  $A$  is the  $4 \times 4$  matrix  $A = \begin{bmatrix} \mathbf{0} & A_1 \\ A_2 & \mathbf{0} \end{bmatrix}$ , where  $A_1 = I_2$  and  $A_2 = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$ , then  $A$  and  $A_1 A_2 = A_2$  are irreducible but  $g \neq 2$ . In fact,  $g = 4$  since  $A$  is actually a permutation matrix corresponding to the permutation (1324). Also note that when  $A_1 = A_2 = I_2$ ,  $A$  is completely reducible since  $\Gamma(A)$  consists of two disjoint cycles.

2. If  $M$  is the irreducible matrix  $M = \begin{bmatrix} 0 & -1 & 0 & -1 \\ 6 & 0 & 3 & 0 \\ 0 & 2 & 0 & 2 \\ 6 & 0 & 3 & 0 \end{bmatrix}$ , then  $g = 2$ , and using the permutation

matrix  $Q = \begin{bmatrix} 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix}$ ,  $N = QMQ^T = \begin{bmatrix} 0 & 0 & 3 & 6 \\ 0 & 0 & 3 & 6 \\ 2 & 2 & 0 & 0 \\ -1 & -1 & 0 & 0 \end{bmatrix}$  is a cyclic normal form for  $M$ .

Note that  $|N_1| |N_2| = \begin{bmatrix} 3 & 6 \\ 3 & 6 \end{bmatrix} \begin{bmatrix} 2 & 2 \\ 1 & 1 \end{bmatrix} = \begin{bmatrix} 12 & 12 \\ 12 & 12 \end{bmatrix}$  is irreducible even though  $N_1 N_2 = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$  is not irreducible.

3. The matrix  $B$  in Example 1 of Section 29.2 is a Frobenius normal form for the matrix  $A$  in that example. Observe that  $B_{11}$  is imprimitive with  $g = 2$ , but  $B_{11}$  is not in cyclic normal form. The remaining diagonal blocks,  $B_{22}$  and  $B_{33}$ , have primitive digraphs, hence, they are in cyclic normal form. Let  $Q = \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}$ . Then  $QB_{11}Q^T = \begin{bmatrix} 0 & 3 & 6 \\ 2 & 0 & 0 \\ -1 & 0 & 0 \end{bmatrix}$  is a cyclic normal form for  $B_{11}$ . Using the permutation matrix  $P = Q \oplus I_1 \oplus I_2 \oplus I_1$ ,  $PBP^T$  is a Frobenius normal form for  $A$  with each irreducible, diagonal block in cyclic normal form.

4. Let  $A = \begin{bmatrix} 2 & 1 & 0 \\ 1 & 2 & 0 \\ 0 & 0 & 3 \end{bmatrix}$  and let  $B = \begin{bmatrix} 2 & 1 & 1 \\ 1 & 2 & 0 \\ 0 & 0 & 3 \end{bmatrix}$ . Observe that  $A$  and  $B$  are each in Frobenius normal form, each with two irreducible, diagonal blocks, and that  $A_{11} = B_{11}$  and  $A_{22} = B_{22}$ . Consequently,  $\sigma(A) = \sigma(B) = \sigma(A_{11}) \cup \sigma(A_{22}) = \{1, 3, 3\}$ . However,  $B$  has only one independent eigenvector for eigenvalue 3, whereas  $A$  has two independent eigenvectors for eigenvalue 3. The underlying cause for this difference is the difference in the access relations as captured in the reduced digraphs  $R(\Gamma(A))$  (two isolated vertices) and  $R(\Gamma(B))$  (two vertices joined by a single arc). The role that the reduced digraph of a matrix plays in connections between the eigenspaces for each of the irreducible, diagonal blocks of a matrix and those of the entire matrix is discussed in [Sch86] and in [BP94, Theorem 2.3.20]. For connections between  $R(\Gamma(A))$  and the structure of the generalized eigenspaces for  $A$ , see also [Rot75].

## 29.8 Minimally Connected Digraphs and Nearly Reducible Matrices

Replacing zero entries in an irreducible matrix with nonzero entries preserves irreducibility, and equivalently, adding arcs to a strongly connected digraph preserves strong connectedness. Consequently, it is of interest to understand how few nonzero entries are needed in a matrix and in what locations to guarantee irreducibility; or equivalently, how few arcs are needed in a digraph and between which vertices to guarantee strong connectedness. Except as noted, all of the results in this section can be found in both [BR91, Sec. 3.3] and [Min88, Sec. 4.5]. Further results on nearly irreducible matrices and on their connections to nearly decomposable matrices can be found in [BH79].

### Definitions:

A digraph is **minimally connected** if it is strongly connected and if the deletion of any arc in the digraph produces a subdigraph that is not strongly connected.

### Facts:

1. A digraph  $\Gamma$  is minimally connected if and only if  $\mathcal{A}_\Gamma$  is nearly reducible.
2. A matrix  $A$  is nearly reducible if and only if  $\Gamma(A)$  is minimally connected.
3. The only minimally connected digraph on one vertex is the simple digraph on one vertex.
4. The only nearly reducible  $1 \times 1$  matrix is the zero matrix.
5. [BR91, Theorem 3.3.5] Let  $\Gamma$  be a minimally connected digraph on  $n$  vertices with  $n \geq 2$ . Then  $\Gamma$  has no loops, at least  $n$  arcs, and at most  $2(n - 1)$  arcs. When  $\Gamma$  has exactly  $n$  arcs,  $\Gamma$  is an  $n$ -cycle. When  $\Gamma$  has exactly  $2(n - 1)$  arcs,  $\Gamma$  is a doubly directed tree.
6. Let  $A$  be an  $n \times n$  nearly reducible matrix with  $n \geq 2$ . Then  $A$  has no nonzeros on its main diagonal,  $A$  has at least  $n$  nonzero entries, and  $A$  has at most  $2(n - 1)$  nonzero entries. When  $A$  has exactly  $n$  nonzero entries,  $\Gamma(A)$  is an  $n$ -cycle. When  $A$  has exactly  $2(n - 1)$  nonzero entries,  $\Gamma(A)$  is a doubly directed tree.
7. [Min88, Theorem 4.5.1] Let  $A$  be an  $n \times n$  nearly reducible matrix with  $n \geq 2$ . Then there exists a positive integer  $m$  and a permutation matrix  $P$  such that

$$PAP^T = \left[ \begin{array}{cccc|cc} 0 & 1 & 0 & \cdots & 0 & \mathbf{0}^T \\ 0 & 0 & 1 & \cdots & 0 & \mathbf{0}^T \\ \vdots & \vdots & \ddots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & 0 & 1 & \mathbf{0}^T \\ 0 & 0 & \cdots & 0 & 0 & \mathbf{v}^T \\ \hline \mathbf{u} & \mathbf{0} & \cdots & \mathbf{0} & \mathbf{0} & B \end{array} \right],$$

where the upper left matrix is  $m \times m$ ,  $B$  is nearly reducible,  $\mathbf{0}$  is a  $(n - m) \times 1$  vector, both of the vectors  $\mathbf{u}$  and  $\mathbf{v}$  are  $(n - m) \times 1$ , and each of  $\mathbf{u}$  and  $\mathbf{v}$  contains a single nonzero entry.

### Examples:

1. Let  $\Gamma$  be the third digraph in Figure 29.1b. Then  $\Gamma$  is minimally connected. The subdigraph  $\Gamma'$  obtained by deleting arc  $(1, 2)$  from  $\Gamma$  is no longer strongly connected, however, it is still connected since its associated undirected graph is the graph in Figure 29.1a.

2. For  $n \geq 1$ , let  $A^{(n)}$  be the  $(n + 1) \times (n + 1)$  matrix be given by

$$A^{(n)} = \left[ \begin{array}{c|cccc} 0 & 1 & 1 & \cdots & 1 \\ \hline 1 & & & & \\ 1 & & & & \\ \vdots & & & & \\ 1 & & & & \end{array} \right].$$

Then  $A^{(n)}$  is nearly reducible. The digraph  $\Gamma(A^{(n)})$  is called a **rosette**, and has the most arcs possible for a minimally connected digraph on  $n + 1$  vertices. Suppose that  $n \geq 2$ , and let  $P =$

$$\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \oplus I_{n-2}.$$

Then

$$PA^{(n)}P^T = \left[ \begin{array}{c|cccc} 0 & 1 & 0 & \cdots & 0 \\ \hline 1 & & & & \\ 0 & & & & \\ \vdots & & & & \\ 0 & & & & \end{array} \right]$$

is the decomposition for  $A^{(n)}$  given in Fact 7 with  $m = 1$ .

	References .....	30-11

An  $m \times n$  matrix is naturally associated with a bipartite graph, and the structure of the matrix is reflected by the combinatorial properties of the associated bipartite graph. This section discusses the fundamental structural theorems for matrices that arise from this association, and describes their implications for linear algebra.

### 30.1 Basics of Bipartite Graphs

---

This section introduces the various properties and families of bipartite graphs that have special significance for linear algebra.

#### Definitions:

A graph  $G$  is **bipartite** provided its vertices can be partitioned into disjoint subsets  $U$  and  $V$  such that each edge of  $G$  has the form  $\{u, v\}$ , where  $u \in U$  and  $v \in V$ . The set  $\{U, V\}$  is a **bipartition** of  $G$ .

A **complete bipartite graph** is a simple bipartite graph with bipartition  $\{U, V\}$  such that each  $\{u, v\}$  ( $u \in U, v \in V$ ) is an edge. The complete bipartite graph with  $|U| = m$  and  $|V| = n$  is denoted by  $K_{m,n}$ .

A **chordal graph** is one in which every cycle of length 4 or more has a chord, that is, an edge joining two nonconsecutive vertices on the cycle.

A **chordal bipartite graph** is a bipartite graph in which every cycle of length 6 or more has a chord.

A bipartite graph is **quadrangular** provided it is simple and each pair of vertices with a common neighbor lies on a cycle of length 4.

A **weighted bipartite graph** consists of a simple bipartite graph  $G$  and a function  $w : E \rightarrow X$ , where  $E$  is the edge set of  $G$  and  $X$  is a set (usually  $\mathbb{Z}, \mathbb{R}, \mathbb{C}, \{-1, 1\}$ , or a set of indeterminates). A **signed bipartite graph** is a weighted bipartite graph with  $X = \{-1, 1\}$ . In a signed bipartite graph, the **sign** of a set  $\alpha$  of edges, denoted  $\text{sgn}(\alpha)$ , is the product of the weights of the edges in  $\alpha$ . The set  $\alpha$  is **positive** or **negative** depending on whether  $\text{sgn}(\alpha)$  is  $+1$  or  $-1$ .

Let  $G$  be a bipartite graph with bipartition  $\{U, V\}$  and let  $u_1, u_2, \dots, u_m$  and  $v_1, v_2, \dots, v_n$  be orderings of the distinct elements of  $U$  and  $V$ , respectively. The **biadjacency matrix** of  $G$  is the  $m \times n$  matrix  $B_G = [b_{ij}]$ , where  $b_{ij}$  is the multiplicity of the edge  $\{u_i, v_j\}$ . Note that if  $U$ , respectively,  $V$ , is empty, then  $B_G$  is a matrix with no rows, respectively, no columns. For a weighted bipartite graph,  $b_{ij}$  is defined to be

the weight of the edge  $\{u_i, v_j\}$  if present, and 0 otherwise. For a signed bipartite graph,  $b_{ij}$  is the sign of the edge  $\{u_i, v_j\}$  if present, and 0 otherwise.

Let  $N'_G$  be an oriented incidence matrix of simple graph  $G$ . The **cut space** of  $G$  is the column space of  $N'_G{}^T$ , and the **cut lattice** of  $G$  is the set of integer vectors in the cut space of  $G$ . The **flow space** of  $G$  is  $\{x \in \mathbb{R}^m : N'_G x = 0\}$ , and the **flow lattice** of  $G$  is  $\{x \in \mathbb{Z}^m : N'_G x = 0\}$ .

A **matching** of  $G$  is a set  $M$  of mutually disjoint edges. If  $M$  has  $k$  edges, then  $M$  is a  **$k$ -matching**, and if each vertex of  $G$  is in some (and hence exactly one) edge of  $M$ , then  $M$  is a **perfect matching**.

### Facts:

Unless otherwise noted, the following can be found in [BR91, Chap. 3] or [Big93]. In the references, the results are stated and proven for simple graphs, but still hold true for graphs.

1. A bipartite graph has no loops. It has more than one bipartition if and only if the graph is disconnected. Each forest (and, hence, each tree and each path) is bipartite. The cycle  $C_n$  is bipartite if and only if  $n$  is even.
2. The following statements are equivalent for a graph  $G$ :
  - (a)  $G$  is bipartite.
  - (b) The vertices of  $G$  can be labeled with the colors red and blue so that each edge of  $G$  has a red vertex and a blue vertex.
  - (c)  $G$  has no cycles of odd length.
  - (d) There exists a permutation matrix  $P$  such that  $P^T \mathcal{A}_G P$  has the form

$$\begin{bmatrix} O & B \\ B^T & O \end{bmatrix}.$$

- (e)  $G$  is loopless and every minor of the vertex-edge incidence matrix  $N_G$  of  $G$  is 0, 1, or  $-1$ .
  - (f) The characteristic polynomial  $p_{\mathcal{A}_G}(x) = \sum_{i=0}^n c_i x^{n-i}$  of  $\mathcal{A}_G$  satisfies  $c_k = 0$  for each odd integer  $k$ .
  - (g)  $\sigma(G) = -\sigma(G)$  (as multisets), where  $\sigma(G)$  is the spectrum of  $\mathcal{A}_G$ .
3. The connected graph  $G$  is bipartite if and only if  $-\rho(\mathcal{A}_G)$  is an eigenvalue of  $\mathcal{A}_G$ .
  4. The bipartite graph  $G$  disconnected if and only if there exist permutation matrices  $P$  and  $Q$  such that  $P B_G Q$  has the form

$$\begin{bmatrix} B_1 & O \\ O & B_2 \end{bmatrix},$$

where both  $B_1$  and  $B_2$  have at least one column or at least one row. More generally, if  $G$  is bipartite and has  $k$  connected components, then there exist permutation matrices  $P$  and  $Q$  such that

$$P B_G Q = \begin{bmatrix} B_1 & O & \cdots & O \\ O & B_2 & \cdots & O \\ \vdots & \vdots & \ddots & \vdots \\ O & O & \cdots & B_k \end{bmatrix},$$

where the  $B_i$  are the biadjacency matrices of the connected components of  $G$ .

5. [GR01] If  $G$  is a simple graph with  $n$  vertices,  $m$  edges, and  $c$  components, then its cut space has dimension  $n - c$ , and its flow space has dimension  $m - n + c$ . If  $G$  is a plane graph, then the edges of  $G$  can be oriented and ordered so that the flow space of  $G$  equals the cut space of its dual graph. The norm,  $\mathbf{x}^T \mathbf{x}$ , is even for each vector  $\mathbf{x}$  in the cut lattice of  $G$  if and only if each vertex has even degree. The norm of each vector in the flow lattice of  $G$  is even if and only if  $G$  is bipartite.

FIGURE 30.1

6. [Bru66], [God85], [Sim89] Let  $G$  be a bipartite graph with a unique perfect matching. Then there exist permutation matrices  $P$  and  $Q$  such that  $P\mathcal{B}_G Q$  is a square, lower triangular matrix with all 1s on its main diagonal. If  $G$  is a tree, then the inverse of  $P\mathcal{B}_G Q$  is a  $(0, 1, -1)$ -matrix. Let  $n$  be the order of  $\mathcal{B}_G$ , and let  $H$  be the simple graph with vertices  $1, 2, \dots, n$  and  $\{i, j\}$  an edge if and only if  $i \neq j$  and either the  $(i, j)$ - or  $(j, i)$ -entry of  $P\mathcal{B}_G Q$  is nonzero. If  $H$  is bipartite, then  $(P\mathcal{B}_G Q)^{-1}$  is diagonally similar to a nonnegative matrix, which equals  $P\mathcal{B}_G Q$  if and only if  $G$  can be obtained by appending a pendant edge to each vertex of a bipartite graph.

**Examples:**

1. Up to matrix transposition and permutations of rows and columns, the biadjacency matrix of the path  $P_{2n}$ , the path  $P_{2n+1}$ , and the cycle  $C_{2n}$  are

$$\begin{bmatrix} 1 & 1 & 0 & \cdots & 0 \\ 0 & 1 & 1 & \cdots & 0 \\ \vdots & & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 & 1 \\ 0 & 0 & \cdots & 0 & 1 \end{bmatrix}_{n \times n}, \quad \begin{bmatrix} 1 & 1 & 0 & \cdots & 0 & 0 \\ 0 & 1 & 1 & \cdots & 0 & 0 \\ \vdots & & \ddots & \ddots & \vdots & 0 \\ 0 & 0 & \cdots & 1 & 1 & 0 \\ 0 & 0 & \cdots & 0 & 1 & 1 \end{bmatrix}_{n \times (n+1)}, \quad \begin{bmatrix} 1 & 1 & 0 & \cdots & 0 \\ 0 & 1 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 & 1 \\ 1 & 0 & \cdots & 0 & 1 \end{bmatrix}_{n \times n}.$$

2. The biadjacency matrix of the complete bipartite graph  $K_{m,n}$  is  $J_{m,n}$ , the  $m \times n$  matrix of all ones.  
 3. Up to row and column permutations, the biadjacency matrix of the graph obtained from  $K_{n,n}$  by removing the edges of a perfect matching is  $J_n - I_n$ .  
 4. Let  $G$  be the bipartite graph (Figure 30.1).

Then

$$\mathcal{B}_G = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 1 & 1 & 0 \\ 0 & 1 & 0 & 1 \end{bmatrix}$$

$G$  has a unique perfect matching, and the graph  $H$  defined in Fact 6 is the path 1–3–2–4. Hence,  $\mathcal{B}_G$  is diagonally similar to a nonnegative matrix. Also, since  $G$  is obtained from the bipartite graph  $v_1-u_3-v_2-u_4$  by appending pendant vertices to each vertex,  $\mathcal{B}_G^{-1}$  is diagonally similar to  $\mathcal{B}_G$ . Indeed,

$$S\mathcal{B}_G^{-1}S = S \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & -1 & 1 & 0 \\ 0 & -1 & 0 & 1 \end{bmatrix} S^{-1} = \mathcal{B}_G,$$

where  $S$  is the diagonal matrix with main diagonal  $(1, 1, -1, -1)$ .

## 30.2 Bipartite Graphs Associated with Matrices

This section presents some of the ways that matrices have been associated to bipartite graphs and surveys resulting consequences.

### Definitions:

The **bigraph** of the  $m \times n$  matrix  $A = [a_{ij}]$  is the simple graph with vertex set  $U \cup V$ , where  $U = \{1, 2, \dots, m\}$  and  $V = \{1', 2', \dots, n'\}$ , and edge set  $\{\{i, j'\} : a_{ij} \neq 0\}$ . If  $A$  is a nonnegative integer matrix, then the **multi-bigraph** of  $A$  has vertex set  $U \cup V$  and edge  $\{i, j'\}$  of multiplicity  $a_{ij}$ . If  $A$  is a general matrix, then the **weighted bigraph** of  $A$  has vertex set  $U \cup V$  and edge  $\{i, j'\}$  of weight  $a_{ij}$ . If  $A$  is a real matrix, then the **signed bigraph** of  $A$  is obtained by weighting the edge  $\{i, j'\}$  of the bigraph by  $+1$  if  $a_{ij} > 0$ , and by  $-1$  if  $a_{ij} < 0$ .

The **(zero) pattern** of the  $m \times n$  matrix  $A = [a_{ij}]$  is the  $m \times n$   $(0, 1)$ -matrix whose  $(i, j)$ -entry is 1 if and only if  $a_{ij} \neq 0$ .

The **sign pattern** of the real  $m \times n$  matrix  $A = [a_{ij}]$  is the  $m \times n$  matrix whose  $(i, j)$ -entry is  $+$ ,  $0$ , or  $-$ , depending on whether  $a_{ij}$  is positive, zero, or negative. (See Chapter 33 for more information on sign patterns.)

A  $(0, 1)$ -matrix is a **Petrie matrix** provided the 1s in each of its columns occur in consecutive rows. A  $(0, 1)$ -matrix  $A$  has the **consecutive ones property** if there exists a permutation  $P$  such that  $PA$  is a Petrie matrix.

The **directed bigraph** of the real  $m \times n$  matrix  $A = [a_{ij}]$  is the directed graph with vertices  $1, 2, \dots, m, 1', 2', \dots, n'$ , the arc  $(i, j')$  if and only if  $a_{ij} > 0$ , and the arc  $(j', i)$  if and only if  $a_{ij} < 0$ .

An  $m \times n$  matrix  $A$  is a **generic matrix** with respect to the field  $F$  provided its nonzero elements are independent indeterminates over the field  $F$ . The matrix  $A$  can be viewed as a matrix whose elements are in the ring of polynomials in these indeterminates with coefficients in  $F$ .

Let  $A$  be an  $n \times n$  matrix with each diagonal entry nonzero. The **bipartite fill-graph** of  $A$ , denoted  $G^+(A)$ , is the simple bipartite graph with vertex set  $\{1, 2, \dots, n\} \cup \{1', 2', \dots, n'\}$  with an edge joining  $i$  and  $j'$  if and only if there exists a path from  $i$  to  $j$  in the digraph,  $\Gamma(A)$ , of  $A$  each of whose intermediate vertices has label less than  $\min\{i, j\}$ . If  $A$  is symmetric, then (by identifying vertices  $i$  and  $i'$  for  $i = 1, 2, \dots, n$  and deleting loops),  $G^+(A)$  can be viewed as a simple graph, and is called the **fill-graph** of  $A$ .

The square matrix  $B$  has a **perfect elimination ordering** provided there exist permutation matrices  $P$  and  $Q$  such that the bipartite fill-graph,  $G^+(PBQ)$ , and the bigraph of  $PBQ$  are the same.

Associated with the  $n \times n$  matrix  $A = [a_{ij}]$  is the sequence  $H_0, H_1, \dots, H_{n-1}$  of bipartite graphs as defined by:

1.  $H_0$  consists of vertices  $1, 2, \dots, n$ , and  $1', 2', \dots, n'$ , and edges of the form  $\{i, j'\}$ , where  $a_{ij} \neq 0$ .
2. For  $k = 1, \dots, n-1$ ,  $H_k$  is the graph obtained from  $H_{k-1}$  by deleting vertices  $k$  and  $k'$  and inserting each edge of the form  $\{r, c'\}$ , where  $r > k, c > k$ , and both  $\{r, k'\}$  and  $\{k, c'\}$  are edges of  $H_{k-1}$ .

The **4-cockades** are the bipartite graphs recursively defined by: A 4-cycle is a 4-cockade, and if  $G$  is a 4-cockade and  $e$  is an edge of  $G$ , then the graph obtained from  $G$  by identifying  $e$  with an edge of a 4-cycle disjoint from  $G$  is a 4-cockade. A **signed 4-cockade** is a 4-cockade whose edges are weighted by  $\pm 1$  in such a way that every 4-cycle is negative.

### Facts:

General references for bipartite graphs associated with matrices are [BR91, Chap. 3] and [BS04].

1. [Rys69] (See also [BR91, p. 18].) If  $A$  is an  $m \times n$   $(0, 1)$ -matrix such that each entry of  $AA^T$  is positive, then either  $A$  has a column with no zeros or the bigraph of  $A$  has a chordless cycle of length 6. The converse is not true.
2. [RT76], [GZ98] If  $G = (V, E)$  is a connected quadrangular graph, then  $|E| \leq 2|V| - 4$ . The connected quadrangular graphs with  $|E| = 2|V| - 4$  are characterized in the first reference.

3. [RT76], If  $A$  is an  $m \times n$   $(0, 1)$ -matrix such that no entry of  $AA^T$  or  $A^T A$  is 1, and the bigraph of  $A$  is connected, then  $A$  has at most  $2(m + n) - 4$  nonzero entries.
4. [Tuc70] The  $(0, 1)$ -matrix  $A$  has the consecutive ones property if and only if it does not have a submatrix whose rows and columns can be permuted to have one of the following forms for  $k \geq 1$ .

$$\begin{bmatrix} 1 & 1 & 0 & \cdots & 0 \\ 0 & 1 & 1 & & 0 \\ \vdots & & \ddots & \ddots & \vdots \\ 0 & 0 & & 1 & 1 \\ 1 & 0 & \cdots & 0 & 1 \end{bmatrix}_{(k+2) \times (k+2)}, \quad \begin{bmatrix} 1 & 0 & \cdots & 0 & 0 \\ 1 & 1 & & 0 & 1 \\ 0 & 1 & \ddots & \vdots & \vdots \\ \vdots & & \ddots & 1 & 1 \\ 0 & 0 & \cdots & 1 & 0 \\ 0 & 0 & \cdots & 0 & 1 \end{bmatrix}_{(k+3) \times (k+2)},$$

$$\begin{bmatrix} 1 & 0 & \cdots & 0 & 0 & 1 \\ 1 & 1 & & 0 & 1 & 1 \\ 0 & 1 & \ddots & \vdots & \vdots & \vdots \\ \vdots & & \ddots & 1 & 1 & 1 \\ 0 & 0 & \cdots & 1 & 1 & 0 \\ 0 & 0 & \cdots & 0 & 1 & 1 \end{bmatrix}_{(k+3) \times (k+3)}, \quad \begin{bmatrix} 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 1 \\ 0 & 1 & 0 & 1 & 0 & 1 \end{bmatrix}_{4 \times 6}, \quad \begin{bmatrix} 1 & 1 & 0 & 0 & 0 \\ 1 & 1 & 1 & 1 & 0 \\ 0 & 0 & 1 & 1 & 0 \\ 1 & 0 & 0 & 1 & 1 \end{bmatrix}_{4 \times 5}.$$

5. [ABH99] Let  $A$  be a  $(0, 1)$ -matrix and let  $L = D - AA^T$ , where  $D$  is the diagonal matrix whose  $i$ th diagonal entry is the  $i$ th row sum of  $AA^T$ . Then  $L$  is a symmetric, singular matrix each of whose eigenvalues is nonnegative. Let  $\mathbf{v}$  be an eigenvector of  $L$  corresponding to the second smallest eigenvalue of  $L$ . If  $A$  has the consecutive ones property and the entries of  $\mathbf{v}$  are distinct, then  $PA$  is a Petrie matrix, where  $P$  is the permutation matrix such that the entries of  $P\mathbf{v}$  are in increasing order. In addition, the reference gives a recursive method for finding a  $P$  such that  $PA$  is a Petrie matrix when the elements of  $\mathbf{v}$  are not distinct.
6. The directed bigraph of the real matrix  $A$  contains at most one of the arcs  $(i, j')$  or  $(j', i)$ .
7. [FG81] The directed bigraph of the real matrix  $A$  is strongly connected if and only if there do not exist subsets  $\alpha$  and  $\beta$  such that  $A[\alpha, \beta] \geq 0$  and  $A(\alpha, \beta) \leq 0$ . Here, either  $\alpha$  or  $\beta$  may be the empty set, and a vacuous matrix  $M$  satisfies both  $M \geq 0$  and  $M \leq 0$ .
8. [FG81] If  $A = [a_{ij}]$  is a fully indecomposable,  $n \times n$  sign pattern, then the following are equivalent:
  - (a) There is a matrix  $\widehat{A}$  with sign pattern  $A$  such that  $\widehat{A}$  is invertible and its inverse is a positive matrix.
  - (b) There do not exist subsets  $\alpha$  and  $\beta$  such that  $A[\alpha, \beta] \geq 0$  and  $A(\alpha, \beta) \leq 0$ .
  - (c) The bipartite directed graph of  $A$  is strongly connected.
  - (d) There exists a matrix with sign pattern  $A$  each of whose line sums is 0.
  - (e) There exists a rank  $n - 1$  matrix with sign pattern  $A$  each of whose line sums is 0.
9. [Gol80] Up to relabeling of vertices,  $G$  is the fill-graph of some  $n \times n$  symmetric matrix if and only if  $G$  is chordal.
10. [GN93] Let  $A$  be an  $n \times n$   $(0, 1)$ -matrix with each diagonal entry equal to 1. Suppose that  $B$  is a matrix with zero pattern  $A$ , and that  $B$  can be factored as  $B = LU$ , where  $L = [\ell_{ij}]$  is a lower triangular matrix and  $U = [u_{ij}]$  is an upper triangular matrix. If  $i \neq j$  and either  $\ell_{ij} \neq 0$  or  $u_{ij} \neq 0$ , then  $\{i, j'\}$  is an edge of  $G^+(A)$ . Moreover, if  $B$  is a generic matrix with zero pattern  $A$ , then such a factorization  $B = LU$  exists, and for each edge  $\{i, j'\}$  of  $G^+(A)$  either  $\ell_{ij} \neq 0$  or  $u_{ij} \neq 0$ .

FIGURE 30.2

11. [GG78] If the bigraph of the generic, square matrix  $A$  is chordal bipartite, then  $A$  has a perfect elimination ordering and, hence, there exist permutation matrices  $P$  and  $Q$  such that performing Gaussian elimination on  $PAQ$  has no fill-in. The converse is not true; see Example 3.
12. [GN93] If  $A$  is a generic  $n \times n$  matrix with each diagonal entry nonzero, and  $\alpha = \{1, 2, \dots, r\}$ , then the bigraph of the Schur complement of  $A[\alpha]$  in  $A$  is the bigraph  $H_r$  defined above.
13. [DG93] For each matrix with a given pattern, small relative perturbations in the nonzero entries cause only small relative perturbations in the singular values (independent of the values of the matrix entries) if and only if the bigraph of the pattern is a forest. The singular values of such a matrix can be computed to high relative accuracy.
14. [DES99] If the signed bipartite graph of the real matrix is a signed 4-cockade, then small relative perturbations in the nonzero entries cause only small relative perturbations in the singular values (independent of the values of the matrix entries). The singular values of such a matrix can be computed to high relative accuracy.

**Examples:**

1. Let

$$A = \begin{bmatrix} - & + & 0 \\ + & - & + \\ + & 0 & - \end{bmatrix}.$$

The directed bigraph of  $A$  is (Figure 30.2).

Since this is strongly connected, Fact 7 implies that there do not exist subsets  $\alpha$  and  $\beta$  such that  $A[\alpha, \beta] \geq O$  and  $A(\alpha, \beta) \leq O$ . Also, there is a matrix with sign pattern  $A$  whose inverse is positive. One such matrix is

$$\begin{bmatrix} -3/2 & 2 & 0 \\ 1 & -2 & 1 \\ 1 & 0 & -1 \end{bmatrix}.$$

2. A signed 4-cockade on 8 vertices (unlabeled edges have sign +1) and its biadjacency matrix are (Figure 30.3)

FIGURE 30.3

$$\begin{bmatrix} 1 & 1 & 0 & 0 \\ 1 & -1 & 1 & 1 \\ 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 1 \end{bmatrix}.$$

3. Both the bipartite fill-graph and the bigraph of the matrix (Figure 30.4) below

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 1 & 0 & 0 \\ 0 & 1 & 1 & 0 & 1 & 0 \\ 1 & 0 & 1 & 0 & 0 & 1 \end{bmatrix}$$

FIGURE 30.4

are the graph illustrated. Since its bigraph has a chordless 6-cycle, this example shows that the converse to Fact 11 is false.

4. Let

$$A = \begin{bmatrix} x_1 & x_2 & x_3 & x_4 \\ x_5 & x_6 & 0 & 0 \\ x_7 & 0 & x_8 & 0 \\ x_9 & 0 & 0 & x_{10} \end{bmatrix},$$

where  $x_1, \dots, x_{10}$  are independent indeterminates. The bigraph of  $A$  is chordal bipartite. The biadjacency matrix of  $H_1$  is  $J_3$ . Thus, by Fact 12, the pattern of the Schur complement of  $A[\{1\}]$  in  $A$  is  $J_3$ . The bipartite fill-graph of  $A$  has biadjacency matrix  $J_4$ . If

$$P = \begin{bmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix},$$

then the bipartite fill-graph of  $PAP^T$  and the bigraph of  $PAP^T$  are the same. Hence, it is possible to perform Gaussian elimination (without pivoting) on  $PAP^T$  without any fill-in.

**Applications:**

1. [Ken69], [ABH99] Petrie matrices are named after the archaeologist Flinders Petrie and were first introduced in the study of seriation, that is, the chronological ordering of archaeological sites. If the rows of the matrix  $A$  represent archaeological sites ordered by their historical time period, the columns of  $A$  represent artifacts, and  $a_{ij} = 1$  if and only if artifact  $j$  is present at site  $i$ , then one would expect  $A$  to be a Petrie matrix. More recently, matrices with the consecutive ones property have arisen in genome sequencing (see [ABH99]).
2. [BBS91], [Sha97] If  $U$  is a unitary matrix and  $A$  is the pattern of  $U$ , then the bigraph of  $A$  is quadrangular. If  $U$  is fully indecomposable, then  $U$  has at most  $4n - 4$  nonzero entries. The matrices achieving equality are characterized in the first reference. (See Fact 2 for more on quadrangular graphs.)

### 30.3 Factorizations and Bipartite Graphs

This section discusses the combinatorial interpretations and applications of certain matrix factorizations.

#### Definitions:

A **biclique** of a graph  $G$  is a subgraph that is a complete bipartite graph. For disjoint subsets  $X$  and  $Y$  of vertices,  $B(X, Y)$  denotes the biclique consisting of all edges of the form  $\{x, y\}$  such that  $x \in X$  and  $y \in Y$  (each of multiplicity 1). If  $G$  is bipartite with bipartition  $\{U, V\}$ , then it is customary to take  $X \subseteq U$  and  $Y \subseteq V$ .

A **biclique partition** of  $G = (V, E)$  is a collection  $B(X_1, Y_1), \dots, B(X_k, Y_k)$  of bicliques of  $G$  whose edges partition  $E$ .

A **biclique cover** of  $G = (V, E)$  is a collection of bicliques such that each edge of  $E$  is in at least one biclique.

The **biclique partition number** of  $G$ , denoted  $\text{bp}(G)$ , is the smallest  $k$  such that there is a partition of  $G$  into  $k$  bicliques. The **biclique cover number** of  $G$ , denoted  $\text{bc}(G)$ , is the smallest  $k$  such that there is a cover of  $G$  by  $k$  bicliques. If  $G$  does not have a biclique partition, respectively, cover, then  $\text{bp}(G)$ , respectively,  $\text{bc}(G)$ , is defined to be infinite.

If  $G$  is a graph, then  $n_+(G)$ , respectively,  $n_-(G)$ , denotes the number of positive, respectively, negative, eigenvalues of  $\mathcal{A}_G$  (including multiplicity).

If  $X \subseteq \{1, 2, \dots, n\}$ , then the **characteristic vector** of  $X$  is the  $n \times 1$  vector  $\vec{\mathbf{X}} = [x_i]$ , where  $x_i = 1$  if  $i \in X$ , and  $x_i = 0$  otherwise.

The **nonnegative integer rank** of the nonnegative integer matrix  $A$  is the minimum  $k$  such that there exist an  $m \times k$  nonnegative integer matrix  $B$  and a  $k \times n$  nonnegative integer matrix  $C$  with  $A = BC$ .

The **(0,1)-Boolean algebra** consists of the elements 0 and 1, endowed with the operations defined by  $0 + 0 = 0$ ,  $0 + 1 = 1 = 1 + 0$ ,  $1 + 1 = 1$ ,  $0 * 1 = 0 = 1 * 0$ ,  $0 * 0 = 0$ , and  $1 * 1 = 1$ . A **Boolean matrix** is a matrix whose entries belong to the (0,1)-Boolean algebra. Addition and multiplication of Boolean matrices is defined as usual, except Boolean arithmetic is used.

The **Boolean rank** of the  $m \times n$  Boolean matrix  $A$  is the minimum  $k$  such that there exists an  $m \times k$  Boolean matrix  $B$  and a  $k \times n$  Boolean matrix  $C$  such that  $A = BC$ .

Let  $G$  be a bipartite graph with bipartition  $\{\{1, 2, \dots, m\}, \{1', 2', \dots, n'\}\}$ . Then  $\mathcal{M}(G)$  denotes the set of all  $m \times n$  matrices  $A = [a_{ij}]$  such that if  $a_{ij} \neq 0$ , then  $\{i, j'\}$  is an edge of  $G$ , that is, the bigraph of  $A$  is a subgraph of  $G$ . The graph  $G$  **supports rank decompositions** provided each matrix  $A \in \mathcal{M}(G)$  is the sum of  $\text{rank}(A)$  elements of  $\mathcal{M}(G)$  each having rank 1.

If  $G$  is a signed bipartite graph, then  $\mathcal{M}(G)$  denotes the set of all matrices  $A = [a_{ij}]$  such that if  $a_{ij} > 0$ , then  $\{i, j'\}$  is a positive edge of  $G$ , and if  $a_{ij} < 0$ , then  $\{i, j'\}$  is a negative edge of  $G$ . The signed bigraph  $G$  **supports rank decompositions** provided each matrix  $A \in \mathcal{M}(G)$  is the sum of  $\text{rank}(A)$  elements of  $\mathcal{M}(G)$  each having rank 1.

#### Facts:

1. [GP71]

- A graph has a biclique partition (and, hence, cover) if and only if it has no loops.
- For every graph  $G$ ,  $\text{bc}(G) \leq \text{bp}(G)$ .
- Every simple graph  $G$  with  $n$  vertices has a biclique partition with at most  $n - 1$  bicliques, namely,  $B(\{i\}, \{j : \{i, j\} \text{ is an edge of } G \text{ and } j > i\})$  ( $i = 1, 2, \dots, n - 1$ ).

2. [CG87] Let  $G$  be a bipartite graph with bipartition  $(U, V)$ , where  $|U| = m$  and  $|V| = n$ . Let  $B(X_1, Y_1), B(X_2, Y_2), \dots, B(X_k, Y_k)$  be bicliques with  $X_i \subseteq U$  and  $Y_i \subseteq V$  for all  $i$ . The following are equivalent:

- (a)  $B(X_1, Y_1), B(X_2, Y_2), \dots, B(X_k, Y_k)$  is a biclique partition of  $G$ .

- (b)  $\sum_{i=1}^k \vec{X}_i \vec{Y}_i^T = \mathcal{B}_G$ .
- (c)  $XY^T = \mathcal{B}_G$ , where  $X$  is the  $n \times k$  matrix whose  $i$ th column is  $\vec{X}_i$ , and  $Y$  is the  $n \times k$  matrix whose  $i$ th column is  $\vec{Y}_i$ .
3. [CG87] For a simple bipartite graph  $G$ ,  $\text{bp}(G)$  equals the nonnegative integer rank of  $\mathcal{B}_G$ .
  4. [CG87]
    - Let  $G$  be the bipartite graph obtained from  $K_{n,n}$  by removing a perfect matching. Then  $\text{bp}(G) = n$ . Furthermore, if  $B(X_i, Y_i)$  ( $i = 1, 2, \dots, n$ ) is a biclique partition of  $G$ , then there exist positive integers  $r$  and  $s$  such that  $rs = n - 1$ ,  $|X_i| = r$  and  $|Y_i| = s$  ( $i = 1, 2, \dots, n$ ),  $k$  is in exactly  $r$  of the  $X_i$ 's and exactly  $s$  of the  $Y_i$ 's ( $k = 1, 2, \dots, n$ ), and  $X_i \cap Y_j = 1$  for  $i \neq j$ .
    - In matrix terminology, if  $X$  and  $Y$  are  $n \times n$   $(0, 1)$ -matrices such that  $XY^T = J_n - I_n$ , then there exist integers  $r$  and  $s$  such that  $rs = n - 1$ ,  $X$  has constant line sums  $r$ ,  $Y$  has constant line sums  $s$ , and  $Y^T X = J_n - I_n$ .
    - In particular, if  $n - 1$  is prime, then either  $X$  is a permutation matrix and  $Y = (J_n - I_n)X$ , or  $Y$  is a permutation matrix and  $X = (J_n - I_n)Y$ .
  5. [BS04, see p. 67] Let  $G$  be a graph on  $n$  vertices with adjacency matrix  $\mathcal{A}_G$ , and let  $B(X_1, Y_1), B(X_2, Y_2), \dots, B(X_k, Y_k)$  be bicliques of  $G$ . Then the following are equivalent:
    - (a)  $B(X_1, Y_1), B(X_2, Y_2), \dots, B(X_k, Y_k)$  is a biclique partition of  $G$ .
    - (b)  $\sum_{i=1}^k \vec{X}_i \vec{Y}_i^T + \sum_{i=1}^k \vec{Y}_i \vec{X}_i^T = \mathcal{A}_G$ .
    - (c)  $XY^T + YX^T = \mathcal{A}_G$ , where  $X$  is the  $n \times k$  matrix whose  $i$ th column is  $\vec{X}_i$ , and  $Y$  is the  $n \times k$  matrix whose  $i$ th column is  $\vec{Y}_i$ .
    - (d)  $\mathcal{A}_G = M \begin{bmatrix} O & I_m \\ I_m & O \end{bmatrix} M^T$ , where  $M$  is the  $n \times 2k$  matrix  $\begin{bmatrix} X & Y \end{bmatrix}$  formed from the matrices  $X$  and  $Y$  defined in (c).
  6. [CH89] The bicliques  $B(X_1, Y_1), B(X_2, Y_2), \dots, B(X_k, Y_k)$  partition  $K_n$  if and only if  $XY^T$  is an  $n \times n$  tournament matrix, where  $X$  is the  $n \times k$  matrix whose  $i$ th column is  $\vec{X}_i$ , and  $Y$  is the  $n \times k$  matrix whose  $i$ th column is  $\vec{Y}_i$ . Thus,  $\text{bp}(K_n)$  is the minimum nonnegative integer rank among all the  $n \times n$  tournament matrices.
  7. [CH89] The rank of an  $n \times n$  tournament matrix is at least  $n - 1$ .
  8. (Attributed to Witsenhausen in [GP71])

$$\text{bp}(K_n) = n - 1,$$

that is, it is impossible to partition the complete graph into  $n - 2$  or fewer bicliques.

9. [GP71] *The Graham–Pollak Theorem*: If  $G$  is a loopless graph, then

$$\text{bp}(G) \geq \max\{n_+(G), n_-(G)\}. \tag{30.1}$$

The graph  $G$  is **eigensharp** if equality holds in (30.1). It is conjectured in [CGP86] that for all  $\lambda$ , and  $n$  sufficiently large, the complete graph  $\lambda K_n$  with each edge of multiplicity  $k$  is eigensharp.

10. [ABS91] If  $B(X_1, Y_1), B(X_2, Y_2), \dots, B(X_k, Y_k)$  is a biclique partition of  $G$ , then there exists an acyclic subgraph of  $G$  with  $\max\{n_+(G), n_-(G)\}$  edges no two in the same  $B(X_i, Y_i)$ . In particular, for each biclique partition of  $K_n$  there exists a spanning tree no two of whose edges belong to the same biclique of the partition.
11. [CH89] For all positive integers  $r$  and  $s$  with  $2 \leq r < s$ , the edges of the complete graph  $K_{2rs}$  cannot be partitioned into copies of the complete bipartite graph  $K_{r,s}$ .

12. [Hof01] If  $m$  and  $n$  are positive integers with  $2m \leq n$ , and  $G_{m,n}$  is the graph obtained from the complete graph  $K_n$  by duplicating the edges of an  $m$ -matching, then  $n_+(G) = n - m - 1$ ,  $n_-(G) = m + 1$ , and  $\text{bp}(G) \geq n - m + \lfloor \sqrt{2m} \rfloor - 1$ .
13. [CGP86] Let  $A$  be an  $m \times n$   $(0, 1)$ -matrix with bigraph  $G$  and let  $B(X_1, Y_1), B(X_2, Y_2), \dots, B(X_k, Y_k)$  be bicliques. The following are equivalent:
  - (a)  $B(X_1, Y_1), B(X_2, Y_2), \dots, B(X_k, Y_k)$  is a biclique cover of  $G$ .
  - (b)  $\sum_{i=1}^k \vec{X}_i \vec{Y}_i^T = A$  (using Boolean arithmetic).
  - (c)  $XY^T = B$  (using Boolean arithmetic), where  $X$  is the  $m \times k$  matrix whose  $j$ th column is  $\vec{X}_j$ , and  $Y$  is the  $m \times k$  matrix whose  $j$  column is  $\vec{Y}_j$ .
14. [CGP86] The Boolean rank of a  $(0, 1)$ -matrix  $A$  equals the biclique cover number of its bigraph.
15. [CSS87] Let  $k$  be a positive integer and let  $t(k)$  be the largest integer  $n$  such that there exists an  $n \times n$  tournament matrix with Boolean rank  $k$ . Then for  $k \geq 2$ ,  $t(k) < k^{\log_2(2k)}$ , and  $n(n^2 + n + 1) + 2 \leq t(n^2 + n + 1)$ .  
It is still an open problem to determine the minimum Boolean rank among  $n \times n$  tournament matrices.
16. [DHM95, JM97] The bipartite graph  $G$  supports rank decompositions if and only if  $G$  is chordal bipartite.
17. [GMS96] The signed bipartite graph  $G$  support rank decompositions if and only if

$$\text{sgn}(\gamma) = (-1)^{(\ell(\gamma)/2)-1} \tag{30.2}$$

for every cycle  $\gamma$  of  $G$  of length  $\ell(\gamma) \geq 6$ . Additionally, every matrix in  $\mathcal{M}(G)$  has its rank equal to its term rank if and only if (30.2) holds for every cycle of  $G$ .

**Examples:**

1. Below, the edges of different textures form the bicliques (Figure 30.5) in a biclique partition of the graph  $G_{2,4}$  obtained from  $K_4$  by duplicating two disjoint edges.
2. Let  $n$  be an integer and  $r$  and  $s$  positive integers with  $n - 1 = rs$ . Then  $XY^T = J_n - I_n$ , where  $X = I + C^s + C^{2s} + \dots + C^{s(r-1)}$ ,  $Y = C + C^2 + C^3 + \dots + C^s$ , and  $C$  is the  $n \times n$  permutation matrix with 1s in positions  $(1, 2), (2, 3), \dots, (n - 1, n)$ , and  $(n, 1)$ .  
This shows that for each pair of positive integers  $r$  and  $s$  with  $rs = n - 1$ , there is a biclique partition of  $J_n - I_n$  with  $X_i$  and  $Y_i$  satisfying the conditions in Fact 4.
3. For  $n$  odd,  $B(\{i\}, \{i + 1, i + 2, \dots, i + \frac{n-1}{2}\})$  ( $i = 1, 2, \dots, n$ ) is a partition of  $K_n$  into bicliques each isomorphic to  $K_{1, \frac{n-1}{2}}$ , where the indices are read mod  $n$  (see Fact 11).

Ian M. Wanless  
*Monash University*

The permanent is a matrix function introduced (independently) by Cauchy and Binet in 1812. At first sight it seems to be a simplified version of the determinant, but this impression is misleading. In some important respects the permanent is much less tractable than the determinant. Nonetheless, permanents have found a wide range of applications from pure combinatorics (e.g., counting problems involving permutations) right through to applied science (e.g., modeling subatomic particles). For further reading see [Min78], [Min83], [Min87], [CW05], and the references therein.

### 31.1 Basic Concepts

---

#### Definitions:

Let  $A = [a_{ij}]$  be an  $m \times n$  matrix over a commutative ring,  $m \leq n$ . Let  $S$  be the set of all injective functions from  $\{1, 2, \dots, m\}$  to  $\{1, 2, \dots, n\}$  (in particular, if  $m = n$ , then  $S$  is the symmetric group on  $\{1, 2, \dots, n\}$ ). The **permanent** of  $A$  is defined by

$$\text{per}(A) = \sum_{\sigma \in S} \prod_{i=1}^m a_{i\sigma(i)}.$$

Two matrices  $A$  and  $B$  are **permutation equivalent** if there exist permutation matrices  $P$  and  $Q$  such that  $B = PAQ$ .

**Facts:**

For facts for which no specific reference is given and for background reading on the material in this subsection, see [Min78].

1. If  $A$  is any square matrix, then  $\text{per}(A) = \text{per}(A^T)$ .
2. Our definition implies that  $\text{per}(A) = 0$  for all  $m \times n$  matrices  $A$ , where  $m > n$ . Some authors prefer to define  $\text{per}(A) = \text{per}(A^T)$  in this case.
3. If  $A$  is any  $m \times n$  matrix and  $P$  and  $Q$  are permutation matrices of respective orders  $m$  and  $n$ , then  $\text{per}(PAQ) = \text{per}(A)$ . That is, the permanent is invariant under permutation equivalence.
4. If  $A$  is any  $m \times n$  matrix and  $c$  is any scalar, then  $\text{per}(cA) = c^m \text{per}(A)$ .
5. The permanent is a multilinear function of the rows. If  $m = n$ , it is also a multilinear function of the columns.
6. It is *not* in general true that  $\text{per}(AB) = \text{per}(A)\text{per}(B)$ .
7. If  $M$  has block decomposition  $M = \begin{bmatrix} A & \mathbf{0} \\ B & C \end{bmatrix}$ , where either  $A$  or  $C$  is square, then  $\text{per}(M) = \text{per}(A)\text{per}(C)$ .
8. Let  $A$  be an  $m \times n$  matrix with  $m \leq n$ . Then  $\text{per}(A) = 0$  if  $A$  contains an  $s \times (n - s + 1)$  submatrix of zeroes, for some  $s \in \{1, 2, \dots, m\}$ .
9. (Laplace expansion) If  $A$  is an  $m \times n$  matrix,  $2 \leq m \leq n$ , and  $\alpha \in Q_{r,m}$ , where  $1 \leq r < m \leq n$  then

$$\text{per}(A) = \sum_{\beta \in Q_{r,n}} \text{per}(A[\alpha, \beta]) \text{per}(A(\alpha, \beta)).$$

In particular, for any  $i \in \{1, 2, \dots, m\}$ ,

$$\text{per}(A) = \sum_{j=1}^n a_{ij} \text{per}(A(i, j)).$$

10. If  $A$  and  $B$  are  $n \times n$  matrices and  $s$  and  $t$  are arbitrary scalars, then

$$\text{per}(sA + tB) = \sum_{r=0}^n s^r t^{n-r} \sum_{\alpha, \beta \in Q_{r,n}} \text{per}(A[\alpha, \beta]) \text{per}(B(\alpha, \beta))$$

(where we interpret the permanent of a  $0 \times 0$  matrix to be 1).

11. (Binet–Cauchy) If  $A$  and  $B$  are  $m \times n$  and  $n \times m$  matrices, respectively, where  $m \leq n$ , then

$$\text{per}(AB) = \sum_{\alpha} \frac{1}{\mu(\alpha)} \text{per}(A[\{1, 2, \dots, m\}, \alpha]) \text{per}(B[\alpha, \{1, 2, \dots, m\}]).$$

The sum is over all nondecreasing sequences  $\alpha$  of  $m$  integers chosen from the set  $\{1, 2, \dots, n\}$  and  $\mu(\alpha) = \alpha_1! \alpha_2! \cdots \alpha_n!$ , where  $\alpha_i$  denotes the number of occurrences of the integer  $i$  in  $\alpha$ .

12. [MM62], [Bot67] Let  $F$  be a field and  $m \geq 3$  an integer. Let  $T$  be a linear transformation for which  $\text{per}(T(X)) = \text{per}(X)$  for all  $X \in F^{m \times m}$ . Then there exist permutation matrices  $P$  and  $Q$  and diagonal matrices  $D_1$  and  $D_2$  such that  $\text{per}(D_1 D_2) = 1$  and either  $T(X) = D_1 P X Q D_2$  for all  $X \in F^{m \times m}$  or  $T(X) = D_1 P X^T Q D_2$  for all  $X \in F^{m \times m}$ .
13. (Alexandrov's inequality) Let  $A = [a_{ij}] \in \mathbb{R}^{n \times n}$  and  $1 \leq r < s \leq n$ . If  $a_{ij} \geq 0$  whenever  $j \neq s$ , then

$$(\text{per}(A))^2 \geq \sum_{i=1}^n a_{ir} \text{per}(A(i, s)) \sum_{i=1}^n a_{is} \text{per}(A(i, r)). \quad (31.1)$$

Moreover, if  $a_{ij} > 0$  whenever  $j \neq s$ , then equality holds in (31.1) iff there exists  $c \in \mathbb{R}$  such that  $a_{ir} = ca_{is}$  for all  $i$ .

14. If  $G$  is a balanced bipartite graph (meaning the two parts have equal size), then  $\text{per}(\mathcal{B}_G)$  counts perfect matchings (also known as 1-factors) in  $G$ .
15. If  $D$  is a directed graph, then  $\text{per}(\mathcal{A}_D)$  counts the cycle covers of  $D$ . A cycle cover is a set of disjoint cycles which include every vertex exactly once.

**Examples:**

1.

$$\begin{aligned} \text{per} \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{bmatrix} &= 1 \text{ per} \begin{bmatrix} 5 & 6 \\ 8 & 9 \end{bmatrix} + 2 \text{ per} \begin{bmatrix} 4 & 6 \\ 7 & 9 \end{bmatrix} + 3 \text{ per} \begin{bmatrix} 4 & 5 \\ 7 & 8 \end{bmatrix} \\ &= 1 \cdot 5 \cdot 9 + 1 \cdot 6 \cdot 8 + 2 \cdot 4 \cdot 9 + 2 \cdot 6 \cdot 7 + 3 \cdot 4 \cdot 8 + 3 \cdot 5 \cdot 7 = 450. \end{aligned}$$

$$2. \text{ per} \begin{bmatrix} 0 & 2 & 3 & 4 \\ 5 & 6 & 0 & 8 \\ 9 & 0 & 0 & 12 \end{bmatrix} = 2 \cdot 5 \cdot 12 + 2 \cdot 8 \cdot 9 + 3 \cdot 5 \cdot 12 + 3 \cdot 6 \cdot 9 + 3 \cdot 6 \cdot 12 + 3 \cdot 8 \cdot 9 + 4 \cdot 6 \cdot 9 = 1254.$$

3. If  $A = \begin{bmatrix} 2 & 3 \\ 2 & -2 \end{bmatrix}$  and  $B = \begin{bmatrix} -4 & -2 \\ 1 & -1 \end{bmatrix}$ , then  $AB = \begin{bmatrix} -5 & -7 \\ -10 & -2 \end{bmatrix}$ . Hence,  $80 = \text{per}(AB) \neq \text{per}(A) \text{per}(B) = 2 \times 2 = 4$ .

4. Below is a bipartite graph  $G$  (Figure 31.1) and its biadjacency matrix  $\mathcal{B}_G$ .

Now,  $\text{per}(\mathcal{B}_G) = 2$ , which means that  $G$  has two perfect matchings (Figure 31.2 and Figure 31.3).

5. The matrix in the previous example can also be interpreted as  $\mathcal{A}_D$  for the directed graph  $D$  (Figure 31.4). It has two cycle covers (Figure 31.5 and Figure 31.6).

## 31.2 Doubly Stochastic Matrices

**Facts:**

For facts for which no specific reference is given and for background reading on the material in this subsection, see [Min78].

1. If  $A \in \Omega_n$ , then  $\text{per}(A) \leq 1$  with equality iff  $A$  is a permutation matrix.
2. [Ego81], [Fal81] If  $A \in \Omega_n$  and  $A \neq \frac{1}{n} J_n$ , then  $\text{per}(A) > \text{per}(\frac{1}{n} J_n) = n!/n^n$ .

3. [Fri82] If  $A \in \Omega_n$  and  $A$  has a  $p \times q$  submatrix of zeros (where  $p + q \leq n$ ), then

$$\text{per}(A) \geq \frac{(n-p)!}{(n-p)^{n-p}} \frac{(n-q)!}{(n-q)^{n-q}} \frac{(n-p-q)^{n-p-q}}{(n-p-q)!}.$$

Equality is achieved by any matrix permutation equivalent to the matrix  $A = [a_{ij}]$  defined by

$$a_{ij} = \begin{cases} 0 & \text{if } i \leq p \text{ and } j \leq q, \\ \frac{1}{n-q} & \text{if } i \leq p \text{ and } j > q, \\ \frac{1}{n-p} & \text{if } i > p \text{ and } j \leq q, \\ \frac{n-p-q}{(n-p)(n-q)} & \text{if } i > p \text{ and } j > q. \end{cases}$$

If  $p + q \neq n - 1$ , then no other matrix achieves equality.

4. [BN66] If  $A$  is any  $n \times n$  row substochastic matrix and  $1 \leq r \leq n$ , then  $\text{per}(A) \leq m_r$ , where  $m_r$  is the maximum permanent over all  $r \times r$  submatrices of  $A$ .
5. [Min78, p. 41] If  $A = [a_{ij}]$  is a fully indecomposable matrix, then the matrix  $S = [s_{ij}]$  defined by  $s_{ij} = a_{ij} \text{per}(A(i, j)) / \text{per}(A)$  is doubly stochastic and has the same zero pattern as  $A$ .

### Examples:

1. The minimum value of the permanent in  $\Omega_5$  is  $24/625$ , which is (uniquely) achieved by

$$\frac{1}{5} J_5 = \begin{bmatrix} 1/5 & 1/5 & 1/5 & 1/5 & 1/5 \\ 1/5 & 1/5 & 1/5 & 1/5 & 1/5 \\ 1/5 & 1/5 & 1/5 & 1/5 & 1/5 \\ 1/5 & 1/5 & 1/5 & 1/5 & 1/5 \\ 1/5 & 1/5 & 1/5 & 1/5 & 1/5 \end{bmatrix}.$$

2. In the previous example, if we require that two specified entries in the same row must be zero, then the minimum value that the permanent can take is  $1/24$ , which is (uniquely, up to permutation equivalence) achieved by

$$\begin{bmatrix} 0 & 0 & 1/3 & 1/3 & 1/3 \\ 1/4 & 1/4 & 1/6 & 1/6 & 1/6 \\ 1/4 & 1/4 & 1/6 & 1/6 & 1/6 \\ 1/4 & 1/4 & 1/6 & 1/6 & 1/6 \\ 1/4 & 1/4 & 1/6 & 1/6 & 1/6 \end{bmatrix}.$$

3. A nonnegative matrix of order  $n \geq 3$  can have zero permanent even if we insist that each row and column sum is at least one. For example,

$$\text{per} \begin{bmatrix} 1 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 1 \end{bmatrix} = 0.$$

4. Suppose  $n$  identical balls are placed, one ball per bucket, in  $n$  labeled buckets on the back of a truck. When the truck goes over a bump the balls are flung into the air, but then fall back into the buckets. Suppose that the probability that the ball from bucket  $i$  lands in bucket  $j$  is  $p_{ij}$ . Then the matrix  $P = [p_{ij}]$  is row stochastic and  $\text{per}(P)$  is the probability that we end up with one ball in each bucket. That is,  $\text{per}(P)$  is the *permanence* of the initial state.

### 31.3 Binary Matrices

**Definitions:**

A **binary matrix** is a matrix in which each entry is either 0 or 1.

$\Lambda_n^k$  is the set of  $n \times n$  binary matrices in which each row and column sum is  $k$ .

For an  $m \times n$  binary matrix  $M$  the **complement**  $M^c$  is defined by  $M^c = J_{mn} - M$ .

A system of distinct representatives (**SDR**) for the finite sets  $S_1, S_2, \dots, S_n$  is a choice of  $x_1, x_2, \dots, x_n$  with the properties that  $x_i \in S_i$  for each  $i$  and  $x_i \neq x_j$  whenever  $i \neq j$ .

The **incidence matrix** for subsets  $S_1, S_2, \dots, S_m$  of a finite set  $\{x_1, x_2, \dots, x_n\}$  is the  $m \times n$  binary matrix  $M = [m_{ij}]$  in which  $m_{ij} = 1$  iff  $x_j \in S_i$ .

$P_{(12 \dots n)}$  is the permutation matrix for the full cycle permutation  $(12 \dots n)$ .

**Facts:**

For facts for which no specific reference is given and for background reading on the material in this section, see [Min78].

1. The number of SDRs for a set of sets with incidence matrix  $M$  is  $\text{per}(M)$ .
2. If  $M \in \Lambda_n^k$ , then  $\frac{1}{k}M \in \Omega_n$ , so the results of the previous subsection apply.
3. [Min78, p. 52] Let  $A$  be an  $m \times n$  binary matrix where  $m \leq n$ . Suppose  $A$  has at least  $t$  positive entries in each row. If  $t < m$  and  $\text{per}(A) > 0$ , then  $\text{per}(A) \geq t!$ . If  $t \geq m$ , then  $\text{per}(A) \geq t!/(t-m)!$ .
4. If  $A \in \Lambda_n^k$ , then there exist permutation matrices  $P_1, P_2, \dots, P_k$  such that

$$A = \sum_{i=1}^k P_i.$$

5. [Brè73], [Sch78] Let  $A$  be any  $n \times n$  binary matrix with row sums  $r_1, r_2, \dots, r_n$ . Then

$$\text{per}(A) \leq \prod_{i=1}^n (r_i!)^{1/r_i} \tag{31.2}$$

with equality iff  $A$  is permutation equivalent to a direct sum of square matrices each of which contains only 1s.

6. [MW98] If  $m \geq 5$ , then  $(J_k \oplus J_k \oplus \dots \oplus J_k)^c$  (where there are  $m$  copies of  $J_k$ ) maximizes the permanent in  $\Lambda_{mk}^{mk-k}$ . The result is not true for  $m = 3$ .
7. [Wan99b] For each  $k \geq 1$  there exists  $N$  such that for all  $n \geq N$  a matrix  $M$  maximizes the permanent in  $\Lambda_n^k$  iff  $M \oplus J_k$  maximizes the permanent in  $\Lambda_{n+k}^k$ .
8. [Wan03] If  $n = tk + r$  with  $0 \leq r < k \leq n$ , then  $k!^t r! \leq \max_{A \in \Lambda_n^k} \text{per}(A) \leq (k!)^{n/k}$ .
9. [Wan03] If  $k = o(n)$  as  $n \rightarrow \infty$ , then  $\left( \max_{A \in \Lambda_n^k} \text{per}(A) \right)^{1/n} \sim (k!)^{1/k}$ .
10. [GM90] Suppose  $0 \leq k = O(n^{1-\delta})$  for a constant  $\delta > 0$  as  $n \rightarrow \infty$ . Then

$$\begin{aligned} \text{per}(A) = n! \left( \frac{n-k}{n} \right)^n \exp \left( \frac{k}{2n} + \frac{3k^2 - k}{6n^2} + \frac{2k^3 - k}{4n^3} \right. \\ \left. + \frac{15k^4 + 70k^3 - 105k^2 + 32k}{60n^4} + \frac{z}{n^4} + \frac{2z(2k-1)}{n^5} + O\left( \frac{k^5}{n^5} \right) \right) \end{aligned}$$

for all  $A \in \Lambda_n^{n-k}$ , where  $z$  denotes the number of  $2 \times 2$  submatrices of  $A$  that contain only zeros. In particular, if  $0 \leq k = O(n^{1-\delta})$  for a constant  $\delta > 0$  as  $n \rightarrow \infty$ , then  $\text{per}(A)$  is asymptotically equal to  $n!(1 - k/n)^n$  for all  $A \in \Lambda_n^{n-k}$ .

11. [Wan06] If  $2 \leq k \leq n$  as  $n \rightarrow \infty$ , then

$$\left( \min_{A \in \Lambda_n^k} \text{per}(A) \right)^{1/n} \sim \frac{(k-1)^{k-1}}{k^{k-2}}.$$

5. [MW98] For  $n \leq 11$  the maximum values of  $\text{per}(A)$  for  $A \in \Lambda_n^k$  are as follows:

$k$	$n = 2$	3	4	5	6	7	8	9	10	11
1	1	1	1	1	1	1	1	1	1	1
2	2	2	4	4	8	8	16	16	32	32
3	—	6	9	13	36	54	81	216	324	486
4	—	—	24	44	82	148	576	1056	1968	3608
5	—	—	—	120	265	580	1313	2916	14400	31800
6	—	—	—	—	720	1854	4752	12108	32826	86400
7	—	—	—	—	—	5040	14833	43424	127044	373208
8	—	—	—	—	—	—	40320	133496	440192	1448640
9	—	—	—	—	—	—	—	362880	1334961	4893072
10	—	—	—	—	—	—	—	—	3628800	14684570
11	—	—	—	—	—	—	—	—	—	39916800

### 31.4 Nonnegative Matrices

**Definitions:**

$\Delta_n^k$  is the set of  $n \times n$  matrices of nonnegative integers in which each row and column sum is  $k$ .

**Facts:**

- [Min78, p. 33] Let  $A$  be an  $m \times n$  nonnegative matrix with  $m \leq n$ . Then  $\text{per}(A) = 0$  iff  $A$  contains an  $s \times (n - s + 1)$  submatrix of zeros, for some  $s \in \{1, 2, \dots, m\}$ .
- [Min78, p. 38] Let  $A$  be a nonnegative matrix of order  $n \geq 2$ . Then  $A$  is fully indecomposable iff  $\text{per}(A(i, j)) > 0$  for all  $i, j$ .
- [Sch98]  $\left(\frac{(k-1)^{k-1}}{k^{k-2}}\right)^n \leq \min_{A \in \Delta_n^k} \text{per}(A) \leq \frac{k^{2n}}{\binom{kn}{n}}$ .
- [Min83] It is conjectured that  $\min_{A \in \Delta_n^k} \text{per}(A) = \min_{A \in \Lambda_n^k} \text{per}(A)$ .
- [Sou03] Let  $\Gamma$  denote the gamma function and let  $A$  be a nonnegative matrix of order  $n$ . In row  $i$  of  $A$ , let  $m_i$  and  $r_i$  denote, respectively, the largest entry and the total of the entries. Then,

$$\text{per}(A) \leq \prod_{i=1}^n m_i \left( \Gamma \left( \frac{r_i}{m_i} + 1 \right) \right)^{m_i/r_i}. \tag{31.3}$$

- [Min78, p. 62] Let  $A$  be a nonnegative matrix of order  $n$ . Define  $s_i$  to be the sum of the  $i$  smallest entries in row  $i$  of  $A$ . Similarly, define  $S_i$  to be the sum of the  $i$  largest entries in row  $i$  of  $A$ . Then

$$\prod_{i=1}^n s_i \leq \text{per}(A) \leq \prod_{i=1}^n S_i.$$

- [Gib72] If  $A$  is nonnegative and  $\pi$  is a root of  $\text{per}(zI - A)$ , then  $|\pi| \leq \rho(A)$ .

**Examples:**

- [BB67] If  $A$  is row substochastic, the roots of  $\text{per}(zI - A) = 0$  satisfy  $|z| \leq 1$ .
- If Soules' bound (31.3) is applied to matrices in  $\Lambda_n^k$  it reduces to Brègman's bound (31.2).

## 31.5 $(\pm 1)$ -Matrices

---

### Facts:

- [KS83] If  $A$  is a  $(\pm 1)$ -matrix of order  $n$ , then  $\text{per}(A)$  is divisible by  $2^{n - \lfloor \log_2(n+1) \rfloor}$ .
- [Wan74] If  $H$  is an  $n \times n$  Hadamard matrix, then  $|\text{per}(H)| \leq |\det(H)| = n^{n/2}$ .
- [KS83], [Wan05] There is no solution to  $|\text{per}(A)| = |\det(A)|$  among the nonsingular  $(\pm 1)$ -matrices of order  $n$  when  $n \in \{2, 3, 4\}$  or  $n = 2^k - 1$  for  $k \geq 2$ , but there are solutions when  $n \in \{5, \dots, 20\} \setminus \{7, 15\}$ .
- [Wan05] There exists a  $(\pm 1)$ -matrix  $A$  of order  $n$  satisfying  $\text{per}(A) = 0$  iff  $n + 1$  is not a power of 2.

### Examples:

- The  $11 \times 11$  matrix  $A = [a_{ij}]$  defined by

$$a_{ij} = \begin{cases} -1 & \text{if } j - i \in \{1, 2, 3, 5, 7, 10\}, \\ +1 & \text{otherwise,} \end{cases}$$

satisfies  $\text{per}(A) = 0$ . No smaller  $(\pm 1)$ -matrix of order  $n \equiv 3 \pmod{4}$  has this property.

- The following matrix has  $\text{per} = \det = 16$ , and is the smallest example (excluding the trivial case of order 1) for which  $\text{per} = \det$  among  $\pm 1$ -matrices.

$$\begin{bmatrix} +1 & +1 & +1 & +1 & +1 \\ +1 & -1 & -1 & +1 & +1 \\ +1 & -1 & +1 & +1 & +1 \\ +1 & +1 & +1 & -1 & -1 \\ +1 & +1 & +1 & -1 & +1 \end{bmatrix}.$$

## 31.6 Matrices over $\mathbb{C}$

---

### Facts:

- If  $A = [a_{ij}] \in \mathbb{C}^{m \times n}$  and  $B = [b_{ij}] \in \mathbb{R}^{m \times n}$  satisfy  $b_{ij} = |a_{ij}|$ , then  $|\text{per}(A)| \leq \text{per}(B)$ .
- If  $A \in \mathbb{C}^{n \times n}$ , then  $\text{per}(\overline{A}) = \overline{\text{per}(A)} = \text{per}(A^*)$ .
- [Min78, p. 113] If  $A \in \mathbb{C}^{n \times n}$  is normal with eigenvalues  $\lambda_1, \lambda_2, \dots, \lambda_n$ , then

$$|\text{per}(A)| \leq \frac{1}{n} \sum_{i=1}^n |\lambda_i|^n.$$

- [Min78, p. 115] Let  $A \in \mathbb{C}^{n \times n}$  and let  $\lambda_1, \dots, \lambda_n$  be the eigenvalues of  $AA^*$ . Then

$$|\text{per}(A)|^2 \leq \frac{1}{n} \sum_{i=1}^n \lambda_i^n.$$

- [Lie66] If  $A = \begin{bmatrix} B & C \\ C^* & D \end{bmatrix} \in \text{PD}_n$ , then  $\text{per}(A) \geq \text{per}(B) \text{per}(D)$ .
- [JP87] Suppose  $\alpha \subseteq \beta \subseteq \{1, 2, \dots, n\}$ . Then for any  $A \in \text{PD}_n$ ,

$$\det(A[\beta, \beta]) \text{per}(A(\beta, \beta)) \leq \det(A[\alpha, \alpha]) \text{per}(A(\alpha, \alpha)).$$

(We interpret  $\det$  or  $\text{per}$  of a  $0 \times 0$  matrix to be 1.)

7. [MN62] If  $A \in \mathbb{C}^{m \times n}$  and  $B \in \mathbb{C}^{n \times m}$ , then

$$|\text{per}(AB)|^2 \leq \text{per}(AA^*) \text{per}(B^*B).$$

8. [Bre59] If  $A = [a_{ij}] \in \mathbb{C}^{n \times n}$  satisfies  $|a_{ii}| > \sum_{j \neq i} |a_{ij}|$  for each  $i$ , then  $\text{per}(A) \neq 0$ .

**Examples:**

1. If  $U$  is a unitary matrix, then  $|\text{per}(U)| \leq 1$ .

## 31.7 Subpermanents

---

**Definitions:**

The  $k$ -th **subpermanent sum**,  $\text{per}_k(A)$  of an  $m \times n$  matrix  $A$ , is defined to be the sum of the permanents of all order  $k$  submatrices of  $A$ . That is,

$$\text{per}_k(A) = \sum_{\substack{\alpha \in Q_{k,m} \\ \beta \in Q_{k,n}}} \text{per}(A[\alpha, \beta]).$$

By convention, we define  $\text{per}_0(A) = 1$ .

**Facts:**

For facts for which no specific reference is given and for background reading on the material in this subsection see [Min78].

1. For each  $k$ ,  $\text{per}_k$  is invariant under permutation equivalence and transposition.
2. If  $A$  is any  $m \times n$  matrix and  $c$  is any scalar, then  $\text{per}_k(cA) = c^k \text{per}_k(A)$ .
3. [BN66] If  $A$  is any  $n \times n$  row substochastic matrix and  $1 \leq r \leq n$ , then  $\text{per}_r(A) \leq \binom{n}{r}$ .
4. [Fri82]  $\text{per}_k(A) \geq \text{per}_k(\frac{1}{n}J_n)$  for every  $A \in \Omega_n$  and integer  $k$ .

5. [Wan03] If  $A \in \Lambda_n^k$  and  $i \leq k$ , then  $\text{per}_i(A) \geq \binom{n}{i} \frac{k!}{(k-i)!}$ .

6. [Wan03] For  $1 \leq i, k \leq n$  and  $A \in \Lambda_n^k$ ,

$$\binom{kn}{i} - kn(k-1) \binom{kn-2}{i-2} \leq \text{per}_i(A) \leq \binom{kn}{i}.$$

7. [Wan03] For  $A \in \Lambda_n^k$ , let  $\xi_i = (\text{per}_i(A) / \binom{n}{i})^{1/i}$ . Then

$$\frac{(k-1)^{k-1}}{k^{k-2}} \leq \xi_n \leq \xi_{n-1} \leq \dots \leq \xi_1 = k.$$

8. [Nij76], [HLP52, p. 104] Let  $A$  be a nonnegative  $m \times n$  matrix with  $\text{per}(A) \neq 0$ . For  $1 \leq i \leq m-1$ ,

$$\frac{\text{per}_i(A)}{\text{per}_{i-1}(A)} \geq \frac{(i+1)(m-i+1)}{i(m-i)} \frac{\text{per}_{i+1}(A)}{\text{per}_i(A)} > \frac{\text{per}_{i+1}(A)}{\text{per}_i(A)}.$$

9. [Wan99b] For  $A \in \Lambda_n^k$ ,

$$\frac{\text{per}_i(A)}{\text{per}_{i+1}(A)} \geq \frac{i+1}{(n-i)^2}.$$

10. [Wan99a] Let  $k \geq 0$  be an integer. There exists no polynomial  $p_k(n)$  such that for all  $n$  and  $A \in \Lambda_n^3$ ,

$$\frac{\text{per}_{n-k-1}(A)}{\text{per}_{n-k}(A)} \leq p_k(n).$$

11. If  $G$  is a bipartite graph, then  $\text{per}_k(\mathcal{B}_G)$  counts the  $k$ -matchings in  $G$ . A  $k$ -matching in  $G$  is a set of  $k$  edges in  $G$  such that no two edges share a vertex.

### Examples:

- For any matrix  $A$  the sum of the entries in  $A$  is  $\text{per}_1(A)$ .
- Any  $m \times n$  matrix  $A$  has  $\text{per}_m(A) = \text{per}(A)$ .
- $\text{per}_k(J_n) = k! \binom{n}{k}^2$ .
- [Wan99a] Let  $A \in \Lambda_n^k$  have  $s$  submatrices which are copies of  $J_2$ . Then
  - $\text{per}_1(A) = kn$ .
  - $\text{per}_2(A) = \frac{1}{2}kn(kn - 2k + 1)$ .
  - $\text{per}_3(A) = \frac{1}{6}kn(k^2n^2 - 6k^2n + 3kn + 10k^2 - 12k + 4)$ .
  - $\text{per}_4(A) = \frac{1}{24}kn(k^3n^3 - 12k^3n^2 + 6k^2n^2 + 52k^3n - 60k^2n + 19kn - 84k^3 + 168k^2 - 120k + 30) + s$ .
  - $\text{per}_5(A) = \frac{1}{120}kn[k^4n^4 - 20k^4n^3 + 10k^3n^3 + 160k^4n^2 - 180k^3n^2 + 55k^2n^2 - 620k^4n + 1180k^3n - 800k^2n + 190kn + 1008k^4 - 2880k^3 + 3240k^2 - 1680k + 336] + (nk - 8k + 8)s$ .
- The subpermanent sums are also known as **rook numbers** since they count the number of placements of rooks in mutually nonattacking positions on a chessboard. Let  $A$  be a binary matrix in which each 1 denotes a permitted position on the board and each 0 denotes a forbidden position for a rook. Then  $\text{per}_i(A)$  is the number of placements of  $i$  rooks on permitted squares so that no two rooks occupy the same row or column. For example, the number of ways of putting 4 nonattacking rooks on the white squares of a standard chessboard is

$$\text{per}_4 \begin{bmatrix} 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 \\ 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 \\ 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 \\ 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 \end{bmatrix} = 8304.$$

## 31.8 Rook Polynomials

### Definitions:

Let  $A$  be an  $m \times n$  binary matrix. The polynomials  $\rho_1(A, x) = \sum_{i=0}^m \text{per}_i(A)x^i$  and  $\rho_2(A, x) = \sum_{i=0}^m (-1)^i \text{per}_i(A)x^{m-i}$  are both called **rook polynomials** because they are generating functions for the rook numbers.

Let  $\ell_k(x)$  be the  $k^{\text{th}}$  Laguerre polynomial, normalized to be monic. That is,

$$\ell_k(x) = (-1)^k k! \sum_{i=0}^k \binom{k}{i} \frac{(-x)^i}{i!}.$$

**Facts:**

For facts for which no specific reference is given and for background reading on the material in this section, see [Rio58].

1. When  $A$  is an  $m \times n$  binary matrix,  $\rho_1(A, x) = (-x)^m \rho_2(A, -\frac{1}{x})$ .
2. If  $A = B \oplus C$ , then  $\rho_1(A, x) = \rho_1(B, x)\rho_1(C, x)$  and  $\rho_2(A, x) = \rho_2(B, x)\rho_2(C, x)$ .
3. [HL72], [Nij76] For any nonnegative matrix  $A$ , all the roots of  $\rho_1(A, x)$  and  $\rho_2(A, x)$  are real.
4. [HL72] For  $2 \leq k \leq n$  and  $A \in \Lambda_n^k$ , the roots of  $\rho_1(A, x)$  are less than  $-1/(4k - 4)$ , while the roots of  $\rho_2(A, x)$  lie in the interval  $(0, 4k - 4)$ .
5. [JR80], [God81] For a square binary matrix  $A$ , with complement  $A^c$ ,

$$\text{per}(A) = \int_0^\infty e^{-x} \rho_2(A^c, x) dx.$$

6. [God81] For an  $n \times n$  binary matrix  $M$ ,

$$\rho_2(M, x) = \sum_{i=0}^n \text{per}_i(M^c) \ell_{n-i}(x).$$

7. [Sze75, p. 100] For any  $j, k$  let  $\delta_{j,k}$  denote the Kronecker delta. Then

$$\int_0^\infty e^{-x} \ell_j(x) \ell_k(x) dx = \delta_{j,k} k!^2.$$

**Examples:**

1.  $\rho_1(P, x) = (x + 1)^n$  and  $\rho_2(P, x) = (x - 1)^n$  for a permutation matrix  $P \in \Lambda_n^1$ .
2.  $\rho_2(J_k, x) = \ell_k(x)$ .
3. Let  $C_n = I_n + P_{(12 \dots n)}$ . Then

$$\rho_1(C_n, x) = \sum_{i=0}^n \frac{2n}{2n-i} \binom{2n-i}{i} x^i$$

and  $\rho_2(C_n, 4x^2) = 2T_{2n}(x)$ , where  $T_n(x)$  is the  $n^{\text{th}}$  Chebyshev polynomial of the first kind.

4.  $\rho_2(I_n^c, x) = \sum_{i=0}^n \binom{n}{i} \ell_i(x)$  for any integer  $n \geq 1$ .
5. The ideas of this chapter allow a quick computation of the permanent of many matrices that are built from blocks of ones by recursive use of direct sums and complementation. For example,

$$\begin{aligned} \text{per}((J_k \oplus I_{k+1}^c)^c) &= \int_0^\infty e^{-x} \rho_2(J_k \oplus I_{k+1}^c) dx = \int_0^\infty e^{-x} \rho_2(J_k) \rho_2(I_{k+1}^c) dx \\ &= \int_0^\infty e^{-x} \ell_k(x) \sum_{i=0}^{k+1} \binom{k+1}{i} \ell_i(x) dx = \binom{k+1}{k} k!^2 = (k+1)! k!. \end{aligned}$$

## 31.9 Evaluating Permanents

---

**Facts:**

For facts for which no specific reference is given and for background reading on the material in this subsection, see [Min78].

1. Since the permanent is *not* invariant under elementary row operations, it cannot be calculated by Gaussian elimination.
2. (Ryser's formula) If  $A = [a_{ij}]$  is any  $n \times n$  matrix,

$$\text{per}(A) = \sum_{r=1}^n (-1)^r \sum_{\alpha \in Q_{r,n}} \prod_{i=1}^r \sum_{j \in \alpha} a_{ij}.$$

3. [NW78] A straightforward implementation of Ryser's formula has time complexity  $\Theta(n^2 2^n)$ . By enumerating the  $\alpha$  in Gray Code order (i.e., by choosing an ordering in which any two consecutive  $\alpha$ 's differ by a single entry), Nijenhuis/Wilf improved this to  $\Theta(n 2^n)$ . They cut the execution time by a further factor of two by exploiting the relationship between the term corresponding to  $\alpha$  and that corresponding to  $\{1, 2, \dots, n\} \setminus \alpha$ . This second savings is not always desirable when calculating permanents of integer matrices, since it introduces fractions.

Ryser/Nijenhuis/Wilf (RNW) Algorithm for calculating  $\text{per}(A)$  for  $A = [a_{ij}]$  of order  $n$ .

```

p := -1;
for i from 1 to n do
  xi := ain - ½ ∑j=1n aij;
  p := p * xi;
  gi := 0;
s := -1;
for k from 2 to 2n-1 do
  if k is even then
    j := 1;
  else
    j := 2;
    while gj-1 = 0 do
      j := j + 1;
  z := 1 - 2 * gj;
  gj := 1 - gj;
  s := -s;
  t := s;
  for i from 1 to n do
    xi := xi + z * aij;
    t := t * xi;
  p := p + t;
return (2(-1)n p)

```

4. For sufficiently sparse matrices, a simple enumeration of nonzero diagonals by backtracking, or a recursive Laplace expansion, will be faster than RNW.
5. A hybrid approach is to use Laplace expansion to expand any rows or columns that have very few nonzero entries, then employ RNW.
6. [DL92] The calculation of the permanent is a #P-complete problem. This is still true if attention is restricted to matrices in  $\Lambda_n^3$ . So, it is extremely unlikely that a polynomial time algorithm for calculating permanents exists.
7. [Lub90] As a result of the above, much work has been done on approximation algorithms for permanents.

## 31.10 Connections between Determinants and Permanents

### Definitions:

For any partition  $\lambda$  of  $n$  let  $\chi_\lambda$  denote the irreducible character of the symmetric group  $S_n$  associated with  $\lambda$  by the standard bijection (see Section 68.6 or [Mac95, p. 114]) between partitions and irreducible characters.

Let  $\varepsilon_n$  be the identity in  $S_n$ .

The matrix function  $f_\lambda$  defined by

$$f_\lambda(M) = \frac{1}{\chi_\lambda(\varepsilon_n)} \sum_{\sigma \in S_n} \chi_\lambda(\sigma) \prod_{i=1}^n m_{i\sigma(i)},$$

for each  $M = [m_{ij}] \in \mathbb{C}^{n \times n}$ , is called a **normalized immanant** (without the factor of  $1/\chi_\lambda(\varepsilon_n)$  it is an **immanant**).

The partial order  $\triangleleft$  is defined on the set of partitions of an integer  $n$  by stating that  $\lambda \triangleleft \mu$  means that  $f_\lambda(H) \leq f_\mu(H)$  for all  $H \in \text{PD}_n$ .

**Facts:**

For facts for which no specific reference is given and for background reading on the material in this subsection, see [Mer97].

1. If  $\lambda = (n)$ , then  $\chi_\lambda$  is the principal/trivial character and  $f_\lambda$  is the permanent.
2. If  $\lambda = (1^n)$ , then  $\chi_\lambda$  is the alternating character and  $f_\lambda$  is the determinant.
3. [Sch18]  $f_\lambda(H)$  is a nonnegative real number for all  $H \in \text{PD}_n$  and all  $\lambda$ .
4. [MM61] For  $n \geq 3$  there is no linear transformation  $T$  such that  $\text{per}(A) = \det(T(A))$  for every  $A \in \mathbb{R}^{n \times n}$ . In particular, there is no way of affixing minus signs to some entries that will convert the permanent into a determinant.
5. [Lev73] For all sufficiently large  $n$  there exists a fully indecomposable matrix  $A \in \Lambda_n^3$  such that  $\text{per}(A) = \det(A)$ .
6. [Sch18], [Mar64] If  $A = [a_{ij}] \in \text{PD}_n$ , then  $\det(A) \leq \prod_{i=1}^n a_{ii} \leq \text{per}(A)$ . Equality holds iff  $A$  is diagonal or  $A$  has a zero row/column.
7. [Sch18] For arbitrary  $\lambda$ , if  $A \in \text{PD}_n$ , then  $f_\lambda(A) \geq \det(A)$ . In other words  $(1^n) \triangleleft \lambda$  for all partitions  $\lambda$  of  $n$ .
8. [Hey88] The hook immanants are linearly ordered between  $\det$  and  $\text{per}$ . That is,  $(1^n) \triangleleft (2, 1^{n-2}) \triangleleft (3, 1^{n-3}) \triangleleft \dots \triangleleft (n-1, 1) \triangleleft (n)$ .
9. A special case of the **permanental dominance conjecture** asserts that  $\lambda \triangleleft (n)$  for all partitions  $\lambda$  of  $n$ . This has been proven only for special cases, which include (a)  $n \leq 13$ , (b) partitions with no more than three parts which exceed 2, and (c) the hook immanants mentioned above.
10. For two partitions  $\lambda, \mu$  of  $n$  to satisfy  $\lambda \triangleleft \mu$ , it is necessary but not sufficient that  $\mu$  majorizes  $\lambda$ .

**Examples:**

1. Although  $\mu = (3, 1)$  majorizes  $\lambda = (2, 2)$ , neither  $\lambda \triangleleft \mu$  nor  $\mu \triangleleft \lambda$ . This is demonstrated by taking  $A = J_2 \oplus J_2$  and  $B = J_1 \oplus J_3$  and noting that  $f_\lambda(A) = 2 > \frac{4}{3} = f_\mu(A)$  but  $f_\lambda(B) = 0 < 2 = f_\mu(B)$ .

<i>California State University/Northridge</i>		References . . . . .	32-12

An  $m \times n$  matrix  $W$  whose entries are all 1 or  $-1$  is called a  $(\pm 1)$ -design matrix; if the entries of  $W$  are 0 or 1, then  $W$  is a  $(0, 1)$ -design matrix. Each design matrix corresponds to a weighing design. That is, a scheme for estimating the weights of  $n$  objects in  $m$  weighings. Since the weights of  $n$  objects cannot be estimated in fewer than  $n$  weighings, we consider only those pairs  $(m, n)$  with  $m \geq n$ . The rows of  $W$  encode a two-pan or one-pan weighing design with  $n$  objects  $x_1, \dots, x_n$  being weighed in  $m$  weighings. If  $W \in \{\pm 1\}^{m \times n}$ , an entry of 1 in the  $(i, j)$ -th position of  $W$  indicates that object  $x_j$  is put in the right pan in the  $i$ -th weighing while an entry of  $-1$  means that  $x_j$  is placed in the left pan. If  $W \in \{0, 1\}^{m \times n}$ , an entry of 1 in the  $(i, j)$ -th position indicates that object  $x_j$  is included in the  $i$ -th weighing while an entry of 0 means that the object is not included. In the presence of errors for the scale, we can expect only to find estimators  $\hat{w}_1, \dots, \hat{w}_n$  for the actual weights  $w_1, \dots, w_n$  of the objects. We want to choose a weighing design that is optimal with respect to some condition, an idea going back to Hotelling [Hot44] and Mood [Moo46]. See also [HS79] and [Slo79]. Under certain assumptions on the error of the scale, we can express optimality conditions in terms of  $W^T W$  (see [Puk93]). The value of  $\det W^T W$  is inversely proportional to the volume of the confidence region of the estimators of the weights of the objects. Thus, matrices for which  $\det W^T W$  is large correspond to weighing designs that are desirable.

### 32.1 Introduction

---

This section includes basic definitions; facts and examples can be found in the following sections.

#### Definitions:

A matrix  $W \in \{\pm 1\}^{m \times n}$  is a  $(\pm 1)$ -**design matrix**;  $W \in \{0, 1\}^{m \times n}$  is a  $(0, 1)$ -**design matrix**.

A matrix  $W \in \{\pm 1\}^{m \times n}$  (respectively,  $W \in \{0, 1\}^{m \times n}$ ) is called **D-optimal** if  $\det W^T W$  is maximal over all matrices in  $\{\pm 1\}^{m \times n}$  (respectively,  $\{0, 1\}^{m \times n}$ ).

$$\alpha(m, n) = \max\{\det W^T W \mid W \in \{\pm 1\}^{m \times n}\}.$$

$$\beta(m, n) = \max\{\det W^T W \mid W \in \{0, 1\}^{m \times n}\}.$$

We write  $\alpha(n)$  and  $\beta(n)$  for  $\alpha(n, n)$  and  $\beta(n, n)$ .

## 32.2 The $(\pm 1)$ and $(0, 1)$ Square Case

### Definitions:

For a matrix  $V \in \{0, 1\}^{(n-1) \times (n-1)}$ , define

$$W_V = \left[ \begin{array}{c|ccc} 1 & 1 & \cdots & 1 \\ \hline -1 & & & \\ \vdots & & 2V - J_{n-1} & \\ -1 & & & \end{array} \right] \in \{\pm 1\}^{n \times n}.$$

For a matrix  $W \in \{\pm 1\}^{n \times n}$ , define  $V_W \in \{0, 1\}^{(n-1) \times (n-1)}$  by

$$V_W = \frac{1}{2} (W(1) + J_{n-1}),$$

where  $W(1)$  is obtained from  $W$  by deleting the first row and column.

A **signature matrix** is a  $\pm 1$  diagonal matrix.

A **Hadamard matrix** of order  $n$  is a matrix  $H_n \in \{\pm 1\}^{n \times n}$  with  $H_n H_n^T = nI_n$ .

A **2-design** with parameters  $(v, k, \lambda)$  (also called a  $(v, k, \lambda)$ -**design**) is a collection of  $k$ -subsets  $B_i$ , called **blocks**, of a finite set  $X$  with cardinality  $v$ , such that each 2-subset of  $X$  is contained in exactly  $\lambda$  blocks.

The  $(\pm 1)$ -**incidence matrix**  $W = (w_{ij})$  of a 2-design is a matrix whose rows are indexed by the elements  $x_i$  of  $X$  and whose columns are indexed by the blocks  $B_j$ . The entry  $w_{ij} = -1$  if  $x_i \in B_j$  and  $w_{ij} = +1$  otherwise.

### Facts:

- For any  $W \in \{\pm 1\}^{n \times n}$ , there exist signature matrices  $S_1, S_2$  such that for  $W' = (S_1 W S_2)$ ,  $W'_{1j} = 1$  for  $j = 1, \dots, n$  and  $W'_{i1} = -1$  for  $i = 2, \dots, n$ .  $W$  is D-optimal if and only if  $W'$  is D-optimal.
- $\det W_V = 2^{n-1} \det V$ .
- [Wil46] The  $(\pm 1)$  square case in dimension  $n$  is related to the  $(0, 1)$  square case in dimension  $n - 1$  by the previous two facts, and  $\alpha(n) = 4^{n-1} \beta(n - 1)$ . Facts are stated here for  $\alpha(n)$  only, since the facts for  $\beta(n)$  can be easily derived from these.
- [Had93], [CRC96], [BJL93], [WPS72] Hadamard matrices
  - A necessary condition for the existence of a Hadamard matrix of order  $n$  is  $n = 1, n = 2$ , or  $n \equiv 0 \pmod{4}$ .
  - Let  $H_m$  and  $H_n$  be two Hadamard matrices of orders  $m$  and  $n$ , respectively. Then  $H_m \otimes H_n$  is a Hadamard matrix of order  $mn$ .
  - There exist infinitely many values  $n$  for which a Hadamard matrix  $H_n$  exists.
  - It is conjectured that for all  $n = 4k$  there exists a Hadamard matrix  $H_n$ .
  - The smallest  $n$  for which the existence of a Hadamard matrix is in question (at the time of the writing of this chapter) is  $n = 668$ .
- [Had93], [CRC96], [BJL93], [WPS72] D-optimal  $(\pm 1)$ -matrices: the case  $n = 4k$ 
  - $\alpha(4k) \leq (4k)^{4k}$ .
  - A necessary and sufficient condition for equality to occur in this case is the existence of a Hadamard matrix of order  $n$ .
- [Bar33], [Woj64], [Ehl64a], [Coh67], [Neu97] D-optimal  $(\pm 1)$ -matrices: the case  $n = 4k + 1$ 
  - $\alpha(4k + 1) \leq (8k + 1)(4k)^{4k}$ .
  - For equality to occur in this case, it is necessary and sufficient that  $8k + 1$  is the square of an integer and that there exists a matrix  $W \in \{\pm 1\}^{m \times n}$  with  $W^T W = (n - 1)I_n + J_n$ .

- Equality occurs for infinitely many values of  $n = 4k + 1$ . A.E. Brouwer ([Bro83]) constructed an infinite family of 2-designs with parameters  $(n = 2q^2 + 2q + 1, q^2, (q^2 - q)/2)$ . The  $(\pm 1)$ -incidence matrix  $W_n$  of such a design satisfies  $W_n^T W_n = (n - 1)I_n + J_n$ .
  - The results in [MK82] and [CMK87] provide upper bounds, which are stronger than  $(8k + 1)(4k)^{4k}$  in case  $8k + 1$  is not the square of an integer.
7. [Ehl64a], [Woj64] D-optimal  $(\pm 1)$ -matrices: the case  $n = 4k + 2$
- $\alpha(4k + 2) \leq (8k + 2)^2 (4k)^{4k}$ .
  - For equality to occur in this case, it is necessary that  $n - 1$  is the sum of two squares and that there exists a matrix  $W_n \in \{\pm 1\}^{n \times n}$  such that

$$W_n^T W_n = \begin{bmatrix} (n - 2)I_{\frac{n}{2}} + 2J_{\frac{n}{2}} & 0_n \\ 0_n & (n - 2)I_{\frac{n}{2}} + 2J_{\frac{n}{2}} \end{bmatrix}. \tag{32.1}$$

- It is conjectured that the bound is attained whenever this is the case.
  - The bound is attained infinitely often.
  - If  $n - 1$  is a square and there exists a matrix  $W_{\frac{n}{2}} \in \{\pm 1\}^{\frac{n}{2} \times \frac{n}{2}}$  such that  $W_{\frac{n}{2}}^T W_{\frac{n}{2}} = \frac{n-2}{2}I_{\frac{n}{2}} + J_{\frac{n}{2}}$ , then construct the matrix  $W_n = W_{\frac{n}{2}} \otimes H_2$  where
- $$H_2 = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}.$$
- Then  $W_n \in \{\pm 1\}^{n \times n}$  satisfies Equation (32.1) and attains the bound. Such a matrix  $W_{\frac{n}{2}}$  exists if  $\frac{n}{2} = 2q^2 + 2q + 1$ .
8. [Ehl64b] D-optimal  $(\pm 1)$ -matrices: The case  $n = 4k + 3$

$$\alpha(4k + 3) \leq (4k)^{4k+3-s} (4k + 4r)^u (4k + 4 + 4r)^v \left( 1 - \frac{ur}{4k + 4r} - \frac{v(r + 1)}{4k + 4 + 4r} \right),$$

where  $s = 5$  for  $k = 1$ ,  $s = 5$  or  $6$  for  $k = 2$ ,  $s = 6$  for  $3 \leq k \leq 14$ , and  $s = 7$  for  $k \geq 15$  and where  $r = \lfloor (4k + 3)/s \rfloor$ ,  $4k + 3 = rs + v$ , and  $u = s - v$ .

- This case is the least well understood of the four.
  - For equality to occur for  $n \geq 63$ , it is necessary that  $n = 112j^2 \pm 28j + 7$  and that there exists a matrix  $W_n \in \{\pm 1\}^{n \times n}$  with
- $$W_n^T W_n = I_7 \otimes \left[ (n - 3)I_{\frac{n}{7}} + 4J_{\frac{n}{7}} \right] - J_n.$$
- However, it is not known if this bound is attainable for any  $n \geq 63$ .
  - The best lower bound seems to be the one in [NR97]. In [NR97], an infinite family of matrices is constructed whose determinants attain about 37% of the bound above.
9. See [OS] for  $(\pm 1)$ -matrices with largest known determinant for  $n \leq 103$ .

**Examples:**

1. The following matrices are Hadamard matrices in  $\{\pm 1\}^{4 \times 4}$  and  $\{\pm 1\}^{12 \times 12}$ :

$$H_4 = \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & -1 & 1 & -1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 \end{bmatrix}$$

$$H_{12} = \begin{bmatrix} 1 & 1 & 1 & 1 & -1 & -1 & -1 & 1 & 1 & 1 & -1 & -1 \\ 1 & 1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 \\ 1 & 1 & 1 & -1 & -1 & 1 & 1 & 1 & -1 & -1 & -1 & 1 \\ 1 & -1 & -1 & 1 & -1 & -1 & 1 & -1 & -1 & -1 & -1 & -1 \\ -1 & 1 & -1 & -1 & 1 & -1 & -1 & 1 & -1 & -1 & -1 & -1 \\ -1 & -1 & 1 & -1 & -1 & 1 & -1 & -1 & 1 & -1 & -1 & -1 \\ -1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 & -1 & -1 & 1 & 1 \\ 1 & -1 & 1 & -1 & 1 & -1 & -1 & -1 & -1 & 1 & -1 & 1 \\ 1 & 1 & -1 & -1 & -1 & 1 & -1 & -1 & -1 & 1 & 1 & -1 \\ 1 & -1 & -1 & -1 & -1 & -1 & -1 & 1 & 1 & -1 & 1 & 1 \\ -1 & 1 & -1 & -1 & -1 & -1 & 1 & -1 & 1 & 1 & -1 & 1 \\ -1 & -1 & 1 & -1 & -1 & -1 & 1 & 1 & -1 & 1 & 1 & -1 \end{bmatrix}$$

$H_4 H_4^T = 4I_4$  and  $H_{12} H_{12}^T = 12I_{12}$ .

2. Let  $A = J_5 - 2I_5$ . Then  $A^T A = 4I_5 + J_5$  and  $\det(A^T A)$  achieves the upper bound in Fact 6.
3. Let

$$W = \begin{bmatrix} A & A \\ A & -A \end{bmatrix} = A \otimes H_2 \in \{\pm 1\}^{10 \times 10},$$

where  $A = J_5 - 2I_5$ . Then

$$W^T W = \begin{bmatrix} 8I_5 + 2J_5 & 0 \\ 0 & 8I_5 + 2J_5 \end{bmatrix},$$

and, hence,  $\det(W^T W)$  achieves the upper bound in Fact 7.

4. To obtain the upper bound in Fact 6 for  $n = 13$ , let  $V \in \{0, 1\}^{13 \times 13}$  be the  $(0, 1)$  line-point incidence matrix for a projective plane of order 3. Then  $V^T V = 3I_{13} + J_{13}$  and the matrix  $W = J_{13} - 2V \in \{\pm 1\}^{13 \times 13}$  satisfies  $W^T W = 12I_{13} + J_{13}$  and its determinant attains the upper bound.
5. For  $n \geq 11$  and  $n \equiv 3 \pmod{4}$ , no  $(\pm 1)$ -matrix is known to have a determinant that equals the upper bound in Fact 8. However, the following matrix  $W \in \{\pm 1\}^{15 \times 15}$ , which is listed in [OS], satisfies

$$\det(W^T W) = 174755568785817600,$$

which is about 94% of the upper bound 185454889323724800 in Fact 8 with  $k = 3, s = 6$ .

$$W = \begin{bmatrix} -1 & -1 & -1 & -1 & 1 & 1 & 1 & 1 & 1 & -1 & 1 & 1 & 1 & 1 & -1 \\ -1 & -1 & -1 & 1 & -1 & 1 & 1 & -1 & 1 & 1 & 1 & 1 & -1 & 1 & 1 \\ -1 & -1 & -1 & 1 & 1 & -1 & 1 & 1 & -1 & 1 & 1 & -1 & 1 & 1 & 1 \\ -1 & 1 & 1 & -1 & -1 & 1 & 1 & 1 & -1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & -1 & 1 & -1 & -1 & 1 & 1 & 1 & -1 & 1 & -1 & -1 & -1 & -1 \\ 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 \\ 1 & 1 & 1 & 1 & 1 & 1 & -1 & 1 & 1 & 1 & 1 & -1 & -1 & 1 & -1 \\ -1 & 1 & 1 & -1 & -1 & -1 & -1 & -1 & 1 & -1 & 1 & -1 & 1 & 1 & 1 \\ 1 & 1 & 1 & -1 & -1 & -1 & 1 & 1 & 1 & 1 & -1 & 1 & 1 & 1 & 1 \\ 1 & -1 & 1 & -1 & -1 & -1 & -1 & 1 & -1 & -1 & 1 & 1 & -1 & 1 & 1 \\ 1 & 1 & -1 & -1 & -1 & -1 & -1 & -1 & -1 & 1 & 1 & 1 & 1 & 1 & -1 \\ 1 & 1 & -1 & -1 & 1 & 1 & 1 & -1 & -1 & -1 & -1 & -1 & -1 & 1 & 1 \\ 1 & -1 & 1 & 1 & -1 & 1 & 1 & -1 & -1 & -1 & -1 & -1 & 1 & 1 & -1 \\ -1 & 1 & 1 & 1 & 1 & -1 & 1 & -1 & -1 & -1 & -1 & 1 & -1 & 1 & -1 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 & -1 & -1 & -1 & 1 & 1 & 1 & -1 & 1 \end{bmatrix}.$$

### 32.3 The $(\pm 1)$ Nonsquare Case

---

#### Facts:

1. [Had93]  $\alpha(4k, n) \leq (4k)^n$ .
2. [Pay74]  $\alpha(4k + 1, n) \leq (4k + n)(4k)^{n-1}$ .
3. [Pay74]

$$\alpha(4k + 2, n) \leq \begin{cases} (4k + n)^2(4k)^{n-2}, & \text{if } n \text{ is even,} \\ (4k + n + 1)(4k + n - 1)(4k)^{n-2}, & \text{if } n \text{ is odd.} \end{cases} \quad (32.2)$$

4. [GK80b] If  $m = 4k - 1 \geq 2n - 5$ , then  $\alpha(m, n) \leq (4k - n)(4k)^{n-1}$ .

#### Examples:

1. If  $m = 4k$ , equality can be achieved by taking  $W_0$  to be the matrix consisting of any  $n$  columns of a Hadamard matrix of order  $4k$ . Then  $W_0^T W_0 = 4kI_n$  and, hence,  $\det W_0^T W_0 = \alpha(4k, n)$ .
2. If  $m = 4k + 1$ , adjoin a row of all 1s to  $W_0$  and call the new matrix  $W_1$ . We have  $W_1 \in \{\pm 1\}^{(4k+1) \times n}$  and  $W_1^T W_1 = mI_n + J$ . Hence,  $\det W_1^T W_1 = \alpha(4k + 1, n)$ .
3. If  $m = 4k + 2$ , let  $r_1 = (1, 1, \dots, 1)$  and  $r_2 = (1, \dots, 1, -1, \dots, -1)$  be  $n$ -tuples with  $r_1 \cdot r_2 = 0$ , if  $n$  is even, and  $r_1 \cdot r_2 = 1$ , if  $n$  is odd. Adjoin rows  $r_1$  and  $r_2$  to  $W_0$ . Call the resulting matrix  $W_2$ . Then  $W_2 \in \{\pm 1\}^{(4k+2) \times n}$  and

$$W_2^T W_2 = \begin{bmatrix} 4kI_l + 2J_l & 0_l \\ 0_l & 4kI_l + 2J_l \end{bmatrix} \quad \text{if } n = 2l \text{ is even}$$

and

$$W_2^T W_2 = \begin{bmatrix} 4kI_{l+1} + 2J_{l+1} & 0_{l+1,l} \\ 0_{l,l+1} & 4kI_l + 2J_l \end{bmatrix} \quad \text{if } n = 2l + 1 \text{ is odd.}$$

Thus,  $\det W_2^T W_2 = \alpha(4k + 2, n)$ .

4. If  $m = 4k - 1$ , we may assume without loss of generality that the first row of  $W_0$  is an all 1s row. Remove this first row of  $W_0$  and call that matrix  $W_{-1}$ . Note that  $W_{-1} \in \{\pm 1\}^{(4k-1) \times n}$  and that  $W_{-1}^T W_{-1} = 4kI_n - J_n$ . Hence,  $\det W_{-1}^T W_{-1} = \alpha(4k - 1, n)$ .
5. It is not necessary to have a Hadamard matrix  $H_m$  of order  $m$ . All we require is the existence of a matrix  $W \in \{\pm 1\}^{4k \times n}$  with  $W^T W = mI_n$ . See [GK80a] for details.
6. Upper bounds on  $\alpha(4k - 1, n)$  when  $m = 4k - 1 \leq 2n - 5$  are given in [GK80b], [KF84], [SS91].

### 32.4 The $(0, 1)$ Nonsquare Case: Regular D-Optimal Matrices

---

#### Definitions:

Let  $W$  be a  $(0, 1)$ -design matrix in  $\{0, 1\}^{m \times n}$ . For  $n$  odd,  $W$  is **balanced** if every row of  $W$  has exactly  $(n + 1)/2$  ones; for  $n$  even,  $W$  is **balanced** if every row of  $W$  has exactly  $n/2$  ones or exactly  $(n + 2)/2$  ones.

A design matrix  $W \in \{0, 1\}^{m \times n}$  is **regular** if it is balanced and  $W^T W = t(I + J)$  for some integer  $t$ .

**Facts:**

- [HKL96] If  $n$  is odd, then  $\beta(m, n) \leq (n+1) \left( \frac{(n+1)m}{4n} \right)^n$ , with equality if and only if  $W$  is regular.
- [NWZ97] If  $n$  is even, then  $\beta(m, n) \leq (n+1) \left( \frac{(n+2)m}{4(n+1)} \right)^n$ , with equality if and only if  $W$  is regular.
- [NWZ98a] A regular matrix exists in  $\{0, 1\}^{m \times n}$  only if

$$2(n+1) \text{ divides } m \text{ for } n \equiv 0 \pmod{4},$$

$$2n \text{ divides } m \text{ for } n \equiv 1 \pmod{4},$$

$$n+1 \text{ divides } m \text{ for } n \equiv 2 \pmod{4},$$

$$n \text{ divides } m \text{ for } n \equiv 3 \pmod{4}.$$

- [NWZ98a] If  $n = 4t - 1$  and  $H \in \{0, 1\}^{m \times n}$  is the incidence matrix for a  $(4t - 1, 2t - 1, t - 1)$ -design,

then  $W = J - H$  is a regular D-optimal matrix and  $\overbrace{[W^T, \dots, W^T]^T}^k$  is a regular D-optimal matrix

in  $\{0, 1\}^{kn \times n}$ . Let  $W_1$  be the matrix obtained by deleting any column from  $W$ . Then  $\overbrace{[W_1^T, \dots, W_1^T]^T}^k$  is a regular D-optimal matrix in  $\{0, 1\}^{kn \times (n-1)}$ .

- [NWZ98a] If  $n = 4t + 1$  is a power of a prime integer, then a D-optimal regular matrix  $W_2 \in \{0, 1\}^{2n \times n}$  exists. Let  $W_3 \in \{0, 1\}^{2n \times (n-1)}$  be the matrix obtained by deleting any column from  $W_2$ .

Then  $\overbrace{[W_2^T, \dots, W_2^T]^T}^k$  and  $\overbrace{[W_3^T, \dots, W_3^T]^T}^k$  are regular D-optimal matrices.

**Examples:**

- Let  $n = 4$  and  $m = 10$ . The following matrix is balanced and regular:

$$W^T = \begin{bmatrix} 1 & 1 & 1 & 0 & 1 & 1 & 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 1 & 1 & 0 & 0 & 1 & 1 & 0 \\ 1 & 0 & 1 & 1 & 0 & 1 & 0 & 1 & 0 & 1 \\ 0 & 1 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 1 \end{bmatrix}, \quad W^T W = \begin{bmatrix} 6 & 3 & 3 & 3 \\ 3 & 6 & 3 & 3 \\ 3 & 3 & 6 & 3 \\ 3 & 3 & 3 & 6 \end{bmatrix}.$$

The inequality in Fact 2 is attained at  $W$ :

$$\beta(10, 4) = 5 \left( \frac{6 \cdot 10}{4 \cdot 5} \right)^4 = 405 = \det(W^T W).$$

Thus  $W$  is D-optimal.

- A regular matrix exists for the case  $n = 9, m = 18$ . (Fact 3, where  $n \equiv 1 \pmod{4}$  and  $2n = 18$  divides  $m = 18$ .) The regular matrix is constructed from the Galois field  $GF(9)$  with nine elements. Choosing  $GF(9) = \mathbb{Z}_3/(x^2 + 1)$ , the element  $\theta = x + 2$  of order 8, generates the nonzero elements in  $GF(9)$ . The nonzero quadratic residues of  $GF(9)$  are  $Q = \{1, \theta^2, \theta^4, \theta^6\}$ . Define  $K_1 \in \{0, 1\}^{9 \times 9}$  by

$$(K_1)_{\rho, \tau} = \begin{cases} 1, & \text{if } \tau \in \rho + Q, \\ 0, & \text{if otherwise,} \end{cases}$$

where the rows and columns  $\rho, \tau$  are indexed by  $\{0, 1, \theta, \theta^2, \dots, \theta^7\}$ . Then

$$K_1 = \begin{bmatrix} 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 1 \\ 0 & 0 & 0 & 1 & 1 & 1 & 0 & 0 & 1 \\ 1 & 0 & 1 & 0 & 0 & 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & 0 & 0 & 1 & 1 & 1 & 0 \\ 1 & 1 & 1 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 & 1 \\ 1 & 0 & 0 & 1 & 1 & 0 & 1 & 0 & 0 \\ 0 & 1 & 1 & 1 & 0 & 0 & 1 & 0 & 0 \end{bmatrix}.$$

Define  $K_2$  in the same way but with the nonzero quadratic nonresidues  $R = \{\theta, \theta^3, \theta^5, \theta^7\}$  in place of  $Q$ . Then the matrix  $[K_1, K_2] \in \{0, 1\}^{9 \times 18}$  satisfies

$$K_1 K_1^T + K_2 K_2^T = 5I_9 + 3J_9.$$

Let  $W = [J_9 - K_1, J_9 - K_2]$ . Then  $W$  is a D-optimal regular design matrix:  $WW^T = 5(I_9 + J_9)$ .

- Let  $t = 2$  and  $n = 7$ . The following matrix  $H$  is the incidence matrix for a  $(7, 3, 1)$ -design:

$$H = \begin{bmatrix} 0 & 1 & 0 & 1 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 & 0 & 1 \\ 1 & 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 1 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & 0 & 1 & 1 & 0 \end{bmatrix}.$$

Then (Fact 4)  $W = J_7 - H$  is a regular D-optimal matrix in  $\{0, 1\}^{7 \times 7}$  and  $[W^T, \dots, W^T]^T$  is a regular D-optimal matrix in  $\{0, 1\}^{7 \times 7}$ .

### 32.5 The (0, 1) Nonsquare Case: Nonregular D-Optimal Matrices

It is clear from Fact 3 in section 32.4 that for most pairs  $(m, n)$ , no regular D-optimal matrix exists. For example, if  $n = 7$ , then the only values of  $m$  for which a regular D-optimal matrix exists are  $m = 7t$ . Thus, for  $m = 7t + r$ , with  $0 \leq r \leq 6$ , a D-optimal matrix cannot be regular unless  $r = 0$ . The only values of  $n$  for which  $\beta(m, n)$  is known for all values of  $m$  are  $n = 2, 3, 4, 5, 6$ .

**Facts:**

- [HKL96]  $n = 2, m = 3t + r$  with  $r = 0, 1, 2$ :

$$\beta(m, 2) = \begin{cases} 3t^2 & , \text{ for } r = 0 \\ 3t^2 + 2t, & \text{ for } r = 1 \end{cases}.$$

- [HKL96]  $n = 3, m = 3t + r$  with  $r = 0, 1, 2$ :

$$\beta(m, 3) = 4t^{3-r}(t + 1)^r.$$

3. [NWZ98b]  $n = 4$ ,  $m = 10t + r$  with  $0 \leq r \leq 9$ :

$$\beta(m, 4) = \begin{cases} 405 t^4 & , \text{ for } r=0 \\ 81 t^3 (2 + 5 t) & , \text{ for } r=1 \\ 3 t (1 + 3 t)^2 (2 + 15 t) & , \text{ for } r=2 \\ 3 t (1 + 3 t)^2 (8 + 15 t) & , \text{ for } r=3 \\ 3 (1 + 3 t)^3 (3 + 5 t) & , \text{ for } r=4 \\ (1 + 3 t)^2 (19 + 60 t + 45 t^2) & , \text{ for } r=5 \\ 3 (2 + 3 t)^3 (2 + 5 t) & , \text{ for } r=6 \\ 3 (1 + t) (2 + 3 t)^2 (7 + 15 t) & , \text{ for } r=7 \\ 3 (1 + t) (2 + 3 t)^2 (13 + 15 t) & , \text{ for } r=8 \\ 81 (1 + t)^3 (3 + 5 t) & , \text{ for } r=9 \end{cases} .$$

4. [NWZ98b] In the case  $n = 5$ , all D-optimal matrices are balanced except when  $m = 5, 6, 7, 8, 15, 16, 17, 27$ . For  $m = 10t + r$  with  $0 \leq r \leq 9$  and  $m$  not equal to any of the exceptional values, we have

$$\beta(m, 5) = \begin{cases} 1458 t^5 & , \text{ for } r=0 \\ 729 t^4 (1 + 2 t) & , \text{ for } r=1 \\ 162 t^3 (1 + 3 t) (2 + 3 t) & , \text{ for } r=2 \\ 27 t^2 (1 + 3 t)^2 (5 + 6 t) & , \text{ for } r=3 \\ 54 t (1 + t) (1 + 3 t)^3 & , \text{ for } r=4 \\ 9 (1 + t) (1 + 3 t)^2 (1 + 15 t + 18 t^2) & , \text{ for } r=5 \\ 54 (1 + t)^2 (1 + 3 t)^3 & , \text{ for } r=6 \\ 27 (1 + t)^2 (1 + 3 t)^2 (5 + 6 t) & , \text{ for } r=7 \\ 162 (1 + t)^3 (1 + 3 t) (2 + 3 t) & , \text{ for } r=8 \\ 729 (1 + t)^4 (1 + 2 t) & , \text{ for } r=9 \end{cases} .$$

The values of  $\beta(m, 5)$  for the eight exceptional values of  $m$  are

$$\begin{aligned} \beta(5, 5) = 25 & & \beta(6, 5) = 64 & & \beta(7, 5) = 192 & & \beta(8, 5) = 384 \\ \beta(15, 5) = 9880 & & \beta(16, 5) = 13975 & & \beta(17, 5) = 19500 & & \beta(27, 5) = 202752. \end{aligned}$$

Each of these is greater than the value of the corresponding polynomial above. For example, if  $m = 16$  so that  $t = 1$  and  $r = 6$ , then  $54(1+t)^2(1+3t)^3 = 13824$ , which is less than 13975.

5. [NWZ00] For  $n = 6$ , all D-optimal matrices are balanced except when  $m = 6, 8, 9, 13$ . For  $m = 7t + r$  with  $0 \leq r \leq 6$  and  $m \neq 6, 8, 9, 13$ :

$$\beta(m, 6) = \begin{cases} 448 t^6 & , \text{ for } r=0 \\ 16 t^4 (1 + 2 t) (5 + 14 t) & , \text{ for } r=1 \\ 4 t^2 (1 + 2 t)^3 (3 + 14 t) & , \text{ for } r=2 \\ (1 + 2 t)^5 (1 + 14 t) & , \text{ for } r=3 \\ (1 + 2 t)^5 (13 + 14 t) & , \text{ for } r=4 \\ 4 (1 + t)^2 (1 + 2 t)^3 (11 + 14 t) & , \text{ for } r=5 \\ 16 (1 + t)^4 (1 + 2 t) (9 + 14 t) & , \text{ for } r=6 \end{cases}$$

The values of  $\beta(6, m)$  for the four exceptional values of  $m$  are

$$\beta(6, 6) = 81 \quad \beta(8, 6) = 832 \quad \beta(9, 6) = 1620 \quad \beta(13, 6) = 16512.$$

As in the case for  $n = 5$ , the values of  $\beta(m, 6)$  exceed the value of the corresponding polynomial.

**Examples:**

- Design matrices are exhibited for the above cases in the sources listed. For example, if  $n = 4$ , let

$$W_0 = \begin{bmatrix} 1 & 1 & 1 & 0 & 1 & 1 & 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 1 & 1 & 0 & 0 & 1 & 1 & 0 \\ 1 & 0 & 1 & 1 & 0 & 1 & 0 & 1 & 0 & 1 \\ 0 & 1 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 1 \end{bmatrix}^T,$$

$v_i$  be the  $i$ th row of  $W_0$ . If  $r = 3$ , then the matrix  $[W_0^T, \dots, \overbrace{W_0^T}^t, v_8^T, v_9^T, v_{10}^T]^T$  is a D-optimal matrix in  $\{0, 1\}^{(4t+3) \times 4}$ .

### 32.6 The (0, 1) Nonsquare Case: Large $m$

---

**Facts:**

- [NWZ98a] For each value of  $n$ , all D-optimal matrices in  $\{0, 1\}^{m \times n}$  are balanced for sufficiently large values of  $m$ .
- [NW02], [AFN03] In addition to the values  $n = 2, 3, 4, 5, 6$ , for which  $\beta(m, n)$  is known for all  $m$ , the only other values of  $n$  for which  $\beta(m, n)$  is known for all sufficiently large values of  $m$  are  $n = 7, 11, 15, 19, 23, 27$ .

**Examples:**

- [NW02]

$$\beta(7t + r, 7) = 2^{10} t^{7-r} (t + 1)^r,$$

for sufficiently large values of  $m = 7t + r$ .

### 32.7 The (0, 1) Nonsquare Case: $n \equiv -1 \pmod{4}$

---

The theory for D-optimal (0, 1)-designs is most developed for the cases where  $n \equiv -1 \pmod{4}$ .

**Definitions:**

For an  $n \times n$  matrix  $A$ , the **trace-sequence**  $A$  is  $(\text{trace}(A), \text{trace}(A^2), \dots, \text{trace}(A^n))$ .

$\mathcal{G}(v, \delta)$  is the set of all  $\delta$ -regular graphs on  $v$  vertices.

Let graph  $G$  be a graph in  $\mathcal{G}(v, \delta)$  and let  $\mathcal{A}_G$  be the adjacency matrix of  $G$ . The graph  $G$  is **trace-minimal** if the **trace-sequence** of its adjacency matrix  $(\text{trace}(\mathcal{A}_G), \text{trace}(\mathcal{A}_G^2), \dots, \text{trace}(\mathcal{A}_G^n))$  is least in lexicographic order among all graphs in  $\mathcal{G}(v, \delta)$ .

**Facts:**

- [AFN03] If  $n \equiv -1 \pmod{4}$ , then for each  $0 \leq r < n$  and all sufficiently large values of  $t$ ,  $\beta(nt + r, n)$  is a polynomial in  $t$  of degree  $n$ . These polynomials are related to the adjacency matrices  $\mathcal{A}_G$  of certain regular graphs  $G$ .

2. [AFN03], [AFN06] The polynomial  $\beta(nt + r, n)$  depends on a trace-minimal graph in  $\mathcal{G}(v, \delta)$ . Once a trace-minimal graph  $G$  is found in the appropriate graph class  $\mathcal{G}(v, \delta)$ , the polynomial  $\beta(nt + r, n)$  can be computed. There are four theorems [AFN03] governing this situation; one for each congruence class of  $r \pmod{4}$ .
3. [AFN03] Trace-minimal graphs are known for all of the graph classes necessary to obtain formulas for  $\beta(nt + r, n)$  for  $n = 3, 7, 11, 15, 19, 23$ , and  $27$  and  $t$  sufficiently large.
4. [AFN06] Let  $G$  be a connected strongly regular graph with no three cycles. Then  $G$  is trace-minimal.
5. [AFN06] The following graphs are trace-minimal in their graph class:

Graph Class	$G$
$\mathcal{G}(v, 0)$	Graph with $v$ vertices and no edges
$\mathcal{G}(2v, 1)$	$vK_2$ , a matching of $2v$ vertices
$\mathcal{G}(v, 2)$	$C_v$ , the cycle graph on $v$ vertices
$\mathcal{G}(2v, v)$	$K_{v,v}$ , the complete bipartite graph with $v$ vertices in each set of the bipartition
$\mathcal{G}(2v, 2v - 2)$	$K_{2v} - vK_2$ , the complement of a matching
$\mathcal{G}(v, v - 1)$	$K_v$ , the complete graph on $v$ vertices

6. [AFN06] Let  $G$  be a connected regular graph with girth  $g$  such that  $\mathcal{A}_G$  has  $k+1$  distinct eigenvalues. If  $g$  is even, then  $g \leq 2k$  with equality only if  $G$  is trace-minimal. If  $g$  is odd, then  $g \leq 2k + 1$  with equality only if  $G$  is trace-minimal.

**Examples:**

1. Let  $n = 4p - 1 \equiv -1 \pmod{4}$  and  $r = 4d + 2 \equiv 2 \pmod{4}$ . Let  $G$  be a trace-minimal graph in  $\mathcal{G}(2p, p + d)$ . Then

$$\beta(nt + r, n) = \frac{4t[p_{\mathcal{A}_G}(pt + d)]^2}{(t - 1)^2},$$

for sufficiently large values of  $t$ . Taking  $n = 15, r = 10$ , we have  $p = 4, d = 2$ . The appropriate graph class is  $\mathcal{G}(8, 6)$ . There is only one graph  $G$  in this class, namely the complement of the matching  $4K_2$ . Thus, it is trace-minimal. Since  $p_{\mathcal{A}_G}(x) = (x - 6)x^4(x + 2)^3$ ,

$$\beta(15t + 10, 15) = \frac{4t[p_{\mathcal{A}_G}(4t + 2)]^2}{(t - 1)^2} = 16(4t)(4t + 2)^8(4t + 4)^6,$$

for sufficiently large  $t$ .

2. Let  $n = 4p - 1 \equiv -1 \pmod{4}$  and  $r = 4d + 1 \equiv 1 \pmod{4}$ . Let  $G$  be a trace-minimal graph in  $\mathcal{G}(2p, d)$ . Then

$$\beta(nt + r, n) = \frac{4(t + 1)[p_{\mathcal{A}_G}(pt + d)]^2}{t^2},$$

for sufficiently large  $t$ . Taking  $n = 15, r = 9$  we have  $p = 4, d = 2$ . The appropriate graph class is  $\mathcal{G}(8, 2)$ . There are three (nonisomorphic) graphs in this class:  $C_8, C_5 \cup C_3$ , and  $C_4 \cup C_4$ , where  $C_k$  stands for a  $k$ -cycle graph. The trace sequences for these three graphs are

$$(\text{trace}(\mathcal{A}_G), \text{trace}(\mathcal{A}_G^2), \dots, \text{trace}(\mathcal{A}_G^8)) = \begin{cases} (0, 16, 0, 48, 0, 160, 0, 576) & , \text{ for } G = C_8 \\ (0, 16, 6, 48, 40, 166, 196, 608) & , \text{ for } G = C_5 \cup C_3 \\ (0, 16, 0, 64, 0, 256, 0, 1024) & , \text{ for } G = C_4 \cup C_4. \end{cases}$$

FIGURE 32.1

Thus,  $C_8$  is the only trace-minimal graph in the graph class  $\mathcal{G}(8, 2)$ . The characteristic polynomial for  $\mathcal{A}_{C_8}$  is

$$(x - 2)x^2(x + 2)(x^2 - 2)^2.$$

Thus,

$$\beta(15t + 9, 15) = \frac{4(t + 1)[p_{\mathcal{A}_G}(4t + 2)]^2}{t^2} = 16(4t + 2)^4(4t + 4)^3(16t^2 + 16t + 2)^4.$$

3. The Petersen graph (Figure 32.1) is an example of a strongly regular graph. (See Fact 4.) It is trace-minimal in  $\mathcal{G}(10, 3)$ :
4. Let  $P$  be the projective geometry with seven points, 1, 2, 3, 4, 5, 6, 7 and seven lines, 123, 147, 156, 257, 246, 367, 345 (Figure 32.2): The line-point incidence matrix for  $P$  is:

$$N = \begin{bmatrix} 1 & 1 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 1 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 0 & 1 & 0 & 1 \\ 0 & 1 & 0 & 1 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & 1 & 1 & 0 & 0 \end{bmatrix}.$$

FIGURE 32.2

Let  $G$  be the incidence graph of  $P$  having 14 vertices and adjacency matrix given by

$$\mathcal{A}_G = \begin{bmatrix} 0 & N \\ N^T & 0 \end{bmatrix}.$$

Then  $G$  is trace-minimal by Fact 6:  $G$  is a regular graph of degree 3. The girth of  $G$  is  $g = 6$ . The characteristic polynomial of  $\mathcal{A}_G$  is  $(x - 3)(x + 3)(x^2 - 2)^6$  and so  $\mathcal{A}_G$  has  $k + 1 = 4$  distinct eigenvalues. Since  $2k = g$ , it follows that  $G$  is trace-minimal in  $\mathcal{G}(14, 3)$ .

## 32.8 Balanced $(0, 1)$ -Matrices and $(\pm 1)$ -Matrices

Let  $n = 2k - 1$  be odd. There is a connection between balanced  $(0, 1)$ -design matrices and  $(\pm 1)$ -design matrices.

### Facts:

1. [NWZ98a] Let  $W$  be a balanced design matrix in  $\{0, 1\}^{m \times n}$ , so that each row of  $W$  contains exactly  $k$  ones and  $k - 1$  zeros. Let  $q$  be a positive integer and

$$L(W) = \begin{bmatrix} J_{n,1} & J_{n,m} - 2W^T \\ J_{q,1} & J_{q,m} \end{bmatrix}.$$

Then  $\det L(W)^T L(W) = q4^m \det W^T W$ . It follows that for sufficiently large  $m$ , if  $W$  is a balanced  $(0, 1)$ -design matrix and  $L(W)$  is a D-optimal design matrix, then  $W$  is also D-optimal.

The origins of sign pattern matrices are in the book [Sam47] by the Nobel Economics Prize winner P. Samuelson, who pointed to the need to solve certain problems in economics and other areas based only on the signs of the entries of the matrices. The study of sign pattern matrices has become somewhat synonymous with qualitative matrix analysis. The dissertation of C. Eschenbach [Esc87], directed by C.R. Johnson, studied sign pattern matrices that “require” or “allow” certain properties and summarized the work on sign patterns up to that point. In 1995, Richard Brualdi and Bryan Shader produced a thorough treatment [BS95] on sign pattern matrices from the sign-solvability vantage point. There is such a wealth of information contained in [BS95] that it is not possible to represent all of it here. Since 1995 there has been a considerable number of papers on sign patterns and some generalized notions such as ray patterns. We remark that in this chapter we mostly use  $\{+, -, 0\}$  notation for sign patterns, whereas in the literature  $\{1, -1, 0\}$  notation is also commonly used, such as in [BS95]. We further note that because of the interplay between sign pattern matrices and graph theory, the study of sign patterns is regarded as a part of combinatorial matrix theory.

---

#### Definitions:

A **sign pattern matrix** (or **sign pattern**) is a matrix whose entries come from the set  $\{+, -, 0\}$ . For a real matrix  $B$ ,  $\text{sgn}(B)$  is the sign pattern whose entries are the signs of the corresponding entries in  $B$ .

If  $A$  is an  $m \times n$  sign pattern matrix, the **sign pattern class** (or **qualitative class**) of  $A$ , denoted  $Q(A)$ , is the set of all  $m \times n$  real matrices  $B$  with  $\text{sgn}(B) = A$ . If  $C$  is a real matrix, its qualitative class is given by  $Q(C) = Q(\text{sgn}(C))$ .

A **generalized sign pattern**  $\tilde{A}$  is a matrix whose entries are from the set  $\{+, -, 0, \#\}$ , where  $\#$  indicates an ambiguous sum (the result of adding  $+$  with  $-$ ). The qualitative class of  $\tilde{A}$  is defined by allowing the  $\#$  entries to be completely free. Two generalized sign patterns are **compatible** if there is a common real matrix in their qualitative classes.

A **subpattern**  $\hat{A}$  of a sign pattern  $A$  is a sign pattern obtained by replacing some (possibly none) of the nonzero entries in  $A$  with 0; this fact is denoted by  $\hat{A} \preceq A$ .

A **diagonal pattern** is a square sign pattern all of whose off-diagonal entries are zero. Similarly, standard matrix terms such as “tridiagonal” and “upper triangular” can be applied to sign patterns having the required pattern of zero entries.

A **permutation pattern** is a square sign pattern matrix with entries 0 and  $+$ , where the entry  $+$  occurs precisely once in each row and in each column.

A **permutational similarity** of the (square) sign pattern  $A$  is a product of the form  $P^T A P$ , where  $P$  is a permutation pattern.

A **permutational equivalence** of the sign pattern  $A$  is a product of the form  $P_1 A P_2$ , where  $P_1$  and  $P_2$  are permutation patterns.

The **identity** pattern of order  $n$ , denoted  $I_n$ , is the  $n \times n$  diagonal pattern with  $+$  diagonal entries.

A **signature pattern** is a diagonal sign pattern matrix, each of whose diagonal entries is  $+$  or  $-$ .

A **signature similarity** of the (square) sign pattern  $A$  is a product of the form  $S A S$ , where  $S$  is a signature pattern.

If  $P$  is a property referring to a real matrix, then a sign pattern  $A$  **requires**  $P$  if every real matrix in  $Q(A)$  has property  $P$ , or **allows**  $P$  if some real matrix in  $Q(A)$  has property  $P$ .

The **digraph** of an  $n \times n$  sign pattern  $A = [a_{ij}]$ , denoted  $\Gamma(A)$ , is the digraph with vertex set  $\{1, 2, \dots, n\}$ , where  $(i, j)$  is an arc iff  $a_{ij} \neq 0$ . (See Chapter 29 for more information on digraphs.)

The **signed digraph** of an  $n \times n$  sign pattern  $A = [a_{ij}]$ , denoted  $D(A)$ , is the digraph with vertex set  $\{1, 2, \dots, n\}$ , where  $(i, j)$  is an arc (bearing  $a_{ij}$  as its sign) iff  $a_{ij} \neq 0$ .

If  $A = [a_{ij}]$  is an  $n \times n$  sign pattern matrix, then a (**simple**) **cycle of length**  $k$  (or a  $k$ -**cycle**) in  $A$  is a formal product of the form  $\gamma = a_{i_1 i_2} a_{i_2 i_3} \dots a_{i_k i_1}$ , where each of the elements is nonzero and the index set  $\{i_1, i_2, \dots, i_k\}$  consists of distinct indices. The **sign** (positive or negative) of a simple cycle in a sign pattern  $A$  is the actual product of the entries in the cycle, following the obvious rules that multiplication is commutative and associative, and  $(+)(+) = +$ ,  $(+)(-) = -$ .

A **composite cycle**  $\gamma$  in  $A$  is a product of simple cycles, say  $\gamma = \gamma_1 \gamma_2 \dots \gamma_m$ , where the index sets of the  $\gamma_i$ 's are mutually disjoint. If the length of  $\gamma_i$  is  $l_i$ , then the length of  $\gamma$  is  $\sum_{i=1}^m l_i$ , and the **signature** of  $\gamma$  is  $(-)^{\sum_{i=1}^m (l_i - 1)}$ . A cycle  $\gamma$  is **odd** (**even**) when the length of the simple or composite cycle  $\gamma$  is odd (even).

If  $A = [a_{ij}]$  is an  $n \times n$  sign pattern matrix, then a **path** of length  $k$  in  $A$  is a formal product of the form  $a_{i_1 i_2} a_{i_2 i_3} \dots a_{i_k i_{k+1}}$ , where each of the elements is nonzero and the indices  $i_1, i_2, \dots, i_{k+1}$  are distinct.

### Facts:

1. Simple cycles and paths in an  $n \times n$  sign pattern matrix  $A$  correspond to simple cycles and paths in the digraph of  $A$ . In particular, the path  $a_{i_1 i_2} a_{i_2 i_3} \dots a_{i_k i_{k+1}}$  in  $A$  corresponds to the path  $i_1 \rightarrow i_2 \rightarrow \dots \rightarrow i_{k+1}$  in the digraph of  $A$ .
2. If  $A$  is an  $n \times n$  sign pattern, then each nonzero term in  $\det(A)$  is the product of the signature of a composite cycle  $\gamma$  of length  $n$  in  $A$  with the actual product of the entries in  $\gamma$ .
3. Two generalized sign patterns are compatible if and only if the signs of each position whose sign is specified in both are equal.

### Examples:

1. The matrix  $\begin{bmatrix} 0 & 5 & -4 \\ -2 & -1 & 7 \end{bmatrix}$  is in  $Q(A)$ , where  $A = \begin{bmatrix} 0 & + & - \\ - & - & + \end{bmatrix}$ .

$$2. \text{ If } A = [a_{ij}] = \begin{bmatrix} + & + & 0 & - & + \\ 0 & - & - & - & + \\ + & - & - & + & + \\ - & - & + & - & + \\ + & - & 0 & - & - \end{bmatrix},$$

then the composite cycle  $\gamma = (a_{12}a_{23}a_{31})(a_{45}a_{54})$  has length 5 and negative signature, and yields the term  $-a_{12}a_{23}a_{31}a_{45}a_{54} = -$  in  $\det(A)$ .

$$3. \text{ If } A = \begin{bmatrix} + & + \\ + & - \end{bmatrix}, \text{ then } A^2 = \begin{bmatrix} + & \# \\ \# & + \end{bmatrix}, \text{ which is compatible with } \begin{bmatrix} + & - \\ 0 & \# \end{bmatrix}.$$

### 33.2 Sign Nonsingularity

---

**Definitions:**

A square sign pattern  $A$  is **sign nonsingular** (SNS) if every matrix  $B \in Q(A)$  is nonsingular.

A **strong sign nonsingular** sign pattern, abbreviated an  $S^2NS$ -pattern, is an SNS-pattern  $A$  such that the matrix  $B^{-1}$  is in the same sign pattern class for all  $B \in Q(A)$ .

A **self-inverse sign pattern** is an  $S^2NS$ -pattern  $A$  such that  $B^{-1} \in Q(A)$  for every matrix  $B \in Q(A)$ .

A **maximal** sign nonsingular sign pattern matrix is an SNS-pattern  $A$  where no zero entry of  $A$  can be set nonzero so that the resulting pattern is SNS.

A **nearly sign nonsingular** (NSNS) sign pattern matrix is a square pattern  $A$  having at least two nonzero terms in the expansion of its determinant, with precisely one nonzero term having opposite sign to the others.

A square sign pattern  $A$  is **sign singular** if every matrix  $B \in Q(A)$  is singular.

The **zero pattern** of a sign pattern  $A$ , denoted  $|A|$ , is the  $(0, +)$ -pattern obtained by replacing each  $-$  entry in  $A$  by a  $+$ .

Since a sign pattern may be represented by any real matrix in its qualitative class, many concepts defined on sign patterns (such as SNS and  $S^2NS$ ) may be applied to real matrices.

**Facts:**

Most of the following facts can be found in [BS95, Chaps. 1–4 and 6–8].

1. The  $n \times n$  sign pattern  $A$  is sign nonsingular if and only if  $\det(A) = +$  or  $\det(A) = -$ , that is, in the standard expansion of  $\det(A)$  into  $n!$  terms, there is at least one nonzero term, and all the nonzero terms have the same sign.
2. An  $n \times n$  pattern  $A$  is an SNS-pattern iff for any  $n \times n$  signature pattern  $D$  and any  $n \times n$  permutation patterns  $P_1, P_2$ ,  $DP_1AP_2$  is an SNS-pattern.
3. [BMQ68] For any SNS-pattern  $A$ , there exist a signature pattern  $D$  and a permutation pattern  $P$  such that  $DPA$  has negative diagonal entries.
4. [BMQ68] An  $n \times n$  sign pattern  $A$  with negative main diagonal is SNS iff the actual product of entries of every simple cycle in  $A$  is negative.
5. [Gib71] If an  $n \times n$ ,  $n \geq 3$ , sign pattern  $A$  is SNS, then  $A$  has at least  $\binom{n-1}{2}$  zero entries, with exactly this number iff there exist permutation patterns  $P_1$  and  $P_2$  such that  $P_1AP_2$  has the same zero/nonzero pattern as the Hessenberg pattern given in Example 1 below.
6. The fully indecomposable maximal SNS-patterns of order  $\leq 9$  are given in [LMV96]. [GOD96] An  $n \times n$  sign pattern  $A$  is a fully indecomposable maximal SNS-pattern with  $\binom{n-1}{2}$  zero entries iff  $A$  is equivalent (namely, one can be transformed into the other by any combination of transposition, multiplication by permutation patterns, and multiplication by signature patterns) to the pattern given in Example 1 below. For  $n \geq 5$ , there is precisely one equivalence class of fully indecomposable

maximal SNS-patterns with  $\binom{n-1}{2} + 1$  zero entries, and there are precisely two such equivalence classes having  $\binom{n-1}{2} + 2$  zero entries.

7. [BS95, Corollary 1.2.8] If  $A$  is an  $n \times n$  sign pattern, then  $A$  is an  $S^2NS$ -pattern iff
  - (a)  $A$  is an SNS-pattern, and
  - (b) For each  $i$  and  $j$  with  $a_{ij} = 0$ , the submatrix  $A(i, j)$  of  $A$  of order  $n - 1$  obtained by deleting row  $i$  and column  $j$  is either an SNS-pattern or a sign singular pattern.
8. [BMQ68] If  $A$  is an  $n \times n$  sign pattern with negative main diagonal, then  $A$  is an  $S^2NS$ -pattern iff
  - (a) The actual product of entries of every simple cycle in  $A$  is negative, and
  - (b) The actual product of entries of every simple path in  $A$  is the same, for any paths with the same initial row index and the same terminal column index.
9. [LLM95] An irreducible sign pattern  $A$  is NSNS iff there exists a permutation pattern  $P$  and a signature pattern  $S$  such that  $B = APS$  satisfies:
  - (a)  $b_{ii} < 0$  for  $i = 1, 2, \dots, n$ .
  - (b) The actual product of entries of every cycle of length at least 2 of  $D(B)$  is positive.
  - (c)  $D(B)$  is intercylic (namely, any two cycles of lengths at least two have a common vertex).
10. [Bru88] An  $n \times n$  sign pattern  $A$  is SNS iff  $\text{per}(|B|) = |\det(B)|$ , where  $B$  is the  $(1, -1, 0)$ -matrix in  $Q(A)$  and  $|B|$  is obtained from  $B$  by replacing every  $-1$  entry with 1.
11. [Tho86] The problem of determining whether a given sign pattern  $A$  is an SNS-pattern is equivalent to the problem of determining whether a certain digraph related to  $D(A)$  has an even cycle.

For further reading, see [Kas63], [Bru88], [BS91], [BC92], [EHJ93], [BCS94a], [LMO96], [SS01], and [SS02].

### Examples:

1. For  $n \geq 2$ , the following Hessenberg pattern is SNS:

$$H_n = \begin{bmatrix} - & + & 0 & \dots & 0 & 0 \\ - & - & + & \dots & 0 & 0 \\ - & - & - & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ - & - & - & \dots & - & + \\ - & - & - & \dots & - & - \end{bmatrix}.$$

2. [BS95, p. 11] For  $n \geq 2$ , the following Hessenberg pattern is  $S^2NS$ :

$$G_n = \begin{bmatrix} + & - & 0 & \dots & 0 & 0 \\ 0 & + & - & \dots & 0 & 0 \\ 0 & 0 & + & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \dots & + & - \\ + & 0 & 0 & \dots & 0 & + \end{bmatrix}.$$

3.

$$A = \begin{bmatrix} - & + & 0 & 0 \\ 0 & - & + & 0 \\ 0 & 0 & - & + \\ - & 0 & 0 & - \end{bmatrix}$$

is  $S^2NS$  with inverse pattern

$$\begin{bmatrix} - & - & - & - \\ + & - & - & - \\ + & + & - & - \\ + & + & + & - \end{bmatrix}.$$

4. [BS95, p. 114] The following patterns are maximal SNS-patterns:

$$\begin{bmatrix} - & + & 0 \\ - & - & + \\ - & - & - \end{bmatrix}, \quad \begin{bmatrix} - & + & 0 & + \\ - & - & + & 0 \\ 0 & - & - & + \\ - & 0 & - & - \end{bmatrix}.$$

### 33.3 Sign-Solvability, $L$ -Matrices, and $S^*$ -Matrices

---

**Definitions:**

A system of linear equations  $Ax = b$  (where  $A$  and  $b$  are both sign patterns or both real matrices) is **sign-solvable** if for each  $\tilde{A} \in Q(A)$  and for each  $\tilde{b} \in Q(b)$ , the system  $\tilde{A}x = \tilde{b}$  is consistent and

$$\{\tilde{x} : \text{there exist } \tilde{A} \in Q(A) \text{ and } \tilde{b} \in Q(b) \text{ with } \tilde{A}\tilde{x} = \tilde{b}\}$$

is entirely contained in one qualitative class.

A sign pattern or real matrix  $A$  is an  **$L$ -matrix** if for every  $B \in Q(A)$ , the rows of  $B$  are linearly independent.

A **barely  $L$ -matrix** is an  $L$ -matrix that is not an  $L$ -matrix if any column is deleted.

An  $n \times (n + 1)$  matrix  $B$  is an  **$S^*$ -matrix** provided that each of the  $n + 1$  matrices obtained by deleting a column of  $B$  is an SNS matrix.

An  $n \times (n + 1)$  matrix  $B$  is an  **$S$ -matrix** if it is an  $S^*$ -matrix and the kernel of every matrix in  $Q(B)$  contains a vector all of whose coordinates are positive.

A **signing** of order  $k$  is a nonzero  $(0, 1, -1)$ - or  $(0, +, -)$ -diagonal matrix of order  $k$ .

A signing  $D' = \text{diag}(d'_1, d'_2, \dots, d'_k)$  is an **extension** of the signing  $D = \text{diag}(d_1, d_2, \dots, d_k)$  if  $D' \neq D$  and  $d'_i = d_i$  whenever  $d_i \neq 0$ .

A **strict signing** is a signing where all the diagonal entries are nonzero.

Let  $D = \text{diag}(d_1, d_2, \dots, d_k)$  be a signing of order  $k$  and let  $A$  be an  $m \times n$  (real or sign pattern) matrix. If  $k = m$ , then  $DA$  is a **row signing** of the matrix  $A$ , and if  $D$  is strict, then  $DA$  is a **strict row signing** of the matrix  $A$ . If  $k = n$ , then  $AD$  is a **column signing** of the matrix  $A$ , and if  $D$  is strict, then  $AD$  is a **strict column signing** of the matrix  $A$ .

A real or sign pattern vector is **balanced** provided either it is a zero vector or it has both a positive entry and a negative entry. A vector  $v$  is **unsigned** if it is not balanced. A **balanced row signing** of the matrix  $A$  is a row signing of  $A$  in which all the columns are balanced. A **balanced column signing** of the matrix  $A$  is a column signing of  $A$  in which all the rows are balanced.

**Facts:**

Most of the following facts can be found in [BS95, Chaps. 1–3].

1. A square sign pattern  $A$  is an  $L$ -matrix iff  $A$  is an SNS matrix.
2. The linear system  $Ax = 0$  is sign-solvable iff  $A^T$  is an  $L$ -matrix
3. If  $Ax = b$  is sign-solvable, then  $A^T$  is an  $L$ -matrix.
4.  $Ax = b$  is sign-solvable for all  $b$  if  $A$  is a square matrix and there exists a permutation matrix  $P$  such that  $PA$  is an invertible diagonal matrix.
5. Sign-solvability has been studied using signed digraphs; see [Man82], [Han83], [BS95, Chap. 3], and [Sha00].
6. [BS95] Let  $A$  be a matrix of order  $n$  and let  $b$  be an  $n \times 1$  vector. Then  $Ax = b$  is sign-solvable iff  $A$  is an SNS-matrix and for each  $i$ ,  $1 \leq i \leq n$ , the matrix  $A(i \leftarrow b)$ , obtained from  $A$  by replacing the  $i$ -th column by  $b$ , is either an SNS matrix or has an identically zero determinant.
7. [BS95] If  $AX = B$  is a sign-solvable linear system where  $A$  and  $B$  are square matrices of order  $n$  and  $B$  does not have an identically zero determinant, then  $A$  is an  $S^2NS$  matrix.
8. [BS95] Let  $Ax = b$  be a linear system such that  $A$  has no zero rows. Then the linear system  $Ax = b$  is sign-solvable and the vectors in its qualitative solution class have no zero coordinates iff the matrix  $[A \mid -b]$  is an  $S^*$ -matrix.
9. An  $n \times (n + 1)$  matrix  $B$  is an  $S^*$ -matrix iff there exists a vector  $w$  with no zero coordinates such that the kernels of the matrices  $\tilde{B} \in Q(B)$  are contained in  $\{0\} \cup Q(w) \cup Q(-w)$ .
10. [Man82] and [KLM84] Let  $A = [a_{ij}]$  be an  $m \times n$  matrix and let  $b$  be an  $m \times 1$  vector. Assume that  $z = (z_1, z_2, \dots, z_n)^T$  is a solution of the linear system  $Ax = b$ . Let

$$\beta = \{j : z_j \neq 0\} \text{ and } \alpha = \{i : a_{ij} \neq 0 \text{ for some } j \in \beta\}.$$

Then  $Ax = b$  is sign-solvable iff the matrix  $[A[\alpha, \beta] \mid -b[\alpha]]$  is an  $S^*$ -matrix and the matrix  $A(\alpha, \beta)^T$  is an  $L$ -matrix.

11. [KLM84] A matrix  $A$  is an  $L$ -matrix iff every row signing of  $A$  contains a unisigned column.
12. [BCS94a] An  $m \times n$  matrix  $A$  is a barely  $L$ -matrix iff
  - (a)  $A$  is an  $L$ -matrix.
  - (b) For each  $i = 1, 2, \dots, n$ , there is a row signing of  $A$  such that column  $i$  is the only unisigned column.
13. [BCS94a] An  $m \times n$  matrix  $A$  is an  $S^*$ -matrix iff  $n = m + 1$  and every row signing of  $A$  contains at least two unisigned columns.
14. [BCS94a] An  $m \times n$  matrix  $A$  is an  $S^*$ -matrix iff  $n = m + 1$  and there exists a strict signing  $D$  such that  $AD$  and  $A(-D)$  are the only balanced column signings of  $A$ .
15. [KLM84] A matrix  $A$  is an  $S$ -matrix iff  $A$  is an  $S^*$ -matrix and every row of  $A$  is balanced.
16. Let  $A$  be an  $m \times n$  sign pattern that does not have a  $p \times q$  zero submatrix for any positive integers  $p$  and  $q$  with  $p + q \geq m$ . Then  $A$  is an  $L$ -matrix iff every strict row signing of  $A$  has a unisigned column.

For further reading, see [Sha95], [Sha99], [KS00], and [SR04].

**Examples:**

1.  $\begin{bmatrix} + & - & + & + \\ + & + & - & + \\ + & + & + & - \end{bmatrix}$  is an  $L$ -matrix by Fact 12, and is a barely  $L$ -matrix by Fact 5 of Section 33.2.

2. [BS95, p. 65] The  $m \times (m + 1)$  matrix

$$H'_{m+1} = \begin{bmatrix} - & + & 0 & \dots & 0 & 0 & 0 \\ - & - & + & \dots & 0 & 0 & 0 \\ - & - & - & \dots & 0 & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\ - & - & - & \dots & - & + & 0 \\ - & - & - & \dots & - & - & + \end{bmatrix}$$

is an  $S$ -matrix. Every strict column signing  $H'_{m+1}D$  of  $H'_{m+1}$  is an  $S^*$ -matrix, with only two such strict column signings yielding  $S$ -matrices (namely, when  $D = \pm I$ ).

### Applications:

[BS95, Sec. 1.1] In supply and demand analysis in economics, linear systems, where the coefficients as well as the constants have prescribed signs, arise naturally. For instance, the sign-solvable linear system

$$\begin{bmatrix} + & - \\ - & - \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 0 \\ - \end{bmatrix}$$

arises from the study of a market with one product, where the price and quantity are determined by the intersection of its supply and demand curves.

## 33.4 Stability

---

### Definitions:

A **negative stable** (respectively, **negative semistable**) real matrix is a square matrix  $B$  where each of the eigenvalues of  $B$  has negative (respectively, nonpositive) real part. In this section the term *(semi)stable* will mean *negative (semi)stable*. More information on matrix stability can be found in Section 9.5 and Chapter 19.

A **sign stable** (respectively, **sign semistable**) sign pattern matrix is a square sign pattern  $A$  where every matrix  $B \in Q(A)$  is stable (respectively, semistable).

A **potentially stable** sign pattern matrix is a square sign pattern  $A$  where some matrix  $B \in Q(A)$  is stable.

An  $n \times n$  sign pattern matrix  $A$  allows a **properly signed nest** if there exists  $B \in Q(A)$  and a permutation matrix  $P$  such that  $\text{sgn}(\det(P^T B P [\{1, \dots, k\}])) = (-1)^k$  for  $k = 1, \dots, n$ .

A **minimally potentially stable** sign pattern matrix is a potentially stable, irreducible pattern such that replacing any nonzero entry by zero results in a pattern that is not potentially stable.

### Facts:

Many of the following facts can be found in [BS95, Chap. 10].

1. A square sign pattern  $A$  is sign stable (respectively, sign semistable) iff each of the irreducible components of  $A$  is sign stable (respectively, sign semistable).
2. [QR65] If  $A$  is an  $n \times n$  irreducible sign pattern, then  $A$  is sign semistable iff
  - (a)  $A$  has nonpositive main diagonal entries.
  - (b) If  $i \neq j$ , then  $a_{ij}a_{ji} \leq 0$ .
  - (c) The digraph of  $A$  is a doubly directed tree.

3. If  $A$  is an  $n \times n$  irreducible sign pattern, then  $A$  is sign stable iff
  - (a)  $A$  has nonpositive main diagonal entries.
  - (b) If  $i \neq j$ , then  $a_{ij}a_{ji} \leq 0$ .
  - (c) The digraph of  $A$  is a doubly directed tree.
  - (d)  $A$  does not have an identically zero determinant.
  - (e) There does not exist a nonempty subset  $\beta$  of  $[1, 2, \dots, n]$  such that each diagonal element of  $A[\beta]$  is zero, each row of  $A[\beta]$  contains at least one nonzero entry, and no row of  $A[\bar{\beta}, \beta]$  contains exactly one nonzero entry.

The original version of this result was in terms of matchings and colorings in a graph ([JKD77, Theorem 2]); the restatement given here comes from [BS95, Theorem 10.2.2].

4. An efficient algorithm for determining whether a pattern is sign stable is given in [KD77], and the sign stable patterns have been characterized in finitely computable terms in [JKD87].
5. The characterization of the potentially stable patterns is a very difficult open question.
6. The potentially stable tree sign patterns (see Section 33.5) for dimensions less than five are given in [JS89].
7. If an  $n \times n$  sign pattern  $A$  allows a properly signed nest, then  $A$  is potentially stable.
8. In [JMO97], sufficient conditions are determined for an  $n \times n$  zero–nonzero pattern to allow a nested sequence of nonzero principal minors, and a method is given to sign a pattern that meets these conditions so that it allows a properly signed nest. It is also shown that if  $A$  is a tree sign pattern that has exactly one nonzero diagonal entry, then  $A$  is potentially stable iff  $A$  allows a properly signed nest.
9. In [LOD02], a measure of the relative distance to the unstable matrices for a stable matrix is defined and extended to a potentially stable sign pattern, and the minimally potentially stable patterns are studied.

### Examples:

1. [BS95] The pattern  $\begin{bmatrix} - & + \\ - & - \end{bmatrix}$  is sign stable, while the pattern  $\begin{bmatrix} 0 & + \\ - & 0 \end{bmatrix}$  is sign semistable, but not sign stable.
2. [JMO97] The matrix  $\begin{bmatrix} -1 & 1 & 0 \\ -1 & -1 & 1 \\ 0 & -3 & 1 \end{bmatrix}$  has a (leading) properly signed nest, so that the pattern  $\begin{bmatrix} - & + & 0 \\ - & - & + \\ 0 & - & + \end{bmatrix}$  is potentially stable.
3. [JMO97] The matrix  $B = \begin{bmatrix} -3 & 1 & 0 \\ 0 & 0 & 1 \\ 8 & -3 & 0 \end{bmatrix}$  has  $-1$  as a triple eigenvalue, and so is stable. Thus, the sign pattern  $A = \text{sgn}(B)$  is potentially stable, but it does not have a properly signed nest.
4. [LOD02] The  $n \times n$  tridiagonal sign pattern  $A$  with  $a_{11} = -, a_{i,i+1} = +, a_{i+1,i} = -$  for  $i = 1, \dots, n-1$ , and all other entries 0, is minimally potentially stable.

### Applications:

[BS95, sec. 10.1] The theory of sign stability is very important in population biology ([Log92]). For instance, a general ecosystem consisting of  $n$  different populations can be modeled by a linear system of differential equations. The entries of the coefficient matrix of this linear system reflect the effects on the ecosystem due to a small perturbation. The signs of the entries of the coefficient matrix can often

be determined from general principles of ecology, while the actual magnitudes are difficult to determine and can only be approximated. The sign stability of the coefficient matrix determines the stability of an equilibrium state of the system.

### 33.5 Other Eigenvalue Characterizations or Allowing Properties

---

#### Definitions:

A **bipartite sign pattern matrix** is a sign pattern matrix whose digraph is bipartite.

A **combinatorially symmetric sign pattern matrix** is a square sign pattern  $A$ , where  $a_{ij} \neq 0$  iff  $a_{ji} \neq 0$ .

The **graph of a combinatorially symmetric  $n \times n$  sign pattern matrix**  $A = [a_{ij}]$  is the graph with vertex set  $\{1, 2, \dots, n\}$ , where  $\{i, j\}$  is an edge iff  $a_{ij} \neq 0$ .

A **tree sign pattern** (t.s.p.) matrix is a combinatorially symmetric sign pattern matrix whose graph is a tree (possibly with loops).

An  **$n$ -cycle pattern** is a sign pattern  $A$  where the digraph of  $A$  is an  $n$ -cycle.

A  **$k$ -consistent sign pattern matrix** is a sign pattern  $A$  where every matrix  $B \in Q(A)$  has exactly  $k$  real eigenvalues.

#### Facts:

- [EJ91] An  $n \times n$  sign pattern  $A$  requires all real eigenvalues iff each irreducible component of  $A$  is a symmetric t.s.p. matrix.
- [EJ91] An  $n \times n$  sign pattern  $A$  requires all nonreal eigenvalues iff each irreducible component of  $A$ 
  - Is bipartite.
  - Has all negative simple cycles.
  - Is SNS.
- [EJ93] For an  $n \times n$  sign pattern  $A$ , the following statements are equivalent for each positive integer  $k \geq 2$ :
  - The minimum algebraic multiplicity of the eigenvalue 0 occurring among matrices in  $Q(A)$  is  $k$ .
  - $A$  requires an eigenvalue with algebraic multiplicity  $k$ , with  $k$  maximal.
  - The maximum composite cycle length in  $A$  is  $n - k$ .
- If an  $n \times n$  sign pattern  $A$  does not require an eigenvalue with algebraic multiplicity 2 (namely, if  $A$  allows  $n$  distinct eigenvalues), then  $A$  allows diagonalizability.
- Sign patterns that require all distinct eigenvalues have many nice properties, such as requiring diagonalizability. In [LH02], a number of sufficient and/or necessary conditions for a sign pattern to require all distinct eigenvalues are established. Characterization of patterns that require diagonalizability is still open.
- [EHL94a] If a sign pattern  $A$  requires all distinct eigenvalues, then  $A$  is  $k$ -consistent for some  $k$ .
- [EHL94a] Let  $A$  be an  $n \times n$  sign pattern and let  $A_I$  denote the sign pattern obtained from  $A$  by replacing all the diagonal entries by  $+$ . Then  $A_I$  requires  $n$  distinct real eigenvalues iff  $A$  is permutation similar to a symmetric irreducible tridiagonal sign pattern.
- [LHZ97] A  $3 \times 3$  nonnegative irreducible nonsymmetric sign pattern  $A$  allows normality iff  $AA^T =$

$$A^T A \text{ and } A \text{ is not permutation similar to } \begin{bmatrix} + & + & 0 \\ + & 0 & + \\ + & + & + \end{bmatrix}.$$

9. [LHZ97] If  $\begin{bmatrix} A_1 & A_2 \\ A_3 & A_4 \end{bmatrix}$  allows normality, where  $A_1$  is square, then the square pattern

$$\begin{bmatrix} A_1 & A_2 & A_2 & \dots & A_2 \\ A_3 & A_4 & A_4 & \dots & A_4 \\ A_3 & A_4 & A_4 & \dots & A_4 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ A_3 & A_4 & A_4 & \dots & A_4 \end{bmatrix}$$

also allows normality. Parallel results hold for allowing idempotence and for allowing nilpotence of index 2. (See [HL99] and [EL99].)

10. [EL99] Suppose an  $n \times n$  sign pattern  $A$  allows nilpotence. Then  $A^n$  is compatible with 0, and for  $1 \leq k \leq n-1$ ,  $\text{tr}(A^k)$  is compatible with 0. Further, for each  $m$ ,  $1 \leq m \leq n$ ,  $E_m(A)$  (the sum of all principal minors of order  $m$ ) is compatible with 0.
11. [HL99] Let  $A$  be a  $5 \times 5$  irreducible symmetric sign pattern such that  $A^2$  is compatible with  $A$ . Then  $A$  allows a symmetric idempotent matrix unless  $A$  can be obtained from the following by using permutation similarity and signature similarity:

$$\begin{bmatrix} + & + & + & + & 0 \\ + & + & - & 0 & - \\ + & - & + & + & + \\ + & 0 & + & + & - \\ 0 & - & + & - & + \end{bmatrix}.$$

12. [SG03] Let  $A$  be an  $n \times n$  sign pattern. If the maximum composite cycle length in  $A$  is equal to the maximum rank (see section 33.6) of  $A$ , then  $A$  allows diagonalizability.
13. [SG03] Every combinatorially symmetric sign pattern allows diagonalizability.
14. A nonzero  $n \times n$  ( $n \geq 2$ ) sign pattern that requires nilpotence does not allow diagonalizability.
15. Complete characterization of sign patterns that allow diagonalizability is still open.

For further reading, see [Esc93a], [Yeh96], and [KMT96].

### Examples:

1. By Fact 1, the pattern

$$\begin{bmatrix} * & + & 0 & 0 \\ + & * & - & - \\ 0 & - & * & 0 \\ 0 & - & 0 & * \end{bmatrix},$$

where each  $*$  entry could be 0, +, or -, requires all real eigenvalues.

2. [LH02] Up to equivalence (negation, transposition, permutational similarity, and signature similarity), the  $3 \times 3$  irreducible sign patterns that require 3 distinct eigenvalues are the irreducible tridiagonal symmetric sign patterns, irreducible tridiagonal skew-symmetric sign patterns, and 3-cycle sign patterns, together with the following:

$$\begin{bmatrix} + & + & 0 \\ 0 & 0 & + \\ + & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & + & 0 \\ - & 0 & + \\ + & - & 0 \end{bmatrix}, \begin{bmatrix} 0 & + & 0 \\ - & 0 & + \\ + & 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & + & - \\ - & 0 & + \\ + & - & 0 \end{bmatrix}, \begin{bmatrix} + & + & 0 \\ 0 & 0 & + \\ + & - & 0 \end{bmatrix}.$$

3. [EL99] The sign pattern  $A = \begin{bmatrix} + & + & 0 \\ - & - & - \\ - & + & + \end{bmatrix}$  does not allow nilpotence, though it satisfies many “obvious” necessary conditions.
4. [LHZ97] The  $n \times n$  sign pattern  $\begin{bmatrix} + & + & + & \cdots & + \\ + & + & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ + & + & 0 & \cdots & 0 \end{bmatrix}$  allows normality.

## 33.6 Inertia, Minimum Rank

---

### Definitions:

Let  $A$  be a sign pattern matrix.

The **minimal rank** of  $A$ , denoted  $\text{mr}(A)$ , is defined by  $\text{mr}(A) = \min\{\text{rank } B : B \in Q(A)\}$ .

The **maximal rank** of  $A$ ,  $\text{MR}(A)$ , is given by  $\text{MR}(A) = \max\{\text{rank } B : B \in Q(A)\}$ .

The **term rank** of  $A$  is the maximum number of nonzero entries of  $A$  no two of which are in the same row or same column.

For a symmetric sign pattern  $A$ ,  $\text{smr}(A)$ , the **symmetric minimal rank** of  $A$  is  $\text{smr}(A) = \min\{\text{rank } B : B = B^T, B \in Q(A)\}$ .

The **symmetric maximal rank** of  $A$ ,  $\text{SMR}(A)$ , is  $\text{SMR}(A) = \max\{\text{rank } B : B = B^T, B \in Q(A)\}$ .

For a symmetric sign pattern  $A$ , the **(symmetric) inertia set of  $A$**  is  $\text{in}(A) = \{\text{in}(B) : B = B^T \in Q(A)\}$ .

$A$  **requires unique inertia** if  $\text{in}(B_1) = \text{in}(B_2)$  for all symmetric matrices  $B_1, B_2 \in Q(A)$ .

A sign pattern  $A$  of order  $n$  is an **inertially arbitrary pattern (IAP)** if every possible ordered triple  $(p, q, z)$  of nonnegative integers  $p, q$ , and  $z$  with  $p + q + z = n$  can be achieved as the inertia of some  $B \in Q(A)$ .

A **spectrally arbitrary pattern (SAP)** is a sign pattern  $A$  of order  $n$  such that every monic real polynomial of degree  $n$  can be achieved as the characteristic polynomial of some matrix  $B \in Q(A)$ .

### Facts:

1.  $\text{MR}(A)$  is equal to the term rank of  $A$ .
2. Starting with a real matrix whose rank is  $\text{mr}(A)$  and changing one entry at a time to eventually reach a real matrix whose rank is  $\text{MR}(A)$ , all ranks between  $\text{mr}(A)$  and  $\text{MR}(A)$  are achieved by real matrices.
3. [HLW01] For every symmetric sign pattern  $A$ ,  $\text{MR}(A) = \text{SMR}(A)$ .
4. [HS93] A sign pattern  $A$  requires a fixed rank  $r$  iff  $A$  is permutationally equivalent to a sign pattern of the form  $\begin{bmatrix} X & Y \\ Z & 0 \end{bmatrix}$ , where  $X$  is  $k \times (r - k)$ ,  $0 \leq k \leq r$ , and  $Y$  and  $Z^T$  are  $L$ -matrices.
5. [HLW01] A symmetric sign pattern  $A$  requires a unique inertia iff  $\text{smr}(A) = \text{SMR}(A)$ .
6. [HLW01] For the symmetric sign pattern  $A = \begin{bmatrix} 0 & A_1 \\ A_1^T & 0 \end{bmatrix}$  of order  $n$ , we have

$$\text{in}(A) = \{(k, k, n - 2k) : \text{mr}(A_1) \leq k \leq \text{MR}(A_1)\}.$$

In particular,  $2 \text{mr}(A_1) = \text{smr}(A)$ .

7. [DJO00], [EOD03] Let  $T_n$  be the  $n \times n$  tridiagonal sign pattern with each superdiagonal entry positive, each subdiagonal entry negative, the  $(1, 1)$  entry negative, the  $(n, n)$  entry positive, and every other entry zero. It is conjectured that  $T_n$  is an SAP for all  $n \geq 2$ . It is shown that for  $3 \leq n \leq 16$ ,  $T_n$  is an SAP.

8. [GS01] Let  $S_n$  be the  $n \times n$  ( $n \geq 2$ ) sign pattern with each strictly upper (resp., lower) triangular entry positive (resp., negative), the  $(1, 1)$  entry negative, the  $(n, n)$  entry positive, and all other diagonal entries zero. Then  $S_n$  is inertially arbitrary.  
[ML02] Further, if the  $(1, n)$  and  $(n, 1)$  entries of  $S_n$  are replaced by zero, the resulting sign pattern is also an IAP.
9. [CV05] Not every inertially arbitrary sign pattern is spectrally arbitrary.
10. [MOT03] Suppose  $1 \leq p \leq n - 1$ . Then every  $n \times n$  sign pattern with  $p$  positive columns and  $n - p$  negative columns is spectrally arbitrary.

For further reading see [CHL03], [SSG04], [Hog05], and references [Nyl96], [JD99], [BFH04], [BF04], and [BHL04] in Chapter 34.

### Examples:

1. [HLW01] Let

$$A = \begin{bmatrix} + & 0 & + & + \\ 0 & + & + & + \\ + & + & - & 0 \\ + & + & 0 & - \end{bmatrix}.$$

Then  $\text{in}(A) = (2, 2, 0)$ ,  $\text{smr}(A) = \text{SMR}(A) = 4$ , but  $3 = \text{mr}(A) < \text{smr}(A) = 4$ .

2. [HL01] Let  $J_n$  be the  $n \times n$  sign pattern with all entries equal to  $+$ . Then

$$\text{in}(J_n) = \{(s, t, n - s - t) : s \geq 1, t \geq 0, s + t \leq n\}.$$

3. [Gao01], [GS03], [HL01] Let  $A$  be the  $n \times n$  ( $n \geq 3$ ) sign pattern all of whose diagonal entries are zero and all of whose off-diagonal entries are  $+$ . Then

$$\text{in}(A) = \{(s, t, n - s - t) : s \geq 1, t \geq 2, s + t \leq n\}.$$

## 33.7 Patterns That Allow Certain Types of Inverses

---

### Definitions:

A sign pattern matrix  $A$  is **nonnegative (positive)**, denoted  $A \geq 0$  ( $A > 0$ ), if all of its entries are nonnegative (positive).

An **inverse nonnegative (inverse positive)** sign pattern matrix is a square sign pattern  $A$  that allows an entrywise nonnegative (positive) inverse.

Let both  $B$  and  $X$  be real matrices or nonnegative sign pattern matrices. Consider the following conditions.

- (1)  $BXB = B$ .
- (2)  $XBX = X$ .
- (3)  $BX$  is symmetric.
- (4)  $XB$  is symmetric.

For a real matrix  $B$ , there is a unique matrix  $X$  satisfying all four conditions above and it is called the **Moore–Penrose inverse** of  $B$ , and denoted by  $B^\dagger$ . More generally, let  $B\{i, j, \dots, l\}$  denote the set of matrices  $X$  satisfying conditions  $(i), (j), \dots, (l)$  from among conditions (1)–(4). A matrix  $X \in B\{i, j, \dots, l\}$  is called an  **$(i, j, \dots, l)$ -inverse** of  $B$ . For example, if (1) holds,  $X$  is called a (1)-inverse of  $B$ ; if (1) and (2) hold,  $X$  is called a (1, 2)-inverse of  $B$ , and so forth. See Section 5.7.

For a nonnegative sign pattern matrix  $B$ , if there is a nonnegative sign pattern  $X$  satisfying (1) to (4), then  $X$  is unique and it is called the Moore–Penrose inverse of  $B$ . An  $(i, j, \dots, l)$ -inverse of  $B$  is defined similarly as in the preceding paragraph.

### Facts:

The first three facts below are contained in [BS95, Chap. 9].

1. [JLR79] Let  $A$  be an  $n \times n$   $(+, -)$ -pattern, where  $n \geq 2$ . Then  $A$  is inverse positive iff  $A$  is not permutationally equivalent to a pattern of the form  $\begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$ , where  $A_{12} < 0, A_{21} > 0$ , the blocks  $A_{11}, A_{22}$  are square or rectangular, and one (but not both) of  $A_{11}, A_{22}$  may be empty.
2. The above result in [JLR79] is generalized in [FG81] to  $(+, -, 0)$ -patterns, and additional equivalent conditions are established. Let  $e$  denote the column vector of all ones,  $J$  the  $n \times n$  matrix all of whose entries equal 1, and  $A'$  the matrix obtained from  $A$  by replacing all negative entries with zeros. For an  $n \times n$  fully indecomposable sign pattern  $A$ , the following are equivalent:
  - (a)  $A$  is inverse positive.
  - (b)  $A$  is not permutationally equivalent to a pattern of the form  $\begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$ , where  $A_{12} \leq 0, A_{21} \geq 0$ , the blocks  $A_{11}, A_{22}$  are square or rectangular, and one (but not both) of  $A_{11}, A_{22}$  may be empty.
  - (c) The pattern  $\begin{bmatrix} 0 & A \\ -A^T & 0 \end{bmatrix}'$  is irreducible.
  - (d) There exists  $B \in Q(A)$  such that  $Be = B^T e = 0$ .
  - (e) There exists a doubly stochastic matrix  $D$  such that  $(D - \frac{1}{n}J) \in Q(A)$ .
3. [Joh83] For an  $n \times n$  fully indecomposable sign pattern  $A$ , the following are equivalent:  $A$  is inverse nonnegative;  $A$  is inverse positive;  $-A$  is inverse nonnegative;  $-A$  is inverse positive.
4. [EHL97] If an  $n \times n$  sign pattern  $A$  allows  $B$  and  $B^{-1}$  to be in  $Q(A)$ , then
  - (a)  $\text{MR}(A) = n$ .
  - (b)  $A^2$  is compatible with  $I$ .
  - (c)  $\text{adj } A$  is compatible with  $A$  and  $\det(A)$  is compatible with  $+$ , or,  $\text{adj } A$  is compatible with  $-A$  and  $\det(A)$  is compatible with  $-$ , where  $\text{adj } A$  is the adjoint of  $A$ .
5. In [EHL94b], the class  $\mathcal{G}$  of all square patterns  $A$  that allow  $B, C \in Q(A)$  where  $BCB = B$  is investigated; it is shown for nonnegative patterns that  $\mathcal{G}$  coincides with the class of square patterns that allow  $B \in Q(A)$  where  $B^3 = B$ .
6. [HLR04] An  $m \times n$  nonnegative sign pattern  $A$  has a nonnegative  $(1, 3)$ -inverse (Moore–Penrose inverse) iff  $A$  allows a nonnegative  $(1, 3)$ -inverse (Moore–Penrose inverse).

For further reading, see [BF87], [BS95, Theorem 9.2.6], [SS01], and [SS02].

### Examples:

1. By Facts 2 and 3, the sign pattern

$$A = \begin{bmatrix} + & 0 & + & + \\ 0 & + & + & + \\ - & - & - & 0 \\ - & - & 0 & - \end{bmatrix}$$

is not inverse nonnegative.

2. [EHL97] The sign pattern

$$A = \begin{bmatrix} + & + & + & + \\ 0 & + & + & + \\ 0 & + & - & - \\ 0 & - & + & + \end{bmatrix}$$

satisfies all the necessary conditions in Fact 4, but it does not allow an inverse pair  $B$  and  $B^{-1}$  in  $Q(A)$ .

## 33.8 Complex Sign Patterns and Ray Patterns

---

### Definitions:

A **complex sign pattern matrix** is a matrix of the form  $A = A_1 + iA_2$  for some  $m \times n$  sign patterns  $A_1$  and  $A_2$ , and the **sign pattern class** or **qualitative class** of  $A$  is

$$Q(A) = \{B_1 + iB_2 : B_1 \in Q(A_1) \text{ and } B_2 \in Q(A_2)\}.$$

Many definitions for sign patterns, such as SNS, extend in the obvious way to complex sign patterns.

The **determinantal region** of a complex sign pattern  $A$  is the set

$$S_A = \{\det(B) : B \in Q(A)\}.$$

A **ray pattern** is a matrix each of whose entries is either 0 or a ray in the complex plane of the form  $\{re^{i\theta} : r > 0\}$  (which is represented by  $e^{i\theta}$ ). The **ray pattern class** of an  $m \times n$  ray pattern  $A$  is

$$Q(A) = \{B = [b_{pq}] \in M_{m \times n}(\mathbb{C}) : b_{pq} = 0 \text{ iff } a_{pq} = 0, \text{ and otherwise } \arg b_{pq} = \arg a_{pq}\}.$$

For  $\alpha < \beta$ , the **open sector** from the ray  $e^{i\alpha}$  to the ray  $e^{i\beta}$  is the set of rays  $\{re^{i\theta} : r > 0, \alpha < \theta < \beta\}$ . The **determinantal region** of a ray pattern  $A$  is the set

$$R_A = \{\det(B) : B \in Q(A)\}.$$

An  $n \times n$  ray pattern  $A$  is **ray nonsingular** if the Hadamard product  $X \circ A$  is nonsingular for every entrywise positive  $n \times n$  matrix  $X$ .

A **cyclically real** ray pattern is a square ray pattern  $A$  where the actual products of every cycle in  $A$  is real.

### Facts:

- [EHL98], [SS05] For a complex sign pattern  $A$ , the boundaries of  $S_A$  are always on the axes on the complex plane.
- [EHL98], [SS05] For a sign nonsingular complex sign pattern  $A$ ,  $S_A$  is either entirely contained in an axis of the complex plane or is an open sector in the complex plane with boundary rays on the axes.
- [SS05] For a complex sign pattern or ray pattern  $A$ , the region  $S_A \setminus \{0\}$  (or  $R_A \setminus \{0\}$ ) is an open set (in fact, a disjoint union of open sectors) in the complex plane, except in the cases that  $S_A$  ( $R_A$ ) is entirely contained in a line through the origin.
- The results of [MOT97], [LMS00], and [LMS04] show that there is an entrywise nonzero ray nonsingular ray pattern of order  $n$  if and only if  $1 \leq n \leq 4$ .
- [EHL00] An irreducible ray pattern  $A$  is cyclically real iff  $A$  is diagonally similar to a real sign pattern. More generally, a ray pattern  $A$  is diagonally similar to a real sign pattern iff  $A$  and  $A + A^*$  are both cyclically real.

**Examples:**

- [EHL98] If  $A = \begin{bmatrix} + & - \\ + & + \end{bmatrix} + i \begin{bmatrix} + & 0 \\ 0 & - \end{bmatrix}$ , then  $A$  is sign nonsingular and  $S_A$  is the open sector from the ray  $e^{-i\pi/2}$  to the ray  $e^{i\pi/2}$ .

- [MOT97] The ray pattern  $\begin{bmatrix} e^{i\pi/2} & + & + & + \\ + & e^{i\pi/2} & + & + \\ + & + & e^{i\pi/2} & + \\ + & + & + & e^{i\pi/2} \end{bmatrix}$  is ray nonsingular.

- [EHL00] Let

$$A = \begin{bmatrix} 0 & e^{-i\theta_1} & 0 & -e^{-i\theta_1} \\ 0 & + & -e^{-i\theta_2} & 0 \\ e^{i(\theta_1+\theta_2)} & -e^{i\theta_2} & 0 & -e^{i\theta_2} \\ e^{i\theta_1} & - & 0 & - \end{bmatrix},$$

where  $\theta_1$  and  $\theta_2$  are arbitrary. Then  $A$  is cyclically real, and  $A$  is diagonally similar (via the diagonal ray pattern  $S = \text{diag}(+, e^{i\theta_1}, e^{i(\theta_1+\theta_2)}, -e^{i\theta_1})$ ) to

$$\begin{bmatrix} 0 & + & 0 & + \\ 0 & + & - & 0 \\ + & - & 0 & + \\ - & + & 0 & - \end{bmatrix}.$$

### 33.9 Powers of Sign Patterns and Ray Patterns

---

**Definitions:**

Let  $J_n$  (or simply  $J$ ) denote the all + sign (ray) pattern of order  $n$ .

A square sign pattern or ray pattern  $A$  is **powerful** if all the powers  $A^1, A^2, A^3, \dots$ , are unambiguously defined, that is, no entry in any  $A^k$  is a sum involving two or more distinct rays. For a powerful pattern  $A$ , the smallest positive integers  $l = l(A)$  and  $p = p(A)$  such that  $A^l = A^{l+p}$  are called the **base** and **period** of  $A$ , respectively.

A square sign pattern or ray pattern  $A$  is  **$k$ -potent** if  $k$  is the smallest positive integer such that  $A = A^{k+1}$ .

**Facts:**

- [LHE94] An irreducible sign pattern  $A$  with index of imprimitivity  $h$  (see Section 29.7) is powerful iff all cycles of  $A$  with lengths odd multiples of  $h$  have the same sign and all cycles (if any) of  $A$  with lengths even multiples of  $h$  are positive (see [SS04]). A sign pattern  $A$  is powerful iff for every positive integer  $d$  and for every pair of matrices  $B, C \in Q(A)$ ,  $\text{sgn}(B^d) = \text{sgn}(C^d)$ .
- [LHE94] Let  $A$  be an irreducible powerful sign pattern, with index of imprimitivity  $h$ . Then the base and the period of  $A$  are given by  $l(A) = l(|A|)$ ,  $p(A) = h$  if  $A$  does not have any negative cycles, and  $p(A) = 2h$  if  $A$  has a negative cycle.
- [Esc93b] The only irreducible idempotent sign pattern of order  $n \geq 2$  is the all + sign pattern.
- [LHE94], [SEK99], [SBS02] Every  $k$ -potent irreducible sign or ray pattern matrix is powerful.
- [EL97] The maximum number of  $-$  entries in the square of a sign pattern of order  $n$  is  $n^2 - 2$ ; the maximum number of  $-$  entries in the square of a  $(+, -)$  sign pattern of order  $n$  is  $\lfloor n^2/2 \rfloor$ .
- [HL01b] Let  $A$  be an  $n \times n$  ( $n \geq 3$ ) sign pattern. If  $A^2$  has only one entry that is not nonpositive, then  $A^2$  has at most  $n^2 - n$  negative entries.
- [LHS02] Let  $A$  be an irreducible ray pattern. Then  $A$  is powerful iff  $A$  is diagonally similar to a subpattern of  $e^{i\alpha} J$  for some  $\alpha \in \mathbb{R}$ , where  $J$  is the all + ray pattern.

8. [LHS05] Suppose that  $A = \begin{bmatrix} A_{11} & A_{12} \\ 0 & A_{22} \end{bmatrix}$  is a powerful ray pattern, where  $A_{11}$  (resp.,  $A_{22}$ ) is irreducible with index of imprimitivity  $h_1$  (resp.,  $h_2$ ) and  $0 \neq A_{11} \leq c_1 J_{n_1}, 0 \neq A_{22} \leq c_2 J_{n_2}$ . If  $A_{12} \neq 0$ , then  $\left(\frac{c_2}{c_1}\right)^{\text{lcm}(h_1, h_2)} = 1$ .

For further reading, the structures of  $k$ -potent sign patterns or ray patterns are studied in [SEK99], [Stu99], [SBS02], [LG01], and [Stu03].

**Examples:**

1. [LHE94] The reducible sign pattern  $A = \begin{bmatrix} 0 & + & + & + \\ 0 & + & 0 & + \\ 0 & 0 & - & - \\ 0 & 0 & 0 & 0 \end{bmatrix}$  satisfies  $A^2 = \begin{bmatrix} 0 & + & - & \# \\ 0 & + & 0 & + \\ 0 & 0 & + & + \\ 0 & 0 & 0 & 0 \end{bmatrix}$  and

$A^3 = A$ . Thus,  $A$  is 2-potent and yet  $A$  is not powerful.

2. [SEK99] Let  $P_n$  be the  $n \times n$  circulant permutation sign pattern with (1, 2) entry equal to +. Let  $Q_n$  be the sign pattern obtained from  $P_n$  by replacing the + in the (n, 1) position with a -. Then  $P_n$  is  $n$ -potent and  $Q_n$  is  $2n$ -potent.

3. [SBS02] Suppose that  $3|k$ . Let  $A = \omega \begin{bmatrix} 0 & J_{p \times q} & 0 \\ 0 & 0 & J_{q \times r} \\ J_{r \times p} & 0 & 0 \end{bmatrix}$ , where  $J_{m \times n}$  denotes the all ones

$m \times n$  matrix and  $\omega^3$  is a primitive  $k/3$ -th root of unity. Then  $A$  is a  $k$ -potent ray pattern.

## 33.10 Orthogonality

---

**Definitions:**

A square sign pattern  $A$  is **potentially orthogonal (PO)** if  $A$  allows an orthogonal matrix.

A square sign pattern  $A$  that does not have a zero row or zero column is **sign potentially orthogonal (SPO)** if every pair of rows and every pair of columns allows orthogonality.

Two vectors  $\mathbf{x} = [x_1, \dots, x_n]$  and  $\mathbf{y} = [y_1, \dots, y_n]$  are **combinatorially orthogonal** if  $|\{i : x_i y_i \neq 0\}| \neq 1$ .

**Facts:**

1. Every PO sign pattern is SPO.
2. [BS94], [Wat96] For  $n \leq 4$ , every  $n \times n$  SPO sign pattern is PO.
3. [Wat96] There is a  $5 \times 5$  fully indecomposable SPO sign pattern that is not PO.
4. [JW98] There is a  $6 \times 6$  (+, -) sign pattern that is SPO but not PO.
5. [BBS93] Let  $A$  be an  $n \times n$  fully indecomposable sign pattern whose rows are combinatorially orthogonal and whose columns are combinatorially orthogonal. Then  $A$  has at least  $4(n - 1)$  nonzero entries. This implies that a conjecture of Fiedler [Fie64], which says a fully indecomposable orthogonal matrix of order  $n$  has at least  $4(n - 1)$  nonzero entries, is true.
6. [CJL99] For  $n \geq 2$ , there is an  $n \times n$  fully indecomposable orthogonal matrix with  $k$  zero entries iff  $0 \leq k \leq (n - 2)^2$ .
7. [EHH99] Let  $S$  be any skew symmetric sign pattern of order  $n$  all of whose off-diagonal entries are nonzero. Then  $I + S$  is PO.
8. [EHH99] It is an open question as to whether every sign pattern  $A$  that allows an inverse in  $Q(A^T)$  is PO.

For further reading see [Lim93], [Sha98], [CS99], and [CHR03].

**Examples:**

1. [BS94] Every  $3 \times 3 \pm$  SPO sign pattern can be obtained from the following sign pattern by using permutation equivalence and multiplication by signature patterns:

$$\begin{bmatrix} + & + & + \\ + & + & - \\ + & - & + \end{bmatrix}.$$

2. [Wat96] The sign pattern

$$\begin{bmatrix} - & + & 0 & + & - \\ + & + & - & 0 & - \\ 0 & + & + & + & + \\ + & 0 & - & + & + \\ - & - & - & + & + \end{bmatrix}$$

is SPO but not PO.

## 33.11 Sign-Central Patterns

---

**Definitions:**

A real matrix  $B$  is **central** if the zero vector is in the convex hull of the columns of  $B$ . A real or sign pattern matrix  $A$  is **sign-central** if  $A$  requires centrality.

A **minimal sign-central matrix**  $A$  is a sign-central matrix that is not sign-central if any column of  $A$  is deleted.

A **tight sign-central** matrix is a sign-central matrix  $A$  for which the Hadamard (entrywise) product of any two columns of  $A$  contains a negative component.

A **nearly sign-central matrix** is a matrix that is not sign-central but can be augmented to a sign-central matrix by adjoining a column.

**Facts:**

1. [AB94] An  $m \times n$  matrix  $A$  is sign-central iff the matrix  $DA$  has a nonnegative column vector for every strict signing  $D$  of order  $m$ .
2. [HKK03] Every tight sign-central matrix is a minimal sign-central matrix.
3. [LC00] If  $A$  is nearly sign-central and  $[A \mid \alpha]$  is sign-central, then  $[A \mid \alpha']$  is also sign-central for every  $\alpha' \neq 0$  obtained from  $\alpha$  by zeroing out some of its entries.

For further reading, see [BS95, Sect. 5.4], [DD90], [LLS97], and [BJS98].

**Examples:**

1. [BS95, p. 100], [HKK03] For each positive integer  $m$ , the  $m \times 2^m \pm$  sign pattern  $E_m$  such that each  $m$ -tuple of  $+$ 's and  $-$ 's is a column of  $E_m$ , is a tight sign-central sign pattern.

This chapter assumes basic terminology from graph theory in Chapter 28; a good general graph theory reference is [CL96]. For standard terms or concepts from matrix analysis, see Part 1: Basic Linear Algebra, particularly Chapter 4.3, and Chapter 8; a good general matrix reference is [HJ85]. As we will be interested in properties of  $A$  that are permutation similarity invariant, primarily eigenvalues and their multiplicities, we will generally view a graph as unlabeled, except when referencing by labels is convenient.

For a given simple graph  $G$  on  $n$  vertices, let  $\mathcal{S}(G)$  (respectively,  $\mathcal{H}(G)$ ) denote the set of all  $n \times n$  real symmetric (respectively, complex Hermitian)  $n \times n$  matrices  $A = [a_{ij}]$  such that for  $i \neq j$ ,  $a_{ij} \neq 0$  if and only if there is an edge between  $i$  and  $j$ .

Our primary interest lies in the following very general question. Given  $G$ , what are all the possible lists of multiplicities for the eigenvalues that occur among matrices in  $\mathcal{S}(G)$  (respectively,  $\mathcal{H}(G)$ )? Much of our focus here is on the case in which  $G = T$  is a tree.

It is important to distinguish two possible interpretations of “multiplicity list.” Since the eigenvalues of a real symmetric or complex Hermitian matrix are real numbers, they may be placed in numerical order. If the multiplicities are placed in an order corresponding to the numerical order of the underlying eigenvalues, then we refer to such a way of listing the multiplicities as *ordered multiplicities*. If, alternatively, the multiplicities are simply listed in nonincreasing order of the values of the multiplicities themselves, we refer to such a list as *unordered multiplicities*. For example, if  $A$  has eigenvalues  $-3, 0, 0, 1, 2, 2, 5, 7$ , the list of ordered multiplicities is  $(1, 2, 1, 3, 1, 1)$ , while the list of unordered multiplicities is  $(3, 2, 1, 1, 1, 1)$ . In either case, such a list means that there are exactly 6 different eigenvalues, of which 4 have multiplicity 1.

If a graph  $G$  is not connected, then the multiplicity lists for  $G$  may be deduced from those of its components via superposition. Also, graphs with many edges admit particularly rich collections of multiplicity lists. For example, the complete graph admits all multiplicity lists with the given number of eigenvalues, except the list in which all eigenvalues are the same. For these reasons, a natural beginning for the study of multiplicity lists for  $\mathcal{S}(G)$  or  $\mathcal{H}(G)$  is the case in which  $G = T$ , a tree. In addition, trees present several attractive features for this problem, so much of the research in this area, and this chapter, focuses on trees.

## 34.1 Multiplicities and Parter Vertices

### Definitions:

Let  $G$  be a simple graph.

For an  $n \times n$  real symmetric or complex Hermitian matrix  $A = [a_{ij}]$ , the **graph** of  $A$ , denoted by  $G(A)$ , is the simple graph on  $n$  vertices, labeled  $1, 2, \dots, n$ , with an edge between  $i$  and  $j$  if and only if  $a_{ij} \neq 0$ .

Let  $\mathcal{S}(G)$  (respectively,  $\mathcal{H}(G)$ ), denote the set of all  $n \times n$  real symmetric (respectively, complex Hermitian) matrices  $A$  such that  $G(A) = G$  (where  $G$  has  $n$  vertices). No restriction is placed upon the diagonal entries of  $A$  by  $G$ , except that they are real.

If  $G'$  is the subgraph of  $G$  induced by  $\beta$ ,  $A(G')$  can be used to denote  $A(\beta)$  and  $A[G']$  to denote  $A[\beta]$ .

Given a tree  $T$ , the components of  $T \setminus \{j\}$  are called **branches** of  $T$  at  $j$ .

If  $A \in \mathcal{H}(G)$ ,  $\lambda \in \sigma(A)$ , and  $j$  is an index such that  $\alpha_{A(j)}(\lambda) = \alpha_A(\lambda) + 1$ , then  $j$  is called a **Parter index** or **Parter vertex** (for  $\lambda$ ,  $A$  and  $G$ ) (where  $\alpha_A(\lambda)$  denotes the multiplicity of  $\lambda$ ). Some authors refer to such a vertex as a **Parter–Wiener vertex** or a **Wiener vertex**.

If  $j$  is a Parter vertex for an eigenvalue  $\lambda$  of an  $A \in \mathcal{H}(G)$  such that  $\lambda$  occurs as an eigenvalue of at least three direct summands of  $A(j)$ ,  $j$  is called a **strong Parter vertex**.

A **downer vertex**  $i$  in a graph  $G$  (for  $\lambda \in \sigma(A)$  and  $A \in \mathcal{H}(G)$ ) is a vertex  $i$  such that  $\alpha_{A(i)}(\lambda) = \alpha_A(\lambda) - 1$ .

A **downer branch** of a tree  $T$  at  $j$  is a branch  $T_i$  at  $j$ , determined by a neighbor  $i$  of  $j$  such that  $i$  is a downer vertex in  $T_i$  (for  $\lambda$  and  $A[T_i]$ ).

If a branch of a tree at a vertex  $j$  is a path and the neighbor of  $j$  in this branch is a pendant vertex of this path, the branch is a **pendant path** at  $j$ .

### Facts:

1. If  $A \in \mathcal{H}(G)$ , then trivially  $A(i) \in \mathcal{H}(G \setminus \{i\})$ .
2. [HJ85] (Interlacing Inequalities) If an  $n \times n$  Hermitian matrix  $A$  has eigenvalues  $\lambda_1 \leq \lambda_2 \leq \dots \leq \lambda_n$  and  $A(i)$  has eigenvalues  $\beta_{i,1} \leq \beta_{i,2} \leq \dots \leq \beta_{i,n-1}$ , then  $\lambda_1 \leq \beta_{i,1} \leq \lambda_2 \leq \beta_{i,2} \leq \dots \leq \beta_{i,n-1} \leq \lambda_n$ ,  $i = 1, \dots, n$ .
3. If  $\lambda$  is an eigenvalue of an Hermitian matrix  $A$ , then  $\alpha_A(\lambda) - 1 \leq \alpha_{A(i)}(\lambda) \leq \alpha_A(\lambda) + 1$  for  $i = 1, \dots, n$ .
4. If  $T$  is a tree, then any matrix of  $\mathcal{H}(T)$  is diagonally unitarily similar to one in  $\mathcal{S}(T)$ .
5. [JLS03a] (Parter–Wiener Theorem: Generalization) Let  $T$  be a tree and  $A \in \mathcal{S}(T)$ . Suppose that there exists an index  $i$  and a real number  $\lambda$  such that  $\lambda \in \sigma(A) \cap \sigma(A(i))$ . Then
  - There is in  $T$  a Parter vertex  $j$  for  $\lambda$ .
  - If  $\alpha_A(\lambda) \geq 2$ , then  $j$  may be chosen so that  $\delta_T(j) \geq 3$  and so that there are at least three components  $T_1, T_2$ , and  $T_3$  of  $T \setminus \{j\}$  such that  $\alpha_{A[T_k]}(\lambda) \geq 1$ ,  $k = 1, 2, 3$ .
  - If  $\alpha_A(\lambda) = 1$ , then  $j$  may be chosen so that there are two components  $T_1$  and  $T_2$  of  $T \setminus \{j\}$  such that  $\alpha_{A[T_k]}(\lambda) = 1$ ,  $k = 1, 2$ .
6. [JLS03a] For  $A \in \mathcal{S}(T)$ ,  $T$  a tree,  $j$  is a Parter vertex for  $\lambda$  if and only if there is a downer branch at  $j$  for  $\lambda$ .

7. [JL] Suppose that  $G$  is a simple graph on  $n$  vertices that is not a tree. Then
  - There is a matrix  $A \in \mathcal{S}(G)$  with an eigenvalue  $\lambda$  such that there is an index  $j$  so that  $\alpha_A(\lambda) = \alpha_{A(j)}(\lambda) = 1$  and  $\alpha_{A(i)}(\lambda) \leq 1$  for every  $i = 1, \dots, n$ .
  - There is a matrix  $B \in \mathcal{S}(G)$  with an eigenvalue  $\lambda$  such that  $\alpha_B(\lambda) \geq 2$  and  $\alpha_{B(i)}(\lambda) = \alpha_B(\lambda) - 1$ , for every  $i = 1, \dots, n$ .
8. [JLSSW03] Let  $T$  be a tree and  $\lambda_1 < \lambda_2$  be eigenvalues of  $A \in \mathcal{S}(T)$  that share a Parter vertex in  $T$ . Then there is at least one  $\lambda \in \sigma(A)$  such that  $\lambda_1 < \lambda < \lambda_2$ .
9. Let  $T$  be a tree and  $A \in \mathcal{S}(T)$ . If  $T'$  is a pendant path of a vertex  $j$  of  $T$ , then  $T'$  is a downer branch for each eigenvalue of the direct summand  $A[T']$ .
10. Let  $T$  be a path and  $A \in \mathcal{S}(T)$ . Then each eigenvalue of  $A$  has multiplicity 1.
11. Let  $A$  be an  $n \times n$  irreducible real symmetric tridiagonal matrix. Then
  - $A$  has distinct eigenvalues.
  - In  $A(i)$ , there are at most  $\min\{i - 1, n - i\}$  interlacing equalities and this number may occur.
  - For each interlacing equality that does occur, the relevant eigenvalues must be an eigenvalue (of multiplicity 1) of both irreducible principal submatrices of  $A(i)$ .

See Example 3 below.

**Examples:**

1. In general, one might expect that in passing from  $A$  to  $A(i)$ , multiplicities typically decline. However, Fact 5 is counter to this intuition in the case for trees. A rather complete statement has evolved through a series of papers ([Par60], [Wie84], [JLS03a]). In particular, Fact 5 says that when  $T$  is a tree and  $\alpha_A(\lambda) \geq 2$ , there must be a strong Parter vertex because, by interlacing, the hypothesis  $\lambda \in \sigma(A) \cap \sigma(A(i))$  must be satisfied for any  $i$ . However,  $i$  itself need not be a Parter vertex. Even when  $\alpha_A(\lambda) \geq 2$ , it can happen that  $\alpha_{A(j)}(\lambda) = \alpha_A(\lambda) + 1$  with  $\delta_T(j) = 1$  or  $\delta_T(j) = 2$  or  $\lambda$  appears in only one or two components of  $T \setminus \{j\}$ , even if  $\delta_T(j) \geq 3$ . There may, as well, be several Parter vertices and even several strong Parter vertices. Much information about Parter vertices may be found in [JLSSW03] and [JLS03a]. Let  $\lambda, \mu \in \mathbb{R}, \lambda \neq \mu$ , and consider real symmetric matrices whose graphs are the following trees, assuming that every diagonal entry corresponds to the label of the corresponding vertex.
  - The vertex  $v$  is a Parter vertex for  $\lambda$  in real symmetric matrices for which the graph is each of the trees in Figure 34.1. We also note that, depending on the tree  $T$ , several different vertices of  $T$  could be Parter for an eigenvalue of the same matrix in  $\mathcal{S}(T)$ . The matrices  $A[T_1]$  and  $A[T_2]$  each have  $u$  and  $v$  as Parter vertices for  $\lambda$ .

FIGURE 34.1 Examples of Parter vertices.

- Also, depending on the tree  $T$ , the same vertex could be a Parter vertex for different eigenvalues of a matrix in  $\mathcal{S}(T)$ . The vertex  $v$  is a Parter vertex for  $\lambda$  and  $\mu$  in a real symmetric matrix  $A$  for which the graph is the tree in Figure 34.2. Such a matrix  $A$  has  $\lambda$  and  $\mu$  as eigenvalues with  $\alpha_A(\lambda) = 2 = \alpha_A(\mu)$ . Since it is clear that we have  $\alpha_{A(v)}(\lambda) = 3 = \alpha_{A(v)}(\mu)$ , it means that  $v$  is Parter for  $\lambda$  and  $\mu$ .

FIGURE 34.2 Vertex  $v$  is a Parter vertex for  $\lambda$  and  $\mu$ .

2. Though a notion of “Parter vertex” can be defined for nontrees, Fact 7 is the converse to Fact 5 that shows that its remarkable conclusions are generally valid only for trees.  
Consider the matrix  $J_3$  whose graph is the cycle  $C_3$  (the possible multiplicities for the eigenvalues of a matrix whose graph is a cycle was studied in [Fer80]), which is not a tree. The matrix  $J_3$  has eigenvalues 0, 0, 3. Since the removal of any vertex from  $C_3$  leaves a path, we conclude that there is no Parter vertex for the multiple eigenvalue 0.
3. If a graph  $G$  is a path on  $n$  vertices, then  $G$  is a tree and if the vertices are labeled consecutively, any matrix in  $\mathcal{S}(G)$  is an irreducible tridiagonal matrix. Conversely, the graph of an irreducible real symmetric tridiagonal matrix is a path. The very special spectral structure of such matrices has been of interest for some time for a variety of reasons. Two well-known classical facts are that all eigenvalues are distinct (i.e., all 1s is the only multiplicity list) and, if a pendant vertex is deleted, the interlacing inequalities are strict. Both statements follow from Fact 5, but more can be gotten from Fact 5 as well. If  $A$  is  $n \times n$  real symmetric and  $1 \leq i \leq n$ , then as many as  $n - 1$  of the eigenvalues of  $A(i)$  might coincide with some eigenvalue of  $A$ . We refer to such an occurrence as an “interlacing equality.” If a pendant vertex is removed from a path, no interlacing equalities can occur, but if an interior vertex is removed, interlacing equalities can occur. The complete picture in this regard may be also be deduced from Fact 5.

## 34.2 Maximum Multiplicity and Minimum Rank

### Definitions:

Let  $G$  be a simple graph.

The **maximum multiplicity** of  $G$ ,  $M(G)$ , is the maximum multiplicity for a single eigenvalue among matrices in  $\mathcal{S}(G)$ .

The **minimum rank** of  $G$  is  $mr(G) = \min_{A \in \mathcal{S}(G)} \text{rank}(A)$ .

The **path cover number** of  $G$ ,  $P(G)$ , is the minimum number of induced paths of  $G$  that do not intersect, but do cover all vertices of  $G$ .

$\Delta(T) = \max[p - q]$  over all ways in which  $q$  vertices may be deleted from  $G$ , so as to leave  $p$  paths. Isolated vertices count as (degenerate) paths.

The **maximum rank deficiency** for  $G$  is  $m(G) = n - mr(G)$ , where the order of  $G$  is  $n$ .

### Facts:

Let  $G$  be a simple connected graph of order  $n$ .

1. If  $G$  is a path,  $P(G) = 1$ ; otherwise  $P(G) > 1$ .
2. There may be many minimum path covers. See Example 2.
3. Maximizing sets of removed vertices (used in the computation of  $\Delta(G)$ ) are not unique; even the number of removed vertices is not unique. See Example 3.

FIGURE 34.3 Two of the forbidden graphs for  $\text{mr}(G) = 2$ .

4. [Fie69]  $M(G) = 1$  if and only if  $G$  is a path.
5.  $M(G) = n - 1$  if and only if  $G$  is the complete graph  $K_n$ .
6.  $M(G) = m(G)$ .
7. [JL99] For a tree  $T$ ,  $M(T) = \Delta(T) = P(T) = m(T)$ .
8. [JS02] For any tree  $T$ , let  $H_T$  denote the subgraph of  $T$  induced by the vertices of degree at least 3. For a tree  $T$ ,  $\Delta(T)$  can be computed by the following algorithm. See Example 4.

**Algorithm 1: Computation of  $\Delta(T)$**   
 Given a tree  $T$ .

1. Set  $Q = \emptyset$  and  $T' = T$ .
2. While  $H_{T'} \neq \emptyset$ :  
 Remove from  $T'$  all vertices  $v$  of  $H_{T'}$  such that  $\delta_{T'}(v) - \delta_{H_{T'}}(v) \geq 2$   
 and add these vertices to  $Q$ .
3.  $\Delta(T) = p - |Q|$  where  $p$  is the number of components (all of which are paths) in  $T \setminus Q$ .

9. [JL99], [BFH04]  $\Delta(G) \leq M(G)$  and  $\Delta(G) \leq P(G)$ .
10. [BFH04], [BFH05] If  $n \geq 2$ ,  $P(K_n) < M(K_n)$ , where  $K_n$  is the complete graph on  $n$  vertices. If  $G$  is unicyclic (i.e., has a unique cycle), then  $P(G) \geq M(G)$  and strict inequality is possible.
11. [BFH04] Minimum rank (and, thus, maximum multiplicity) of a graph with a cut vertex can be computed from the minimum ranks of induced subgraphs.
12. [BHL04] If  $H$  is an induced subgraph of  $G$ , then  $\text{mr}(H) \leq \text{mr}(G)$ . Furthermore,  $\text{mr}(G) = 2$  (i.e.,  $M(G) = n - 2$ ) if and only if  $G$  does not contain as an induced subgraph one of the following four forbidden graphs: the path on 4 vertices  $P_4$ , the complete tripartite graph  $K_{3,3,3}$ , the two graphs shown in Figure 34.3. Other characterizations are also given.

**Examples:**

1. Considering the tree  $T$  in Figure 34.4, we have  $P(T) = 2$  (e.g., 1-3-2 and 5-4-6 constitute a minimal path cover of the vertices) and, of course,  $\Delta(T) = 2$ , as removal of vertex 4 leaves the 3 paths 1-3-2, 5, and 6 (and neither can be improved upon). Note that if submatrices  $A[\{1, 2, 3\}]$ ,  $A[\{5\}]$ , and  $A[\{6\}]$  of  $A \in \mathcal{S}(T)$  are constructed so that  $\lambda$  is an eigenvalue of each (this is always possible and no higher multiplicity in any of them is possible), then  $\alpha_A(\lambda) \geq 3 - 1 = 2$ , which is the maximum possible.
2. Consider the tree  $T$  on 12 vertices in Figure 34.5. It is not difficult to see that the path cover number of  $T$ ,  $P(T)$ , is 4. However, it can be achieved by different collections of paths. For example,  $P(T)$  can be achieved from the collection of 4 paths of  $T$ , 1-2-3, 4-5-6, 7-8 and 12-9-10-11. Similarly,

FIGURE 34.4 A tree with path cover number 2.

FIGURE 34.5 A tree with path cover number 4.

the paths of  $T$ , 1-2-3, 4-5-8-7, 6 and 12-9-10-11, form a collection of vertex disjoint paths (each one is an induced subgraph of  $T$ ) that cover all the vertices of  $T$ .

3. Consider the tree  $T$  on 12 vertices in Figure 34.5. As we can see in Table 34.1,  $\Delta(T)$  can be achieved for  $q = 1, 2, 3$ . When  $q = 2$ , there are 3 different sets of vertices whose removal from  $T$  leaves 6 components (paths), i.e.,  $p - q = 4$ .
4. The algorithm in Fact 8 applied to the tree  $T$  in Figure 34.6 gives, in one step, a subset of vertices of  $T$ ,  $Q = \{v_2, v_3, v_4, v_5\}$ , with cardinality 4 and such that  $T \setminus Q$  has 13 components, each of which is a path. Therefore,  $\Delta(T) = 13 - 4 = 9$ .

Note that, in any stage of the process to determine  $\Delta(T)$ , we may not choose just any vertex with degree greater than or equal to 3.

TABLE 34.1  $\Delta(T)$  for the tree  $T$  in Figure 34.5

Removed Vertices from $T$	$q$	$p$	$p - q (= \Delta(T))$
5	1	5	4

FIGURE 34.7 A tree of diameter 6 for which the minimum number of distinct eigenvalues is  $8 > 6 + 1$ .

### 34.3 The Minimum Number of Distinct Eigenvalues

---

**Definitions:**

Let  $T$  be a tree.

The **diameter** of  $T$ ,  $d(T)$ , is the maximum number of edges in a path occurring as an induced subgraph of  $T$ .

The **minimum number of distinct eigenvalues** of  $T$ ,  $\mathcal{N}(T)$ , is the minimum, among  $A \in \mathcal{S}(T)$ , number of distinct eigenvalues of  $A$ .

**Facts:**

1. [JL02a] Let  $T$  be a tree. Then  $\mathcal{N}(T) \geq d(T) + 1$ .
2. [JSa2] If  $T$  is a tree such that  $d(T) < 5$ , then there exist matrices in  $\mathcal{S}(T)$  attaining as few distinct eigenvalues as  $d(T) + 1$ .

**Examples:**

1. Since each entry in a multiplicity list represents a distinct eigenvalue, the “length” of a list represents the number of different eigenvalues. This number can be as large as  $n$  (the number of vertices), of course, but it cannot be too small. Restrictions upon length limit the possible multiplicity lists. Just as a path has many distinct eigenvalues, a long (chordless) path occurring as an induced subgraph of a tree forces a large number of distinct eigenvalues.
2. For many trees  $T$ , there exist matrices in  $\mathcal{S}(T)$  attaining as few distinct eigenvalues as  $d(T) + 1$ . However, for the tree  $T$  in Figure 34.7,  $d(T) = 6$  and, in [BF04], the authors have shown that  $\mathcal{N}(T) = 8 > d(T) + 1$ . It is not known how to deduce the minimum number of distinct eigenvalues from the structure of the tree, in general.

### 34.4 The Number of Eigenvalues Having Multiplicity 1

---

**Definitions:**

Given a tree  $T$ , let  $\mathcal{U}(T)$  be the minimum number of 1s among multiplicity lists occurring for  $T$ .

**Facts:**

1. [JLS03a] For any tree  $T$ , the largest and smallest eigenvalues of any  $A \in \mathcal{S}(T)$  necessarily have multiplicity 1.
2. [JLS03a] For any tree  $T$  on  $n \geq 2$  vertices,  $\mathcal{U}(T) \geq 2$  and, for each  $n$ , there exist trees  $T$  for which  $\mathcal{U}(T) = 2$ .
3. Let  $T$  be a tree on  $n$  vertices.  $\mathcal{U}(T) \geq 2\mathcal{N}(T) - n$ . In particular,  $\mathcal{U}(T) \geq 2(d(T) + 1) - n$ .

**Examples:**

- As with the length of lists, it is relatively easy to have many 1s in a multiplicity list. The more interesting issue is how few of 1s may occur among lists for a given tree  $T$ . It certainly depends upon the tree, as the star (see Figure 34.8) may have just two 1s, while a path (see Figure 34.9) always has as many as the number of vertices.
- If  $T$  has a diameter that is large relative to its number of vertices (a path is an extremal example), then it may have to have a minimum number of distinct eigenvalues, which forces  $\mathcal{U}(T)$  to be much greater than 2. However,  $\mathcal{U}(T)$  may be greater than 2 for other reasons. For example, for the tree  $T$  in Figure 34.10,  $d(T) = 4$ ,  $n = 8$ , but  $\mathcal{U}(T) = 3$ . It is not known how  $\mathcal{U}(T)$  is determined by  $T$ , and it appears to be quite subtle.

FIGURE 34.8 A star.

### 34.5 Existence/Construction of Trees with Given Multiplicities

**Definitions:**

For a given graph  $G$ , the collection of all **multiplicity lists** is denoted by  $\mathcal{L}(G)$ . If it is not clear from the context, we will distinguish the unordered lists as  $\mathcal{L}_u(G)$  from the ordered lists  $\mathcal{L}_o(G)$ .

**General Inverse Eigenvalue Problem (GIEP) for  $\mathcal{S}(T)$ :** Given a vertex  $v$  of a tree  $T$ , what are all the sequences of real numbers that may occur as eigenvalues of  $A$  and  $A(v)$ , as  $A$  runs over  $\mathcal{S}(T)$ ?

**Inverse Eigenvalue Problem (IEP) for  $\mathcal{S}(T)$ :** What are all possible spectra that occur among matrices in  $\mathcal{S}(T)$ ,  $T$  being a tree?

A tree  $T$  has **equivalence of the ordered multiplicity lists and the IEP** if a spectrum occurs for some matrix in  $\mathcal{S}(T)$  whenever it is consistent with some list of ordered multiplicities of  $\mathcal{L}_o(T)$ .

**Facts:**

- [Lea89] Let  $T$  be a tree on  $n$  vertices and  $v$  be a vertex of  $T$ . Let  $\lambda_1, \lambda_2, \dots, \lambda_n$  and  $\mu_1, \mu_2, \dots, \mu_{n-1}$  be real numbers. If

$$\lambda_1 < \mu_1 < \lambda_2 < \dots < \mu_{n-1} < \lambda_n,$$

then there exists a matrix  $A$  in  $\mathcal{S}(T)$  with eigenvalues  $\lambda_1, \lambda_2, \dots, \lambda_n$ , and such that,  $A(v)$  has eigenvalues  $\mu_1, \mu_2, \dots, \mu_{n-1}$ .

- For any tree  $T$  on  $n$  vertices and any given sequence of  $n$  distinct real numbers, there exists a matrix

FIGURE 34.9 A path.

FIGURE 34.10 A tree  $T$  on 8 vertices with  $d(T) = 4$  and  $\mathcal{U}(T) = 3$ .

FIGURE 34.11 A tree for which there is not equivalence between ordered multiplicity lists and the IEP.

in  $\mathcal{S}(T)$  having these numbers as eigenvalues.

3. Any path has equivalence of the ordered multiplicity lists and the IEP.
4. [BF04] There exists a tree for which the equivalence of the ordered multiplicity lists and the IEP is not verified. (See Example 1.)

**Examples:**

1. For remarkably many small trees and many of the families of trees to be discussed in the next section, the ordered multiplicity lists are equivalent to the IEP. This is not always the case. Extremal multiplicity lists for large numbers of vertices can force numerical relations upon the eigenvalues, as in the tree  $T$  shown in Figure 34.11.

Let  $\mathcal{A}$  be the adjacency matrix of  $T$  (i.e., the 0,1-matrix in  $\mathcal{S}(T)$  with all diagonal entries 0). The Parter–Wiener Theorem (Fact 5 Section 34.1) guarantees that  $\alpha_{\mathcal{A}}(0) = 4$ , and likewise guarantees two eigenvalues of multiplicity 2 (the nonzero eigenvalues of  $\mathcal{A}[\{2, 3, 4\}] = \mathcal{A}[\{5, 6, 7\}] = \mathcal{A}[\{8, 9, 10\}]$ , so the ordered multiplicity list of  $\mathcal{A}$  is  $(1, 2, 4, 2, 1)$ . In fact, direct computation shows that  $\sigma(\mathcal{A}) = (-\sqrt{5}, -\sqrt{2}, -\sqrt{2}, 0, 0, 0, \sqrt{2}, \sqrt{2}, \sqrt{5})$ .

However, it is not possible to prescribe arbitrary real numbers as the eigenvalues with this ordered multiplicity list. If  $A = [a_{ij}] \in \mathcal{S}(T)$  has eigenvalues  $\lambda_1 < \lambda_2 < \lambda_3 < \lambda_4 < \lambda_5$  with multiplicities 1, 2, 4, 2, 1, respectively, then  $\lambda_1 + \lambda_5 = \lambda_2 + \lambda_4$ . The method used to establish this restriction comes from [BF04]. By the Parter–Wiener Theorem and an examination of subsets of vertices,  $a_{11} = \lambda_3$ . The restriction then follows from comparison of the traces of  $A$  and  $A(1)$ .

It is not known for which trees the determination of all possible ordered multiplicity lists is equivalent to the solution of the IEP. Even when the two are not equivalent for some ordered list, they may be for all other ordered lists.

2. In the construction of multiplicity lists for a tree, it is often useful (and, perhaps necessary) to know the solution of the GIEP (or some weak form of it) for some of the subtrees of the tree.

It is often more difficult (than giving necessary restrictions) to construct matrices  $A \in \mathcal{S}(T)$  with a given, especially extremal, multiplicity list, even when that list does occur. There are three basic approaches besides ad hoc methods and computer assisted solution of equations. They are

- (a) Manipulation of polynomials, viewing the nonzero entries as variables and targeting a desired characteristic polynomial (see [Lea89] for an initial reference; this method, based on some nice formulas for the characteristic polynomial in the case of a tree (see, e.g., [Par60], [MOD89]), can be quite tedious for larger, more complicated trees).
- (b) Careful use of the implicit function theorem (initiated in [JSW]).
- (c) Division of the tree into understood parts and using the interlacing inequalities to give lower bounds that are forced to be attained by known constraints (this is along the lines of the brief discussion in Example 1 Section 34.2 involving  $\Delta(T)$ , but for larger trees can lead to complicated simultaneity conditions).

As an example of method (c) and its subtleties (see also Example 2 Section 34.7), consider again the tree  $T$  in Figure 34.4. Since  $P(T) = 2$ , the maximum multiplicity is 2, and because  $d(T) = 3$ , there must be at least four distinct eigenvalues, two of which have multiplicity 1. This leaves the

question of whether the list  $(2, 2, 1, 1)$  (which would have to be the ordered list  $(1, 2, 2, 1)$ ) can occur. It can, but this is the nontrivial example with smallest number of vertices. Suppose that the two multiple eigenvalues are  $\lambda$  and  $\mu$ . We want  $A \in \mathcal{S}(T)$  with  $\alpha_A(\lambda) = 2$  and  $\alpha_A(\mu) = 2$ . Each must have a Parter vertex, which must be either vertex 3 or 4. One must be for  $\lambda$  (and not  $\mu$ ) and the other for  $\mu$  (and not  $\lambda$ ), as two consecutive eigenvalues cannot share a Parter vertex (Fact 8 section 34.1). So assume that 3 is Parter for  $\lambda$  and 4 for  $\mu$ . Then, we must have  $A[\{1\}] = \lambda = A[\{2\}]$  and  $\lambda \in \sigma(A[\{4, 5, 6\}])$ ; and  $A[\{5\}] = \mu = A[\{6\}]$  and  $\mu \in \sigma(A[\{1, 2, 3\}])$ . A calculation (or other methods) shows this can be achieved simultaneously.

## 34.6 Generalized Stars

### Definitions:

A tree  $T$  in which there is at most one vertex of degree greater than two is a **generalized star**.

In a generalized star, a vertex  $v$  is a **central vertex** if its neighbors are pendant vertices of their branches, and each branch is a path. (Note that, under this definition, a path is a (degenerate) generalized star, in which any vertex is a central vertex. When referring to a path as a generalized star, one vertex has been fixed as the central vertex.)

For a central vertex  $v$  of a generalized star  $T$ , each branch of  $T$  at  $v$  is called an **arm** of  $T$ ; the **lengths** of an arm are the number of vertices in the arm.

Supposing that  $v$  is a central vertex of a generalized star  $T$ , with  $\delta_T(v) = k$ . Denote by  $T_1, \dots, T_k$  its arms and by  $l_1, \dots, l_k$  the lengths of  $T_1, \dots, T_k$ , respectively.

A **star** on  $n$  vertices is a tree in which there is a vertex of degree  $n - 1$ .

Let  $u = (u_1, \dots, u_b)$ ,  $u_1 \geq \dots \geq u_b$ , and  $v = (v_1, \dots, v_c)$ ,  $v_1 \geq \dots \geq v_c$ , be two nonincreasing partitions of integers  $M$  and  $N$ , respectively. If  $M < N$ , denote by  $u_e$  the partition of  $N$  obtained from  $u$  appending 1s to the partition  $u$ . Note that if  $M = N$ , then  $u_e = u$ .

### Facts:

1. A star is trivially a generalized star.
2. If  $u$  and  $v$  are two nonincreasing partitions of integers  $M$  and  $N$ , respectively,  $M \leq N$ , such that  $u_1 + \dots + u_s \leq v_1 + \dots + v_s$  for all  $s$  (interpreting  $u_s$  or  $v_s$  as 0 when  $s$  exceeds  $b$  or  $c$ , respectively), then trivially  $v$  majorizes  $u_e$ , denoted  $u_e \leq v$ . See Preliminaries.
3. [JLS03b] Let  $T$  be a generalized star on  $n$  vertices with central vertex  $v$  of degree  $k$ ,  $l_1, \dots, l_k$  be the lengths of the arms  $T_1, \dots, T_k$ , and  $f(x), g_1(x), \dots, g_k(x)$  be monic polynomials with all their roots real in which  $\deg f = n$ ,  $\deg g_1 = l_1, \dots, \deg g_k = l_k$ . There exists  $A \in \mathcal{S}(T)$  such that  $A$  has characteristic polynomial  $f(x)$  and  $A[T_i]$  has characteristic polynomial  $g_i(x)$  if and only if
  - Each  $g_i(x)$  has only simple roots.
  - If  $\lambda$  is a root of  $g_1(x) \cdots g_k(x)$  of multiplicity  $m \geq 1$ , then  $\lambda$  is a root of  $f(x)$  of multiplicity  $m - 1$ .
  - The roots of  $f(x)$  that are not roots of  $g_1(x) \cdots g_k(x)$  are simple and strictly interlace the set of roots of  $g_1(x) \cdots g_k(x)$  (multiple roots counting only once).
4. [JL02b] Let  $T$  be a generalized star on  $n$  vertices with central vertex of degree  $s$  and arm lengths  $l_1 \geq \dots \geq l_s$ . Then  $(p_1, \dots, p_r) \in \mathcal{L}_u(T)$  if and only if
  - $\sum_{i=1}^r p_i = n$ .
  - $r \geq l_1 + l_2 + 1$ .
  - $p_h = p_{h+1} = \dots = p_r = 1$ , in which  $h = \lceil \frac{r+1}{2} \rceil$ .
  - $(p_1, p_2, \dots, p_{r-l_1-1}) \leq (l_1^* - 1, \dots, l_{l_1}^* - 1)$ .

FIGURE 34.12  $T_1$ ,  $T_2$ , and  $T_3$  are generalized stars on 9 vertices with central vertices  $v_1$ ,  $v_2$ , and  $v_3$ , respectively.

5. [JLS03b] Let  $T$  be a generalized star on  $n$  vertices with central vertex of degree  $s$  and arm lengths  $l_1 \geq \dots \geq l_s$ . Let  $\lambda_1 < \dots < \lambda_r$  be any sequence of real numbers. Then there exists a matrix  $A \in \mathcal{S}(T)$  with distinct eigenvalues  $\lambda_1 < \dots < \lambda_r$  and list of ordered multiplicities  $q = (q_1, \dots, q_r)$  if and only if  $q$  satisfies the following conditions:

- $\sum_{i=1}^r q_i = n$ .
- If  $q_i > 1$ , then  $1 < i < r$  and  $q_{i-1} = 1 = q_{i+1}$ .
- $(q_{i_1} + 1, \dots, q_{i_h} + 1)_e \preceq (l_1, \dots, l_s)^*$ , in which  $q_{i_1} \geq \dots \geq q_{i_h}$  are the entries of the  $r$ -tuple  $(q_1, \dots, q_r)$  greater than 1.

(That is, when  $T$  is a generalized star, there is equivalence of the ordered multiplicity lists and the IEP.)

**Examples:**

1. Let  $T_1$ ,  $T_2$ , and  $T_3$  be the generalized stars in Figure 34.12. We have

$$\begin{aligned} \mathcal{L}_u(T_1) &= \{(1, 1, 1, 1, 1, 1, 1, 1, 1), (2, 1, 1, 1, 1, 1, 1, 1)\}, \\ \mathcal{L}_u(T_2) &= \{(1, 1, 1, 1, 1, 1, 1, 1, 1), (2, 1, 1, 1, 1, 1, 1, 1), (2, 2, 1, 1, 1, 1, 1), \\ &\quad (3, 1, 1, 1, 1, 1, 1), (3, 2, 1, 1, 1, 1), (3, 3, 1, 1, 1), (4, 1, 1, 1, 1, 1), \\ &\quad (4, 2, 1, 1, 1)\}, \end{aligned}$$

and

$$\begin{aligned} \mathcal{L}_u(T_3) &= \{(1, 1, 1, 1, 1, 1, 1, 1, 1), (2, 1, 1, 1, 1, 1, 1, 1), (2, 2, 1, 1, 1, 1, 1), \\ &\quad (3, 1, 1, 1, 1, 1, 1), (3, 2, 1, 1, 1, 1), (3, 3, 1, 1, 1), (4, 1, 1, 1, 1, 1), \\ &\quad (4, 2, 1, 1, 1), (5, 1, 1, 1, 1), (6, 1, 1, 1), (7, 1, 1)\}. \end{aligned}$$

### 34.7 Double Generalized Stars

---

**Definitions:**

A **double generalized star** is a tree resulting from joining the central vertices of two generalized stars  $T_1$  and  $T_2$  by an edge. Such a tree will be denoted by  $D(T_1, T_2)$ .

A **double star** is a double generalized star  $D(T_1, T_2)$  in which  $T_1$  and  $T_2$  are stars.

FIGURE 34.13 A double path.

A **double path** is a double generalized star  $D(T_1, T_2)$  in which  $T_1$  and  $T_2$  are paths. When we refer to a double path  $T$  on  $n = p + q$  vertices we suppose  $T$  is represented as in Figure 34.13, in which the only constraint on the connecting edge  $\{i_k, j_l\}$  is that not both  $k \in \{1, p\}$  and  $l \in \{1, q\}$ . The upper ( $i$ ) path has  $k - 1$  vertices to the left of the connecting vertex and another  $p - k$  vertices to the right; set  $s_1 = \min\{k - 1, p - k\}$ ,  $s_2 = \min\{l - 1, q - l\}$ , and  $s = \min\{q, p, s_1 + s_2\}$ .

Let  $G$  be a tree. Let  $v$  be a vertex of  $G$  of degree  $k$  and  $G_1, \dots, G_k$  be the components of  $G \setminus \{v\}$  having order  $l_1, \dots, l_k$ , respectively. To the tree  $G$  is **associated the generalized star**,  $S_v(G)$ , with central vertex  $v$  of degree  $k$ , and with arms  $T_1, \dots, T_k$  of lengths  $l_1, \dots, l_k$ , respectively.

Let  $u_1$  and  $u_2$  be adjacent vertices of a tree  $G$ . Denote by  $G_{u_1}$  the connected component of  $G \setminus \{u_2\}$  that contains  $u_1$  and by  $G_{u_2}$  the connected component of  $G \setminus \{u_1\}$  that contains  $u_2$ . Put  $S_1 = S_{u_1}(G_{u_1})$  and  $S_2 = S_{u_2}(G_{u_2})$ . Now, to the tree  $G$  is **associated the double generalized star**  $D(S_1, S_2)$ , which is denoted by  $D_{u_1, u_2}(G)$ .

Given a vertex  $v$  of a tree  $T$  and an eigenvalue  $\lambda$  of a matrix  $A \in \mathcal{S}(T)$ ,  $\lambda$  is an **upward eigenvalue** of  $A$  at  $v$  if  $\alpha_{A(v)}(\lambda) = \alpha_A(\lambda) + 1$ , and  $\alpha_A(\lambda)$  is an **upward multiplicity** of  $A$  at  $v$ .

If  $q = q(A) = (q_1, \dots, q_r)$  is the list of ordered multiplicities of  $A$ , define the **list of upward multiplicities** of  $A$  at  $v$ , denoted by  $\hat{q}$ , as the list with the same entries as  $q$  but in which any upward multiplicity  $q_i$  of  $A$  at  $v$  is marked as  $\hat{q}_i$  in  $\hat{q}$ .

Given a generalized star  $T$  with central vertex  $v$ , we denote by  $\hat{\mathcal{L}}_o(T)$  the **set of all lists of upward multiplicities** at  $v$  occurring among matrices in  $\mathcal{S}(T)$ .

**Facts:**

1. A double path is a tree whose path cover number is 2.
2. [JLS03b] Let  $T$  be a generalized star on  $n$  vertices with central vertex  $v$  of degree  $k$  and arm lengths  $l_1 \geq \dots \geq l_k$ . Let  $\lambda_1 < \dots < \lambda_r$  be any sequence of real numbers. Then there exists a matrix  $A$  in  $\mathcal{S}(T)$  with distinct eigenvalues  $\lambda_1 < \dots < \lambda_r$  and a list of upward multiplicities  $\hat{q} = (\hat{q}_1, \dots, \hat{q}_r)$  if and only if  $\hat{q}$  satisfies the following conditions:
  - $\sum_{i=1}^r q_i = n$ .
  - If  $q_i$  is an upward multiplicity in  $\hat{q}$ , then  $1 < i < r$  and neither  $q_{i-1}$  nor  $q_{i+1}$  is an upward multiplicity in  $\hat{q}$ .
  - $(q_{i_1} + 1, \dots, q_{i_h} + 1)_e \leq (l_1, \dots, l_k)^*$ , in which  $q_{i_1} \geq \dots \geq q_{i_h}$  are the upward multiplicities of  $\hat{q}$ .
3. [JLS03b] (Superposition Principle) Let  $D(T_1, T_2)$  be a double generalized star,  $\hat{b} = (\widehat{b_1, \dots, b_{s_1}}) \in \hat{\mathcal{L}}_o(T_1)$ , and  $\hat{c} = (\widehat{c_1, \dots, c_{s_2}}) \in \hat{\mathcal{L}}_o(T_2)$ . Construct any  $b^+ = (b_1^+, \dots, b_{s_1+t_1}^+)$  and  $c^+ = (c_1^+, \dots, c_{s_2+t_2}^+)$  subject to the following conditions:
  - $t_1, t_2 \in \mathbb{N}_0$  and  $s_1 + t_1 = s_2 + t_2$ .
  - $b^+$  (respectively,  $c^+$ ) is obtained from  $\hat{b}$  (respectively,  $\hat{c}$ ) by inserting  $t_1$  (respectively,  $t_2$ ) 0s.
  - $b_i^+$  and  $c_i^+$  cannot both be 0.
  - If  $b_i^+ > 0$  and  $c_i^+ > 0$ , then at least one of the  $b_i^+$  or  $c_i^+$  must be an upward multiplicity of  $\hat{b}$  or  $\hat{c}$ .

Then  $b^+ + c^+ \in \mathcal{L}_o(D(T_1, T_2))$ . Moreover,  $a \in \mathcal{L}_o(D(T_1, T_2))$  if and only if there are  $\hat{b} \in \hat{\mathcal{L}}_o(T_1)$ ,  $\hat{c} \in \hat{\mathcal{L}}_o(T_2)$  such that  $a = b^+ + c^+$ .

4. Let  $T$  be a tree,  $v$  be a vertex of  $T$ , and  $v_1, v_2$  be adjacent vertices of  $T$ . Then
  - $\mathcal{L}_u(S_v(T)) \subseteq \mathcal{L}_u(T)$ ,  $\mathcal{L}_o(S_v(T)) \subseteq \mathcal{L}_o(T)$ .
  - $\mathcal{L}_u(D_{v_1, v_2}(T)) \subseteq \mathcal{L}_u(T)$ ,  $\mathcal{L}_o(D_{v_1, v_2}(T)) \subseteq \mathcal{L}_o(T)$ .
5. [JL02b] Let  $T$  be a double path on  $n = p + q$  vertices and suppose that  $A \in \mathcal{S}(T)$ . Then
  - The maximum multiplicity of an eigenvalue of  $A$  is 2.
  - The diameter of  $G$  is  $\max\{p, q, p + q - (s_1 + s_2)\} - 1$ , so that  $A$  has at least  $\max\{p, q, p + q - (s_1 + s_2)\}$  distinct eigenvalues.
  - $A$  has at most  $s$  multiplicity 2 eigenvalues.
  - The possible list of unordered multiplicities for  $T$ ,  $\mathcal{L}_u(T)$ , consists of all partitions of  $p + q$  into parts each one not greater than two and with at most  $s$  equal to 2.
  - Any list in  $\mathcal{L}_u(T)$  has at least  $n - 2s$  1s.

**Examples:**

1. Let  $T_1$  and  $T_2$  be the stars in Figure 34.14 with central vertices  $v_1$  and  $v_2$ , respectively, and  $G$  be the double star  $D(T_1, T_2)$ . By Fact 2, we have that

$$\hat{\mathcal{L}}_o(T_1) = \{(1, \hat{2}, 1), (1, \hat{1}, 1, 1), (1, 1, \hat{1}, 1), (1, 1, 1, 1)\}$$

and

$$\hat{\mathcal{L}}_o(T_2) = \{(1, \hat{1}, 1), (1, 1, 1)\}.$$

Applying the Superposition Principle (Fact 3) to the lists of upward multiplicities of  $T_1$  and  $T_2$ , it follows that

$$\begin{aligned} \mathcal{L}_o(G) = & \{(1, 3, 2, 1), (1, 2, 3, 1), (1, 3, 1, 1, 1), (1, 1, 3, 1, 1), (1, 1, 1, 3, 1), \\ & (1, 2, 2, 1, 1), (1, 2, 1, 2, 1), (1, 1, 2, 2, 1), (1, 2, 1, 1, 1, 1), \\ & (1, 1, 2, 1, 1, 1), (1, 1, 1, 2, 1, 1), (1, 1, 1, 1, 2, 1), (1, 1, 1, 1, 1, 1, 1)\}. \end{aligned}$$

For example,  $(1, 3, 2, 1) \in \mathcal{L}_o(G)$  because  $\hat{b} = (1, \hat{2}, 1) \in \hat{\mathcal{L}}_o(T_1)$ ,  $\hat{c} = (1, \hat{1}, 1) \in \hat{\mathcal{L}}_o(T_2)$ , and

$$(1, 3, 2, 1) = b^+ + c^+ = (1, \hat{2}, 1, 0) + (0, 1, \hat{1}, 1).$$

FIGURE 34.14 Stars and a double star.

FIGURE 34.15 A double path on 11 vertices.

- Consider the double path  $T$  on 11 vertices in Figure 34.15. Let  $T_1$  be the path with vertices  $i_1, \dots, i_6$  and  $T_2$  be the path with vertices  $j_1, \dots, j_5$  (subgraphs of  $T$  induced by the mentioned vertices). Because  $T_1$  and  $T_2$  are generalized stars with central vertices  $i_3$  and  $j_3$ , respectively, from Fact 2 we conclude that  $\hat{b} = (1, \hat{1}, 1, \hat{1}, 1, 1) \in \hat{\mathcal{L}}_o(T_1)$  and  $\hat{c} = (1, \hat{1}, 1, \hat{1}, 1) \in \hat{\mathcal{L}}_o(T_2)$ . Since, for example,

$$(1, 2, 2, 2, 2, 1, 1) = b^+ + c^+ = (0, 1, \hat{1}, 1, \hat{1}, 1, 1) + (1, \hat{1}, 1, \hat{1}, 1, 0, 0),$$

by the Superposition Principle, we conclude that  $(1, 2, 2, 2, 2, 1, 1) \in \mathcal{L}_o(T)$  and, therefore,  $(2, 2, 2, 2, 1, 1, 1) \in \mathcal{L}_u(T)$ . We may construct a matrix  $A \in \mathcal{S}(T)$  with list of multiplicities  $(2, 2, 2, 2, 1, 1, 1)$  in the following way.

Pick real numbers  $\lambda_1 > \mu_1 > \lambda_2 > \mu_2 > \lambda_3 > \mu_3 > \lambda_4$ . Construct  $A_1$  with graph  $T_1$  such that  $A_1$  has eigenvalues  $\lambda_1, \mu_1, \lambda_2, \mu_2, \lambda_3, \lambda_4$  and such that the eigenvalues of  $A_1[\{i_1, i_2\}]$  and  $A_1[\{i_4, i_5, i_6\}]$  are  $\mu_1, \mu_2$  and  $\mu_1, \mu_2, \mu_3$ , respectively; construct  $A_2$  with graph  $T_2$  such that  $A_2$  has eigenvalues  $\mu_1, \lambda_2, \mu_2, \lambda_3, \mu_3$  and such that the eigenvalues of both  $A_2[\{j_1, j_2\}]$  and  $A_2[\{j_4, j_5\}]$  are  $\lambda_2, \lambda_3$ . According to Fact 3 section 34.6, these constructions are possible. Now construct  $A$  with graph  $T$  and such that  $A[T_1] = A_1$  and  $A[T_2] = A_2$ . Then  $i_3$  is a strong Parter vertex for  $\mu_1, \mu_2$ , while  $j_3$  is a strong Parter for  $\lambda_2, \lambda_3$  and so  $(2, 2, 2, 2, 1, 1, 1)$  is the list of unordered multiplicities of  $A$ .

- Regarding Fact 4, the results for generalized stars or double generalized stars may be extended to a general tree  $T$  by associating with  $T$  either a generalized star or a double generalized star according to the given definitions. (See also [JLS03b, Theorem 10] for a corresponding result for the GIEP.)

Note that, under our definition, there are many different possibilities to associate either a generalized star or a double generalized star to a given tree  $T$ , and so Fact 3 provides many possible lists for  $\mathcal{L}(T)$ . The natural question is to ask whether all the elements of  $\mathcal{L}(T)$  can be obtained in this manner. The answer is no. It suffices to note that the path cover number of  $T$  will be, in general, strictly greater than that of either of  $S_\nu(T)$  or  $D_{\nu_1, \nu_2}(T)$  for any possible choice of  $\nu, \nu_1$ , and  $\nu_2$ . So any lists for which the maximum multiplicity occurs cannot generally be obtained from the inclusions in Fact 4. For example, the tree  $T$  in Figure 34.16 has path cover number 3, which is strictly greater than the maximum path cover number 2, of any generalized star or double generalized star associated with  $T$ .

FIGURE 34.16 A tree with path cover number 3.

## 34.8 Vines

---

### Definitions:

A **binary tree** is a tree in which no vertex has degree greater than 3.

A **vine** is a binary tree in which every degree 3 vertex is adjacent to at least one vertex of degree 1 and no two vertices of degree 3 are adjacent.

### Facts:

- [JSW] Let  $T$  be a vine on  $n$  vertices. The set  $\mathcal{L}_u(T)$  consists of all sequences that are majorized by the sequence  $s = (P(T), 1, \dots, 1)$  ( $s$  being a partition of  $n$ ).  
(The description of  $\mathcal{L}_u(T)$  was given by using the implicit function theorem technique referred to in section 34.5.)

A partial matrix is a rectangular array of numbers in which some entries are specified while others are free to be chosen. A completion of a partial matrix is a specific choice of values for the unspecified entries. A matrix completion problem asks whether a partial matrix (or family of partial matrices with a given pattern of specified entries) has a completion of a specific type, such as a positive definite matrix. In some cases, a “best” completion is sought.

Matrix completion problems arise in applications whenever a full set of data is not available, but it is known that the full matrix of data must have certain properties. Such applications include molecular biology and chemistry (see Chapter 60), seismic reconstruction problems, mathematical programming, and data transmission, coding, and image enhancement problems in electrical and computer engineering.

A matrix completion problem for a family of partial matrices with a given pattern of specified entries is usually studied by means of graphs or digraphs. If a pattern of specified entries does not always allow completion to the desired type of matrix, conditions on the entries that will allow such completion are sought. A question of finding the “best completion” often involves optimization techniques. Matrix completion results are usually constructive, with the result established by giving a specific construction for a completion.

In this chapter, we focus on completion problems involving classes of matrices that generalize the positive definite matrices, and emphasize graph theoretic techniques that allow completion of families of matrices. This chapter is organized by class of matrices, with the symmetric classes first. The authors also maintain a Web page containing updated information [HW].

Organizing the information by classes of matrices provides easy access to results about a particular class, but obscures techniques that apply to the matrix completion problems of many classes and relationships between completion problems for different classes. For information on these subjects, see for example [FJT00], [Hog01], and [Hog03a].

## 35.1 Introduction

---

All matrices and partial matrices discussed here are square. Graphs allow loops but do not allow multiple edges. The definitions and terminology about graphs and digraphs given in Chapter 28 and Chapter 29 is used here; however, the association between matrices and digraphs is different from the association in those chapters, where an arc is associated with a nonzero entry. Here an arc is associated with a specified entry.

### Definitions:

A **partial matrix** is a square array in which some entries are specified and others are not. An unspecified entry is denoted by ? or by  $x_{ij}$ . An ordinary matrix is considered a partial matrix, as is a matrix with no specified entries.

A **completion** of a partial matrix is a choice of values for the unspecified entries.

A partial matrix  $B$  is **combinatorially symmetric** (also called **positionally symmetric**) if  $b_{ij}$  specified implies  $b_{ji}$  specified.

Let  $B$  be an  $n \times n$  partial matrix. The **digraph** of  $B$ ,  $\mathcal{D}(B) = (V, E)$ , has vertices  $V = \{1, \dots, n\}$ , and for each  $i$  and  $j$  in  $V$ , the arc  $(i, j) \in E$  exactly when  $b_{ij}$  is specified.

Let  $B$  be an  $n \times n$  combinatorially symmetric partial matrix. The **graph** of  $B$ ,  $\mathcal{G}(B) = (V, E)$ , has vertices  $V = \{1, \dots, n\}$ , and for each  $i$  and  $j$  in  $V$ , the edge  $\{i, j\} \in E$  exactly when  $b_{ij}$  is specified.

A connected graph or digraph is **nonseparable** if it does not have a cut-vertex.

A **block** of a graph or digraph is a maximal nonseparable sub(di)graph. This use of “block” is for graphs and digraphs and differs from “block” in a block matrix.

A graph (respectively, digraph) is a **clique** if every vertex has a loop and for any two distinct vertices  $u, v$ , the edge  $\{u, v\}$  is present (respectively, both arcs  $(u, v), (v, u)$  are present).

A graph or digraph is **block-clique** (also called **1-chordal**) if every block is a clique.

A digraph  $G = (V, E)$  is **symmetric** if  $(i, j) \in E$  implies  $(j, i) \in E$  for all  $i, j \in V$ .

A digraph  $G = (V, E)$  is **asymmetric** if  $(i, j) \in E$  implies  $(j, i) \notin E$  for all distinct  $i, j \in V$ .

A **simple cycle** in a digraph is an induced subdigraph that is a cycle.

A digraph (respectively, graph)  $G$  has the  **$X$ -completion property** (where  $X$  is a type of matrix) if every partial  $X$ -matrix  $B$  such that  $\mathcal{D}(B) = G$  (respectively,  $\mathcal{G}(B) = G$ ) can be completed to an  $X$ -matrix. In the literature, the phrase “has  $X$ -completion” is sometimes used for “has the  $X$ -completion property.”

A class  $X$  is **closed under permutation similarity** if whenever  $A$  is an  $X$ -matrix and  $P$  is a permutation matrix, then  $P^T A P$  is an  $X$ -matrix.

A class  $X$  is **hereditary** (or **closed under taking principal submatrices**) if whenever  $A$  is an  $X$ -matrix and  $\alpha \subseteq \{1, \dots, n\}$ , then  $A[\alpha]$  is an  $X$ -matrix.

A class  $X$  is **closed under matrix direct sums** if whenever  $A_1, A_2, \dots, A_k$  are  $X$ -matrices, then  $A_1 \oplus A_2 \oplus \dots \oplus A_k$  is an  $X$ -matrix.

A class  $X$  has the **triangular property** if whenever  $A$  is a block triangular matrix and every diagonal block is an  $X$ -matrix, then  $A$  is an  $X$  matrix.

A partial matrix  $B$  is in **pattern block triangular form** if the adjacency matrix of  $\mathcal{D}(B)$  is in block triangular form.

*Note:* Many matrix terms, such as size, entry, submatrix, etc., are applied in the obvious way to partial matrices.

**Facts:**

Let  $X$  be one of the following classes of matrices: positive (semi)definite matrices, Euclidean distance matrices, (symmetric)  $M$ -matrices, (symmetric)  $M_0$ -matrices, (symmetric) inverse  $M$ -matrices, completely positive matrices, doubly nonnegative matrices, (strictly) copositive matrices,  $P$ -matrices,  $P_0$ -matrices,  $P_{0,1}$ -matrices, nonnegative  $P$ -matrices, nonnegative  $P_0$ -matrices, positive  $P$ -matrices, entry (weakly) sign symmetric  $P$ -matrices, entry (weakly) sign symmetric  $P_0$ -matrices, entry (weakly) sign symmetric  $P_{0,1}$ -matrices. (The definitions of these classes can be found in the relevant sections.)

Proofs of the facts below can be found in [Hog01] for most of the classes discussed, and the proofs given there apply to all the classes  $X$  listed above. Most of these facts are also in the original papers discussing the completion problem for a specific class; those references are listed in the section devoted to the class. In the literature, when it is assumed that a partial matrix  $B$  has every diagonal entry specified (equivalently, every vertex of the graph  $\mathcal{G}(B)$  or digraph  $\mathcal{D}(B)$  has a loop), it is customary to suppress all the loops and treat  $\mathcal{G}(B)$  or  $\mathcal{D}(B)$  as a simple graph or digraph. That is not done in this chapter because of the danger of confusion. Also, in some references, such as [Hog01], a mark is used to indicate a specified vertex instead of a loop. This has no effect on the results (but requires translation of the notation). If  $X$  is a symmetric class of matrices, then there is no loss of generality in assuming every partial matrix is combinatorially symmetric and this assumption is standard practice.

1. If  $B$  is a combinatorially symmetric partial matrix, then  $\mathcal{D}(B)$  is a symmetric digraph and  $\mathcal{G}(B)$  is the graph associated with  $\mathcal{D}(B)$ . Combinatorially symmetric partial matrices are usually studied by means of graphs rather than digraphs, and it is understood that the graph represents the associated symmetric digraph.
2. Each of the classes  $X$  listed at the beginning of the facts is closed under permutation similarity. This fact is not true for the classes of totally nonnegative and totally positive matrices. (See [FJS00] for information about matrix completion problems for these matrices.)
3. Applying a permutation similarity to a partial matrix  $B$  corresponds to renumbering the vertices of the digraph  $\mathcal{D}(B)$  (or graph  $\mathcal{G}(B)$  if  $B$  is combinatorially symmetric).
4. Renumbering the vertices of a graph or digraph does not affect whether it has the  $X$ -completion property. It is customary to use unlabeled (di)graph diagrams. This fact is not true for the classes of totally nonnegative and totally positive matrices.
5. Each of the classes  $X$  listed at the beginning of the facts is hereditary.
6. Let  $B$  be a partial matrix and  $\alpha \subseteq \{1, \dots, n\}$ . The digraph of the principal submatrix  $B[\alpha]$  is isomorphic to the subdigraph of  $\mathcal{D}(B)$  induced by  $\alpha$  (and is customarily identified with it). The same is true for the graph if  $B$  is combinatorially symmetric.
7. If a graph or digraph  $G$  has the  $X$ -completion property, then every induced subgraph or induced subdigraph of  $G$  has the  $X$ -completion property.
8. Each of the classes  $X$  listed at the beginning of the facts is closed under matrix direct sums.
9. Let  $B$  be a partial matrix such that all specified entries are contained in diagonal blocks  $B_1, B_2, \dots, B_k$ . The connected components of  $\mathcal{D}(B)$  are isomorphic to the  $\mathcal{D}(B_i)$ ,  $i = 1, \dots, k$ . The same is true for  $\mathcal{G}(B)$  if  $B$  is combinatorially symmetric.
10. A graph or digraph  $G$  has the  $X$ -completion property if and only if every connected component of  $G$  has the  $X$ -completion property.
11. If  $X$  has the triangular property,  $B$  is a partial matrix in pattern block triangular form, and each pattern diagonal block can be completed to an  $X$ -matrix, then  $B$  can be completed to an  $X$ -matrix.
12. If  $X$  has the triangular property and is closed under permutation similarity, then a graph or digraph  $G$  has the  $X$ -completion property if and only if every strongly connected component of  $G$  has the  $X$ -completion property.
13. A block-clique graph is chordal.
14. A block-clique digraph is symmetric.

**Examples:**

1. Graphs (a) through (n) will be used in the examples in the following sections.

2. The matrix  $\begin{bmatrix} 1 & 3 & ? & 0 \\ -1 & 1 & -7 & ? \\ ? & -7 & 1 & 2 \\ 8 & ? & 0 & 1 \end{bmatrix}$  is a partial matrix specifying the graph 1a with vertices numbered 1, 2, 3, 4 clockwise from upper left (or any other numbering around the cycle in order).

3. The graph 1f is block-clique, and this is the only block-clique graph in Example 1.
4. The following digraphs ((a) through (r)) will be used in the examples in the following sections. Note that when both arcs  $(i, j)$  and  $(j, i)$  are present, the arrows are omitted.

5. None of the digraphs in Example 4 are symmetric. (We diagram a symmetric digraph by its associated graph.) Digraphs 4b, 4h, 4i, 4j, and 4l are asymmetric.

## 35.2 Positive Definite and Positive Semidefinite Matrices

In this section, all matrices are real or complex.

### Definitions:

The matrix  $A$  is **positive definite** (respectively, **positive semidefinite**) if  $A$  is Hermitian and for all  $\mathbf{x} \neq 0$ ,  $\mathbf{x}^* A \mathbf{x} > 0$  (respectively,  $\mathbf{x}^* A \mathbf{x} \geq 0$ ).

The partial matrix  $B$  is a **partial positive definite matrix** (respectively, **partial positive semidefinite matrix**) if every fully specified principal submatrix of  $B$  is a positive definite matrix (respectively, positive semidefinite matrix), and whenever  $b_{ij}$  is specified then so is  $b_{ji}$  and  $b_{ji} = \overline{b_{ij}}$ .

### Facts:

1. A Hermitian matrix  $A$  is positive definite (respectively, positive semidefinite) if and only if it is positive stable (respectively, positive semistable) if and only if all principal minors are positive (respectively, nonnegative). There are many additional characterizations. (See Chapter 8.4 for more information.)
2. [GJS84] A graph that has a loop at every vertex has the positive definite (positive semidefinite) completion property if and only if it is chordal. (For information on how to construct such a completion, see [GJS84] and [DG81].)

3. [GJS84] A graph has the positive definite completion property if and only if the subgraph induced by the vertices with loops has the positive definite completion property.
4. [Hog01] A graph  $G$  has the positive semidefinite completion property if and only if for each connected component  $H$  of  $G$ , either  $H$  has a loop at every vertex and is chordal, or  $H$  has no loops.
5. [GJS84] If  $B$  is a partial positive definite matrix with all diagonal entries specified such that  $\mathcal{G}(B)$  is chordal, then there is a unique positive definite completion  $A$  of  $B$  that maximizes the determinant, and this completion has the property that whenever the  $i, j$ -entry of  $B$  is unspecified, the  $i, j$ -entry of  $A^{-1}$  is zero.
6. [Fie66] Let  $C$  be a partial positive semidefinite matrix such that every diagonal entry is specified and  $\mathcal{G}(B)$  with loops suppressed is a cycle. If any diagonal entry is 0, then  $B$  can be completed to a positive semidefinite matrix. If every diagonal entry is nonzero, there is a positive diagonal matrix  $D$  such that every diagonal entry of  $C = DBD$  is equal to 1. Let the specified off-diagonal entries of  $C$  be denoted  $c_1, \dots, c_n$ . Then  $C$  (and, hence,  $B$ ) can be completed to a positive semidefinite matrix if and only if the following *cycle conditions* are satisfied:

$$\begin{aligned}
 2 \max_{1 \leq k \leq n} \arccos|c_k| &\leq \sum_{k=1}^n \arccos|c_k| && \text{for } c_1 \dots c_n > 0, \\
 \sum_{k=1}^n \arccos|c_k| &\geq \pi && \text{for } c_1 \dots c_n \leq 0.
 \end{aligned}$$

(See [BJL96] for additional information.)

**Examples:**

The graphs for the examples can be found in Example 1 of Section 35.1.

1. The graphs 1d, 1f, and 1h have both the positive definite and positive semidefinite completion properties by Fact 2.
2. The graphs 1a, 1b, 1c, 1e, and 1g have neither the positive definite nor the positive semidefinite completion property by Fact 2.
3. The graphs 1j, 1k, 1l, 1m, and 1n have the positive definite completion property by Facts 3 and 2.
4. The graph 1i does not have the positive definite completion property by Facts 3 and 2.
5. The graph 1l has the positive semidefinite completion property by Fact 4.
6. The graphs 1i, 1j, 1k, 1m, and 1n do not have the positive semidefinite completion property by Fact 4.

7. The partial matrix  $B = \begin{bmatrix} 1 & .3 & ? & ? & -.1 \\ .3 & 1 & 1 & ? & ? \\ ? & 1 & 1 & .2 & ? \\ ? & ? & .2 & 1 & 1 \\ -.1 & ? & ? & 1 & 1 \end{bmatrix}$  can be completed to a positive semidefinite

matrix by Fact 6 because

$$\sum_{k=1}^n \arccos|c_k| = 4.10617 \geq \pi.$$

### 35.3 Euclidean Distance Matrices

---

In this section, all matrices are real.

**Definitions:**

The matrix  $A = [a_{ij}]$  is a **Euclidean distance matrix** if there exist vectors  $\mathbf{x}_1, \dots, \mathbf{x}_n \in \mathbb{R}^d$  (for some  $d \geq 1$ ) such that  $a_{ij} = \|\mathbf{x}_i - \mathbf{x}_j\|_2$  for all  $i, j = 1, \dots, n$ .

The partial matrix  $B$  is a **partial Euclidean distance matrix** if every diagonal entry is specified and equal to 0, every fully specified principal submatrix of  $B$  is a Euclidean distance matrix, and whenever  $b_{ij}$  is specified then so is  $b_{ji}$  and  $b_{ji} = b_{ij}$ .

**Facts:**

1. Every Euclidean distance matrix has all diagonal elements equal to 0. There is no loss of generality by considering only a graph that has loops at every vertex, and requiring all diagonal entries of partial Euclidean distance matrices to be 0.
2. [Lau98] A graph with a loop at every vertex has the Euclidean distance completion property if and only if it is chordal.
3. [Lau98] A graph with a loop at every vertex has the Euclidean distance completion property if and only if it has the positive semidefinite completion property. There is a method for transforming the Euclidean distance completion problem into the positive semidefinite completion problem via the Schoenberg transform that provides additional information about conditions on entries that are sufficient to guarantee completion.

**Examples:**

The graphs for the examples can be found in Example 1 of Section 35.1.

1. The graphs 1d, 1f, and 1h have the Euclidean distance completion property by Fact 2.
2. The graphs 1a, 1b, 1c, 1e, and 1g do not have the Euclidean distance completion property by Fact 2.

## 35.4 Completely Positive and Doubly Nonnegative Matrices

---

In this section, all matrices are real.

**Definitions:**

The matrix  $A$  is a **completely positive matrix** if  $A = CC^T$  for some nonnegative  $n \times m$  matrix  $C$ .

A matrix is a **doubly nonnegative matrix** if it is positive semidefinite and every entry is nonnegative.

The partial matrix  $B$  is a **partial completely positive matrix** (respectively, **partial doubly nonnegative matrix**) if every fully specified principal submatrix of  $B$  is a completely positive matrix (respectively, doubly nonnegative matrix), and whenever  $b_{ij}$  is specified then so is  $b_{ji}$  and  $b_{ji} = b_{ij}$ , and all specified off-diagonal entries are nonnegative.

**Facts:**

1. A completely positive matrix is doubly nonnegative.
2. [DJ98] A graph that has a loop at every vertex has the completely positive completion property (respectively, doubly nonnegative completion property) if and only if it is block-clique.
3. [Hog02] A graph  $G$  has the completely positive completion property (respectively, doubly nonnegative completion property) if and only if for every connected component  $H$  of  $G$ ,  $H$  is block-clique, or  $H$  has no loops.
4. A graph has the completely positive completion property if and only if it has the doubly nonnegative completion property.
5. [DJK00] A partial matrix that satisfies the conditions of Fact 6 of Section 35.2 can be completed to a CP- (respectively, DN-) matrix.

**Examples:**

The graphs for the examples can be found in Example 1 of Section 35.1.

1. The graph 1f has both the completely positive completion property and the doubly nonnegative completion property by Fact 2.

2. The graphs 1a, 1b, 1c, 1d, 1e, 1g, and 1h have neither the completely positive completion property nor the doubly nonnegative completion property by Fact 2.
3. The graph 1l has both the completely positive completion property and the doubly nonnegative completion property by Fact 3.
4. The graphs 1i, 1j, 1k, 1m, and 1n have neither the completely positive completion property nor the doubly nonnegative completion property by Fact 3.

## 35.5 Copositive and Strictly Copositive Matrices

In this section, all matrices are real.

### Definitions:

The symmetric matrix  $A$  is **strictly copositive** if  $\mathbf{x}^T A \mathbf{x} > 0$  for all  $\mathbf{x} \geq 0$  and  $\mathbf{x} \neq 0$ ;  $A$  is **copositive** if  $\mathbf{x}^T A \mathbf{x} \geq 0$  for all  $\mathbf{x} \geq 0$ .

The partial matrix  $B$  is a **partial strictly copositive matrix** (respectively, **partial copositive matrix**) if every fully specified principal submatrix of  $B$  is a strictly copositive matrix (respectively, copositive matrix) and whenever  $b_{ij}$  is specified then so is  $b_{ji}$  and  $b_{ji} = b_{ij}$ .

### Facts:

1. If  $A$  is (strictly) copositive, then so is  $A + M$  for any symmetric nonnegative matrix  $M$ .
2. [HJR05] [Hog] Every partial strictly copositive matrix can be completed to a strictly copositive matrix using the method described in Facts 4 and 5 below.
3. [HJR05] Every partial copositive matrix that has every diagonal entry specified can be completed to a copositive matrix using the completion described in Fact 4 below. There exists a partial copositive matrix with an unspecified diagonal entry that cannot be completed to a copositive matrix (see Example 2 below).
4. [HJR05] Let  $B$  be a partial copositive matrix with every diagonal entry specified. For each pair of unspecified off-diagonal entries, set  $x_{ij} = x_{ji} = \sqrt{b_{ii}b_{jj}}$ . The resulting matrix is copositive, and is strictly copositive if  $B$  is a partial strictly copositive matrix.
5. [Hog] Any completion of a partial strictly copositive matrix omitting only one diagonal entry found by Algorithm 1 is a strictly copositive matrix. If  $B$  is a partial strictly copositive matrix that omits some diagonal entries, values for these entries can be chosen one at a time using Algorithm 1, using the largest value obtained by considering all principal submatrices that are completed by the choice of that diagonal entry, to obtain a partial strictly copositive matrix with specified diagonal that agrees with  $B$  on every specified entry of  $B$ .

#### Algorithm 1: Completing one unspecified diagonal entry

Let  $B = \begin{bmatrix} x_{11} & \mathbf{b}^T \\ \mathbf{b} & B_1 \end{bmatrix}$  be a partial strictly copositive  $n \times n$  matrix having all entries

except the 1,1-entry specified. Let  $\|\cdot\|$  be a vector norm.

Complete  $B$  by choosing a value for  $x_{11}$  as follows:

1.  $\beta = \min_{\mathbf{y} \in \mathbb{R}^{n-1}, \mathbf{y} \geq 0, \|\mathbf{y}\|=1} \mathbf{b}^T \mathbf{y}$ .
2.  $\gamma = \min_{\mathbf{y} \in \mathbb{R}^{n-1}, \mathbf{y} \geq 0, \|\mathbf{y}\|=1} \mathbf{y}^T B_1 \mathbf{y}$ .
3.  $x_{11} > \frac{\beta^2}{\gamma}$ .

6. [HJR05], [Hog] Every graph has the strictly copositive completion property.
7. [HJR05], [Hog] A graph has the copositive completion property if and only if for each connected component  $H$  of  $G$ , either  $H$  has a loop at every vertex, or  $H$  has no loops.

**Examples:**

1. The partial matrix  $B = \begin{bmatrix} x_{11} & -5 & 1 & x_{14} & x_{15} & x_{16} \\ -5 & 1 & -2 & x_{24} & x_{25} & 1 \\ 1 & -2 & 5 & 1 & -1 & -1 \\ x_{14} & x_{24} & 1 & 1 & x_{45} & 1 \\ x_{15} & x_{25} & -1 & x_{45} & x_{55} & x_{56} \\ x_{16} & 1 & -1 & 1 & x_{56} & 3 \end{bmatrix}$  is a partial strictly copositive matrix.

We use the method in Facts 4 and 5 to complete  $B$  to a strictly copositive matrix:  
 Select index 5. The only principal submatrix completed by a choice of  $b_{55}$  is  $B[\{3, 5\}]$ . Any value that makes  $x_{55}b_{33} > b_{35}^2$  will work; we choose  $x_{55} = 1$ .  
 Select index 1. The only principal submatrices completed by a choice of  $b_{11}$  are principal submatrices

of  $B[\{1, 2, 3\}] = \begin{bmatrix} x_{11} & \mathbf{b}^T \\ \mathbf{b} & B[\{2, 3\}] \end{bmatrix}$ . Apply Algorithm 1 (using  $\|\cdot\|_1$ ):

1.  $\beta = \min_{\|y\|_1=1} \mathbf{b}^T y = -5$ .
2.  $\gamma = \min_{\|y\|_1=1} y^T B[\{2, 3\}]y = \frac{1}{10}$ .
3. Choose  $x_{11} > \frac{\beta^2}{\gamma}$ ; we choose  $b_{11} = 256$ .

Then by Fact 4,  $B = \begin{bmatrix} 256 & -5 & 1 & 16 & 16 & 16\sqrt{3} \\ -5 & 1 & -2 & 1 & 1 & 1 \\ 1 & -2 & 5 & 1 & -1 & -1 \\ 16 & 1 & 1 & 1 & 1 & 1 \\ 16 & 1 & -1 & 1 & 1 & \sqrt{3} \\ 16\sqrt{3} & 1 & -1 & 1 & \sqrt{3} & 3 \end{bmatrix}$  is a strictly copositive matrix.

2.  $B = \begin{bmatrix} x_{11} & -1 \\ -1 & 0 \end{bmatrix}$  is a partial copositive matrix that cannot be completed to a copositive matrix because once  $x_{11}$  is chosen (clearly  $x_{11} > 0$ ), then  $\mathbf{v} = [\frac{1}{x_{11}}, 1]^T$  results in  $\mathbf{v}^T B \mathbf{v} = \frac{-1}{x_{11}} < 0$ .
3. The graphs 1a, 1b, 1c, 1d, 1e, 1f, 1g, 1h, and 1l have copositive completion by Fact 7, and these are the only graphs in Example 1 of section 35.1 that have the copositive completion property.

### 35.6 $M$ - and $M_0$ -Matrices

In this section, all matrices are real.

**Definitions:**

The matrix  $A$  is an  $M$ -matrix (respectively,  $M_0$ -matrix) if there exist a nonnegative matrix  $P$  and a real number  $s > \rho(P)$  (respectively,  $s \geq \rho(P)$ ) such that  $A = sI - P$ .

The partial matrix  $B$  is a **partial  $M$ -matrix** (respectively, **partial  $M_0$ -matrix**) if every fully specified principal submatrix of  $B$  is an  $M$ -matrix (respectively,  $M_0$ -matrix) and every specified off-diagonal entry of  $B$  is nonpositive.

If  $B$  is a partial matrix that includes all diagonal entries, the **zero completion** of  $B$ , denoted  $B_0$ , is obtained by setting all unspecified (off-diagonal) entries to 0.

**Facts:**

1. For a  $Z$ -matrix  $A$  (i.e., every off-diagonal entry of  $A$  is nonpositive), the following are equivalent:
  - (a)  $A$  is an  $M$ -matrix.
  - (b) Every principal minor of  $A$  is positive.
  - (c)  $A$  is positive stable.
  - (d)  $A^{-1}$  is nonnegative.

The analogs of the first three conditions are equivalent to  $A$  being an  $M_0$ -matrix. See Section 9.5 for more information about  $M$ - and  $M_0$ -matrices.

2. A principal submatrix of an  $M$ - ( $M_0$ -) matrix is an  $M$ - ( $M_0$ -) matrix (cf. Fact 5 in Section 35.1).
3. [JS96], [Hog01] A partial  $M$ - ( $M_0$ -) matrix  $B$  that includes all diagonal entries can be completed to an  $M$ - ( $M_0$ -) matrix if and only if the zero completion  $B_0$  is an  $M$ - ( $M_0$ -) matrix.
4. [Hog98b], [Hog01] A digraph  $G$  with a loop at every vertex has the  $M$ - ( $M_0$ -) completion property if and only if every strongly connected induced subdigraph of  $G$  is a clique.
5. [Hog98b] A digraph  $G$  has the  $M$ -completion property if and only if the subdigraph induced by the vertices of  $G$  that have loops has  $M$ -completion.
6. [Hog01] A digraph  $G$  has the  $M_0$ -completion property if and only if for every strongly connected induced subdigraph  $H$  of  $G$ , either  $H$  is a clique or  $H$  has no loops.
7. [Hog02] Symmetric  $M$ - and  $M_0$ -matrices and partial matrices are defined in the obvious way. A graph has the symmetric  $M$ -completion property if and only if every connected component of the subgraph induced by the vertices with loops is a clique. A graph has the symmetric  $M_0$ -completion property if and only if every connected component is either a clique or has no loops.

**Examples:**

The graphs and digraphs for the examples can be found in Examples 1 and 4 of Section 35.1.

1. Even if the digraph of a partial  $M$ -matrix does not have the  $M$ -matrix completion property, the matrix may still have an  $M$ -matrix completion. By Fact 3 it is easy to determine whether there

is an  $M$ -completion. For example, complete the partial  $M$ -matrix  $B = \begin{bmatrix} 1 & ? & ? & -2 \\ -0.5 & 2 & ? & ? \\ ? & -1 & 1 & ? \\ ? & ? & -1 & 1 \end{bmatrix}$

to  $B_0$  by setting every unspecified entry to 0. To determine whether  $B_0$  is an  $M$ -matrix, compute the eigenvalues:  $\sigma(B_0) = \{2.38028, 1.21945 \pm 0.914474i, 0.180827\}$ . If we change the values of entries we can obtain a partial  $M$ -matrix that does not have an  $M$ -matrix completion,

e.g.,  $C = \begin{bmatrix} 1 & ? & ? & -2 \\ -2.5 & 2 & ? & ? \\ ? & -1 & 1 & ? \\ ? & ? & -1 & 1 \end{bmatrix}$ . Then  $\sigma(C_0) = \{2.82397, 1.23609 \pm 1.43499i, -0.296153\}$ , so

by Fact 3,  $C$  cannot be completed to an  $M$ -matrix. Note  $\mathcal{D}(B) = \mathcal{D}(C)$  is the digraph 4i, which does not have the  $M$ -matrix completion property by Fact 4.

2. The digraphs 4j, 4m, 4p, and 4q have the  $M$ - and  $M_0$ -completion properties by Fact 4.
3. The graphs 1a, 1b, 1c, 1d, 1e, 1f, 1g, and 1h and the digraphs 4f, 4g, 4h, 4i, 4k, 4l, 4n, 4o, and 4r have neither the  $M$ -completion property nor the  $M_0$ -completion property by Fact 4.
4. The graphs 1j, 1l, and 1m and the digraphs 4a, 4b, 4c, and 4d have the  $M$ -completion property by Facts 5 and 4. Of these (di)graphs, only 1l and 4c have the  $M_0$  completion property, by Fact 6.
5. The graphs 1i, 1k, and 1n and the digraph 4e do not have the  $M$ -completion property (respectively, the  $M_0$ -completion property) by Facts 5 and 4 (respectively, Fact 6).

## 35.7 Inverse $M$ -Matrices

In this section, all matrices are real.

### Definitions:

The matrix  $A$  is an **inverse  $M$ -matrix** if  $A$  is the inverse of an  $M$ -matrix.

The partial matrix  $B$  is a **partial inverse  $M$ -matrix** if every fully specified principal submatrix of  $B$  is an inverse  $M$ -matrix and every specified entry of  $B$  is nonnegative.

A digraph is **cycle-clique** if the induced subdigraph of every cycle is a clique.

An **alternate path to a single arc** in a digraph  $G$  is a path of length greater than 1 between vertices  $i$  and  $j$  such that the arc  $(i, j)$  is in  $G$ .

A digraph  $G$  is **path-clique** if the induced subdigraph of every alternate path to a single arc is a clique.

A digraph is **homogeneous** if it is either symmetric or asymmetric.

### Facts:

1. A matrix  $A$  is an inverse  $M$ -matrix if and only if all entries of  $A$  are nonnegative and all off-diagonal entries of  $A^{-1}$  are nonpositive. There are many equivalent characterizations of inverse  $M$ -matrices; see Section 9.5 for more information.

2. [JS96] Let  $B = \begin{bmatrix} B_{11} & \mathbf{b}_{12} & ? \\ \mathbf{b}_{21}^T & b_{22} & \mathbf{b}_{23}^T \\ ? & \mathbf{b}_{32} & B_{33} \end{bmatrix}$  be an  $n \times n$  partial inverse  $M$  matrix, where  $B_{11}$  and  $B_{33}$  are

square matrices of size  $k$  and  $n - k - 1$ , and all entries of the submatrices shown are specified. Then

$$A = \begin{bmatrix} B_{11} & \mathbf{b}_{12} & \mathbf{b}_{12} b_{22}^{-1} \mathbf{b}_{21}^T \\ \mathbf{b}_{21}^T & b_{22} & \mathbf{b}_{23}^T \\ \mathbf{b}_{32} b_{22}^{-1} \mathbf{b}_{21}^T & \mathbf{b}_{32} & B_{33} \end{bmatrix}$$

is the unique inverse  $M$ -completion of  $B$  such that  $A^{-1}$  has

zeros in all the positions where  $B$  has unspecified entries. This method can be used to complete a partial inverse  $M$ -matrix whose digraph is block-clique.

3. [JS96], [JS99], [Hog98a], [Hog00], [Hog02] A symmetric digraph with a loop at every vertex has the inverse  $M$ -completion property if and only if it is block-clique. A digraph obtained from a block-clique digraph by deleting loops from vertices not contained in any block of order greater than 2 also has the inverse  $M$ -completion property, and any symmetric digraph that has the inverse  $M$ -completion property has that form. The same is true for the symmetric inverse  $M$ -completion property (with the obvious definition).
4. [Hog98a] A digraph with a loop at every vertex has the inverse  $M$ -completion property if and only if  $G$  is path-clique and cycle-clique.
5. [Hog00], [Hog01] A digraph  $G$  has the inverse  $M$ -completion property if and only if it is path-clique and every strongly connected nonseparable induced subdigraph has the inverse  $M$ -completion property. A strongly connected nonseparable digraph is homogeneous. A simple cycle with at least one vertex that does not have a loop has the inverse  $M$ -completion property.

### Examples:

The graphs and digraphs for the examples can be found in Examples 1 and 4 of Section 35.1.

1. Let  $B = \begin{bmatrix} 3 & 1 & ? & ? \\ 4 & 2 & 4 & 2 \\ ? & 1 & 5 & 1 \\ ? & 1 & 2 & 2 \end{bmatrix}$ . The completion given by Fact 2 is  $A = \begin{bmatrix} 3 & 1 & 2 & 1 \\ 4 & 2 & 4 & 2 \\ 2 & 1 & 5 & 1 \\ 2 & 1 & 2 & 2 \end{bmatrix}$ , and

$$A^{-1} = \begin{bmatrix} 1 & -\frac{1}{2} & 0 & 0 \\ -2 & \frac{7}{3} & -\frac{2}{3} & -1 \\ 0 & -\frac{1}{6} & \frac{1}{3} & 0 \\ 0 & -\frac{1}{2} & 0 & 1 \end{bmatrix}.$$

2. By Fact 3, the graphs 1f and 1k have the inverse  $M$ -completion property, and these are the only graphs in Example 1 that do.
3. The digraphs 4j and 4m have the inverse  $M$ -completion property by Fact 4.
4. The digraphs 4f, 4g, 4h, 4i, 4k, 4l, 4n, 4o, 4p, 4q, and 4r do not have the inverse  $M$ -completion property by Fact 4.
5. The digraphs 4a, 4b, 4c, 4d, and 4e do not have the inverse  $M$ -completion property by Fact 5.

## 35.8 $P$ -, $P_{0,1}$ -, and $P_0$ -Matrices

---

In this section, all matrices are real.

### Definitions:

The matrix  $A$  is a  $P$ -**matrix** (respectively,  $P_0$ -**matrix**,  $P_{0,1}$ -**matrix**) if every principal minor of  $A$  is positive (respectively, nonnegative, nonnegative and every diagonal element is positive).

The partial matrix  $B$  is a **partial  $P$ -matrix** (respectively, **partial  $P_0$ -matrix**, **partial  $P_{0,1}$ -matrix**) if every fully specified principal submatrix of  $B$  is a  $P$ -matrix (respectively,  $P_0$ -matrix,  $P_{0,1}$ -matrix).

### Facts:

1. A positive definite matrix,  $M$ -matrix, or inverse  $M$ -matrix is a  $P$ -matrix. A positive semidefinite matrix or  $M_0$ -matrix is a  $P_0$ -matrix. See [HJ91] for more information on  $P$ -,  $P_{0,1}$ -, and  $P_0$ -matrices. A principal submatrix of a  $P$ - ( $P_{0,1}$ -,  $P_0$ -) matrix is a  $P$ - ( $P_{0,1}$ -,  $P_0$ -) matrix (cf. Fact 5 in section 35.1).
2. [Hog03a] If a digraph has the  $P_0$ -completion property, then it has the  $P_{0,1}$ -completion property. If a digraph has the  $P_{0,1}$ -completion property, then it has the  $P$ -completion property.
3. [JK96], [Hog01] A digraph has the  $P$ -completion property if and only if the subdigraph induced by the vertices that have loops has the  $P$ -completion property.
4. [JK96] Every symmetric digraph has the  $P$ -completion property. The  $P$ -completion of a combinatorially symmetric partial  $P$ -matrix can be accomplished by selecting one pair of unspecified entries at a time and choosing the entries of opposite sign and large enough magnitude to make the determinants of all principal matrices completed positive.
5. [JK96] Every order 3 digraph has the  $P$ -completion property, but there is an order 4 digraph (see the digraph 4k in Example 4 of Section 35.1) that does not have the  $P$ -completion property. [DH00] extended a revised version of this example, digraph 4r, to a family of digraphs, called *minimally chordal symmetric Hamiltonian*, that do not have the  $P$ -completion property. The digraph 4n is another example of a digraph in this family (so both 4r and 4n do not have the  $P$ -completion property).
6. [DH00] A digraph that can be made symmetric by adding arcs one at a time so that at each stage at most one order 3 induced subdigraph (and no larger) becomes a clique, has the  $P$ -completion property.
7. [CDH02] A partial  $P$ - ( $P_{0,1}$ -,  $P_0$ -) matrix whose digraph is asymmetric can be completed to a  $P$ - ( $P_{0,1}$ -,  $P_0$ -) matrix as follows: If  $i \neq j$  and  $b_{ji}$  is specified, then set  $x_{ij} = -b_{ji}$ . Otherwise, set  $x_{ij} = 0$ . Every asymmetric digraph has the  $P$ - ( $P_{0,1}$ -,  $P_0$ -) completion property.

8. [FJT00] Let  $B = \begin{bmatrix} B_{11} & \mathbf{b}_{12} & ? \\ \mathbf{b}_{21}^T & b_{22} & \mathbf{b}_{23}^T \\ ? & \mathbf{b}_{32} & B_{33} \end{bmatrix}$  be an  $n \times n$  partial  $P$ - ( $P_{0,1}$ -) matrix, where  $B_{11}$  and  $B_{33}$  are square matrices of size  $k$  and  $n - k - 1$ , and all entries of the submatrices shown are specified.

Then  $A = \begin{bmatrix} B_{11} & \mathbf{b}_{12} & \mathbf{b}_{12} b_{22}^{-1} \mathbf{b}_{21}^T \\ \mathbf{b}_{21}^T & b_{22} & \mathbf{b}_{23}^T \\ 0 & \mathbf{b}_{32} & B_{33} \end{bmatrix}$  is a  $P$ - ( $P_{0,1}$ -) completion of  $B$ . This method can be used to

complete any partial  $P$ - ( $P_{0,1}$ -) matrix whose digraph is block-clique. (See [Hog01] for the details of the analogous completion for  $P_0$ -matrices.)

9. [FJT00] Every block-clique digraph has the  $P$ - ( $P_{0,1^-}$ ,  $P_{0^-}$ ) completion property.
10. [Hog01] A digraph  $G$  has the  $P$ - (respectively,  $P_{0,1^-}$ ,  $P_{0^-}$ ) completion property if and only if every strongly connected and nonseparable induced subdigraph of  $G$  has the  $P$ - (respectively,  $P_{0,1^-}$ ,  $P_{0^-}$ ) completion property. A method to obtain such a completion is given in Algorithm 2.

**Algorithm 2:**

Let  $B$  be a partial  $P$ - ( $P_{0,1^-}$ ,  $P_{0^-}$ ) matrix such that every strongly connected and nonseparable induced subdigraph  $K$  of  $\mathcal{D}(B)$  has the  $P$ - ( $P_{0,1^-}$ ,  $P_{0^-}$ ) property.

1. For each such  $K$ , complete the principal submatrix of  $B$  corresponding to  $K$  to obtain a partial  $P$ - ( $P_{0,1^-}$ ,  $P_{0^-}$ ) matrix  $B_1$  such that each strongly connected induced subdigraph  $S$  of  $\mathcal{D}(B_1)$  is block-clique.
2. For each such  $S$ , complete the principal submatrix of  $B_1$  corresponding to  $S$  to obtain a partial  $P$ - ( $P_{0,1^-}$ ,  $P_{0^-}$ ) matrix  $B_2$ .
3. Set any remaining unspecified entries to 0.

11. [Hog01] A digraph that omits all loops has the  $P$ - ( $P_{0,1^-}$ ,  $P_{0^-}$ ) completion property. Each connected component of a symmetric digraph that has the  $P_{0^-}$ -completion property must have a loop at every vertex or omit all loops.
12. [Hog01], [CDH02], [JK96] A symmetric  $n$ -cycle with a loop at every vertex has the  $P_{0^-}$ -completion property if and only if  $n \neq 4$ . A symmetric  $n$ -cycle with a loop at every vertex has the  $P$ - and  $P_{0,1^-}$ -completion properties for all  $n$ .
13. [CDH02] All order 2, order 3, and order 4 digraphs with a loop at every vertex have been classified as having or not having the  $P_{0^-}$ -completion property. There are some order 4 digraphs that (in 2005) have not been classified as to the  $P$ - and  $P_{0,1^-}$ -completion properties.

**Examples:**

The graphs and digraphs for the examples can be found in Examples 1 and 4 of Section 35.1.

1. It is easy to verify that  $B = \begin{bmatrix} 1 & 2 & x_{13} & -1 \\ 1 & 3 & -2 & x_{24} \\ x_{31} & 2 & 1 & 1 \\ -1 & x_{42} & 1 & 2 \end{bmatrix}$  is a partial  $P$ -matrix. The graph 1d, called the

*double triangle*, is interpreted as the digraph of  $B$ . Let  $x_{24} = y$  and  $x_{42} = -y$ . A choice of  $y$  completes three principal minors,  $\det B[\{2, 4\}] = 6 + y^2$ ,  $\det B[\{1, 2, 4\}] = -1 - y + y^2$ , and  $\det B[\{2, 3, 4\}] = 11 + 4y + y^2$ . The choice  $y = 2$  makes all three minors positive. Let  $x_{24} = z$  and  $x_{42} = -z$ . With  $y = 2$ , a choice of  $z$  completes four principal minors,  $\det B[\{1, 3\}] = 1 + z^2$ ,  $\det B[\{1, 2, 3\}] = 5 + 6z + 3z^2$ ,  $\det B[\{1, 3, 4\}] = 2z^2$ , and  $\det B = 10 + 18z + 10z^2$ , so setting  $z = 0$  completes  $B$

to the  $P$ -matrix  $\begin{bmatrix} 1 & 2 & 0 & -1 \\ 1 & 3 & -2 & 2 \\ 0 & 2 & 1 & 1 \\ -1 & -2 & 1 & 2 \end{bmatrix}$ . Any partial  $P$ -matrix specifying the double triangle can

be completed in a similar manner, so the double triangle has the  $P$ -completion property.

2. The double triangle 1d does not have the  $P_{0^-}$ -completion property because  $B = \begin{bmatrix} 1 & 2 & 1 & ? \\ -1 & 0 & 0 & -2 \\ -1 & 0 & 0 & -1 \\ ? & 1 & 1 & 1 \end{bmatrix}$

cannot be completed to a  $P_{0^-}$ -matrix ([JK96]). This implies the graphs 1g and 1h do not have the

$P_0$ -completion property by Fact 7 in Section 35.1. The double triangle does have the  $P_{0,1}$ -completion property [Wan05].

3. All graphs in Example 1 have the  $P$ -completion property by Fact 4.
4. The digraphs 4c and 4d have the  $P$ -completion property by Fact 3. Fact 3 can also be applied in conjunction with other facts to several other digraphs in Example 4.
5. The digraphs 4f, 4g, 4h, 4p, and 4q have the  $P$ -completion property by Fact 5.
6. The digraphs 4a, 4b, 4c, 4d, 4i, 4j, 4l, 4m, and 4o have the  $P$ -completion property by Fact 6.
7. The digraphs 4b, 4h, 4i, 4j, and 4l have the  $P$ -,  $P_{0,1}$ -, and  $P_0$ -completion properties by Fact 7.

8. The completion of  $\begin{bmatrix} 1 & -1 & ? & ? \\ 3 & 2 & -4 & 2 \\ ? & 1 & 5 & -1 \\ ? & 1 & 2 & 2 \end{bmatrix}$  given by Fact 8 is  $\begin{bmatrix} 1 & -1 & 2 & -1 \\ 3 & 2 & -4 & 2 \\ 0 & 1 & 5 & -1 \\ 0 & 1 & 2 & 2 \end{bmatrix}$ .

9. The graph 1f has the  $P_0$ - and  $P_{0,1}$ -completion properties by Fact 9. (It also has the  $P$ -completion property but one would not normally cite Fact 9 for that.)
10. The digraphs 4m, 4p, and 4q have the  $P$ -,  $P_{0,1}$ -, and  $P_0$ -completion properties by Fact 10. Fact 10 can also be applied in conjunction with other facts to several other digraphs in Example 4.
11. The graph 1l and the digraph 4c have the  $P$ -,  $P_0$ -, and  $P_{0,1}$ -completion properties by Fact 11.
12. The graphs 1i, 1j, 1k, 1m, and 1n do not have the  $P_0$ -completion property by Fact 11.
13. The graphs 1b and 1c have the  $P_0$ - ( $P_{0,1}$ )-completion property by Fact 12.
14. The graph 1a does not have the  $P_0$ -completion property, but does have the  $P_{0,1}$ -completion property, by Fact 12.
15. The graphs 1e and 1g do not have the  $P_0$ -completion property by Fact 12 and by Fact 7 in Section 35.1.

### 35.9 Positive $P$ -, Nonnegative $P$ -, Nonnegative $P_{0,1}$ -, and Nonnegative $P_0$ -Matrices

---

In this section, all matrices are real.

#### Definitions:

The matrix  $A$  is a **positive** (respectively, **nonnegative**)  $P$ -**matrix** if  $A$  is a  $P$ -matrix and every entry of  $A$  is positive (respectively, nonnegative). The matrix  $A$  is a **nonnegative  $P_0$ -matrix** (respectively, **nonnegative  $P_{0,1}$ -matrix**) if  $A$  is a  $P_0$ -matrix (respectively,  $P_{0,1}$ -matrix) and every entry of  $A$  is nonnegative.

The partial matrix  $B$  is a **partial positive  $P$ -matrix** (respectively, **partial nonnegative  $P$ -matrix**, **partial nonnegative  $P_0$ -matrix**, **partial nonnegative  $P_{0,1}$ -matrix**) if and only if every fully specified principal submatrix of  $B$  is a positive  $P$ -matrix (respectively, nonnegative  $P$ -matrix, nonnegative  $P_0$ -matrix, partial nonnegative  $P_{0,1}$ -matrix) and all specified entries are positive (respectively, nonnegative, nonnegative, nonnegative).

#### Facts:

1. [Hog03a], [Hog03b] If a digraph has the nonnegative  $P_0$ -completion property, then it has the nonnegative  $P_{0,1}$ -completion property. If a digraph has the nonnegative  $P_{0,1}$ -completion property, then it has the nonnegative  $P$ -completion property. If a digraph has the nonnegative  $P$ -completion property, then it has the positive  $P$ -completion property.
2. [Hog01] A digraph has the positive (respectively, nonnegative)  $P$ -completion property if and only if the subdigraph induced by vertices that have loops has the positive (respectively, nonnegative)  $P$ -completion property.

3. [FJT00], [Hog01], [CDH03] All order 2 and order 3 digraphs that have a loop at every vertex have the positive  $P$ - (nonnegative  $P$ -, nonnegative  $P_{0,-}$ , nonnegative  $P_{0,1-}$ ) completion property.
4. [BEH06] Suppose  $G$  is a digraph such that by adding arcs one at a time so that at each stage at most one order 3 induced subdigraph (and no larger) becomes a clique, it is possible to obtain a digraph  $G'$  that has the positive  $P$ - (respectively, nonnegative  $P$ -, nonnegative  $P_{0,-}$ , nonnegative  $P_{0,1-}$ ) completion property. Then  $G$  has the positive  $P$ - (respectively, nonnegative  $P$ -, nonnegative  $P_{0,-}$ , nonnegative  $P_{0,1-}$ ) completion property.
5. [FJT00] A block-clique digraph has the positive  $P$ - (nonnegative  $P$ -, nonnegative  $P_{0,-}$ , nonnegative  $P_{0,1-}$ ) completion property. See Fact 8 of section 35.8 for information on the construction.
6. [Hog01] A digraph  $G$  has the positive  $P$ - (respectively, nonnegative  $P$ -, nonnegative  $P_{0,-}$ , nonnegative  $P_{0,1-}$ ) completion property if and only if every strongly connected and nonseparable induced subdigraph of  $G$  has the positive  $P$ - (respectively, nonnegative  $P$ -, nonnegative  $P_{0,-}$ , nonnegative  $P_{0,1-}$ ) completion property. See Algorithm 2 of section 35.8 for information on the construction.
7. [Hog01] A digraph that omits all loops has the positive  $P$ - (nonnegative  $P$ -, nonnegative  $P_{0,1-}$ , nonnegative  $P_{0,-}$ ) completion property. Each connected component of a symmetric digraph that has the nonnegative  $P_{0,-}$ -completion property must have a loop at every vertex or omit all loops.
8. [CDH03] An order 4 digraph with a loop at every vertex has the nonnegative  $P_{0,-}$ -completion property if and only if it does not contain a 4-cycle or is the clique on 4-vertices. This characterization does not extend to higher order digraphs.
9. [BEH06], [JTU03] All order 4 digraphs that have a loop at every vertex have been classified as to the positive  $P$ - (nonnegative  $P$ -) completion property.
10. [CDH03], [FJT00] A symmetric  $n$ -cycle that has a loop at every vertex has the nonnegative  $P_{0,-}$ -completion property if and only if  $n \neq 4$ . A symmetric  $n$ -cycle that has a loop at every vertex has the positive  $P$ - (nonnegative  $P$ -, nonnegative  $P_{0,1-}$ ) completion property.
11. [BEH06] A minimally chordal symmetric Hamiltonian digraph (cf. Fact 5 in Section 35.8) has neither the positive nor the nonnegative  $P$ -completion property.

### Examples:

The graphs and digraphs for the examples can be found in Examples 1 and 4 of Section 35.1.

1. The digraphs 4f, 4g, 4h, 4p, and 4q have the positive  $P$ - (nonnegative  $P$ -, nonnegative  $P_{0,-}$ , nonnegative  $P_{0,1-}$ ) completion property by Fact 3.
2. The graph 1f has the positive  $P$ - (nonnegative  $P$ -, nonnegative  $P_{0,-}$ , nonnegative  $P_{0,1-}$ ) completion property by Fact 5.
3. The graphs 1j, 1k, 1l, 1m, and 1n and the digraphs 4c and 4d have the positive  $P$ - (nonnegative  $P$ -) completion property by Facts 2 and 5.
4. The digraphs 4j, 4m, 4p, and 4q have the positive  $P$ - (nonnegative  $P$ -, nonnegative  $P_{0,-}$ , nonnegative  $P_{0,1-}$ ) completion property by Fact 6.
5. The graph 1l and the digraph 4c have the positive  $P$ -, nonnegative  $P$ -, nonnegative  $P_{0,-}$ , and nonnegative  $P_{0,1-}$ -completion properties by Fact 7.
6. The graphs 1i, 1j, 1k, 1m, and 1n do not have the nonnegative  $P_{0,-}$ -completion property by Fact 7.
7. The graphs 1a and 1d and the digraphs 4i, 4k, and 4r do not have the nonnegative  $P_{0,-}$ -completion property by Fact 8. The graphs 1e, 1g, and 1h and the digraphs 4l, 4n, and 4o do not have the nonnegative  $P_{0,-}$ -completion property by Fact 8, using Fact 7 of Section 35.1.
8. By Fact 10, the graph 1a does not have and the graphs 1b and 1c do have the nonnegative  $P_{0,-}$ -completion property.
9. The graphs 1a, 1b, and 1c have the positive  $P$ - (nonnegative  $P$ -, nonnegative  $P_{0,1-}$ ) completion property by Fact 10.

## 35.10 Entry Sign Symmetric $P$ -, Entry Sign Symmetric $P_0$ -, Entry Sign Symmetric $P_{0,1}$ -, Entry Weakly Sign Symmetric $P$ -, and Entry Weakly Sign Symmetric $P_0$ -Matrices

In this section, all matrices are real. In the literature, *entry sign symmetric* is often called *sign symmetric*; as defined in Chapter 19.2, the latter term is used for a different condition.

### Definitions:

The matrix  $A$  is an **entry sign symmetric  $P$ -** (respectively,  $P_{0,1}$ -,  $P_0$ -) **matrix** if and only if  $A$  is a  $P$ -matrix (respectively,  $P_{0,1}$ -matrix,  $P_0$ -matrix) and for all  $i, j$ , either  $a_{ij}a_{ji} > 0$  or  $a_{ij} = a_{ji} = 0$ .

The matrix  $A$  is an **entry weakly sign symmetric  $P$ -** (respectively,  $P_{0,1}$ -,  $P_0$ -) **matrix** if and only if  $A$  is a  $P$ -matrix (respectively,  $P_{0,1}$ -matrix,  $P_0$ -matrix) and for all  $i, j$ ,  $a_{ij}a_{ji} \geq 0$ .

The partial matrix  $B$  is a **partial entry sign symmetric  $P$ -** (respectively,  $P_{0,1}$ -,  $P_0$ -) **matrix** if and only if every fully specified principal submatrix of  $B$  is an entry sign symmetric  $P$ - (respectively,  $P_{0,1}$ -,  $P_0$ -) matrix and if both  $b_{ij}$  and  $b_{ji}$  are specified then  $b_{ij}b_{ji} > 0$  or  $b_{ij} = b_{ji} = 0$ .

The partial matrix  $B$  is a **partial entry weakly sign symmetric  $P$ -** (respectively,  $P_{0,1}$ -,  $P_0$ -) **matrix** if and only if every fully specified principal submatrix of  $B$  is an entry weakly sign symmetric  $P$ - (respectively,  $P_{0,1}$ -,  $P_0$ -) matrix and if both  $b_{ij}$  and  $b_{ji}$  are specified then  $b_{ij}b_{ji} \geq 0$ .

### Facts:

- [Hog03a] Any pattern that has the entry sign symmetric  $P_0$ - (respectively, entry weakly sign symmetric  $P_0$ -) completion property also has the entry sign symmetric  $P_{0,1}$ - (respectively, entry weakly sign symmetric  $P_{0,1}$ -) completion property. Any pattern that has the entry sign symmetric  $P_{0,1}$ - (respectively, entry weakly sign symmetric  $P_{0,1}$ -) completion property also has the entry sign symmetric  $P$ - (respectively, entry weakly sign symmetric  $P$ -) completion property.
- [Hog01] A digraph  $G$  has the (weakly) entry sign symmetric  $P$ -completion property if and only if the subdigraph of  $G$  induced by vertices that have loops has the entry (weakly) sign symmetric  $P$ -completion property.
- [FJT00], [Hog01] A digraph  $G$  has the entry sign symmetric  $P_0$ -completion property if and only if for every connected component  $H$  of  $G$ , either  $H$  omits all loops or  $H$  has a loop at every vertex and is block-clique.
- [FJT00] A symmetric digraph with a loop at every vertex has the entry sign symmetric  $P_{0,1}$ -completion property if and only if every connected component is block-clique.
- [FJT00] A block-clique digraph has the entry sign symmetric  $P$ - (entry sign symmetric  $P_{0,1}$ -, entry sign symmetric  $P_0$ -, entry weakly sign symmetric  $P$ -, entry weakly sign symmetric  $P_{0,1}$ -, entry weakly sign symmetric  $P_0$ -) completion property. (See Fact 8 of Section 35.8 for information on the construction.)
- [Hog01] A digraph  $G$  has the entry sign symmetric  $P$ - (entry weakly sign symmetric  $P$ -, entry weakly sign symmetric  $P_{0,1}$ -, entry weakly sign symmetric  $P_0$ -) completion property if and only if every strongly connected and nonseparable induced subdigraph of  $G$  has the entry sign symmetric  $P$ - (entry weakly sign symmetric  $P$ -, entry weakly sign symmetric  $P_{0,1}$ -, entry weakly sign symmetric  $P_0$ -) completion property. (See Algorithm 2 of Section 35.8 for information on the construction.)
- Fact 6 is not true for the entry sign symmetric  $P_0$ -matrices (cf. Fact 3) or for the entry sign symmetric  $P_{0,1}$ -matrices [Wan05]. In particular, the digraphs 4p and 4q in Example 4 of Section 35.1 have neither the entry sign symmetric  $P_0$ -completion property nor the entry sign symmetric  $P_{0,1}$ -completion property.
- [DHH03] A symmetric  $n$ -cycle with a loop at every vertex has the entry sign symmetric  $P$ - (entry weakly sign symmetric  $P$ -, entry weakly sign symmetric  $P_{0,1}$ -, entry weakly sign symmetric  $P_0$ -) completion property if and only if  $n \neq 4$  and  $n \neq 5$ .

9. [DHH03] An order 3 digraph  $G$  with a loop at every vertex has the entry sign symmetric  $P$ - (entry weakly sign symmetric  $P$ -, entry weakly sign symmetric  $P_{0,1}$ -, entry weakly sign symmetric  $P_0$ -) completion property if and only if its digraph does not contain a 3-cycle or is a clique.
10. [DHH03], [Wan05] All order 4 digraphs that have a loop at every vertex have been classified as to the entry sign symmetric  $P$ - (entry sign symmetric  $P_{0,1}$ -, entry sign symmetric  $P_0$ -, entry weakly sign symmetric  $P$ -, entry weakly sign symmetric  $P_{0,1}$ -, entry weakly sign symmetric  $P_0$ -) completion property.

### Examples:

The graphs and digraphs for the examples can be found in Examples 1 and 4 of section 35.1.

1. By Fact 3, the graphs 1f and 1l and the digraph 4c have the entry sign symmetric  $P_0$ -completion property and none of the other graphs or digraphs pictured do.
2. The graphs 1a, 1b, 1c, 1d, 1e, 1g, and 1h do not have the entry sign symmetric  $P_{0,1}$ -completion proper by Fact 4.
3. The graph 1f has the entry sign symmetric  $P$ - (entry sign symmetric  $P_{0,1}$ -, entry sign symmetric  $P_0$ -, entry weakly sign symmetric  $P$ -, entry sign symmetric  $P_{0,1}$ -, entry weakly sign symmetric  $P_0$ -) completion proper by Fact 5.
4. The graphs 1j, 1k, 1l, 1m, and 1n and the digraphs 4c and 4d and have the entry (weakly) sign symmetric  $P$ -completion property by Facts 2 and 5.
5. The digraphs 4j, 4m, 4p, and 4q have the entry sign symmetric  $P$ - (entry weakly sign symmetric  $P$ -, entry weakly sign symmetric  $P_{0,1}$ -, entry weakly sign symmetric  $P_0$ -) completion property by Fact 6.
6. The graphs 1a and 1b do not have the entry sign symmetric  $P$ - (entry weakly sign symmetric  $P$ -, entry weakly sign symmetric  $P_{0,1}$ -, entry weakly sign symmetric  $P_0$ -) completion property by Fact 8.
7. The graph 1c has the entry sign symmetric  $P$ - (entry weakly sign symmetric  $P$ -, entry weakly sign symmetric  $P_{0,1}$ -, entry weakly sign symmetric  $P_0$ -) completion property by Fact 8.
8. The digraphs 4f, 4g, 4h, 4k, 4l, 4n, 4o, and 4r do not have the entry sign symmetric  $P$ - (entry weakly sign symmetric  $P$ -, entry weakly sign symmetric  $P_{0,1}$ -, entry weakly sign symmetric  $P_0$ -) completion property by Fact 9 and Fact 7 in section 35.1.

### 36.1 Algebraic Connectivity for Simple Graphs: Basic Theory

---

Let  $G$  be a simple graph on  $n \geq 2$  vertices with Laplacian matrix  $L_G$ , and label the eigenvalues of  $L_G$  as  $0 = \mu_1 \leq \mu_2 \leq \dots \leq \mu_n$ . Throughout this chapter, we consider only Laplacian matrices for graphs on at least two vertices. Henceforth, we use the term *graph* to refer to a simple graph.

#### Definitions:

The **algebraic connectivity** of  $G$ , denoted  $\alpha(G)$ , is given by  $\alpha(G) = \mu_2$ .

A **Fiedler vector** is an eigenvector of  $L_G$  corresponding to  $\alpha(G)$ .

Given graphs  $G_1 = (V_1, E_1)$  and  $G_2 = (V_2, E_2)$ , their **product**,  $G_1 \times G_2$ , is the graph with vertex set  $V_1 \times V_2$ , with vertices  $(u_1, u_2)$  and  $(w_1, w_2)$  adjacent if and only if either  $u_1$  is adjacent to  $w_1$  in  $G_1$  and  $u_2 = w_2$ , or  $u_2$  is adjacent to  $w_2$  in  $G_2$  and  $u_1 = w_1$ .

#### Facts:

- [Fie89] Let  $G$  be a graph of order  $n$  with Laplacian matrix  $L_G$ . Then  $\alpha(G) = \min\{\sum_{i < j, \{i,j\} \in E} (x_i - x_j)^2 \mid \sum_{1 \leq i \leq n} x_i^2 = 1, \sum_{1 \leq i \leq n} x_i = 0\} = \min\{x^T L_G x \mid x^T x = 1, x^T \mathbf{1} = 0\}$ .
- [Fie73] The algebraic connectivity of a graph is nonnegative, and is equal to 0 if and only if the graph is disconnected.
- [Fie73] Let  $G$  be a connected graph on  $n$  vertices with vertex connectivity  $\kappa_v(G)$ , and suppose that  $G \neq K_n$ . Then  $\alpha(G) \leq \kappa_v(G)$ . (See Fact 13 below for a discussion of the equality case.)
- [Fie73] Suppose that  $G$  is a graph on  $n$  vertices, and let  $\overline{G}$  denote the complement of  $G$ . Then  $\alpha(\overline{G}) = n - \mu_n$ , where  $\mu_n$  denotes the largest Laplacian eigenvalue for  $G$ .

5. ([GR01], p. 280) If  $G$  is a graph on  $n \geq 2$  vertices that is regular of degree  $k$ , then denoting the eigenvalues of  $\mathcal{A}_G$  by  $\lambda_1 \leq \dots \leq \lambda_n$ , we have  $\alpha(G) = k - \lambda_{n-1}$ .
6. [Mer94] Suppose that  $G_1$  and  $G_2$  are two graphs on  $n_1$  and  $n_2$  vertices, respectively, with  $n_1, n_2 \geq 2$ . Then  $\alpha(G_1 + G_2) = \min\{\alpha(G_1) + n_2, \alpha(G_2) + n_1\}$ . Similarly, if  $H$  is a graph on  $k \geq 2$  vertices, then  $\alpha(H + K_1) = \alpha(H) + 1$ .
7. [Fie73] Suppose that  $G_1$  and  $G_2$  are graphs, each of which has at least two vertices. Then  $\alpha(G_1 \times G_2) = \min\{\alpha(G_1), \alpha(G_2)\}$ .
8. [Fie73] Suppose that the graph  $\hat{G}$  is formed from the graph  $G$  by adding an edge not already present in  $G$ . Then  $\alpha(G) \leq \alpha(\hat{G})$ .
9. [FK98] Let  $G$  and  $H$  be graphs, and suppose that the graph  $\hat{G}$  is formed from  $G \cup H$  as follows: Fix a vertex  $v$  of  $G$  and a subset  $S$  of the vertex set for  $H$ , and for each  $w \in S$ , add in the edge between  $v$  and  $w$ . Then  $\alpha(\hat{G}) \leq \alpha(G)$ .
10. [Fie73] Let  $G$  be a graph, and suppose that the graph  $\hat{G}$  is formed from  $G$  by deleting a collection of  $k$  vertices and all edges incident with them. Then  $\alpha(\hat{G}) \geq \alpha(G) - k$ .
11. [GMS90] Let  $G$  be a graph on  $n \geq 3$  vertices and suppose that the edge  $e$  of  $G$  is not on any 3-cycles. Form  $\hat{G}$  from  $G$  by deleting  $e$  and identifying the two vertices incident with it. Then  $\alpha(\hat{G}) \geq \alpha(G)$ .
12. [Fie73] If  $G$  is a graph on  $n$  vertices, then  $\alpha(G) \leq n$ . Equality holds if and only if  $G = K_n$ .
13. [KMNS02] Let  $G$  be a connected graph on  $n$  vertices with vertex connectivity  $\kappa_v(G)$ , and suppose that  $G \neq K_n$ . Then  $\alpha(G) = \kappa_v(G)$  if and only if  $G$  can be written as  $G = G_1 + G_2$ , where  $G_1$  is disconnected,  $G_2$  has  $\kappa_v(G)$  vertices, and  $\alpha(G_2) \geq 2\kappa_v(G) - n$ .
14. [Fie89] If  $G$  is a connected graph on  $n$  vertices with edge connectivity  $\kappa_e(G)$ , then  $2(1 - \cos(\frac{\pi}{n}))\kappa_e(G) \leq \alpha(G)$ . Equality holds if and only if  $G = P_n$ .

### Examples:

1. ([GK69], p. 138) For  $n \geq 2$ , the algebraic connectivity of the path  $P_n$  is  $2(1 - \cos(\frac{\pi}{n}))$ , and it is a simple eigenvalue of the corresponding Laplacian matrix.
2. The following can be deduced from basic results on circulant matrices. If  $n \geq 3$ , the algebraic connectivity of the cycle  $C_n$  is  $2(1 - \cos(\frac{2\pi}{n}))$ , and it is an eigenvalue of multiplicity 2 of the corresponding Laplacian matrix.
3. The algebraic connectivity of  $K_n$  is  $n$ , and it is an eigenvalue of multiplicity  $n - 1$  of the corresponding Laplacian matrix.
4. If  $m \leq n$  and  $2 \leq n$ , then  $\alpha(K_{m,n}) = m$ . If  $1 \leq m < n$ , then  $m$  is an eigenvalue of multiplicity  $n - 1$  of the corresponding Laplacian matrix, while if  $2 \leq m = n$ , then  $m$  is an eigenvalue of multiplicity  $2m - 2$  of the corresponding Laplacian matrix.
5. The algebraic connectivity of the Petersen graph is 2, and it is an eigenvalue of multiplicity 5 of the corresponding Laplacian matrix.
6. The algebraic connectivity of the ladder on 6 vertices, shown in Figure 36.1, is 1.
7. Graphs with large algebraic connectivity arise in the study of the class of so-called expander graphs. (See Section 28.5 or [Alo86] for definitions and discussion.)
8. A Fiedler vector for a graph provides a heuristic for partitioning its vertex set so that the number of edges between the two parts is small (see [Moh92] for a discussion), and that heuristic has applications to sparse matrix computations (see [PSL90]).

FIGURE 36.1

## 36.2 Algebraic Connectivity for Simple Graphs: Further Results

The term *graph* means *simple graph* in this section.

### Definitions:

Let  $G = (V, E)$  be a graph, and let  $X, V \setminus X$  be a nontrivial partitioning of  $V$ . The corresponding **edge cut** is the set  $E_X$  of edges of  $G$  that have one end point in  $X$  and the other end point in  $V \setminus X$ .

Suppose that  $G_1$  and  $G_2$  are graphs. A graph  $H$  is formed by **appending  $G_2$  at vertex  $v$  of  $G_1$**  if  $H$  is constructed from  $G_1 \cup G_2$  by adding an edge between  $v$  and a vertex of  $G_2$ .

Suppose that  $g, n \in \mathbb{N}$  with  $n > g \geq 3$ . The graph  $C_{n,g}$  is formed by appending the cycle  $C_g$  at a pendent vertex of the path  $P_{n-g}$ .

Suppose that  $g, n \in \mathbb{N}$  with  $n > g \geq 3$ . Let  $D_{g,n-g}$  denote the graph formed from the cycle  $C_g$  by appending  $n - g$  isolated vertices at a single vertex of that cycle.

For a connected graph  $G$ , a vertex  $v$  is a **cut-vertex** if  $G - v$ , the graph formed from  $G$  by deleting the vertex  $v$  and all edges incident with it, is disconnected.

A graph is **unicyclic** if it contains precisely one cycle.

### Facts:

1. [Moh91] If  $G$  is a connected graph on  $n$  vertices with diameter  $d$ , then  $\alpha(G) \geq \frac{4}{dn}$ .
2. [AM85] If  $G$  is a connected graph on  $n$  vertices with diameter  $d$  and maximum degree  $\Delta$ , then  $d \leq 2 \lceil \sqrt{\frac{2\Delta}{\alpha(G)}} \log_2 n \rceil$ .
3. [Moh91] If  $G$  is a connected graph on  $n$  vertices with diameter  $d$  and maximum degree  $\Delta$ , then  $d \leq 2 \lceil \frac{\Delta + \alpha(G)}{4\alpha(G)} \ln(n-1) \rceil$ .
4. [Moh92] Let  $G = (V, E)$  be a graph, let  $X, V \setminus X$  be a nontrivial partitioning of its vertex set, and let  $E_X$  denote the corresponding edge cut. Then  $\alpha(G) \leq \frac{|V||E_X|}{|X||V \setminus X|}$  and ([FKP03a]) if  $\alpha(G) = \frac{|V||E_X|}{|X||V \setminus X|}$ , then necessarily there are integers  $d_1, d_2$  such that:
  - Each vertex in  $X$  is adjacent to precisely  $d_1$  vertices in  $V \setminus X$ .
  - Each vertex in  $V \setminus X$  is adjacent to precisely  $d_2$  vertices in  $X$ .
  - $|X|d_1 = |V \setminus X|d_2$ .
  - $\alpha(G) = d_1 + d_2$ .
5. [Moh89] Let  $G = (V, E)$  be a graph on at least four vertices, with maximum degree  $\Delta$ . Then  $\frac{\alpha(G)}{2} \leq \Phi(G) \leq \sqrt{\alpha(G)(2\Delta - \alpha(G))}$ , where  $\Phi(G)$  is the isoperimetric number of  $G$ . (See Section 32.5.)
6. [FK98] Among all connected graphs on  $n$  vertices with girth 3, the algebraic connectivity is uniquely minimized by  $C_{n,3}$ .
7. [FKP02] If  $g \geq 4$  and  $n \geq 3g - 1$ , then among all connected graphs on  $n$  vertices with girth  $g$ , the algebraic connectivity is uniquely minimized by  $C_{n,g}$ .
8. [Kir00] Let  $G$  be a graph on  $n$  vertices, and suppose that  $G$  has  $k$  cut-vertices, where  $2 \leq k \leq \frac{n}{2}$ . Then  $\alpha(G) \leq \frac{2(n-k)}{n-k+2+\sqrt{(n-k)^2+4}}$ . For each such  $k$  and  $n$ , there is a graph on  $n$  vertices with  $k$  cut-vertices such that equality is attained in the upper bound on  $\alpha$ .
9. [Kir01] Suppose that  $n \geq 5$  and  $\frac{n}{2} < k$ , and let  $G$  be a graph on  $n$  vertices with  $k$  cut-vertices. Let  $q = \lfloor \frac{k}{n-k} \rfloor$  and  $l = k - (n-k)q$ .
  - If  $l = 1$ , then  $\alpha(G) \leq 2(1 - \cos(\frac{\pi}{2q+3}))$ .
  - If  $l = 0$ , let  $\theta_0$  be the unique element of  $[\frac{\pi}{2q+3}, \frac{\pi}{2q+1}]$  such that  $(n-k-1)\cos((2q+1)\theta_0/2) + \cos((2q+3)\theta_0/2) = 0$ . Then  $\alpha(G) \leq 2(1 - \cos(\theta_0))$ .

FIGURE 36.2 The graph  $C_{6,3}$ .

- If  $2 \leq l$ , let  $\theta_0$  be the unique element of  $\left[\frac{\pi}{2q+5}, \frac{\pi}{2q+3}\right]$  such that  $(n - k - 1)\cos((2q + 3)\theta_0/2) + \cos((2q + 5)\theta_0/2) = 0$ . Then  $\alpha(G) \leq 2(1 - \cos(\theta_0))$ .

For each  $k$  and  $n$  with  $\frac{n}{2} < k$ , there is a graph on  $n$  vertices with  $k$  cut-vertices such that equality is attained in the corresponding upper bound on  $\alpha$ .

- [FK98] Over the class of unicyclic graphs on  $n$  vertices having girth 3, the algebraic connectivity is uniquely maximized by  $D_{3,n-3}$ .
- [FKP03b] Over the class of unicyclic graphs on  $n$  vertices having girth 4, the algebraic connectivity is uniquely maximized by  $D_{4,n-4}$ .
- [FKP03b] Fix  $g \geq 5$ . There is an  $N$  such that if  $n > N$ , then over the class of unicyclic graphs on  $n$  vertices having girth  $g$ , the algebraic connectivity is uniquely maximized by  $D_{g,n-g}$ .
- [Kir03] For each real number  $r \geq 0$ , there is a sequence of graphs  $G_k$  with distinct algebraic connectivities, such that  $\alpha(G_k)$  converges monotonically to  $r$  as  $k \rightarrow \infty$ .

FIGURE 36.3 The graph  $D_{4,3}$ .

**Examples:**

- The graph  $C_{6,3}$  is shown in Figure 36.2; its algebraic connectivity is approximately 0.3249.
- The graph  $D_{4,3}$  is shown in Figure 36.3.
- [FK98] The algebraic connectivity of  $D_{3,n-3}$  is 1, and it is an eigenvalue of multiplicity  $n - 3$  of the corresponding Laplacian matrix.
- Consider the graph  $G$  pictured in Figure 36.4. Its algebraic connectivity is 2, so that from Fact 5 above, we deduce that  $1 \leq \Phi(G) \leq 2\sqrt{2}$ . It turns out that the value of  $\Phi(G)$  is  $\frac{3}{2}$ .

FIGURE 36.4 The graph  $G$  for Example 4

### 36.3 Algebraic Connectivity for Trees

The term *graph* means *simple graph* in this section.

**Definitions:**

Let  $T$  be a tree, and let  $\mathbf{y}$  be a Fiedler vector for  $T$ . A **characteristic vertex** of  $T$  is a vertex  $i$  satisfying one of the following conditions:

- I  $y_i = 0$ , and vertex  $i$  is adjacent to a vertex  $j$  such that  $y_j \neq 0$ .
- II There is a vertex  $j$  adjacent to vertex  $i$  such that  $y_i y_j < 0$ .

A tree is called **type I** if it has a single characteristic vertex, and **type II** if it has two characteristic vertices.

Let  $T$  be a tree and suppose that  $v$  is a vertex of  $T$ . The **bottleneck matrix** of a branch of  $T$  at  $v$  is the inverse of the principal submatrix of the Laplacian matrix corresponding to the vertices of that branch.

A branch at vertex  $v$  is called a **Perron branch at  $v$**  if the Perron value of the corresponding bottleneck matrix is maximal among all branches at  $v$ .

Suppose that  $T$  is a type I tree with characteristic vertex  $i$ . A branch at  $i$  is called an **active branch** if, for some Fiedler vector  $\mathbf{y}$ , the entries in  $\mathbf{y}$  corresponding to the vertices in the branch are nonzero.

Suppose that  $n \geq d + 1$ . Denote by  $P(n, d)$  the tree constructed as follows: Begin with the path  $P_{d+1}$ , on vertices  $1, \dots, d + 1$ , labeled so that vertices 1 and  $d + 1$  are pendent, while for each  $i = 2, \dots, d$ , vertex  $i$  is adjacent to vertices  $i - 1$  and  $i + 1$ , then append  $n - d - 1$  isolated vertices at vertex  $\lfloor \frac{d}{2} \rfloor + 1$  of that path.

Let  $T(k, l, d)$  be the tree on  $n = d + k + l$  vertices constructed from the path  $P_d$  by appending  $k$  isolated vertices at one end vertex of  $P_d$ , and appending  $l$  isolated vertices at the other end vertex of  $P_d$ .

### Facts:

1. The bottleneck matrix for a branch is the inverse of an irreducible  $M$ -matrix, and so is entrywise positive (see Chapter 9.5 and/or [KNS96]).
2. [Fie89] If  $T$  is a tree on  $n$  vertices, then  $2(1 - \cos(\frac{\pi}{n})) \leq \alpha(T)$ ; equality holds if and only if  $G = P_n$ .
3. [Mer87] If  $T$  is a tree on  $n \geq 3$  vertices, then  $\alpha(G) \leq 1$ ; equality holds if and only if  $G = K_{1, n-1}$ .
4. [GMS90] If  $T$  is a tree with diameter  $d$ , then  $\alpha(T) \leq 2(1 - \cos(\frac{\pi}{d+1}))$ .
5. [Fie75b] Let  $T$  be a tree on vertices labeled  $1, \dots, n$ , and suppose that  $\mathbf{y}$  is a Fiedler vector of  $T$ . Then exactly one of two cases can occur.
  - There are no zero entries in  $\mathbf{y}$ . Then  $T$  contains a unique edge  $\{i, j\}$  such that  $y_j < 0 < y_i$ . As we move along any path in  $T$  that starts at  $i$  and does not contain  $j$ , the corresponding entries in  $\mathbf{y}$  are positive and increasing. As we move along any path in  $T$  that starts at  $j$  and does not contain  $i$ , the corresponding entries in  $\mathbf{y}$  are negative and decreasing. In this case  $T$  is type II.
  - The vector  $\mathbf{y}$  has at least one zero entry. Then there is a unique vertex  $i$  of  $T$  such that  $y_i = 0$  and  $i$  is adjacent to a vertex  $j$  such that  $y_j \neq 0$ . As we move along any path in  $T$  that starts at vertex  $i$ , the corresponding entries in  $\mathbf{y}$  are either increasing, decreasing, or identically zero. In this case  $T$  is type I.
6. [KNS96] Let  $T$  be a tree and  $\mathbf{y}$  be a Fiedler vector for  $T$ . Let  $P$  be a path in  $T$  that starts at a characteristic vertex  $i$  of  $T$ , and does not contain any other characteristic vertices of  $T$ . If, as we move along  $P$  away from  $i$  the entries of  $\mathbf{y}$  are increasing, then they are also concave down. If, as we move along  $P$  away from  $i$  the entries of  $\mathbf{y}$  are decreasing, then they are also concave up.
7. [Mer87] Let  $T$  be a tree. Then each Fiedler vector for  $T$  identifies the same vertex (or vertices) as the characteristic vertex (or vertices). Consequently, the type of the tree is independent of the particular choice of the Fiedler vector.
8. [Fie75a] If  $T$  is a type II tree, then  $\alpha(T)$  is a simple eigenvalue.
9. [KNS96] A tree  $T$  is type I if and only if at some vertex  $i$ , there are two or more Perron branches. In that case,  $i$  is the characteristic vertex of  $T$ ,  $\alpha(T)$  is the reciprocal of the Perron value of the bottleneck matrix of a Perron branch at  $i$ , and ([KF98]) the multiplicity of  $\alpha(T)$  is one less than the number of Perron branches at  $i$ .
10. [KNS96] A tree  $T$  is type II if and only if there is a unique Perron branch at every vertex. In this case, the characteristic vertices of  $T$  are the unique adjacent vertices  $i, j$  such that the Perron branch at vertex  $i$  is the branch containing vertex  $j$ , and the Perron branch at vertex  $j$  is the branch containing vertex  $i$ . Letting  $B_i$  and  $B_j$  denote the bottleneck matrices for the Perron branches at vertices  $i$  and  $j$ , respectively,  $\exists! \gamma \in (0, 1)$  such that  $\rho(B_i - \gamma J) = \rho(B_j - (1 - \gamma)J)$ , and the common Perron value for these matrices is  $1/\alpha(T)$ .
11. The following is a consequence of results in [GM87] and [KNS96]. Suppose that  $T$  is a type I tree with characteristic vertex  $i$ ; then a branch at  $i$  is an active branch if and only if it is a Perron branch at  $i$ .
12. [FK98] Among all trees on  $n$  vertices with diameter  $d$ , the algebraic connectivity is maximized by  $P(n, d)$ .
13. [FK98] Let  $T$  be a tree on  $n$  vertices with diameter  $d$ . Then  $\alpha(T) \geq \alpha(T(\lfloor \frac{n-d+1}{2} \rfloor, \lfloor \frac{n-d+1}{2} \rfloor, d-1))$ , with equality holding if and only if  $T = T(\lfloor \frac{n-d+1}{2} \rfloor, \lfloor \frac{n-d+1}{2} \rfloor, d-1)$ .

**Examples:**

- [GM90] The algebraic connectivity of  $T(k, l, 2)$  is the smallest root of the polynomial  $x^3 - (k + l + 4)x^2 + (2k + 2l + kl + 5)x - (k + l + 2)$ .
- Let  $T$  be the tree constructed as follows: At a single vertex  $v$ , append  $k \geq 2$  copies of the path  $P_2$  and  $l \geq 0$  pendent vertices. For each branch at  $v$  consisting of a path on two vertices, the bottleneck matrix can be written as  $\begin{bmatrix} 2 & 1 \\ 1 & 1 \end{bmatrix}$ , which has Perron value  $\frac{3+\sqrt{5}}{2}$ , while each branch at  $v$  consisting of a single vertex has bottleneck matrix equal to  $[1]$ . Then  $\alpha(T) = \frac{3-\sqrt{5}}{2}$ , and is an eigenvalue of multiplicity  $k - 1$  of the corresponding Laplacian matrix. In particular,  $T$  is a type I tree with characteristic vertex  $v$ .
- [FK98] If  $d \geq 4$  is even,  $\alpha(P(n, d)) = 2(1 - \cos(\frac{\pi}{d+1}))$ , and is a simple eigenvalue of the corresponding Laplacian matrix.

- Consider the tree  $T(2, 2, 2)$  shown in Figure 36.5. At both of its nonpendent vertices, the bottleneck matrix for the corresponding Perron component can be written as  $\begin{bmatrix} 2 & 1 & 1 \\ 1 & 2 & 1 \\ 1 & 1 & 1 \end{bmatrix}$ .

FIGURE 36.5 The tree  $T(2, 2, 2)$ .

It follows that  $1/\alpha(T) = \rho \left( \begin{bmatrix} 2 & 1 & 1 \\ 1 & 2 & 1 \\ 1 & 1 & 1 \end{bmatrix} - 1/2J \right) = (5 +$

$\sqrt{17})/4$ . Hence, the algebraic connectivity for  $T(2, 2, 2)$  is  $(5 - \sqrt{17})/2$ , and it is a type II tree, with the two nonpendent vertices as the characteristic vertices.  $[\frac{3+\sqrt{17}}{4}, \frac{3+\sqrt{17}}{4}, 1, -\frac{3+\sqrt{17}}{4}, -\frac{3+\sqrt{17}}{4}, -1]^T$  is a Fiedler vector.

- [GM87] Consider the tree  $T$  shown in Figure 36.6; this is a type I tree with characteristic vertex  $v$ . The numbers above the vertices are the vertex numbers and the numbers below are (to four decimal places) the entries in a Fiedler vector for  $T$ . The bottleneck matrix for the branch at  $v$  on 5 vertices

can be written as  $\begin{bmatrix} 3 & 1 & 2 & 1 & 1 \\ 1 & 3 & 1 & 2 & 1 \\ 2 & 1 & 2 & 1 & 1 \\ 1 & 2 & 1 & 2 & 1 \\ 1 & 1 & 1 & 1 & 1 \end{bmatrix}$ , while that for the branch at  $v$  on 4 vertices can be written

$\begin{bmatrix} 3 & 2 & 2 & 1 \\ 2 & 3 & 2 & 1 \\ 2 & 2 & 2 & 1 \\ 1 & 1 & 1 & 1 \end{bmatrix}$ . The algebraic connectivity is the smallest root of the polynomial  $x^3 - 6x^2 + 8x - 1$ , and is approximately 0.1392.

FIGURE 36.6 The tree  $T$  in Example 5.

## 36.4 Fiedler Vectors and Algebraic Connectivity for Weighted Graphs

---

The term *graph* means *simple graph* in this section.

### Definitions:

Let  $G = (V, E)$  be a graph on  $n \geq 2$  vertices, and suppose that for each edge  $e \in E$  we have an associated positive number  $w(e)$ .

- Then  $w(e)$  is the **weight** of  $e$ .
- The function  $w : E \rightarrow \mathbb{R}^+$  is a **weight function** on  $G$ .
- The graph  $G$ , together with the function  $w : E \rightarrow \mathbb{R}^+$ , is a **weighted graph**, and is denoted  $G_w$ .

The **Laplacian matrix**  $L(G_w)$  for the weighted graph  $G_w$  is the  $n \times n$  matrix  $L(G_w) = [l_{i,j}]$  such that  $l_{i,j} = 0$  if vertices  $i$  and  $j$  are distinct and not adjacent in  $G$ ,  $l_{i,j} = -w(e)$  if  $e = \{i, j\} \in E$ , and  $l_{i,i} = \sum w(e)$ , where the sum is taken over all edges  $e$  incident with vertex  $i$ .

Throughout this chapter, we only consider Laplacian matrices for weighted graphs on at least two vertices. The notation  $L(G_w)$  for the Laplacian matrix of the weighted graph  $G_w$  should not be confused with the notation for the line graph introduced in Section 28.2.

Let  $G_w$  be a weighted graph on  $n$  vertices, and denote the eigenvalues of  $L(G_w)$  by  $0 = \mu_1 \leq \mu_2 \leq \dots \leq \mu_n$ . The **algebraic connectivity** of  $G_w$  is  $\mu_2$  and is denoted  $\alpha(G_w)$ .

Let  $G_w$  be a weighted graph. A **Fiedler vector** for  $G_w$  is an eigenvector of  $L(G_w)$  corresponding to the eigenvalue  $\alpha(G_w)$ .

Let  $G_w$  be a weighted graph and  $\mathbf{y}$  be a Fiedler vector for  $G_w$ . For each vertex  $i$  of  $G_w$ , the **valuation** of  $i$  is equal to the corresponding entry in  $\mathbf{y}$ . A vertex is **valuated positively, negatively, or zero** accordingly, as the corresponding entry in  $\mathbf{y}$  is positive, negative, or zero.

### Facts:

1. [Fie75b] Let  $G_w$  be a weighted graph and let  $\mathbf{y}$  be a Fiedler vector for  $G_w$ . Then exactly one of the following holds.
  - Case A—There is a single block  $B_0$  in  $G_w$  containing both positively valuated vertices and negatively valuated vertices. For every other block of  $G_w$ , the vertices are either all valuated positively or all valuated negatively or all valuated zero. Along any path in  $G$  that starts at a vertex  $k \in B_0$  and contains at most two cut-vertices from each block, the valuations of the cut-vertices form either an increasing sequence, a decreasing sequence, or an all zero sequence, according as  $y_k > 0$ ,  $y_k < 0$ , or  $y_k = 0$ , respectively. In the case where  $y_k = 0$ , then each vertex on that path is valuated zero.
  - Case B — No block in  $G_w$  has both positively and negatively valuated vertices. Then there is a unique vertex  $i$  of  $G_w$  having zero valuation that is adjacent to a vertex  $j$  with nonzero valuation. The vertex  $i$  is a cut-vertex. Each block of  $G_w$  contains (with the exception of  $i$ ) only vertices of positive valuation, or only vertices of negative valuation, or only vertices of zero valuation. Along any path that starts at vertex  $i$  and contains at most two cut-vertices from each block, the valuations of the cut-vertices form either an increasing sequence, a decreasing sequence, or an all zero sequence. Any path in  $G_w$  that contains both positively and negatively valuated vertices must pass through vertex  $i$ .
2. [KF98] Let  $G_w$  be a weighted graph. If case A holds for some Fiedler vector, then case A holds for every Fiedler vector and, moreover, every Fiedler vector identifies the same block of  $G_w$  having vertices of both positive and negative valuations. Similarly, if case B holds for some Fiedler vector, then case B holds for every Fiedler vector and, moreover, every vector identifies the same vertex  $i$  that is valuated zero and is adjacent to a vertex with nonzero valuation.

3. [KF98] Suppose that for a weighted graph  $G_w$ , case A holds, and let  $B_0$  be the unique block of  $G_w$  containing both positively and negatively valuated vertices. Fix an edge  $e \in B_0$ , and let  $\hat{w}$  be the weighting of  $G$  formed from  $w$  by replacing  $w(e)$  by  $t$ , where  $0 < t < w(e)$ . Then for the weighted graph  $G_{\hat{w}}$ , case A also holds, and  $B_0$  is still the block of  $G$  containing both positively and negatively valuated vertices. Similarly, if  $B_0 - e$  is a block of  $G - e$ , then case A still holds for the weighting  $\hat{w}$  of  $G - e$  arising from setting  $\hat{w}(f) = w(f)$  for each  $f \in E \setminus \{e\}$ , and  $B_0 - e$  is still the block containing both positively and negatively valuated vertices.
4. [KF98] Suppose that  $G$  is a graph, that  $w$  is weight function on  $G$ , and consider the weighted graph  $G_w$ . Suppose that  $B$  is a block of  $G_w$  that is valuated all nonnegatively or all nonpositively by some Fiedler vector. Let  $\hat{G}_w$  be the weighted graph formed from  $G_w$  by either adding a weighted edge to  $B$ , or raising the weight of an existing edge in  $B$ , and denote the modified block by  $\hat{B}$ . Then every Fiedler vector for  $\hat{G}_w$  valuates the vertices of  $\hat{B}$  all nonnegatively, or all nonpositively.
5. [FN02] Suppose that  $G_w$  is a weighted graph on  $n$  vertices with Laplacian matrix  $L(G_w)$ . For each nonempty subset  $U$  of the vertex set  $V$ , let  $L(G_w)[U]$  denote the principal submatrix of  $L(G_w)$  on the rows and columns corresponding to the vertices in  $U$ , and let  $\tau(L(G_w)[U])$  denote its smallest eigenvalue. Then  $\alpha(G_w) \geq \min\{\max\{\tau(L(G_w)[U]), \tau(L(G_w)[V \setminus U])\} \mid U \subset V, 0 < |U| \leq \lfloor \frac{n}{2} \rfloor\}$ .
6. [KN04] Suppose that  $G = (V, E)$  is a graph, that  $w$  is weight function on  $G$ , and consider the weighted graph  $G_w$ . Fix an edge  $e = \{i, j\} \in E$ . For each  $t \geq w(e)$ , let  $w_t$  be the weight function on  $G$  constructed from  $w$  by setting the weight of the edge  $e$  to  $t$ .
  - If some Fiedler vector  $\mathbf{y}$  for  $G_w$  has the property that  $y_i = y_j$ , then for any  $t \geq w(e)$ ,  $\alpha(G_{w_t}) = \alpha(G_w)$ . In particular, if  $\alpha(G_w)$  is an eigenvalue of multiplicity at least two, then  $\alpha(G_{w_t}) = \alpha(G_w)$  for all  $t \geq w(e)$ .
  - If  $\alpha(G_w)$  is a simple eigenvalue, then  $\exists t_0 > 0$  such that for each  $t \in [0, t_0)$ ,  $\alpha(G_{w_t})$  is a twice differentiable function of  $t$ , with  $0 \leq \frac{d\alpha(G_{w_t})}{dt} \leq 2$  and  $\frac{d^2\alpha(G_{w_t})}{dt^2} \leq 0$ . Further, let  $\mathbf{y}(t)$  denote a Fiedler vector for  $G_{w_t}$  of norm 1 that is analytic for  $t \in [0, t_0)$ ; then  $|(\mathbf{y}(t))_i - (\mathbf{y}(t))_j|$  is nonincreasing for  $t \in [0, t_0)$ .

**Examples:**

1. Consider the weighting of  $K_n$  in which each edge has weight 1. Then any vector that is orthogonal to  $\mathbf{1}_n$  is a Fiedler vector.
2. Consider the weighting of  $K_{1,n-1}$  in which edge has weight 1. If  $i$  and  $j$  are pendent vertices of  $K_{1,n-1}$ , then  $\mathbf{e}_i - \mathbf{e}_j$  is a Fiedler vector.
3. Consider the weighting of the path  $P_n$  in which each edge has weight 1, and label the vertices of  $P_n$  so that vertices 1 and  $n$  are pendent, while for each  $i = 2, \dots, n - 1$ , vertex  $i$  is adjacent to vertices  $i - 1$  and  $i + 1$ . Then the vector  $\mathbf{y}$  with  $y_i = \cos((2i - 1)\pi/(2n))$  is a Fiedler vector.
4. Suppose that  $a, b > 0$ , and let  $T_w$  be the weighting of the path  $P_4$  arising by assigning the pendent edges weight  $a$ , and the nonpendent edge weight  $b$ . The corresponding Laplacian matrix can be

written as 
$$\begin{bmatrix} a & 0 & -a & 0 \\ 0 & a & 0 & -a \\ -a & 0 & a+b & -b \\ 0 & -a & -b & a+b \end{bmatrix},$$
 which has eigenvalues  $0, a + b \pm \sqrt{a^2 + b^2}$ , and  $2a$ . In

particular,  $\alpha(T_w) = a + b - \sqrt{a^2 + b^2}$ , with corresponding Fiedler vector 
$$\begin{bmatrix} a \\ -a \\ \sqrt{a^2 + b^2} - b \\ b - \sqrt{a^2 + b^2} \end{bmatrix}.$$

5. Figure 36.7 shows a weighted graph  $G_w$ , where the parameters  $a, b, c$  are the weights of the edges, and where the vertices are labeled  $1, \dots, 4$ , as indicated in that figure. The corresponding Laplacian matrix is  $L(G_w) =$

FIGURE 36.7 The weighted graph  $G_w$  in Example 5.

$$\begin{bmatrix} b & 0 & 0 & -b \\ 0 & a+c & -c & -a \\ 0 & -c & a+c & -a \\ -b & -a & -a & 2a+b \end{bmatrix}.$$

The eigenvalues of  $L(G_w)$  are 0,

$a+2c$ , and  $\frac{3a+2b \pm \sqrt{9a^2-4ab+4b^2}}{2}$ , so that  $\alpha(G_w) = \min\{a+2c, \frac{3a+2b-\sqrt{9a^2-4ab+4b^2}}{2}\}$ . If  $\alpha(G_w) = a+2c$ ,

then  $\begin{bmatrix} 0 \\ 1 \\ -1 \\ 0 \end{bmatrix}$  is a Fiedler vector for  $G_w$ , while if  $\alpha(G_w) = \frac{3a+2b-\sqrt{9a^2-4ab+4b^2}}{2}$ , then  $\begin{bmatrix} \frac{3a+\sqrt{9a^2-4ab+4b^2}}{2} \\ -\frac{a+2b+\sqrt{9a^2-4ab+4b^2}}{4} \\ -\frac{a+2b+\sqrt{9a^2-4ab+4b^2}}{4} \\ b-a \end{bmatrix}$

is a Fiedler vector for  $G_w$ .

### 36.5 Absolute Algebraic Connectivity for Simple Graphs

The term *graph* means *simple graph* in this section.

#### Definitions:

Let  $G = (V, E)$  be a graph on  $n \geq 2$  vertices. Let  $W$  denote the set of all nonnegative weightings of  $G$  with the property that for each weighting  $w$ , we have  $\sum_{e \in E} w_e = |E|$  (observe that here we relax the restriction that each edge weight be positive, and allow zero weights). The **absolute algebraic connectivity** of  $G$  is denoted by  $\hat{\alpha}(G)$ , and is given by  $\hat{\alpha}(G) = \max\{\alpha(G_w) | w \in W\}$ .

Let  $T = (V, E)$  be a tree. For each vertex  $u$  of  $T$ , define  $S(u) = \sum_{k \in V} (d(u, k))^2$ .

#### Facts:

1. [Fie90] For a graph  $G$ ,  $\hat{\alpha}(G) = 0$  if and only if  $G$  is disconnected.
2. [Fie90] If  $G$  is a graph and  $\Omega$  is its automorphism group, then  $\hat{\alpha}(G) = \max\{\alpha(G_w) | w \in W_0\}$ , where  $W_0$  is the subclass of  $W$  consisting of weightings for which equivalent edges in  $\Omega$  have the same weight.
3. [KP02] If  $G$  is a graph with  $m$  edges, and  $H$  is the graph formed from  $G$  by adding an edge not already present in  $G$ , then  $\frac{m+1}{m} \hat{\alpha}(G) \leq \hat{\alpha}(H)$ .
4. [Fie90] Let  $T$  be a tree on  $n$  vertices. Then one of the following two cases occurs:

- There is a vertex  $v$  of  $T$  such that for any vertex  $k \neq v$ ,  $S(v) \leq S(k) - n$ . In this case,  $\hat{\alpha}(T) = \frac{n-1}{S(v)}$ .
- There is an edge  $\{u, v\}$  of  $T$  such that  $|S(u) - S(v)| < n$ . In this case,  $\hat{\alpha}(T) = \frac{4n(n-1)}{4nS(u) - (n+S(u)-S(v))^2}$ .

Weightings of trees that yield the maximum value  $\hat{\alpha}$  are also discussed in [Fie90].

5. [Fie93] If  $T$  is a tree on  $n$  vertices, then  $\frac{12}{n(n+1)} \leq \hat{\alpha}(T) \leq 1$ . Equality holds in the lower bound if  $T = P_n$ , and equality holds in the upper bound if  $T = K_{1,n-1}$ .
6. [KP02] Suppose that  $G$  is a graph on  $n \geq 7$  vertices that has a cut-vertex. Then  $\hat{\alpha}(G) \leq \left(\frac{n^2-3n+4}{n-3}\right) \left(1 - \frac{4}{2(n-1)-(n-3)\sqrt{2(n-2)/(n-1)}}\right)$ . Further, the upper bound in attained by the graph formed by appending a pendent vertex at a vertex of  $K_{n-1}$ ; a weighting of that graph that yields the maximum value  $\hat{\alpha}$  is also given in [KP02].

FIGURE 36.8 The tree  $P(9, 5)$ .

FIGURE 36.9 The tree  $T(2, 3, 4)$ .

**Examples:**

1. The absolute algebraic connectivity of  $K_n$  is  $n$ .
2. If  $m \leq n$  and  $2 \leq n$ , then  $\hat{\alpha}(K_{m,n}) = m$ .
3. [KP02] Let  $e$  be an edge of  $K_n$ . Then  $\hat{\alpha}(K_n - e) = \frac{(n-2)(n^2-n-2)}{n^2-3n+4}$ .
4. Consider the tree  $P(9, 5)$  shown in Figure 36.8; we have  $S(v) = 22$ , and  $S(v) \leq S(k) - 9$  for any vertex  $k \neq v$ , so that the first case of Fact 4 above holds. Hence,  $\hat{\alpha}(P(9, 5)) = \frac{4}{11}$ .
5. Consider the tree  $T(2, 3, 4)$  pictured in Figure 36.9. We have  $S(u) = 41$  and  $S(v) = 36$ , so that the second case of Fact 4 above holds. Hence,  $\hat{\alpha}(T(2, 3, 4)) = \frac{9}{40}$ .

## 36.6 Generalized Laplacians and Multiplicity

---

The term *graph* means *simple graph* in this section.

**Definitions:**

Let  $G = (V, E)$  be a graph on  $n \geq 2$  vertices. A **generalized Laplacian** of  $G$  is a symmetric  $n \times n$  matrix  $M$  with the property that for each  $i \neq j$ ,  $m_{i,j} < 0$  if  $\{i, j\} \in E$  and  $m_{i,j} = 0$  if  $\{i, j\} \notin E$ .

We only consider generalized Laplacian matrices for graphs on at least two vertices.

For any symmetric matrix  $B$ , let  $\tau(B)$  denote its smallest eigenvalue, let  $\mu(B)$  denote its second smallest eigenvalue, and let  $\lambda(B)$  denote its largest eigenvalue.

Let  $G$  be a graph, and let  $v$  be a vertex of  $G$ . Suppose that  $M$  is a generalized Laplacian matrix for  $G$ . Let  $C_1, \dots, C_k$  denote the components of  $G - v$ ; a component  $C_j$  is called a **Perron component at  $v$**  if  $\tau(M[C_j])$  is minimal among all  $\tau(M[C_i]), i = 1, \dots, k$ .

**Facts:**

1. [BKP01] Let  $G$  be a connected graph and let  $v$  be a cut-vertex of  $G$ . Suppose that  $M$  is a generalized Laplacian matrix for  $G$ . If there are  $p \geq 2$  Perron components at  $v$ , say  $C_1, \dots, C_p$ , then  $\mu(M) = \tau(M[C_1])$ . Further,  $\mu(M)$  is an eigenvalue of  $M$  of multiplicity  $p - 1$ .
2. [BKP01] Let  $G$  be a connected graph, and let  $v$  be a cut-vertex of  $G$ . Let  $M$  be a generalized Laplacian matrix for  $G$ . Suppose that there is a unique Perron component  $A_0$  at  $v$ ; denote the other connected components at  $v$  by  $B_1, \dots, B_k$ , and set  $A_1 = G \setminus A_0$ . Let  $\mathbf{z}$  be an eigenvector of  $M$  corresponding to  $\tau(M)$ , and let  $\mathbf{z}_0, \mathbf{z}_1$  be the subvectors of  $\mathbf{z}$  corresponding to the vertices in  $A_0, A_1$ , respectively. For each  $i = 1, \dots, k$ , denote the principal submatrix of  $M$  corresponding to

the vertices of  $B_i$  by  $M[B_i]$ . Let  $S = (M[B_1])^{-1} \oplus \dots \oplus (M[B_k])^{-1} \oplus [0]$ , and let  $M_0$  denote the principal submatrix of  $M$  corresponding to the vertices of  $A_0$ . There is a unique  $\gamma > 0$  such that  $\lambda(M_0^{-1} - \gamma \mathbf{z}_0 \mathbf{z}_0^T) = \lambda(S + \gamma \mathbf{z}_1 \mathbf{z}_1^T) = 1/\mu(M)$ . Further, the multiplicity of  $\mu(M)$  as an eigenvalue of  $M$  coincides with the multiplicity of  $1/\mu(M)$  as an eigenvalue of  $M_0^{-1} - \gamma \mathbf{z}_0 \mathbf{z}_0^T$ .

### Examples:

1. Consider the generalized Laplacian matrix  $M = \begin{bmatrix} 0 & -1 & -1 & -1 & -2 \\ -1 & 3 & -1 & 0 & 0 \\ -1 & -1 & 3 & 0 & 0 \\ -1 & 0 & 0 & 2 & 0 \\ -2 & 0 & 0 & 0 & 2 \end{bmatrix}$ . There are three

Perron components at vertex 1, induced by the vertex sets  $\{2, 3\}$ ,  $\{4\}$ , and  $\{5\}$ . We have  $\mu(M) = 2$ , which is an eigenvalue of multiplicity two.

2. Consider the generalized Laplacian matrix  $M = \begin{bmatrix} -3 & -1 & -1 & -1 & -2 \\ -1 & 2 & -1 & 0 & 0 \\ -1 & -1 & 2 & 0 & 0 \\ -1 & 0 & 0 & 2 & 0 \\ -2 & 0 & 0 & 0 & 2 \end{bmatrix}$ . The unique Perron

component at vertex 1 is induced by the vertex set  $\{2, 3\}$ . We have  $\mu(M) = \frac{-3+\sqrt{29}}{2}$ , which is a simple eigenvalue.

Calculations are subject to errors. There may be modeling errors, measurement errors, manufacturing errors, noise, equipment is subject to wear and damage, etc. In preparation for computation, data must often be perturbed by rounding it to fit a particular finite precision, floating-point format. Further errors may be introduced during a computation by using finite precision arithmetic and by truncating an infinite process down to a finite number of steps.

This chapter outlines aspects of how such errors affect the results of a mathematical computation with an emphasis on matrix computations. Topics include:

- Vector and matrix norms and seminorms that are often used to analyze errors and express error bounds.
- Floating point arithmetic.
- Condition numbers that measure how much data errors may affect computational results.
- Numerical stability, an assessment of whether excessive amounts of data may be lost to rounding errors during a finite precision computation.

For elaborative discussions of vector and matrix norms, consult [HJ85]. See [Ove01] for a textbook introduction to IEEE standard floating point arithmetic. Complete details of the standard are available in [IEEE754] and [IEEE854]. Basic concepts of numerical stability and conditioning appear in numerical linear algebra books, e.g., [GV96], [Ste98], [TB97], and [Dat95]. The two particularly authoritative books on these topics are the classical book by Wilkinson [Wil65] and the more recent one by Higham [Hig96]. For perturbation analysis, see the classic monograph [Kat66] and the more modern treatments in [SS90] and [Bha96].

The set  $\mathbb{C}^n = \mathbb{C}^{n \times 1}$  is the complex vector space of  $n$ -row, 1-column matrices, and  $\mathbb{R}^n = \mathbb{R}^{n \times 1}$  is the real vector space of  $n$ -row, 1-column matrices. Unless otherwise specified,  $\mathbb{F}^n$  is either  $\mathbb{R}^n$  or  $\mathbb{C}^n$ ,  $\mathbf{x}$  and  $\mathbf{y}$  are members of  $\mathbb{F}^n$ , and  $\alpha \in \mathbb{F}$  is a scalar  $\alpha \in \mathbb{R}$  or  $\alpha \in \mathbb{C}$ , respectively. For  $\mathbf{x} \in \mathbb{R}^n$ ,  $\mathbf{x}^T$  is the one row  $n$ -column transpose of  $\mathbf{x}$ . For  $\mathbf{x} \in \mathbb{C}^n$ ,  $\mathbf{x}^*$  is the one row  $n$ -column complex-conjugate-transpose of  $\mathbf{x}$ .  $A$  and  $B$  are members of  $\mathbb{F}^{m \times n}$ . For  $A \in \mathbb{R}^{m \times n}$ ,  $A^* \in \mathbb{R}^{n \times m}$  is the transpose of  $A$ . For  $A \in \mathbb{C}^{m \times n}$ ,  $A^* \in \mathbb{C}^{n \times m}$  is the complex-conjugate-transpose of  $A$ .

## 37.1 Vector Norms

Most uses of vector norms involve  $\mathbb{R}^n$  or  $\mathbb{C}^n$ , so the focus of this section is on those vector spaces. However, the definitions given here can be extended in the obvious way to any finite dimensional real or complex vector space.

Let  $\mathbf{x}, \mathbf{y} \in \mathbb{F}^n$  and  $\alpha \in \mathbb{F}$ , where  $\mathbb{F}$  is either  $\mathbb{R}$  or  $\mathbb{C}$ .

### Definitions:

A vector **norm** is a real-valued function on  $\mathbb{F}^n$  denoted  $\|\mathbf{x}\|$  with the following properties for all  $\mathbf{x}, \mathbf{y} \in \mathbb{F}^n$  and all scalars  $\alpha \in \mathbb{F}$ .

- **Positive definiteness:**  $\|\mathbf{x}\| \geq 0$  and  $\|\mathbf{x}\| = 0$  if and only if  $\mathbf{x}$  is the zero vector.
- **Homogeneity:**  $\|\alpha\mathbf{x}\| = |\alpha|\|\mathbf{x}\|$ .
- **Triangle inequality:**  $\|\mathbf{x} + \mathbf{y}\| \leq \|\mathbf{x}\| + \|\mathbf{y}\|$ .

For  $\mathbf{x} = [x_1, x_2, x_3, \dots, x_n]^* \in \mathbb{F}^n$ , the following are commonly encountered vector norms.

- **Sum-norm or 1-norm:**  $\|\mathbf{x}\|_1 = |x_1| + |x_2| + \dots + |x_n|$ .
- **Euclidean norm or 2-norm:**  $\|\mathbf{x}\|_2 = \sqrt{|x_1|^2 + |x_2|^2 + \dots + |x_n|^2}$ .
- **Sup-norm or  $\infty$ -norm:**  $\|\mathbf{x}\|_\infty = \max_{1 \leq i \leq n} |x_i|$ .
- **Hölder norm or  $p$ -norm:** For  $p \geq 1$ ,  $\|\mathbf{x}\|_p = (|x_1|^p + \dots + |x_n|^p)^{\frac{1}{p}}$ .

If  $\|\cdot\|$  is a vector norm on  $\mathbb{F}^n$  and  $M \in \mathbb{F}^{n \times n}$  is a nonsingular matrix, then  $\|\mathbf{y}\|_M \equiv \|M\mathbf{y}\|$  is an  **$M$ -norm** or **energy norm**. (Note that this notation is ambiguous, since  $\|\cdot\|$  is not specified; it either doesn't matter or must be stated explicitly when used.)

A vector norm  $\|\cdot\|$  is **absolute** if for all  $\mathbf{x} \in \mathbb{F}^n$ ,  $\|\mathbf{x}\| = \|\mathbf{x}\|$ , where  $|[x_1, \dots, x_n]^*| = [|x_1|, \dots, |x_n|]^*$ .

A vector norm  $\|\cdot\|$  is **monotone** if for all  $\mathbf{x}, \mathbf{y} \in \mathbb{F}^n$ ,  $|\mathbf{x}| \leq |\mathbf{y}|$  implies  $\|\mathbf{x}\| \leq \|\mathbf{y}\|$ .

A vector norm  $\|\cdot\|$  is **permutation invariant** if  $\|P\mathbf{x}\| = \|\mathbf{x}\|$  for all  $\mathbf{x} \in \mathbb{R}^n$  and all permutation matrices  $P \in \mathbb{R}^{n \times n}$ .

Let  $\|\cdot\|$  be a vector norm. The **dual norm** is defined by  $\|\mathbf{y}\|^D = \max_{\mathbf{x} \neq 0} \frac{|\mathbf{y}^* \mathbf{x}|}{\|\mathbf{x}\|}$ .

The unit disk corresponding to a vector norm  $\|\cdot\|$  is the set  $\{\mathbf{x} \in \mathbb{F}^n \mid \|\mathbf{x}\| \leq 1\}$ .

The unit sphere corresponding to a vector norm  $\|\cdot\|$  is the set  $\{\mathbf{x} \in \mathbb{F}^n \mid \|\mathbf{x}\| = 1\}$ .

### Facts:

For proofs and additional background, see, for example, [HJ85, Chap. 5].

Let  $\mathbf{x}, \mathbf{y} \in \mathbb{F}^n$  and  $\alpha \in \mathbb{F}$ , where  $\mathbb{F}$  is either  $\mathbb{R}$  or  $\mathbb{C}$ .

1. The commonly encountered norms,  $\|\cdot\|_1, \|\cdot\|_2, \|\cdot\|_\infty, \|\cdot\|_p$ , are permutation invariant, absolute, monotone vector norms.
2. If  $M \in \mathbb{F}^{n \times n}$  is a nonsingular matrix and  $\|\cdot\|$  is a vector norm, then the  $M$ -norm  $\|\cdot\|_M$  is a vector norm.
3. If  $\|\cdot\|$  is a vector norm, then  $|\|\mathbf{x}\| - \|\mathbf{y}\|| \leq \|\mathbf{x} - \mathbf{y}\|$ .
4. A sum of vector norms is a vector norm.
5.  $\lim_{k \rightarrow \infty} \mathbf{x}_k = \mathbf{x}_*$  if and only if in any norm  $\lim_{k \rightarrow \infty} \|\mathbf{x}_k - \mathbf{x}_*\| = 0$ .

**6. Cauchy–Schwartz inequality:**

- (a)  $|\mathbf{x}^* \mathbf{y}| \leq \|\mathbf{x}\|_2 \|\mathbf{y}\|_2$ .
- (b)  $|\mathbf{x}^* \mathbf{y}| = \|\mathbf{x}\|_2 \|\mathbf{y}\|_2$  if and only if there exist scalars  $\alpha$  and  $\beta$ , not both zero, for which  $\alpha \mathbf{x} = \beta \mathbf{y}$ .
- 7. **Hölder inequality:** If  $p \geq 1$  and  $q \geq 1$  satisfy  $\frac{1}{p} + \frac{1}{q} = 1$ , then  $|\mathbf{x}^* \mathbf{y}| \leq \|\mathbf{x}\|_p \|\mathbf{y}\|_q$ .
- 8. If  $\|\cdot\|$  is a vector norm on  $\mathbb{F}^n$ , then its dual  $\|\cdot\|^D$  is also a vector norm on  $\mathbb{F}^n$ , and  $\|\cdot\|^D = \|\cdot\|$ .
- 9. If  $p > 0$  and  $q > 0$  satisfy  $\frac{1}{p} + \frac{1}{q} = 1$ , then  $\|\cdot\|^D = \|\cdot\|_q$ . In particular,  $\|\cdot\|_2^D = \|\cdot\|_2$ . Also,  $\|\cdot\|_1^D = \|\cdot\|_\infty$ .
- 10. If  $\|\cdot\|$  is a vector norm on  $\mathbb{F}^n$ , then for any  $\mathbf{x} \in \mathbb{F}^n$ ,  $|\mathbf{x}^* \mathbf{y}| \leq \|\mathbf{x}\| \|\mathbf{y}\|^D$ .
- 11. A vector norm is absolute if and only if it is monotone.
- 12. **Equivalence of norms:** All vector norms on  $\mathbb{F}^n$  are equivalent in the sense that for any two vector norms  $\|\cdot\|_\mu$  and  $\|\cdot\|_\nu$  there constants  $\alpha > 0$  and  $\beta > 0$  such that for all  $\mathbf{x} \in \mathbb{F}^n$ ,  $\alpha \|\mathbf{x}\|_\mu \leq \|\mathbf{x}\|_\nu \leq \beta \|\mathbf{x}\|_\mu$ . The constants  $\alpha$  and  $\beta$  are independent of  $\mathbf{x}$  but typically depend on the dimension  $n$ .  
In particular,
  - (a)  $\|\mathbf{x}\|_2 \leq \|\mathbf{x}\|_1 \leq \sqrt{n} \|\mathbf{x}\|_2$ .
  - (b)  $\|\mathbf{x}\|_\infty \leq \|\mathbf{x}\|_2 \leq \sqrt{n} \|\mathbf{x}\|_\infty$ .
  - (c)  $\|\mathbf{x}\|_\infty \leq \|\mathbf{x}\|_1 \leq n \|\mathbf{x}\|_\infty$ .
- 13. A set  $D \subset \mathbb{F}^n$  is the unit disk of a vector norm if and only if it has the following properties.
  - (a) **Point-wise bounded:** For every vector  $\mathbf{x} \in \mathbb{F}^n$  there is a number  $\delta > 0$  for which  $\delta \mathbf{x} \notin D$ .
  - (b) **Absorbing:** For every vector  $\mathbf{x} \in \mathbb{F}^n$  there is a number  $\tau > 0$  for which  $|\alpha| \leq \tau$  implies  $\alpha \mathbf{x} \in D$ .
  - (c) **Convex:** For every pair of vectors  $\mathbf{x}, \mathbf{y} \in D$  and every number  $t, 0 \leq t \leq 1$ ,  $t\mathbf{x} + (1-t)\mathbf{y} \in D$ .

**Examples:**

- 1. Let  $\mathbf{x} = [1, 1, -2]^*$ . Then  $\|\mathbf{x}\|_1 = 4$ ,  $\|\mathbf{x}\|_2 = \sqrt{1^2 + 1^2 + (-2)^2} = \sqrt{6}$ , and  $\|\mathbf{x}\|_\infty = 2$ .
- 2. Let  $M = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}$ . Using the 1-norm,  $\left\| \begin{bmatrix} 0 \\ 1 \end{bmatrix} \right\|_M = \left\| \begin{bmatrix} 2 \\ 4 \end{bmatrix} \right\|_1 = 6$ .

## 37.2 Vector Seminorms

---

**Definitions:**

A **vector seminorm** is a real-valued function on  $\mathbb{F}^n$ , denoted  $v(\mathbf{x})$ , with the following properties for all  $\mathbf{x}, \mathbf{y} \in \mathbb{F}^n$  and all scalars  $\alpha \in \mathbb{F}$ .

- 1. **Positiveness:**  $v(\mathbf{x}) \geq 0$ .
- 2. **Homogeneity:**  $\|\alpha \mathbf{x}\| = |\alpha| \|\mathbf{x}\|$ .
- 3. **Triangle inequality:**  $\|\mathbf{x} + \mathbf{y}\| \leq \|\mathbf{x}\| + \|\mathbf{y}\|$ .

Vector norms are *a fortiori* also vector seminorms.

The unit disk corresponding to a vector seminorm  $\|\cdot\|$  is the set  $\{\mathbf{x} \in \mathbb{F}^n \mid v(\mathbf{x}) \leq 1\}$ .

The unit sphere corresponding to a vector seminorm  $\|\cdot\|$  is the set  $\{\mathbf{x} \in \mathbb{F}^n \mid v(\mathbf{x}) = 1\}$ .

**Facts:**

For proofs and additional background, see, for example, [HJ85, Chap. 5].

Let  $\mathbf{x}, \mathbf{y} \in \mathbb{F}^n$  and  $\alpha \in \mathbb{F}$ , where  $\mathbb{F}$  is either  $\mathbb{R}$  or  $\mathbb{C}$ .

- 1.  $v(0) = 0$ .
- 2.  $v(\mathbf{x} - \mathbf{y}) \geq |v(\mathbf{x}) - v(\mathbf{y})|$ .

3. A sum of vector seminorms is a vector seminorm. If one of the summands is a vector norm, then the sum is a vector norm.
4. A set  $D \subset \mathbb{F}^n$  is the unit disk of a seminorm if and only if it has the following properties.
  - (a) **Absorbing:** For every vector  $\mathbf{x} \in \mathbb{F}^n$  there is a number  $\tau > 0$  for which  $|\alpha| \leq \tau$  implies  $\alpha\mathbf{x} \in D$ .
  - (b) **Convex:** For every pair of vectors  $\mathbf{x}, \mathbf{y} \in D$  and every number  $t, 0 \leq t \leq 1$ ,  $t\mathbf{x} + (1-t)\mathbf{y} \in D$ .

### Examples:

1. For  $\mathbf{x} = [x_1, x_2, x_3, \dots, x_n]^T \in \mathbb{F}^n$ , the function  $v(\mathbf{x}) = |x_1|$  is a vector seminorm that is not a vector norm. For  $n \geq 2$ , this seminorm is not equivalent to any vector norm  $\|\cdot\|$ , since  $\|\mathbf{e}_2\| > 0$  but  $v(\mathbf{e}_2) = 0$ , for  $\mathbf{e}_2 = [0, 1, 0, \dots, 0]^T$ .

## 37.3 Matrix Norms

---

### Definitions:

A **matrix norm** is a family of real-valued functions on  $\mathbb{F}^{m \times n}$  for all positive integers  $m$  and  $n$ , denoted uniformly by  $\|A\|$  with the following properties for all matrices  $A$  and  $B$  and all scalars  $\alpha \in \mathbb{F}$ .

- **Positive definiteness:**  $\|A\| \geq 0$ ;  $\|A\| = 0$  only if  $A = 0$ .
- **Homogeneity:**  $\|\alpha A\| = |\alpha| \|A\|$ .
- **Triangle inequality:**  $\|A + B\| \leq \|A\| + \|B\|$ , where  $A$  and  $B$  are compatible for matrix addition.
- **Consistency:**  $\|AB\| \leq \|A\| \|B\|$ , where  $A$  and  $B$  are compatible for matrix multiplication.

If  $\|\cdot\|$  is a family of vector norms on  $\mathbb{F}^n$  for  $n = 1, 2, 3, \dots$ , then the matrix norm on  $\mathbb{F}^{m \times n}$  **induced** by (or **subordinate** to)  $\|\cdot\|$  is  $\|A\| = \max_{\mathbf{x} \neq 0} \frac{\|A\mathbf{x}\|}{\|\mathbf{x}\|}$ . Induced matrix norms are also called **operator norms** or **natural norms**. The matrix norm  $\|A\|_p$  denotes the norm induced by the Hölder vector norm  $\|\mathbf{x}\|_p$ . The following are commonly encountered matrix norms.

- **Maximum absolute column sum norm:**  $\|A\|_1 = \max_{1 \leq j \leq n} \sum_{i=1}^m |a_{ij}|$ .
- **Spectral norm:**  $\|A\|_2 = \sqrt{\rho(A^*A)}$ , where  $\rho(A^*A)$  is the largest eigenvalue of  $A^*A$ .
- **Maximum absolute row sum norm:**  $\|A\|_\infty = \max_{1 \leq i \leq m} \sum_{j=1}^n |a_{ij}|$ .
- **Euclidean norm or Frobenius norm:**  $\|A\|_F = \sqrt{\sum_{i,j=1}^n |a_{ij}|^2}$ .

Let  $\mathcal{M} = \{M_n \in F^{n \times n} : n \geq 1\}$  be a family of nonsingular matrices and let  $\|\cdot\|$  be a family of vector norms. Define a family of vector norms by  $\|\mathbf{x}\|_{\mathcal{M}}$  for  $\mathbf{x} \in \mathbb{F}^n$  by  $\|\mathbf{x}\|_{\mathcal{M}} = \|M_n \mathbf{x}\|$ . This family of vector norms is also called the  **$\mathcal{M}$ -norm** and denoted by  $\|\cdot\|_{\mathcal{M}}$ . (Note that this notation is ambiguous, since  $\|\cdot\|$  is not specified; it either does not matter or must be stated explicitly when used.)

A matrix norm  $\|\cdot\|$  is **minimal** if for any matrix norm  $\|\cdot\|_v$ ,  $\|A\|_v \leq \|A\|$  for all  $A \in F^{n \times n}$  implies  $\|\cdot\|_v = \|\cdot\|$ .

A matrix norm is **absolute** if as a vector norm, each member of the family is absolute.

**Facts:**

For proofs and additional background, see, for example, [HJ85, Chap. 5]. Let  $\mathbf{x}, \mathbf{y} \in \mathbb{F}^n$ ,  $A, B \in \mathbb{F}^{m \times n}$ , and  $\alpha \in \mathbb{F}$ , where  $\mathbb{F}$  is either  $\mathbb{R}$  or  $\mathbb{C}$ .

1. A matrix norm is a family of vector norms, but not every family of vector norms is a matrix norm (see Example 2).
2. The commonly encountered norms,  $\|\cdot\|_1$ ,  $\|\cdot\|_2$ ,  $\|\cdot\|_\infty$ ,  $\|\cdot\|_F$ , and norms induced by vector norms are matrix norms. Furthermore,
  - (a)  $\|A\|_1$  is the matrix norm induced by the vector norm  $\|\cdot\|_1$ .
  - (b)  $\|A\|_2$  is the matrix norm induced by the vector norm  $\|\cdot\|_2$ .
  - (c)  $\|A\|_\infty$  is the matrix norm induced by the vector norm  $\|\cdot\|_\infty$ .
  - (d)  $\|A\|_F$  is not induced by any vector norm.
  - (e) If  $\mathcal{M} = \{M_n\}$  is a family of nonsingular matrices and  $\|\cdot\|$  is an induced matrix norm, then for  $A \in \mathbb{F}^{m \times n}$ ,  $\|A\|_{\mathcal{M}} = \|M_m A M_n^{-1}\|$ .
3. If  $\|\cdot\|$  is the matrix norm induced by a family of vector norms  $\|\cdot\|$ , then  $\|I_n\| = 1$  for all positive integers  $n$  (where  $I_n$  is the  $n \times n$  identity matrix).
4. If  $\|\cdot\|$  is the matrix norm induced by a family of vector norms  $\|\cdot\|$ , then for all  $A \in \mathbb{F}^{m \times n}$  and all  $\mathbf{x} \in \mathbb{F}^n$ ,  $\|A\mathbf{x}\| \leq \|A\| \|\mathbf{x}\|$ .
5. For all  $A \in \mathbb{F}^{m \times n}$  and all  $\mathbf{x} \in \mathbb{F}^n$ ,  $\|A\mathbf{x}\|_F \leq \|A\|_F \|\mathbf{x}\|_2$ .
6.  $\|\cdot\|_1, \|\cdot\|_\infty, \|\cdot\|_F$  are absolute norms. However, for some matrices  $A$ ,  $\| |A| \|_2 \neq \|A\|_2$  (see Example 3).
7. A matrix norm is minimal if and only if it is an induced norm.
8. All matrix norms are equivalent in the sense that for any two matrix norms  $\|\cdot\|_\mu$  and  $\|\cdot\|_\nu$ , there exist constants  $\alpha > 0$  and  $\beta > 0$  such that for all  $A \in \mathbb{F}^{m \times n}$ ,  $\alpha \|A\|_\mu \leq \|A\|_\nu \leq \beta \|A\|_\mu$ . The constants  $\alpha$  and  $\beta$  are independent of  $A$  but typically depend on  $n$  and  $m$ . In particular,
  - (a)  $\frac{1}{\sqrt{n}} \|A\|_\infty \leq \|A\|_2 \leq \sqrt{m} \|A\|_\infty$ .
  - (b)  $\|A\|_2 \leq \|A\|_F \leq \sqrt{n} \|A\|_2$ .
  - (c)  $\frac{1}{\sqrt{m}} \|A\|_1 \leq \|A\|_2 \leq \sqrt{n} \|A\|_1$ .
9.  $\|A\|_2 \leq \sqrt{\|A\|_1 \|A\|_\infty}$ .
10.  $\|AB\|_F \leq \|A\|_F \|B\|_2$  and  $\|AB\|_F \leq \|A\|_2 \|B\|_F$  whenever  $A$  and  $B$  are compatible for matrix multiplication.
11.  $\|A\|_2 \leq \|A\|_F$  and  $\|A\|_2 = \|A\|_F$  if and only if  $A$  has rank less than or equal to 1.
12. If  $A = \mathbf{xy}^*$  for some  $\mathbf{x} \in \mathbb{F}^n$  and  $\mathbf{y} \in \mathbb{F}^m$ , then  $\|A\|_2 = \|A\|_F = \|\mathbf{x}\|_2 \|\mathbf{y}\|_2$ .
13.  $\|A\|_2 = \|A^*\|_2$  and  $\|A\|_F = \|A^*\|_F$ .
14. If  $U \in F^{n \times n}$  is a unitary matrix, i.e., if  $U^* = U^{-1}$ , then the following hold.
  - (a)  $\|U\|_2 = 1$  and  $\|U\|_F = \sqrt{n}$ .
  - (b) If  $A \in \mathbb{F}^{m \times n}$ , then  $\|AU\|_2 = \|A\|_2$  and  $\|AU\|_F = \|A\|_F$ .
  - (c) If  $A \in \mathbb{F}^{n \times m}$ , then  $\|UA\|_2 = \|A\|_2$  and  $\|UA\|_F = \|A\|_F$ .
15. For any matrix norm  $\|\cdot\|$  and any  $A \in F^{n \times n}$ ,  $\rho(A) \leq \|A\|$ , where  $\rho(A)$  is the spectral radius of  $A$ . This need not be true for a vector norm on matrices (see Example 2).
16. For any  $A \in F^{n \times n}$  and  $\varepsilon > 0$ , there exists a matrix norm  $\|\cdot\|$  such that  $\|A\| < \rho(A) + \varepsilon$ . A method for finding such a norm is given in Example 5.
17. For any matrix norm  $\|\cdot\|$  and  $A \in F^{n \times n}$ ,  $\lim_{k \rightarrow \infty} \|A^k\|^{1/k} = \rho(A)$ .
18. For  $A \in F^{n \times n}$ ,  $\lim_{k \rightarrow \infty} A^k = 0$  if and only if  $\rho(A) < 1$ .

**Examples:**

1. If  $A = \begin{bmatrix} 1 & -2 \\ 3 & -4 \end{bmatrix}$ , then  $\|A\|_1 = 6$ ,  $\|A\|_\infty = 7$ ,  $\|A\|_2 = \sqrt{15 + \sqrt{221}}$ , and  $\|A\|_F = \sqrt{30}$ .
2. The family of matrix functions defined for  $A \in \mathbb{F}^{m \times n}$  by

$$v(A) = \max_{\substack{1 \leq i \leq m \\ 1 \leq j \leq n}} |a_{ij}|$$

is *not* a matrix norm because consistency fails. For example, if  $J = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}$ , then  $v(J^2) = 2 > 1 = v(J)v(J)$ . Note that  $v$  is a family of vector norms on matrices (it is the  $\infty$  norm on the  $n^2$ -tuple of entries), and  $v(J) = 1 < 2 = \rho(J)$ .

3. If  $A = \begin{bmatrix} 3 & 4 \\ -4 & 3 \end{bmatrix}$ , then  $\|A\|_2 = 5$  but  $\| |A| \|_2 = 7$ .
4. If  $A$  is perturbed by an error matrix  $E$  and  $U$  is unitary (i.e.,  $U^* = U^{-1}$ ), then  $U(A+E) = UA+UE$  and  $\|UE\|_2 = \|E\|_2$ . Numerical analysts often use unitary matrices in numerical algorithms because multiplication by unitary matrices does not magnify errors.
5. Given  $A \in F^{n \times n}$  and  $\varepsilon > 0$ , we show how an  $\mathcal{M}$ -norm can be constructed such that  $\|A\|_{\mathcal{M}} < \rho + \varepsilon$ , where  $\rho$  is the spectral radius of  $A$ . The procedure below determines  $M_n$  where  $A \in F^{n \times n}$ . The

procedure is illustrated with the matrix  $A = \begin{bmatrix} -38 & 13 & 52 \\ 3 & 0 & -4 \\ -30 & 10 & 41 \end{bmatrix}$  and with  $\varepsilon = 0.1$ . The norm used

to construct the  $\mathcal{M}$ -norm will be the 1-norm; note the 1-norm of  $A = 97$ .

- (a) Determine  $\rho$ : The characteristic polynomial of  $A$  is  $p_A(x) = \det(A-xI) = x^3 - 3x^2 + 3x - 1 = (x-1)^3$ , so  $\rho = 1$ .
- (b) Find a unitary matrix  $U$  such that  $T = UAU^*$  is triangular. Using the method in Example 5 of Chapter 7.1, we find

$$U = \begin{bmatrix} \frac{1}{\sqrt{10}} & \frac{6}{\sqrt{65}} & -\frac{3}{\sqrt{26}} \\ \frac{3}{\sqrt{10}} & -\frac{2}{\sqrt{65}} & \frac{1}{\sqrt{26}} \\ 0 & \sqrt{\frac{5}{13}} & 2\sqrt{\frac{2}{13}} \end{bmatrix} \approx \begin{bmatrix} 0.316228 & 0.744208 & -0.588348 \\ 0.948683 & -0.248069 & 0.196116 \\ 0 & 0.620174 & 0.784465 \end{bmatrix} \text{ and}$$

$$T = U^*AU = \begin{bmatrix} 1 & 0 & 2\sqrt{65} \\ 0 & 1 & 26\sqrt{10} \\ 0 & 0 & 1 \end{bmatrix} \approx \begin{bmatrix} 1 & 0 & 16.1245 \\ 0 & 1 & 82.2192 \\ 0 & 0 & 1 \end{bmatrix}.$$

- (c) Find a diagonal matrix  $\text{diag}(1, \alpha, \alpha^2, \dots, \alpha^{n-1})$  such that  $\|DTD^{-1}\|_1 < \rho + \varepsilon$  (this is always possible, since  $\lim_{\alpha \rightarrow \infty} \|DTD^{-1}\|_1 = \rho$ ).

$$\text{In the example, for } \alpha = 1000, DTD^{-1} \approx \begin{bmatrix} 1 & 0 & 0.0000161245 \\ 0 & 1 & 0.0822192 \\ 0 & 0 & 1 \end{bmatrix} \text{ and } \|DTD^{-1}\|_1 \approx$$

$$1.08224 < 1.1.$$

- (d) Then  $\|DU^*AUD^{-1}\|_1 < \rho + \varepsilon$ . That is,  $\|A\|_{\mathcal{M}} < 2.1$ , where  $M_3 = DU^*$

$$\approx \begin{bmatrix} 0.316228 & 0.948683 & 0. \\ 744.208 & -248.069 & 620.174 \\ -588348. & 196116. & 784465. \end{bmatrix}.$$

## 37.4 Conditioning and Condition Numbers

Data have limited precision. Measurements are inexact, equipment wears, manufactured components meet specifications only to some error tolerance, floating point arithmetic introduces errors. Consequently, the results of nontrivial calculations using data of limited precision also have limited precision. This section summarizes the topic of **conditioning**: How much errors in data can affect the results of a calculation.

(See [Ric66] for an authoritative treatment of conditioning.)

### Definitions:

Consider a computational problem to be the task of evaluating a function  $P : \mathbb{R}^n \rightarrow \mathbb{R}^m$  at a nominal data point  $\mathbf{z} \in \mathbb{R}^n$ , which, because data errors are ubiquitous, is known only to within a small relative-to- $\|\mathbf{z}\|$  error  $\varepsilon$ .

If  $\hat{\mathbf{z}} \in \mathbb{F}^n$  is an approximation to  $\mathbf{z} \in \mathbb{F}^n$ , the **absolute error** in  $\hat{\mathbf{z}}$  is  $\|\mathbf{z} - \hat{\mathbf{z}}\|$  and the **relative error** in  $\hat{\mathbf{z}}$  is  $\|\mathbf{z} - \hat{\mathbf{z}}\|/\|\mathbf{z}\|$ . If  $\mathbf{z} = 0$ , then the relative error is undefined.

The data  $\mathbf{z}$  are **well-conditioned** if small relative perturbations of  $\mathbf{z}$  cause small relative perturbations of  $P(\mathbf{z})$ . The data are **ill-conditioned** or **badly conditioned** if some small relative perturbation of  $\mathbf{z}$  causes a large relative perturbation of  $P(\mathbf{z})$ . Precise meanings of “small” and “large” are dependent on the precision required in the context of the computational task.

Note that it is the data  $\mathbf{z}$  — not the solution  $P(\mathbf{z})$  — that is ill-conditioned or well-conditioned.

If  $\mathbf{z} \neq 0$  and  $P(\mathbf{z}) \neq 0$ , then the **relative condition number**, or simply **condition number**  $\mathbf{cond}(\mathbf{z}) = \mathbf{cond}_P(\mathbf{z})$  of the data  $\mathbf{z} \in \mathbb{F}^n$  with respect to the computational task of evaluating  $P(\mathbf{z})$  may be defined as

$$\mathbf{cond}_P(\mathbf{z}) = \limsup_{\varepsilon \rightarrow 0} \left\{ \left( \frac{\|P(\mathbf{z} + \delta\mathbf{z}) - P(\mathbf{z})\|}{\|P(\mathbf{z})\|} \right) \left( \frac{\|\mathbf{z}\|}{\|\delta\mathbf{z}\|} \right) \mid \|\delta\mathbf{z}\| \leq \varepsilon \right\}. \quad (37.1)$$

Sometimes it is useful to extend the definition to  $\mathbf{z} = 0$  or to an isolated root of  $P(\mathbf{z})$  by  $\mathbf{cond}_P(\mathbf{z}) = \limsup_{\mathbf{x} \rightarrow \mathbf{z}} \mathbf{cond}_P(\mathbf{x})$ .

Note that although the condition number depends on  $P$  and on the choice of norm,  $\mathbf{cond}(\mathbf{z}) = \mathbf{cond}_P(\mathbf{z})$  is the condition number of the data  $\mathbf{z}$  — not the condition number of the solution  $P(\mathbf{z})$  and not the condition number of an algorithm that may be used to evaluate  $P(\mathbf{z})$ .

### Facts:

For proofs and additional background, see, for example, [Dat95], [GV96], [Ste98], or [Wil65].

1. Because rounding errors are ubiquitous, a finite precision computational procedure can at best produce  $P(\mathbf{z} + \delta\mathbf{z})$  where, in a suitably chosen norm,  $\|\delta\mathbf{z}\| \leq \varepsilon\|\mathbf{z}\|$  and  $\varepsilon$  is a modest multiple of the unit round of the floating point system. (See section 37.6.)
2. The relative condition number determines the tight, asymptotic relative error bound

$$\frac{\|P(\mathbf{z} + \delta\mathbf{z}) - P(\mathbf{z})\|}{\|P(\mathbf{z})\|} \leq \mathbf{cond}_P(\mathbf{z}) \frac{\|\delta\mathbf{z}\|}{\|\mathbf{z}\|} + o\left(\frac{\|\delta\mathbf{z}\|}{\|\mathbf{z}\|}\right)$$

as  $\delta\mathbf{z}$  tends to zero. Very roughly speaking, if the larger components of the data  $\mathbf{z}$  have  $p$  correct significant digits and the condition number is  $\mathbf{cond}_P(\mathbf{z}) \approx 10^s$ , then the larger components of the result  $P(\mathbf{z})$  have  $p - s$  correct significant digits.

3. [Hig96, p. 9] If  $P(\mathbf{x})$  has a Frechet derivative  $D(\mathbf{z})$  at  $\mathbf{z} \in \mathbb{F}^n$ , then the relative condition number is

$$\mathbf{cond}_P(\mathbf{z}) = \frac{\|D(\mathbf{z})\| \|\mathbf{z}\|}{\|P(\mathbf{z})\|}.$$

In particular, if  $f(x)$  is a smooth real function of a real variable  $x$ , then  $\mathbf{cond}_f(z) = |zf'(z)/f(z)|$ .

**Examples:**

1. If  $P(x) = \sin(x)$  and the nominal data point  $z = 22/7$  may be in error by as much as  $\pi - 22/7 \approx .00126$ , then  $P(z) = \sin(z)$  may be in error by as much as 100%. With such an uncertainty in  $z = 22/7$ ,  $\sin(z)$  may be off by 100%, i.e.,  $\sin(z)$  may have relative error equal to one. In most circumstances,  $z = 22/7$  is considered to be ill-conditioned.

The condition number of  $z \in \mathbb{R}$  with respect to  $\sin(z)$  is  $\mathbf{cond}_{\sin}(z) = |z \cot(z)|$ , and, in particular,  $\mathbf{cond}(22/7) \approx 2485.47$ . If  $z = 22/7$  is perturbed to  $z + \delta z = \pi$ , then the asymptotic relative error bound in Fact 2 becomes

$$\begin{aligned} \left| \frac{\sin(z + \delta z) - \sin(z)}{\sin(z)} \right| &\leq \mathbf{cond}(z) \left| \frac{\delta z}{z} \right| + o(|(\delta z)/z|) \\ &= 0.9999995 \dots + o(|(\delta z)/z|). \end{aligned}$$

The actual relative error in  $\sin(z)$  is  $\left| \frac{\sin(z+\delta z) - \sin(z)}{\sin(z)} \right| = 1$ .

2. *Subtractive Cancellation:* For  $\mathbf{x} \in \mathbb{R}^2$ , define  $P(\mathbf{x})$  by  $P(\mathbf{x}) = [1, -1]\mathbf{x}$ . The gradient of  $P(\mathbf{x})$  is  $\nabla P(\mathbf{x}) = [1, -1]$  independent of  $\mathbf{x}$ , so, using the  $\infty$ -norm, Fact 3 gives

$$\mathbf{cond}_P(\mathbf{x}) = \frac{\|\nabla f\|_{\infty} \|\mathbf{x}\|_{\infty}}{\|f(\mathbf{x})\|_{\infty}} = \frac{2 \max\{|x_1|, |x_2|\}}{|x_1 - x_2|}.$$

Reflecting the trouble associated with subtractive cancellation,  $\mathbf{cond}_P(\mathbf{x})$  shows that  $\mathbf{x}$  is ill-conditioned when  $x_1 \approx x_2$ .

3. *Conditioning of Matrix–Vector Multiplication:* More generally, for a fixed matrix  $A \in \mathbb{F}^{m \times n}$  that is not subject to perturbation, define  $P(\mathbf{x}) : \mathbb{F}^n \rightarrow \mathbb{F}^m$  by  $P(\mathbf{x}) = A\mathbf{x}$ . The relative condition number of  $\mathbf{x} \in \mathbb{F}^n$  is

$$\mathbf{cond}(\mathbf{x}) = \|A\| \frac{\|\mathbf{x}\|}{\|A\mathbf{x}\|}, \quad (37.2)$$

where the matrix norm is the operator norm induced by the chosen vector norm. If  $A$  is square and nonsingular, then  $\mathbf{cond}(\mathbf{x}) \leq \|A\| \|A^{-1}\|$ .

4. *Conditioning of the Polynomial Zeros:* Let  $q(x) = x^2 - 2x + 1$  and consider the computational task of determining the roots of  $q(x)$  from the power basis coefficients  $[1, -2, 1]$ . Formally, the computational problem is to evaluate the function  $P : \mathbb{R}^3 \rightarrow \mathbb{C}$  that maps the power basis coefficients of quadratic polynomials to their roots. If  $q(x)$  is perturbed to  $q(x) + \varepsilon$ , then the roots change from a double root at  $x = 1$  to  $x = 1 \pm \sqrt{\varepsilon}$ . A relative error of  $\varepsilon$  in the data  $[1, -2, 1]$  induces a relative error of  $\sqrt{|\varepsilon|}$  in the roots. In particular, the roots suffer an infinite rate of change at  $\varepsilon = 0$ . The condition number of the coefficients  $[1, -2, 1]$  is infinite (with respect to root finding).

The example illustrates the fact that the problem of calculating the roots of a polynomial  $q$  from its coefficients is highly ill-conditioned when  $q$  has multiple or near multiple roots. Although it is common to say that “multiple roots are ill-conditioned,” strictly speaking, this is incorrect. It is the coefficients that are ill-conditioned because they are the initial data for the calculation.

5. [Dat95, p. 81], [Wil64, Wil65] *Wilkinson Polynomial:* Let  $w(x)$  be the degree 20 polynomial

$$w(x) = (x - 1)(x - 2) \dots (x - 20) = x^{20} - 210x^{19} + 20615x^{18} \dots + 2432902008176640000.$$

The roots of  $w(x)$  are the integers 1, 2, 3, ..., 20. Although distinct, the roots are highly ill-conditioned functions of the power basis coefficients. For simplicity, consider only perturbations to the coefficient of  $x^{19}$ . Perturbing the coefficient of  $x^{19}$  from  $-210$  to  $-210 - 2^{-23} \approx 210 - 1.12 \times 10^{-7}$  drastically changes some of the roots. For example, the roots 16 and 17 become a complex conjugate pair approximately equal to  $16.73 \pm 2.81i$ .

Let  $P_{16}(z)$  be the root of  $\hat{w}(x) = w(x) + (z - 210)x^{19}$  nearest 16 and let  $P_{17}(z)$  be the root nearest 17. So, for  $z = 210$ ,  $P_{16}(z) = 16$  and  $P_{17}(z) = 17$ . The condition numbers of  $z = 210$  with respect to  $P_{16}$  and  $P_{17}$  are  $\mathbf{cond}_{16}(210) = 210(16^{19}/(16w'(16))) \approx 3 \times 10^{10}$  and  $\mathbf{cond}_{17}(210) = 210(17^{19}/(17w'(17))) \approx 2 \times 10^{10}$ , respectively. The condition numbers are so large that even perturbations as small as  $2^{-23}$  are outside the asymptotic region in which  $o\left(\frac{\|\delta z\|}{\|z\|}\right)$  is negligible in Fact 2.

### 37.5 Conditioning of Linear Systems

This section applies conditioning concepts to the computational task of finding a solution to the system of linear equations  $Ax = b$  for a given matrix  $A \in \mathbb{R}^{n \times n}$  and right-hand side vector  $b \in \mathbb{R}^n$ .

Throughout this section,  $A \in \mathbb{R}^{n \times n}$  is nonsingular. Let the matrix norm  $\|\cdot\|$  be an operator matrix norm induced by the vector norm  $\|\cdot\|$ . Use  $\|A\| + \|b\|$  to measure the magnitude of the data  $A$  and  $b$ . If  $E \in \mathbb{R}^{n \times n}$  is a perturbation of  $A$  and  $r \in \mathbb{R}^n$  is a perturbation of  $b$ , then  $\|E\| + \|r\|$  is the magnitude of the perturbation to the linear system  $Ax = b$ .

**Definitions:**

The norm-wise **condition number** of a nonsingular matrix  $A$  (for solving a linear system) is  $\kappa(A) = \|A^{-1}\| \|A\|$ . If  $A$  is singular, then by convention,  $\kappa(A) = \infty$ . For a specific norm  $\|\cdot\|_\mu$ , the condition number of  $A$  is denoted  $\kappa_\mu(A)$ .

**Facts:**

For proofs and additional background, see, for example, [Dat95], [GV96], [Ste98], or [Wil65].

1. *Properties of the Condition Number:*

- (a)  $\kappa(A) \geq 1$ .
- (b)  $\kappa(AB) \leq \kappa(A)\kappa(B)$ .
- (c)  $\kappa(\alpha A) = \kappa(A)$ , for all scalars  $\alpha \neq 0$ .
- (d)  $\kappa_2(A) = 1$  if and only if  $A$  is a nonzero scalar multiple of an orthogonal matrix, i.e.,  $A^T A = \alpha I$  for some scalar  $\alpha$ .
- (e)  $\kappa_2(A) = \kappa_2(A^T)$ .
- (f)  $\kappa_2(A^T A) = (\kappa_2(A))^2$ .
- (g)  $\kappa_2(A) = \|A\|_2 \|A^{-1}\|_2 = \sigma_{\max}/\sigma_{\min}$ , where  $\sigma_{\max}$  and  $\sigma_{\min}$  are the largest and smallest singular values of  $A$ .

2. For the  $p$ -norms (including  $\|\cdot\|_1$ ,  $\|\cdot\|_2$ , and  $\|\cdot\|_\infty$ ),

$$\frac{1}{\kappa(A)} = \min \left\{ \frac{\|\delta A\|}{\|A\|} \mid A + \delta A \text{ is singular} \right\}.$$

So,  $\kappa(A)$  is one over the relative-to- $\|A\|$  distance from  $A$  to the nearest singular matrix, and, in particular,  $\kappa(A)$  is large if and only if a small-relative-to- $\|A\|$  perturbation of  $A$  is singular.

3. Regarding  $A$  as fixed and not subject to errors, it follows from Equation 37.2 that the condition number of  $b$  with respect to solving  $Ax = b$  as defined in Equation 37.1 is

$$\mathbf{cond}(b) = \frac{\|A^{-1}\| \|b\|}{\|A^{-1}b\|} \leq \kappa(A).$$

If the matrix norm is  $\|A^{-1}\|$  is induced by the vector norm  $\|b\|$ , then equality is possible.

4. Regarding  $\mathbf{b}$  as fixed and not subject to errors, the condition number of  $A$  with respect to solving  $A\mathbf{x} = \mathbf{b}$  as defined in Equation 37.1 is  $\mathbf{cond}(A) = \|A^{-1}\| \|A\| = \kappa(A)$ .
5.  $\kappa(A) \leq \mathbf{cond}([A, \mathbf{b}]) \leq \left( \frac{\|A\| + \|\mathbf{b}\|}{\|A\| \|\mathbf{b}\|} \right) \kappa(A)$ , where  $\mathbf{cond}([A, \mathbf{b}])$  is the condition number of the data  $[A, \mathbf{b}]$  with respect to solving  $A\mathbf{x} = \mathbf{b}$  as defined in Equation 37.1. Hence, the data  $[A, \mathbf{b}]$  are norm-wise ill-conditioned for the problem of solving  $A\mathbf{x} = \mathbf{b}$  if and only if  $\kappa(A)$  is large.
6. If  $\mathbf{r} = \mathbf{b} - A(\mathbf{x} + \delta\mathbf{x})$ , then the 2-norm and Frobenius norm smallest perturbation  $\delta A \in \mathbb{R}^{n \times n}$  satisfying  $(A + \delta A)(\mathbf{x} + \delta\mathbf{x}) = \mathbf{b}$  is  $\delta A = \frac{\mathbf{r}\mathbf{x}^T}{\mathbf{x}^T\mathbf{x}}$  and  $\|\delta A\|_2 = \|\delta A\|_F = \frac{\|\mathbf{r}\|_2}{\|\mathbf{x}\|_2}$ .
7. Let  $\delta A$  and  $\delta\mathbf{b}$  be perturbations of the data  $A$  and  $\mathbf{b}$ , respectively. If  $\|A^{-1}\delta A\| < 1$ , then  $A + \delta A$  is nonsingular, there is a unique solution  $\mathbf{x} + \delta\mathbf{x}$  to  $(A + \delta A)(\mathbf{x} + \delta\mathbf{x}) = (\mathbf{b} - \delta\mathbf{b})$ , and

$$\frac{\|\delta\mathbf{x}\|}{\|\mathbf{x}\|} \leq \frac{\|A\| \|A^{-1}\|}{(1 - \|A^{-1}\delta A\|)} \left( \frac{\|\delta A\|}{\|A\|} + \frac{\|\delta\mathbf{b}\|}{\|\mathbf{b}\|} \right).$$

### Examples:

1. *An Ill-Conditioned Linear System:* For  $\varepsilon \in \mathbb{R}$ , let  $A = \begin{bmatrix} 1 & 1 \\ 1 & 1 + \varepsilon \end{bmatrix}$  and  $\mathbf{b} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$ . For  $\varepsilon \neq 0$ ,  $A$  is

nonsingular and  $\mathbf{x} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$  satisfies  $A\mathbf{x} = \mathbf{b}$ . The system of equations is ill-conditioned when  $\varepsilon$  is small because some small changes in the data cause a large change in the solution. For example, perturbing  $\mathbf{b}$  to  $\mathbf{b} + \delta\mathbf{b}$ , where  $\delta\mathbf{b} = \begin{bmatrix} 0 \\ \varepsilon \end{bmatrix} \in \mathbb{R}^2$ , changes the solution  $\mathbf{x}$  to  $\mathbf{x} + \delta\mathbf{x} = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$  independent of the choice of  $\varepsilon$  no matter how small.

Using the 1-norm,  $\kappa_1(A) = \|A^{-1}\|_1 \|A\|_1 = (2 + \varepsilon)^2 \varepsilon^{-1}$ . As  $\varepsilon$  tends to zero, the perturbation  $\delta\mathbf{b}$  tends to zero, but the condition number  $\kappa_1(A)$  explodes to infinity.

Geometrically,  $\mathbf{x}$  gives the coordinates of the intersection of the two lines  $x + y = 1$  and  $x + (1 + \varepsilon)y = 1$ . If  $\varepsilon$  is small, then these lines are nearly parallel, so a small change in them may move the intersection a long distance.

Also notice that the singular matrix  $\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}$  is a  $\varepsilon$  perturbation of  $A$ .

2. *A Well-Conditioned Linear System Problem:* Let  $A = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$ . For  $\mathbf{b} \in \mathbb{R}^2$ , the solution to  $A\mathbf{x} = \mathbf{b}$

is  $\mathbf{x} = \frac{1}{2} \begin{bmatrix} b_1 + b_2 \\ b_1 - b_2 \end{bmatrix}$ . In particular, perturbing  $\mathbf{b}$  to  $\mathbf{b} + \delta\mathbf{b}$  changes  $\mathbf{x}$  to  $\mathbf{x} + \delta\mathbf{x}$  with  $\|\delta\mathbf{x}\|_1 \leq \|\mathbf{b}\|_1$

and  $\|\delta\mathbf{x}\|_2 = \|\delta\mathbf{b}\|_2$ , i.e.,  $\mathbf{x}$  is perturbed by no more than  $\mathbf{b}$  is perturbed. This is a well-conditioned system of equations.

The 1-norm condition number of  $A$  is  $\kappa_1(A) = 2$ , and the 2-norm condition number is  $\kappa_2(A) = 1$ , which is as small as possible.

Geometrically,  $\mathbf{x}$  gives the coordinates of the intersection of the perpendicular lines  $x + y = 1$  and  $x - y = 1$ . Slightly perturbing the lines only slightly perturbs their intersection.

Also notice that for both the 1-norm and 2-norm  $\min_{\|\mathbf{x}\|=1} \|A\mathbf{x}\| = 1$ , so no small-relative-to- $\|A\|$  perturbation of  $A$  is singular. If  $A + \delta A$  is singular, then  $\|\delta A\| \geq 1$ .

3. *Some Well-known Ill-conditioned Matrices:*

(a) The upper triangular matrices  $B_n \in \mathbb{R}^n$  of the form

$$B_3 = \begin{bmatrix} 1 & -1 & -1 \\ 0 & 1 & -1 \\ 0 & 0 & 1 \end{bmatrix}$$

have  $\infty$ -norm condition number  $\kappa_\infty = n2^{n-1}$ . Replacing the  $(n, 1)$  entry by  $-2^{2-n}$  makes  $B_n$  singular. Note that the determinant  $\det(B_n) = 1$  gives no indication of how nearly singular the matrices  $B_n$  are.

- (b) *The Hilbert matrix:* The order  $n$  Hilbert matrix  $H_n \in \mathbb{R}^{n \times n}$  is defined by  $h_{ij} = 1/(i + j - 1)$ . The Hilbert matrix arises naturally in calculating best  $L_2$  polynomial approximations. The following table lists the 2-norm condition numbers to the nearest power of 10 of selected Hilbert matrices.

$n:$	1	2	3	4	5	6	7	8	9	10
$\kappa_2(H_n):$	1	10	$10^3$	$10^4$	$10^5$	$10^7$	$10^8$	$10^{10}$	$10^{11}$	$10^{13}$

- (c) *Vandermonde matrix:* The Vandermonde matrix corresponding to  $\mathbf{x} \in \mathbb{R}^n$  is  $V_{\mathbf{x}} \in \mathbb{R}^{n \times n}$  given by  $v_{ij} = x_i^{n-j}$ . Vandermonde matrices arise naturally in polynomial interpolation computations. The following table lists the 2-norm condition numbers to the nearest power of 10 of selected Vandermonde matrices.

$n:$	1	2	3	4	5	6	7	8	9	10
$\kappa_2(V_{[1,2,3,\dots,n]}):$	1	10	10	$10^3$	$10^4$	$10^5$	$10^7$	$10^9$	$10^{10}$	$10^{12}$

## 37.6 Floating Point Numbers

Most scientific and engineering computations rely on **floating point arithmetic**. At this writing, the IEEE 754 standard of binary floating point arithmetic [IEEE754] and the IEEE 854 standard of radix-independent floating point arithmetic [IEEE854] are the most widely accepted standards for floating point arithmetic. The still incomplete revised floating point arithmetic standard [IEEE754r] is planned to incorporate both [IEEE754] and [IEEE854] along with extensions, revisions, and clarifications. See [Ove01] for a textbook introduction to IEEE standard floating point arithmetic.

Even 20 years after publication of [IEEE754], implementations of floating point arithmetic vary in so many different ways that few axiomatic statements hold for all of them. Reflecting this unfortunate state of affairs, the summary of floating point arithmetic here is based upon IEEE 754r draft standard [IEEE754r] (necessarily omitting most of it), with frequent digressions to nonstandard floating point arithmetic.

In this section, the phrase *standard-conforming* refers to the October 20, 2005 IEEE 754r draft standard.

### Definitions:

A  $p$ -digit, radix  $b$  **floating point number** with exponent bounds  $e_{\max}$  and  $e_{\min}$  is a real number of the form  $x = \pm \left(\frac{m}{b^{p-1}}\right) b^e$ , where  $e$  is an integer **exponent**,  $e_{\min} \leq e \leq e_{\max}$ , and  $m$  is a  $p$ -digit, base  $b$  integer **significand**. The related quantity  $m/b^p$  is called the **mantissa**. Virtually all floating point systems allow  $m = 0$  and  $b^{p-1} \leq m < b^p$ . Standard-conforming, floating point systems allow all significands  $0 \leq m < b^p$ . If two or more different choices of significand  $m$  and exponent  $e$  yield the same floating point number, then the largest possible significand  $m$  with smallest possible exponent  $e$  is preferred.

In addition to finite floating point numbers, standard-conforming, floating point systems include elements that are not numbers, including  $\infty$ ,  $-\infty$ , and not-a-number elements collectively called NaNs. Invalid or indeterminate arithmetic operations like  $0/0$  or  $\infty - \infty$  as well as arithmetic operations involving NaNs result in NaNs.

The representation  $\pm(m/b^{p-1})b^e$  of a floating point number is said to be **normalized** or **normal**, if  $b^{p-1} \leq m < b^p$ .

Floating point numbers of magnitude less than  $b^{e_{\min}}$  are said to be **subnormal**, because they are too small to be normalized. The term **gradual underflow** refers to the use of subnormal floating point numbers. Standard-conforming, floating point arithmetic allows gradual underflow.

For  $x \in \mathbb{R}$ , a **rounding mode** maps  $x$  to a floating point number  $\text{fl}(x)$ . Except in cases of overflow discussed below,  $\text{fl}(x)$  is either the smallest floating point number greater than or equal to  $x$  or the largest floating point number less than or equal to  $x$ . Standard-conforming, floating point arithmetic allows program control over which choice is used. The default rounding mode in standard conforming arithmetic is **round-to-nearest, ties-to-even** in which, except for overflow (described below),  $\text{fl}(x)$  is the nearest floating point number to  $x$ . In case there are two floating point numbers equally distant from  $x$ ,  $\text{fl}(x)$  is the one with even significant.

**Underflow** occurs in  $\text{fl}(x) = 0$  when  $0 < |x| \leq b^{e_{\min}}$ . Often, underflows are set quietly to zero. **Gradual underflow** occurs when  $\text{fl}(x)$  is a subnormal floating point number. **Overflow** occurs when  $|x|$  equals or exceeds a threshold at or near the largest floating point number  $(b - \frac{1}{2})b^{e_{\max}}$ . Standard-conforming arithmetic allows some, very limited program control over the overflow and underflow threshold, whether to set overflows to  $\pm\infty$  and whether to trap program execution on overflow or underflow in order to take corrective action or to issue error messages. In the default round-to-nearest, ties-to-even rounding mode, overflow occurs if  $|x| \geq (b - \frac{1}{2})b^{e_{\max}}$ , and in that case,  $\text{fl}(x) = \pm\infty$  with the sign chosen to agree with the sign of  $x$ . By default, program execution continues without traps or interruption.

A variety of terms describe the precision with which a floating point system models real numbers.

- The **precision** is the number  $p$  of base- $b$  digits in the significant.
- **Big M** is the largest integer  $M$  with the property that all integers  $1, 2, 3, \dots, M$  are floating point numbers, but  $M + 1$  is not a floating point number. If the exponent upper bound  $e_{\max}$  is greater than the precision  $p$ , then  $M = b^p$ .
- The **machine epsilon**,  $\epsilon = b^{1-p}$ , is the distance between the number one and the next larger floating point number.
- The **unit round**  $u = \inf\{\delta > 0 \mid \text{fl}(1 + \delta) > 1\}$ . Depending on the rounding mode,  $u$  may be as large as the machine epsilon  $\epsilon$ . In round-to-nearest, ties-to-even rounding mode,  $u = \frac{1}{2}\epsilon$ .

In standard-conforming, floating point arithmetic, if  $\alpha$  and  $\beta$  are floating point numbers, then **floating point addition**  $\oplus$ , **floating point subtraction**  $\ominus$ , **floating point multiplication**  $\otimes$ , and **floating point division**  $\oslash$  are defined by

$$\alpha \oplus \beta = \text{fl}(\alpha + \beta), \quad (37.3)$$

$$\alpha \ominus \beta = \text{fl}(\alpha - \beta), \quad (37.4)$$

$$\alpha \otimes \beta = \text{fl}(\alpha \times \beta), \quad (37.5)$$

$$\alpha \oslash \beta = \text{fl}(\alpha \div \beta), \quad (37.6)$$

The IEEE 754r [IEEE754r] standard also includes a fused addition-multiply operation that evaluates  $\alpha\beta + \gamma$  with only one rounding error.

In particular, if the exact, infinitely precise value of  $\alpha + \beta$ ,  $\alpha - \beta$ ,  $\alpha \times \beta$ , or  $\alpha \div \beta$  is also a floating point number, then the corresponding floating point arithmetic operation occurs without rounding error. Floating point sums, products, and differences of small integers have zero rounding error.

Nonstandard-conforming, floating point arithmetics do not always conform to this definition, but often they do. Even when they deviate, it is nearly always the case that if  $\bullet$  is one of the arithmetic operations  $+$ ,  $-$ ,  $\times$ , or  $\div$  and  $\odot$  is the corresponding nonstandard floating point operation, then  $\alpha \odot \beta$  is a floating point number satisfying  $\alpha \odot \beta = \alpha(1 + \delta\alpha) \bullet \beta(1 + \delta\beta)$  with  $|\delta\alpha| \leq b^{2-p}$  and  $|\delta\beta| \leq b^{2-p}$ .

If  $\bullet$  is one of the arithmetic operations  $+$ ,  $-$ ,  $\times$ , or  $\div$  and  $\odot$  is the corresponding floating point operation, then the **rounding error** in  $\alpha \odot \beta$  is  $(\alpha \bullet \beta) - (\alpha \cdot \beta)$ , i.e., rounding error is the difference between the exact, infinitely precise arithmetic operation and the floating point arithmetic operation. In more extensive calculations, **rounding error** refers to the cumulative effect of the rounding errors in the individual floating point operations.

In machine computation, **truncation error** refers to the error made by replacing an infinite process by a finite process, e.g., truncating an infinite series of numbers to a finite partial sum.

Many computers implement floating point numbers of two or more different precisions. Typical **single precision** floating point numbers have machine epsilon roughly  $10^{-7}$  and precision roughly 7 decimal digits or 24 binary digits. Typical **double precision** floating point numbers have machine epsilon roughly  $10^{-16}$  and precision roughly 16 decimal digits or 53 binary digits. Specification of IEEE standard arithmetic [IEEE754r] includes these three precisions. See the table in Example 1. In addition, it is not unusual to also implement **extended precision** floating point numbers with even greater precision.

If  $\hat{x} \in \mathbb{F}$  is an approximation to  $x \in \mathbb{F}$ , the **absolute error** in  $\hat{x}$  is  $|x - \hat{x}|$  and the **relative error** in  $\hat{x}$  is  $|(x - \hat{x})/x|$ . If  $x = 0$ , then the relative error is undefined.

**Subtractive cancellation of significant digits** occurs in floating point sums when the relative error in the rounding-error-corrupted approximate sum is substantially greater than the relative error in the summands. In cases of subtractive cancellation, the sum has magnitude substantially smaller than the magnitude of the individual summands.

**Facts:**

For proofs and additional background, see, for example, [Ove01].

In this section, we make the following assumptions.

- The numbers  $\alpha$ ,  $\beta$ , and  $\gamma$  are  $p$ -digit radix  $b$  floating point numbers with exponent bounds  $e_{\max}$  and  $e_{\min}$ .
- The floating point arithmetic operations satisfy Equation 37.3 to Equation 37.6.
- In the absence of overflows, the rounding mode  $\text{fl}(x)$  maps  $x \in \mathbb{R}$  to the closest floating point number or to one of the two closest in case of a tie. In particular, the unit round is  $\frac{1}{2}b^{1-p}$ .

Standard-conforming arithmetic in round-to-nearest, ties-to-even rounding mode satisfies these assumptions.

For vectors  $\mathbf{x} \in \mathbb{R}^n$  and matrices  $M \in \mathbb{R}^{m \times n}$ , the notation  $|\mathbf{x}|$  and  $|M|$  indicates the vector and matrix whose entries are the absolute values of the corresponding entries of  $\mathbf{x}$  and  $M$ , respectively. For  $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$  the inequality  $\mathbf{x} \leq \mathbf{y}$  represents the  $n$  scalar inequalities  $x_i \leq y_i, i = 1, 2, 3, \dots, n$ . Similarly, for  $A, B \in \mathbb{R}^{m \times n}$ , the inequality  $A \leq B$  represents the  $mn$  inequalities  $a_{ij} \leq b_{ij}, i = 1, 2, 3, \dots, m$  and  $j = 1, 2, 3, \dots, n$ .

If  $e$  is an arithmetic expression involving only floating point numbers, the notation  $\text{fl}(e)$  represents the expression obtained by replacing each arithmetic operation by the corresponding floating point arithmetic operation 37.3, 37.4, 37.5, or 37.6. Note that  $\text{fl}(\cdot)$  is not a function, because its value may depend on the order of operations in  $e$ —not value of  $e$ .

1. At this writing, the only radices in common use on computers and calculators are  $b = 2$  and  $b = 10$ .
2. The commutative properties of addition and multiplication hold for floating point addition 37.3 and floating point multiplication 37.5, i.e.,  $\alpha \oplus \beta = \beta \oplus \alpha$  and  $\alpha \otimes \beta = \beta \otimes \alpha$ . (Examples below show that the associative and distributive properties of addition and multiplication *do not* in general hold for floating point arithmetic.)
3. In the absence of overflow or any kind of underflow,  $\text{fl}(x) = x(1 + \delta)$  with  $|\delta| < \frac{1}{2}b^{1-p}$ .
4. *Rounding in Arithmetic Operations:* If  $\bullet$  is an arithmetic operation and  $\odot$  is the corresponding floating point operation, then

$$\alpha \odot \beta = (\alpha \bullet \beta)(1 + \delta)$$

with  $|\delta| \leq \frac{1}{2}b^{1-p}$ . The error  $\delta$  may depend on  $\alpha$  and  $\beta$  as well as the arithmetic operation.

5. *Differences of Nearby Floating Point Numbers:* If  $\alpha > 0$  and  $\beta > 0$  are normalized floating point numbers and  $\frac{1}{2} < \alpha/\beta < 2$ , then  $\text{fl}(\alpha - \beta) = \alpha \ominus \beta = \alpha - \beta$ , i.e., there is zero rounding error in floating point subtraction of nearby numbers.

6. *Product of Floating Point Numbers:* If  $\alpha_i, i = 1, 2, 3, \dots, n$  are  $n$  floating point numbers, then

$$\text{fl} \left( \prod_{i=1}^n \alpha_i \right) = \left( \prod_{i=1}^n \alpha_i \right) (1 + \delta)^n$$

with  $|\delta| < \frac{1}{2}b^{1-p}$ . Consequently, rounding errors in floating point products create only minute relative errors.

7. [Ste98], [Wil65] *Dot (or Inner) Product of Floating Point Numbers:* Let  $\mathbf{x} \in \mathbb{R}^n$  and  $\mathbf{y} \in \mathbb{R}^n$  be vectors of floating point numbers and let  $s$  be the finite precision dot product  $s = \text{fl}(\mathbf{x}^T \mathbf{y}) = x_1 \otimes y_1 \oplus x_2 \otimes y_2 \oplus x_3 \otimes y_3 \oplus \dots \oplus x_n \otimes y_n$  evaluated in the order shown, multiplications first followed by additions from left to right. If  $n < 0.1/(\frac{1}{2}b^{1-p})$  and neither overflow nor any kind of underflow occurs, then the following hold.

(a)  $s = \text{fl}(\mathbf{x}^T \mathbf{y}) = x_1 y_1 (1 + \delta_1) + x_2 y_2 (1 + \delta_2) + x_3 y_3 (1 + \delta_3) + \dots + x_n y_n (1 + \delta_n)$  with  $|\delta_j| < 1.06n(\frac{1}{2}b^{1-p})$  and  $|\delta_j| < 1.06(n - j + 2)(\frac{1}{2}b^{1-p}) \leq 1.06n(\frac{1}{2}b^{1-p})$ , for  $j = 2, 3, 4, \dots, n$ .

(b)  $s = \text{fl}(\mathbf{x}^T \mathbf{y}) = \hat{\mathbf{x}}^T \hat{\mathbf{y}}$  for some vectors  $\hat{\mathbf{x}}, \hat{\mathbf{y}} \in \mathbb{R}^n$  satisfying  $|\mathbf{x} - \hat{\mathbf{x}}| \leq |\mathbf{x}|(1 + 1.06n(\frac{1}{2}b^{1-p}))$  and  $|\mathbf{y} - \hat{\mathbf{y}}| \leq |\mathbf{y}|(1 + 1.06n(\frac{1}{2}b^{1-p}))$ . So,  $s$  is the mathematically correct product of the vectors  $\hat{\mathbf{x}}$  and  $\hat{\mathbf{y}}$  each of whose entries differ from the corresponding entries of  $\mathbf{x}$  or  $\mathbf{y}$  by minute relative errors.

There are infinitely many choices of  $\hat{\mathbf{x}}$  and  $\hat{\mathbf{y}}$ . In the notation of Fact 7(a), two are  $\hat{x}_j = x_j(1 + \delta_j)$ ,  $\hat{y}_j = y_j$  and  $\hat{x}_j = x_j(1 + \delta_j)^{1/2}$ ,  $\hat{y}_j = y_j(1 + \delta_j)^{1/2}$ ,  $j = 1, 2, 3, \dots, n$ .

(c) If  $x^T y \neq 0$ , then the relative error in  $s$  is bounded as

$$\left| \frac{s - x^T y}{x^T y} \right| \leq 1.06n(\frac{1}{2}b^{1-p}) \frac{|x|^T |y|}{|x^T y|}.$$

The bound shows that if there is little cancellation in the sum, then  $s$  has small relative error. The bound allows the possibility that  $s$  has large relative error when there is substantial cancellation in the sum. Indeed this is often the case.

8. *Rounding Error Bounds for Floating Point Matrix Operations:* In the following,  $A$  and  $B$  are matrices each of whose entries is a floating point number,  $\mathbf{x}$  is a vector of floating point numbers, and  $c$  is a floating point number. The matrices  $A$  and  $B$  are compatible for matrix addition or matrix multiplication as necessary and  $E$  is an error matrix (usually different in each case) whose entries may or may not be floating point numbers. The integer dimension  $n$  is assumed to satisfy  $n < 0.1/(\frac{1}{2}b^{1-p})$ .

If neither overflows nor any kind of underflow occurs, then

(a)  $\text{fl}(cA) = cA + E$  with  $|E| \leq \frac{1}{2}b^{1-p}|cA|$ .

(b)  $\text{fl}(A + B) = (A + B) + E$  with  $|E| \leq \frac{1}{2}b^{1-p}|A + B|$ .

(c) If  $\mathbf{x} \in \mathbb{R}^n$  and  $A \in \mathbb{R}^{m \times n}$ , then  $\text{fl}(A\mathbf{x}) = (A + E)\mathbf{x}$  with  $|E| \leq 1.06n(\frac{1}{2}b^{1-p})$ .

(d) *Matrix multiplication:* If  $A \in \mathbb{R}^{m \times n}$  and  $B \in \mathbb{R}^{n \times q}$ ,  $\text{fl}(AB) = AB + E$  with  $|E| \leq 1.06n(\frac{1}{2}b^{1-p})|A||B|$ .

Note that if  $|AB| \approx |A||B|$ , then each entry in  $\text{fl}(AB)$  is correct to within a minute relative error. Otherwise, subtractive cancellation is possible and some entries of  $\text{fl}(AB)$  may have large relative errors.

(e) Let  $\|\cdot\|$  be a matrix norm satisfying  $\|E\| \leq \| |E| \|$ . (All of  $\|\cdot\|_1, \|\cdot\|_2, \|\cdot\|_p, \|\cdot\|_\infty$  and  $\|\cdot\|_F$  satisfy this requirement.) If  $A \in \mathbb{R}^{m \times n}$  and  $B \in \mathbb{R}^{n \times q}$ , then  $\text{fl}(AB) = AB + E$  with  $\|E\| \leq 1.06n(\frac{1}{2}b^{1-p})\|A\| \|B\|$ .

(f) *Matrix multiplication by an orthogonal matrix:* If  $Q \in \mathbb{R}^{n \times n}$  is an orthogonal matrix, i.e., if  $Q^T = Q^{-1}$ , and if  $A \in \mathbb{R}^{m \times n}$ , then

(i)  $\text{fl}(QA) = QA + E$  with  $\|E\|_2 \leq 1.06n^2 \left(\frac{1}{2}b^{1-p}\right) \|A\|_2$  and  $\|E\|_F \leq 1.06n^{3/2} \left(\frac{1}{2}b^{1-p}\right) \|A\|_F$ .

(ii)  $\text{fl}(QA) = Q(A + \hat{E})$  with  $\|\hat{E}\|_2 \leq 1.06n^2 \left(\frac{1}{2}b^{1-p}\right) \|A\|_2$  and  $\|\hat{E}\|_F \leq 1.06n^{3/2} \left(\frac{1}{2}b^{1-p}\right) \|A\|_F$ .

Note that this bound shows that if one of the factors is an orthogonal matrix, then subtractive cancellation in floating point matrix multiplication is limited to those entries (if any) that have magnitude substantially smaller than the other, possibly nonorthogonal factor. Many particularly successful numerical methods derive their robustness in the presence of rounding errors from this observation. (See, for example, [Dat95], [GV96], [Ste98], or [Wil65].)

**Examples:**

1. The following table lists typical floating point systems in common use at the time of this writing.

	radix $b$	precision $p$	$e_{\min}$	$e_{\max}$
Some calculators	10	14	-99	99
Some calculators	10	14	-999	999
IEEE 754r decimal 64 [IEEE754r]	10	16	-383	384
IEEE 754r decimal 128 [IEEE754r]	10	34	-6143	6144
IEEE 754r binary 32 (Single) [IEEE754r]	2	24	-126	127
IEEE 754r binary 64 (Double) [IEEE754r]	2	53	-1022	1023
IEEE 754r binary 128 (Double Extended) [IEEE754r]	2	113	-16382	16383

2. Consider  $p = 5$  digit, radix  $b = 10$  floating-point arithmetic with round-to-nearest, ties-to-even rounding mode.

(a) *Floating point addition is not associative:* If  $\alpha = 1$ ,  $\beta = 10^5$ , and  $\gamma = -10^5$ , then  $(\alpha \oplus \beta) \oplus \gamma = 0$  but  $\alpha \oplus (\beta \oplus \gamma) = 1$ . (This is also an example of subtractive cancellation.)

(b) *Floating point multiplication/division is not associative:* If  $\alpha = 3$ ,  $\beta = 1$ , and  $\gamma = 3$ , then  $\alpha \otimes (\beta \oslash \gamma) = .99999$  but  $(\alpha \otimes \beta) \oslash \gamma = 1$ . If  $\alpha = 44444$ ,  $\beta = 55555$  and  $\gamma = 66666$ , then  $\alpha \otimes (\beta \otimes \gamma) = 1.6460 \times 10^{14}$  but  $(\alpha \otimes \beta) \otimes \gamma = 1.6461 \times 10^{14}$ . Although different, both expressions have minute relative error. It is generally the case that floating point products have small relative errors. (See Fact 6.)

(c) *Floating point multiplication does not distribute across floating point addition:* If  $\alpha = 9$ ,  $\beta = 1$ , and  $\gamma = -.99999$ , then  $\alpha \otimes (\beta \oplus \gamma) = 9.0000 \times 10^{-5}$  but  $(\alpha \otimes \beta) \oplus (\alpha \otimes \gamma) = 1.0000 \times 10^{-4}$ .

3. *Subtractive Cancellation:* In  $p = 5$ , radix  $b = 10$  arithmetic with round-to-nearest, ties-to-even rounding, the expression  $(\sqrt{1 + 10^{-4}} - 1)/10^{-4}$  evaluates as follows. (Here we assume that the floating point evaluation of the square root gives the same result as rounding the exact square root to  $p = 5$ , radix  $b = 10$  digits.)

$$\begin{aligned} (\text{fl}(\sqrt{1.0000 \oplus 10^{-4}}) \ominus 1) \oslash 10^{-4} &= (\text{fl}(\sqrt{1.0001}) \ominus 1.0000) \oslash 10^{-4} \\ &= (\text{fl}(1.000049999 \dots) \ominus 1.0000) \oslash 10^{-4} \\ &= (1.0000 \ominus 1.0000) \oslash 10^{-4} \\ &= 0.0000. \end{aligned}$$

In exact, infinite precision arithmetic,  $(\sqrt{1 + 10^{-4}} - 1)/10^{-4} = .4999875 \dots$ , so the relative error is 1. Note that zero rounding error occurs in the subtraction. The only nonzero rounding error is the square root, which has minute relative error roughly  $5 \times 10^{-5}$ , but this is enough to ruin the final

result. Subtractive cancellation did not cause the large relative error. It only exposed the unfortunate fact that the result was ruined by earlier rounding errors.

4. *Relative vs. Absolute Errors:* Consider  $\hat{x}_1 = 31416$  as an approximation to  $x_1 = 10000\pi$  and  $\hat{x}_2 = 3.07$  as an approximation to  $x_2 = \pi$ . The absolute errors are nearly the same:  $|\hat{x}_1 - x_1| \approx -0.0735$  and  $|\hat{x}_2 - x_2| \approx -0.0716$ . On the other hand, the relative error in the first case,  $\frac{|\hat{x}_1 - x_1|}{|x_1|} \approx 2 \times 10^{-6}$ , is much smaller than the relative error in the second case,  $\frac{|\hat{x}_2 - x_2|}{|x_2|} \approx 2 \times 10^{-2}$ . The smaller relative error shows that  $\hat{x}_1 = 31416$  is a better approximation to  $10000\pi$  than  $\hat{x}_2 = 3.07$  is to  $\pi$ . The absolute errors gave no indication of this.

## 37.7 Algorithms and Efficiency

---

In this section, we introduce efficiency of algorithms.

### Definitions:

An **algorithm** is a precise set of instructions to perform a task. The algorithms discussed here perform mathematical tasks that transform an initial data set called the **input** into a desired result final data set called the **output** using an ordered list of arithmetic operations, comparisons, and decisions. For example, the Gaussian elimination algorithm (see Chapter 39.3) solves the linear system of equations  $A\mathbf{x} = \mathbf{b}$  by transforming the given, nonsingular matrix  $A \in \mathbb{R}^{n \times n}$  and right-hand-side  $\mathbf{b} \in \mathbb{R}^n$  into a vector  $\mathbf{x}$  satisfying  $A\mathbf{x} = \mathbf{b}$ .

One algorithm is more **efficient** than another if it accomplishes the same task with a lower cost of computation. Cost of computation is usually dominated by the direct and indirection cost of execution time. So, in general, in a given computational environment, the more efficient algorithm finishes its task sooner. (The very real economic cost of algorithm development and implementation is not a part of the efficiency of an algorithm.) However, the amount of primary and secondary memory required by an algorithm or the expense of and availability of the necessary equipment to execute the algorithm may also be significant part of the cost. In this sense, an algorithm that can accomplish its task on an inexpensive, programmable calculator is more efficient than one that needs a supercomputer.

For this discussion, a floating point operation or **flop** consists of a floating point addition, subtraction, multiplication, division, or square root along with any necessary subscripting and loop index overhead. In Fortran  $A(I, J) = A(I, J) + C * A(K, J)$  performs two flops. (Note that this is a slightly different definition of flop than is used in computer engineering.)

Formal algorithms are often specified in terms of an informal computer program called **pseudo-code**.

On early digital computers, computation time was heavily dominated by evaluating floating point operations. So, traditionally, numerical analysts compare the efficiency of two algorithms by counting the number of floating point operations each of them executes. If  $n$  measures the input data set size, e.g., an input matrix  $A \in \mathbb{R}^{n \times n}$ , then an  $O(n^p)$  algorithm is one that, for some positive constant  $c$ , performs  $cn^p$  plus a sum of lower powers of  $n$  floating point operations.

### Facts:

For proofs and additional background, see, for example, [Dat95], [GV96], [Ste98], or [Wil65].

In choosing a numerical method, efficiency must be balanced against considerations like robustness against rounding error and likelihood of failure.

Despite tradition, execution time has never been more than roughly proportional to the amount of floating point arithmetic. On modern computers with fast floating point arithmetic, multiple levels of cache memory, overlapped instruction execution, and parallel processing, execution time is correlated more closely with the number of cache misses (i.e., references to main RAM memory) than it is to the number of floating point operations. In addition, the relative execution time of algorithms depends strongly on the environment in which they are executed.

Nevertheless, for algorithms highly dominated by floating point arithmetic, flop counts are still useful. Despite the complexities of modern computers, flop counts typically expose the rate at which execution time increases as the size of the problem increases. Solving linear equations  $\mathbf{Ax} = \mathbf{b}$  for given  $A \in \mathbb{R}^{n \times n}$  and  $\mathbf{b} \in \mathbb{R}^n$  by Gaussian elimination with partial pivoting is an  $O(n^3)$  algorithm. For larger values of  $n$ , solving a  $2n$ -by- $2n$  system of equations takes roughly eight times longer than an  $n$ -by- $n$  system.

1. Triangular back substitution is an  $O(n^2)$  algorithm to solve a triangular system of linear equations  $T\mathbf{x} = \mathbf{b}$ ,  $\mathbf{b} \in \mathbb{R}^n$  and  $T \in \mathbb{R}^{n \times n}$ , with  $t_{ij} = 0$  whenever  $i > j$  [GV96]. (See the pseudo-code algorithm below.)
2. [GV96] Gaussian elimination with partial pivoting (cf. Algorithm 1, Section 38.3) is an  $O(n^3)$  algorithm to solve a system of equations  $\mathbf{Ax} = \mathbf{b}$  with  $A \in \mathbb{R}^{n \times n}$  and  $\mathbf{b} \in \mathbb{R}^n$ .
3. Because of the need to repeatedly search an entire submatrix, Gaussian elimination with complete pivoting is an  $O(n^4)$  algorithm to solve a system of equations  $\mathbf{Ax} = \mathbf{b}$  with  $A \in \mathbb{R}^{n \times n}$  and  $\mathbf{b} \in \mathbb{R}^n$  [GV96]. Hence, complete pivoting is not competitive with  $O(n^3)$  methods like Gaussian elimination with partial pivoting.
4. [GV96] The  $QR$ -factorization by Householder's method is an  $O(n^3)$  algorithm to solve a system of equations  $\mathbf{Ax} = \mathbf{b}$  with  $A \in \mathbb{R}^{n \times n}$  and  $\mathbf{b} \in \mathbb{R}^n$ .
5. [GV96] The  $QR$  factorization by Householder's method to solve the least squares problem  $\min \|\mathbf{Ax} - \mathbf{b}\|_2$  for given  $A \in \mathbb{R}^{m \times n}$  and  $\mathbf{b} \in \mathbb{R}^m$  is an  $O(n^2(m - n/3))$  algorithm.
6. [GV96] The singular value decomposition using the Golub–Kahan–Reinsch algorithm to solve the least squares problem  $\min \|\mathbf{Ax} - \mathbf{b}\|_2$  for given  $A \in \mathbb{R}^{m \times n}$  and  $\mathbf{b} \in \mathbb{R}^m$  is an  $O(m^2n + mn^2 + n^3)$  algorithm.
7. [GV96] The implicit, double-shift  $QR$  iteration algorithm to find all eigenvalues of a given matrix  $A \in \mathbb{R}^{n \times n}$  is an  $O(n^3)$  algorithm.
8. Cramer's rule for solving the system of equations  $\mathbf{Ax} = \mathbf{b}$  for given  $A \in \mathbb{R}^{n \times n}$  and  $\mathbf{b} \in \mathbb{R}^n$  in which determinants are evaluated using minors and cofactors is an  $O((n + 1)n!)$  algorithm and is impractical for all but small values of  $n$ .
9. Cramer's rule for solving the system of equations  $\mathbf{Ax} = \mathbf{b}$  for given  $A \in \mathbb{R}^{n \times n}$  and  $\mathbf{b} \in \mathbb{R}^n$  in which determinants are evaluated using Gaussian elimination is an  $O(n^4)$  algorithm and is not competitive with  $O(n^3)$  methods like Gaussian elimination with partial pivoting.

### Examples:

1. It takes roughly 4.6 seconds on a 2GHz Pentium workstation, using Gaussian elimination with partial pivoting, to solve the  $n = 2000$  linear equations in 2000 unknowns  $\mathbf{Ax} = \mathbf{b}$  in which the entries of  $\mathbf{A}$  and  $\mathbf{b}$  are normally distributed pseudo-random numbers with mean zero and variance one. It takes roughly 34 seconds to solve a similar  $n = 4000$  system of equations. This is consistent with the estimate that Gaussian elimination with partial pivoting is an  $O(n^3)$  algorithm.
2. This is an example of a formal algorithm specified in pseudo-code. Consider the problem of solving for  $\mathbf{y}$  in the upper triangular system of equations  $T\mathbf{y} = \mathbf{b}$ , where  $\mathbf{b} \in \mathbb{R}^n$  is a given right-hand-side vector and  $T \in \mathbb{R}^{n \times n}$  is a given nonsingular upper triangular matrix; i.e.,  $t_{ij} = 0$  for  $i > j$  and  $t_{ii} \neq 0$  for  $i = 1, 2, 3, \dots, n$ .

**Input:** A nonsingular, upper triangular matrix  $T \in \mathbb{R}^{n \times n}$  and a vector  $\mathbf{b} \in \mathbb{R}^n$ .

**Output:** The vector  $\mathbf{y} \in \mathbb{R}^n$  satisfying  $T\mathbf{y} = \mathbf{b}$ .

**Step 1.**  $y_n \leftarrow b_n/t_{nn}$

**Step 2.** For  $i = n - 1, n - 2, \dots, 2, 1$  do

$$2.1 \quad s_i \leftarrow b_i - \sum_{j=i+1}^n t_{ij}y_j$$

$$2.2 \quad y_i = s_i/t_{ii}$$

## 37.8 Numerical Stability and Instability

*Numerically stable* algorithms, despite rounding and truncation errors, produce results that are roughly as accurate as the errors in the input data allow. *Numerically unstable* algorithms allow rounding and truncation errors to produce results that are substantially less accurate than the errors in the input data allow. This section concerns numerical stability and instability and is loosely based on [Bun87].

### Definitions:

A computational problem is the task of evaluating a function  $f : \mathbb{R}^n \rightarrow \mathbb{R}^m$  at a particular data point  $\mathbf{x} \in \mathbb{R}^n$ . A numerical algorithm that is subject to rounding and truncation errors evaluates a perturbed function  $\hat{f}(\mathbf{x})$ . Throughout this section  $\varepsilon$  represents a modest multiple of the unit round.

The **forward error** is  $f(\mathbf{x}) - \hat{f}(\mathbf{x})$ , the difference between the mathematically exact function evaluation and the perturbed function evaluation.

The **backward error** is a vector  $\mathbf{e} \in \mathbb{R}^n$  of smallest norm for which  $f(\mathbf{x} + \mathbf{e}) = \hat{f}(\mathbf{x})$ . If no such  $\mathbf{e}$  exists, then the backward error is undefined. This definition is illustrated in Figure 37.1 [Ste98, p. 123].

An algorithm is **forward stable** if, despite rounding and truncation errors,

$$\frac{\|f(\mathbf{x}) - \hat{f}(\mathbf{x})\|}{\|f(\mathbf{x})\|} \leq \varepsilon$$

for all valid input data  $\mathbf{x}$ . In a forward stable algorithm, the forward relative error is small for all valid input data  $\mathbf{x}$  despite rounding and truncation errors in the algorithm.

An algorithm is **backward stable** or **strongly stable** if the backward relative error  $\mathbf{e}$  exists and satisfies the relative error bound  $\|\mathbf{e}\| \leq \varepsilon \|\mathbf{x}\|$  for all valid input data  $\mathbf{x}$  despite rounding and truncation errors.

In this context, “small” means a modest multiple of the size of the errors in the data  $\mathbf{x}$ . If rounding errors are the only relevant errors, then “small” means a modest multiple of the unit round.

**FIGURE 37.1** A computational problem is the task of evaluating a function  $f$  at a particular data point  $\mathbf{x}$ . A numerical algorithm that is subject to rounding and truncation errors evaluates a perturbed function  $\hat{f}(\mathbf{x})$ . The **forward error** is  $f(\mathbf{x}) - \hat{f}(\mathbf{x})$ , the difference between the mathematically exact function evaluation and the perturbed function evaluation. The **backward error** is a vector  $\mathbf{e} \in \mathbb{R}^n$  of smallest norm for which  $f(\mathbf{x} + \mathbf{e}) = \hat{f}(\mathbf{x})$  [Ste98, p. 123]. If no such vector  $\mathbf{e}$  exists, then there is no backward error.

A finite precision numerical algorithm is **weakly numerically stable** if rounding and truncation errors cause it to evaluate a perturbed function  $\hat{f}(\mathbf{x})$  satisfying the relative error bound

$$\frac{\|f(\mathbf{x}) - \hat{f}(\mathbf{x})\|}{\|f(\mathbf{x})\|} \leq \varepsilon \mathbf{cond}_f(\mathbf{x})$$

for all valid input data  $\mathbf{x}$ . In a weakly stable algorithm, the *magnitude* of the forward error is no greater than magnitude of an error that could be induced by perturbing the data by small multiple of the unit round. Note that this does *not* imply that there is a small backward error or even that a backward error exists. (An even weaker kind of “weak stability” requires the relative error bound only when  $\mathbf{x}$  is well-conditioned [Bun87].)

An algorithm is **numerically stable** if rounding errors and truncation errors cause it to evaluate a perturbed function  $\hat{f}(\mathbf{x})$  satisfying

$$\frac{\|f(\mathbf{x} + \mathbf{e}) - \hat{f}(\mathbf{x})\|}{\|f(\mathbf{x})\|} \leq \varepsilon$$

for some small relative-to- $\|\mathbf{x}\|$  backward error  $\mathbf{e}$ ,  $\|\mathbf{e}\| \leq \varepsilon \|\mathbf{x}\|$ . In a numerically stable algorithm,  $\hat{f}(\mathbf{x})$  lies near a function with small backward error.

Figure 37.2 illustrates the definitions of stability. The black dot on the left represents a nominal data point  $\mathbf{x}$ . The black dot on the right is the exact, unperturbed value of  $f(\mathbf{x})$ . The shaded region on the left represents the small relative-to- $\|\mathbf{x}\|$  perturbations of  $\mathbf{x}$ . The shaded region on the right is its exact image under  $f(\mathbf{x})$ .

In a weakly stable numerical method, the computed function value  $\hat{f}(\mathbf{x})$  lies inside the large circle with radius equal to the longest distance from the black dot  $f(\mathbf{x})$  to the furthest point in the shaded region containing it. The error in a weakly stable algorithm is no larger than would have been obtained from a backward stable algorithm. However, the actual result may or may not correspond to a small perturbation of the data.

In a numerically stable algorithm,  $\hat{f}(\mathbf{x})$  lies either near or inside the shaded region on the right.

In a backward stable algorithm,  $\hat{f}(\mathbf{x})$  lies in the shaded region, but, if the data are ill-conditioned as in the illustration,  $\hat{f}(\mathbf{x})$  may have a large relative error. (To avoid clutter, there is no arrow illustrating a backward stable algorithm.)

In a forward stable algorithm,  $\hat{f}(\mathbf{x})$  has a small relative error, but  $\hat{f}(\mathbf{x})$  may or may not correspond to a small perturbation of the data.

**FIGURE 37.2** The black dot on the left represents a nominal data point  $\mathbf{x}$ . The black dot on the right is the exact, unperturbed value of  $f(\mathbf{x})$ . The shaded region on the left represents the small relative-to- $\|\mathbf{x}\|$  perturbations of  $\mathbf{x}$ . The shaded region on the right is its exact image under  $f(\mathbf{x})$ . The diagram illustrates the error behavior of a weakly numerically stable algorithm, a numerically stable algorithm, and a forward stable algorithm.

**Facts:**

1. A numerically stable algorithm applied to an ill-conditioned problem may produce inaccurate results. For ill-conditioned problems even small errors in the input data may lead to large errors in the computed solution. Just as no numerical algorithm can reliably correct errors in the data or create information not originally implicit in the data, nor can a numerical algorithm reliably calculate accurate solutions to ill-conditioned problems.
2. Rounding and truncation errors in a backward stable algorithm are equivalent to a further perturbation of the data. The computed results of a backward stable algorithm are realistic in the sense that they are what would have been obtained in exact arithmetic from an extra rounding-error-small relative perturbation of the data. Typically this extra error is negligible compared to other errors already present in the data.
3. The forward error that occurs in a backward stable algorithm obeys the asymptotic condition number bound in Fact 2 of Section 37.4. **Backward error analysis** is based on this observation.
4. [Dat95], [GV96] *Some Well-Known Backward Stable Algorithms*:
  - (a) Fact 4 in Section 37.6 implies that a single floating point operation is both forward and backward stable.
  - (b) Fact 7b in section 37.6 shows that the given naive dot product algorithm is backward stable. The algorithm is not, in general, forward stable because there may be cancellation of significant digits in the summation.
  - (c) *Gaussian elimination*: Gaussian elimination with complete pivoting is backward stable. Gaussian elimination with partial pivoting is not, strictly speaking, backward stable. However, linear equations for which the algorithm exhibits instability are so extraordinarily rare that the algorithm is said to be “backward stable in practice” [Dat95, GV96].
  - (d) *Triangular back substitution*: The back-substitution algorithm in Example 2 in Section 37.7 is backward stable. It can be shown that the rounding error corrupted computed solution  $\hat{\mathbf{x}}$  satisfies  $(T + E)\hat{\mathbf{x}} = \mathbf{b}$ , where  $|e_{ij}| \leq \epsilon |t_{ij}|$ ,  $i, j = 1, 2, 3, \dots, n$ . Thus, the computed solution  $\hat{\mathbf{x}}$  solves a nearby system. The back-substitution process is, therefore, backward stable.
  - (e) *QR factorization*: The Householder and Givens methods for factorization of  $A = QR$ , where  $Q$  is orthogonal and  $R$  is upper triangular, are backward stable.
  - (f) *SVD computation*: The Golub–Kahan–Reinsch algorithm is a backward stable algorithm for finding the singular value decomposition  $A = U\Sigma V^T$ , where  $\Sigma$  is diagonal and  $U$  and  $V$  are orthogonal.
  - (g) *Least-square problem*: The Householder  $QR$  factorization, the Givens  $QR$  factorization, and Singular Value Decomposition (SVD) methods for solving linear least squares problems are backward stable.
  - (h) *Eigenvalue computations*: The implicit double-shift  $QR$  iteration is backward stable.

**Examples:**

1. An example of an algorithm that is forward stable but not backward stable is the natural computation of the outer product  $A = \mathbf{xy}^T$  from vectors  $\mathbf{x}, \mathbf{y} \in \mathbb{R}^n$ : for  $i, j = 1, 2, 3, \dots, n$ , set  $a_{ij} \leftarrow x_i \otimes y_j$ . This algorithm produces the correctly rounded value of the exact outer product, so it is forward stable. However, in general, rounding errors perturb the rank 1 matrix  $\mathbf{xy}^T$  into a matrix of higher rank. So, the rounding error perturbed outer product is not equal to the outer product of any pair of vectors; i.e., there is no backward error, so the algorithm is not backward stable.
2. *Backward vs. Forward Errors*: Consider the problem of evaluating  $f(x) = e^x$  at  $x = 1$ . One numerical method is to sum several terms of the Taylor series for  $e^x$ . If  $f(x)$  is approximated by the truncated Taylor series  $\hat{f}(x) = 1 + x + \frac{x^2}{2} + \frac{x^3}{3!}$ , then  $f(1) = e \approx 2.7183$  and  $\hat{f}(1) \approx 2.6667$ .

The forward error is  $f(1) - \hat{f}(1) \approx 2.7183 - 2.6667 = 0.0516$ . The backward error is  $1 - y$ , where  $f(y) = \hat{f}(1)$ , i.e., the backward error is  $1 - \ln(\hat{f}(1)) \approx .0192$ .

3. *A Numerically Unstable Algorithm:* Consider the computational problem of evaluating the function  $f(x) = \ln(1 + x)$  for  $x$  near zero. The naive approach is to use  $\text{fl}(\ln(1 \oplus x))$ , i.e., add one to  $x$  in finite precision arithmetic and evaluate the natural logarithm of the result also in finite precision arithmetic. (For this discussion, assume that if  $z$  is a floating point number, then  $\ln(z)$  returns the correctly rounded exact value of  $\ln(z)$ .) Applying this very simple algorithm to  $x = 10^{-16}$  in  $p = 16$ , radix  $b = 10$  arithmetic, gives  $\text{fl}(\ln(1 \oplus 10^{-16})) = \text{fl}(\ln(1)) = 0$ . The exact value of  $\ln(1 + 10^{-16}) \approx 10^{-16}$ , so the rounding error corrupted result has relative error 1. It is 100% incorrect.

However, the function  $f(x) = \ln(1 + x)$  is well-conditioned when  $x$  is near zero. Moreover,  $\lim_{x \rightarrow 0} \text{cond}_f(x) = 1$ . The large relative error is not due to ill-conditioning. It demonstrates that this simple algorithm is numerically unstable for  $x$  near zero.

4. An alternative algorithm to evaluate  $f(x) = \ln(1 + x)$  that does not suffer the above gross numerical instability for  $x$  near zero is to sum several terms of the Taylor series

$$\ln(1 + x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \dots$$

Although it is adequate for many purposes, this method can be improved. Note also that the series does not converge for  $|x| > 1$  and converges slowly if  $|x| \approx 1$ , so some other method (perhaps  $\text{fl}(\ln(1 \oplus x))$ ) is needed when  $x$  is not near zero.

5. *Gaussian Elimination without Pivoting:* Gaussian elimination without pivoting is not numerically stable. For example, consider solving a system of two equations in two unknowns

$$\begin{aligned} 10^{-10}x_1 + x_2 &= 1 \\ x_1 + 2x_2 &= 3 \end{aligned}$$

using  $p = 9$  digit, radix  $b = 10$  arithmetic. Eliminating  $x_2$  from the second equation, we obtain

$$\begin{aligned} 10^{-10}x_1 + x_2 &= 1 \\ (2 \ominus 10^{10})x_2 &= 3 \ominus 10^{10}, \end{aligned}$$

which becomes

$$\begin{aligned} 10^{-10}x_1 + x_2 &= 1 \\ -10^{10}x_2 &= -10^{10}, \end{aligned}$$

giving  $x_2 = 1, x_1 = 0$ . The exact solution is  $x_1 = (1 - 2 \times 10^{-10}) \approx 1, x_2 = (1 - 3 \times 10^{-10}) / (1 - 2 \times 10^{-10}) \approx 1$ .

The  $\infty$ -norm condition number of the coefficient matrix  $A = \begin{bmatrix} 10^{-10} & 1 \\ 1 & 2 \end{bmatrix}$  is  $\kappa(A) \approx 9$ , so the

large error in the rounding error corrupted solution is not due to ill-conditioning. Hence, Gaussian elimination without pivoting is numerically unstable.

6. *An Unstable Algorithm for Eigenvalue Computations:* Finding the eigenvalues of a matrix by finding the roots of its characteristic polynomial is a numerically unstable process because the roots of the characteristic polynomial may be ill-conditioned when the eigenvalues of the corresponding matrix are well-conditioned. Transforming a matrix to companion form often requires an ill-conditioned similarity transformation, so even calculating the coefficients of the characteristic polynomial may be an unstable process. A well-known example is the diagonal matrix  $A = \text{diag}(1, 2, 3, \dots, 20)$ . The Wielandt-Hoffman theorem [GV96] shows that perturbing  $A$  to a nearby matrix  $A + E$  perturbs the eigenvalues by no more than  $\|E\|_F$ . However, the characteristic polynomial is the infamous Wilkinson polynomial discussed in Example 5 of Section 37.4, which has highly ill-conditioned roots.

The need to solve systems of linear equations arises often within diverse disciplines of science, engineering, and finance. The expression “direct solution of linear systems” refers generally to computational strategies that can produce solutions to linear systems after a predetermined number of arithmetic operations that depends only on the structure and dimension of the coefficient matrix. The evolution of computers has and continues to influence the development of these strategies as well as fostering particular styles of perturbation analysis suited to illuminating their behavior. Some general themes have become dominant, as a result; others have been pushed aside. For example, Cramer’s Rule may be properly thought of as a direct solution strategy for solving linear systems; however it requires a much larger number of arithmetic operations than Gauss elimination and is generally much more susceptible to the deleterious effects of rounding. Most current approaches for the direct solution of a linear system,  $A\mathbf{x} = \mathbf{b}$ , are patterned after Gauss elimination and favor systematically decoupling the system of equations. Zeros are introduced systematically into the coefficient matrix, transforming it into triangular form; the resulting triangular system is easily solved. The entire process can be viewed in this way:

1. Find invertible matrices  $\{S_i\}_{i=1}^{\rho}$  such that  $S_{\rho} \dots S_2 S_1 A = U$  is triangular; then
2. Calculate a modified right-hand side  $\mathbf{y} = S_{\rho} \dots S_2 S_1 \mathbf{b}$ ; and then
3. Determine the solution set to the triangular system  $U\mathbf{x} = \mathbf{y}$ .

The matrices  $S_1, S_2, \dots, S_{\rho}$  are typically either row permutations of lower triangular matrices (Gauss transformations) or unitary matrices and so have readily available inverses. Evidently  $A$  can be written as  $A = NU$ , where  $N = (S_{\rho} \dots S_2 S_1)^{-1}$ , A solution framework may be built around the availability of decompositions such as this:

1. Find a decomposition  $A = NU$  such that  $U$  is triangular and  $N\mathbf{y} = \mathbf{b}$  is easily solved;
2. Solve  $N\mathbf{y} = \mathbf{b}$ ; then
3. Determine the solution set to triangular system  $U\mathbf{x} = \mathbf{y}$ .

## 38.1 Perturbations of Linear Systems

In the computational environment afforded by current computers, the finite representation of real numbers creates a small but persistent source of errors that may on occasion severely degrade the overall accuracy of a calculation. This effect is of fundamental concern in assessing strategies for solving linear systems.

Rounding errors can be introduced into the solution process for linear systems often before any calculations are performed — as soon as data are stored within the computer and represented within the internal floating point number system of the computer. Further errors that may be introduced in the course of computation often may be viewed in aggregate as an effective additional contribution to the initial representation error. Inevitably then the linear system for which a solution is computed deviates slightly from the “true” linear system and it becomes of critical interest to determine whether such deviations will have a significant effect on the accuracy of the final computed result.

### Definitions:

Let  $A \in \mathbb{C}^{n \times n}$  be a nonsingular matrix,  $\mathbf{b} \in \mathbb{C}^n$ , and then denote by  $\hat{\mathbf{x}} = A^{-1}\mathbf{b}$  the unique solution of the linear system  $A\mathbf{x} = \mathbf{b}$ .

Given **data perturbations**  $\delta A \in \mathbb{C}^{n \times n}$  and  $\delta \mathbf{b} \in \mathbb{C}^n$  to  $A$  and  $\mathbf{b}$ , respectively, the **solution perturbation**,  $\delta \mathbf{x} \in \mathbb{C}^n$  satisfies the associated **perturbed linear system**  $(A + \delta A)(\hat{\mathbf{x}} + \delta \mathbf{x}) = \mathbf{b} + \delta \mathbf{b}$  (presuming then that the perturbed system is consistent).

For any  $\tilde{\mathbf{x}} \in \mathbb{C}^n$ , the **residual vector** associated with the linear system  $A\mathbf{x} = \mathbf{b}$  is defined as  $\mathbf{r}(\tilde{\mathbf{x}}) = \mathbf{b} - A\tilde{\mathbf{x}}$ .

For any  $\tilde{\mathbf{x}} \in \mathbb{C}^n$ , the associated (norm-wise) **relative backward error of the linear system**  $A\mathbf{x} = \mathbf{b}$  (with respect to the the  $p$ -norm) is

$$\eta_p(A, \mathbf{b}; \tilde{\mathbf{x}}) = \min \left\{ \varepsilon \left| \begin{array}{l} \text{there exist } \delta A, \delta \mathbf{b} \text{ such that} \\ (A + \delta A)\tilde{\mathbf{x}} = \mathbf{b} + \delta \mathbf{b} \text{ with} \end{array} \right. \begin{array}{l} \|\delta A\|_p \leq \varepsilon \|A\|_p \\ \|\delta \mathbf{b}\|_p \leq \varepsilon \|\mathbf{b}\|_p \end{array} \right\}$$

for  $1 \leq p \leq \infty$ .

For any  $\tilde{\mathbf{x}} \in \mathbb{C}^n$ , the associated **component-wise relative backward error of the linear system**  $A\mathbf{x} = \mathbf{b}$  is

$$\omega(A, \mathbf{b}; \tilde{\mathbf{x}}) = \min \left\{ \varepsilon \left| \begin{array}{l} \text{there exist } \delta A, \delta \mathbf{b} \text{ such that} \\ (A + \delta A)\tilde{\mathbf{x}} = \mathbf{b} + \delta \mathbf{b} \text{ with} \end{array} \right. \begin{array}{l} |\delta A| \leq \varepsilon |A| \\ |\delta \mathbf{b}| \leq \varepsilon |\mathbf{b}| \end{array} \right\},$$

where the absolute values and inequalities applied to vectors and matrices are interpreted component-wise:  $|B| \leq |A|$  means  $|b_{ij}| \leq |a_{ij}|$  for all index pairs  $i, j$ .

The (norm-wise) **condition number of the linear system**  $A\mathbf{x} = \mathbf{b}$  (relative to the the  $p$ -norm) is

$$\kappa_p(A, \hat{\mathbf{x}}) = \|A^{-1}\|_p \frac{\|\mathbf{b}\|_p}{\|\hat{\mathbf{x}}\|_p}$$

for  $1 \leq p \leq \infty$ .

The **matrix condition number** relative to the the  $p$ -norm of  $A$  is

$$\kappa_p(A) = \|A\|_p \|A^{-1}\|_p$$

for  $1 \leq p \leq \infty$ .

The **Skeel condition number of the linear system**  $A\mathbf{x} = \mathbf{b}$  is

$$\text{cond}(A, \hat{\mathbf{x}}) = \frac{\| |A^{-1}| |A| |\hat{\mathbf{x}} \|_\infty}{\|\hat{\mathbf{x}}\|_\infty}.$$

The **Skeel matrix condition number** is  $\text{cond}(A) = \| |A^{-1}| |A| \|_\infty$ .

**Facts:** [Hig96],[StS90]

1. For any  $\tilde{\mathbf{x}} \in \mathbb{C}^n$ ,  $\tilde{\mathbf{x}}$  is the exact solution to any one of the family of perturbed linear systems

$$(A + \delta A_\theta)\tilde{\mathbf{x}} = \mathbf{b} + \delta \mathbf{b}_\theta,$$

where  $\theta \in \mathbb{C}$ ,  $\delta \mathbf{b}_\theta = (\theta - 1) \mathbf{r}(\tilde{\mathbf{x}})$ ,  $\delta A_\theta = \theta \mathbf{r}(\tilde{\mathbf{x}})\tilde{\mathbf{y}}^*$ , and  $\tilde{\mathbf{y}} \in \mathbb{C}^n$  is any vector such that  $\tilde{\mathbf{y}}^*\tilde{\mathbf{x}} = 1$ . In particular, for  $\theta = 0$ ,  $\delta A = 0$  and  $\delta \mathbf{b} = -\mathbf{r}(\tilde{\mathbf{x}})$ ; for  $\theta = 1$ ,  $\delta A = \mathbf{r}(\tilde{\mathbf{x}})\tilde{\mathbf{y}}^*$  and  $\delta \mathbf{b} = 0$ .

2. (Rigal–Gaches Theorem) For any  $\tilde{\mathbf{x}} \in \mathbb{C}^n$ ,

$$\eta_p(A, \mathbf{b}; \tilde{\mathbf{x}}) = \frac{\|\mathbf{r}(\tilde{\mathbf{x}})\|_p}{\|A\|_p \|\tilde{\mathbf{x}}\|_p + \|\mathbf{b}\|_p}.$$

If  $\tilde{\mathbf{y}}$  is the dual vector to  $\tilde{\mathbf{x}}$  with respect to the  $p$ -norm ( $\tilde{\mathbf{y}}^*\tilde{\mathbf{x}} = \|\tilde{\mathbf{y}}\|_q \|\tilde{\mathbf{x}}\|_p = 1$  with  $\frac{1}{p} + \frac{1}{q} = 1$ ), then  $\tilde{\mathbf{x}}$  is an exact solution to the perturbed linear system  $(A + \delta A_{\tilde{\theta}})\tilde{\mathbf{x}} = \mathbf{b} + \delta \mathbf{b}_{\tilde{\theta}}$  with data perturbations as in (1) and  $\tilde{\theta} = \frac{\|A\|_p \|\tilde{\mathbf{x}}\|_p}{\|A\|_p \|\tilde{\mathbf{x}}\|_p + \|\mathbf{b}\|_p}$ , and as a result

$$\frac{\|\delta A_{\tilde{\theta}}\|_p}{\|A\|_p} = \frac{\|\delta \mathbf{b}_{\tilde{\theta}}\|_p}{\|\mathbf{b}\|_p} = \eta_p(A, \mathbf{b}; \tilde{\mathbf{x}}).$$

3. (Oettli–Prager Theorem) For any  $\tilde{\mathbf{x}} \in \mathbb{C}^n$ ,

$$\omega(A, \mathbf{b}; \tilde{\mathbf{x}}) = \max_i \frac{|r_i|}{(|A| |\tilde{\mathbf{x}}| + |\mathbf{b}|)_i}.$$

If  $D_1 = \text{diag} \left( \frac{r_i}{(|A| |\tilde{\mathbf{x}}| + |\mathbf{b}|)_i} \right)$  and  $D_2 = \text{diag}(\text{sign}(\tilde{\mathbf{x}})_i)$ , then  $\tilde{\mathbf{x}}$  is an exact solution to the perturbed linear system  $(A + \delta A)\tilde{\mathbf{x}} = \mathbf{b} + \delta \mathbf{b}$  with  $\delta A = D_1 |A| D_2$  and  $\delta \mathbf{b} = -D_1 |\mathbf{b}|$

$$|\delta A| \leq \omega(A, \mathbf{b}; \tilde{\mathbf{x}}) |A| \quad \text{and} \quad |\delta \mathbf{b}| \leq \omega(A, \mathbf{b}; \tilde{\mathbf{x}}) |A|$$

and no smaller constant can be used in place of  $\omega(A, \mathbf{b}; \tilde{\mathbf{x}})$ .

4. The reciprocal of  $\kappa_p(A)$  is the smallest norm-wise relative distance of  $A$  to a singular matrix, i.e.,

$$\frac{1}{\kappa_p(A)} = \min \left\{ \frac{\|\delta A\|_p}{\|A\|_p} \mid A + \delta A \text{ is singular} \right\}.$$

In particular, the perturbed coefficient matrix  $A + \delta A$  is nonsingular if

$$\frac{\|\delta A\|_p}{\|A\|_p} < \frac{1}{\kappa_p(A)}.$$

5.  $1 \leq \kappa_p(A, \hat{\mathbf{x}}) \leq \kappa_p(A)$  and  $1 \leq \text{cond}(A, \hat{\mathbf{x}}) \leq \text{cond}(A) \leq \kappa_\infty(A)$ .
6.  $\text{cond}(A) = \min \{ \kappa_\infty(DA) \mid D \text{ diagonal} \}$ .
7. If  $\delta A = 0$ , then

$$\frac{\|\delta \mathbf{x}\|_p}{\|\hat{\mathbf{x}}\|_p} \leq \kappa_p(A, \hat{\mathbf{x}}) \frac{\|\delta \mathbf{b}\|_p}{\|\mathbf{b}\|_p}.$$

8. If  $\delta \mathbf{b} = 0$  and  $A + \delta A$  is nonsingular, then

$$\frac{\|\delta \mathbf{x}\|_p}{\|\hat{\mathbf{x}} + \delta \mathbf{x}\|_p} \leq \kappa_p(A) \frac{\|\delta A\|_p}{\|A\|_p}.$$

9. If  $\|\delta A\|_p \leq \epsilon \|A\|_p$ ,  $\|\delta \mathbf{b}\|_p \leq \epsilon \|\mathbf{b}\|_p$ , and  $\epsilon < \frac{1}{\kappa_p(A)}$ , then

$$\frac{\|\delta \mathbf{x}\|_p}{\|\hat{\mathbf{x}}\|_p} \leq \frac{2 \epsilon \kappa_p(A)}{1 - \epsilon \kappa_p(A)}.$$

10. If  $|\delta A| \leq \epsilon |A|$ ,  $|\delta \mathbf{b}| \leq \epsilon \|\mathbf{b}\|$ , and  $\epsilon < \frac{1}{\text{cond}(A)}$ , then

$$\frac{\|\delta \mathbf{x}\|_\infty}{\|\hat{\mathbf{x}}\|_\infty} \leq \frac{2 \epsilon \text{cond}(A, \hat{\mathbf{x}})}{1 - \epsilon \text{cond}(A)}.$$

**Examples:**

1. Let  $A = \begin{bmatrix} 1000 & 999 \\ 999 & 998 \end{bmatrix}$  so  $A^{-1} = \begin{bmatrix} -998 & 999 \\ 999 & -1000 \end{bmatrix}$ . Then  $\|A\|_1 = \|A^{-1}\|_1 = 1999$  so that  $\kappa_1(A) \approx 3.996 \times 10^6$ . Consider

$$\mathbf{b} = \begin{bmatrix} 1999 \\ 1997 \end{bmatrix} \text{ associated with a solution } \hat{\mathbf{x}} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}.$$

A perturbation of right-hand side  $\delta \mathbf{b} = \begin{bmatrix} -0.01 \\ 0.01 \end{bmatrix}$  constitutes a relative change in the right-hand side of  $\frac{\|\delta \mathbf{b}\|_1}{\|\mathbf{b}\|_1} \approx 5.005 \times 10^{-6}$  yet it produces a perturbed solution  $\hat{\mathbf{x}} + \delta \mathbf{x} = \begin{bmatrix} 20.97 \\ -18.99 \end{bmatrix}$  constituting a relative change  $\frac{\|\delta \mathbf{x}\|_1}{\|\hat{\mathbf{x}}\|_1} = 19.98 \leq 20 = \kappa_1(A) \frac{\|\delta \mathbf{b}\|_1}{\|\mathbf{b}\|_1}$ . The bound determined by the condition number is very nearly achieved. Note that the same perturbed solution  $\hat{\mathbf{x}} + \delta \mathbf{x}$  could be produced by a change in the coefficient matrix

$$\delta A = \tilde{\mathbf{r}}\tilde{\mathbf{y}}^* = - \begin{bmatrix} -0.01 \\ 0.01 \end{bmatrix} \begin{bmatrix} 1 & -1 \\ 39.96 & -39.96 \end{bmatrix} = (1/3996) \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix}$$

constituting a relative change  $\frac{\|\delta A\|_1}{\|A\|_1} \approx 2.5 \times 10^{-7}$ . Then  $(A + \delta A)(\hat{\mathbf{x}} + \delta \mathbf{x}) = \mathbf{b}$ .

2. Let  $n = 100$  and  $A$  be tridiagonal with diagonal entries equal to  $-2$  and all superdiagonal and subdiagonal entries equal to  $1$  (associated with a centered difference approximation to the second derivative). Let  $\mathbf{b}$  be a vector with a quadratic variation in entries

$$b_k = (k - 1)(100 - k)/10,000.$$

Then

$$\kappa_2(A, \hat{\mathbf{x}}) \approx 1, \quad \text{but} \quad \kappa_2(A) \approx 4.1336 \times 10^3.$$

Since the elements of  $\mathbf{b}$  do not have an exact binary representation, the linear system that is presented to any computational algorithm will be  $A\mathbf{x} = \mathbf{b} + \delta \mathbf{b}$  with  $\|\delta \mathbf{b}\|_2 \leq \epsilon \|\mathbf{b}\|_2$ , where  $\epsilon$  is the unit roundoff error. For example, if the linear system data is stored in IEEE single precision format,  $\epsilon \approx 6 \times 10^{-8}$ . The matrix condition number,  $\kappa_2(A)$ , would yield a bound of  $(6 \times 10^{-8})(4.1336 \times 10^3) \approx 2.5 \times 10^{-4}$  anticipating the loss of more than 4 significant digits in solution components even if all computations were done on the stored data with no further error. However, the condition number of the linear system,  $\kappa_2(A, \hat{\mathbf{x}})$ , is substantially smaller and the predicted error for the system is roughly the same as the initial representation error  $\approx 6 \times 10^{-8}$ , indicating that the solution will be fairly insensitive to the consequences of rounding of the right-hand side data—assuming no further errors occur. But, in fact, this conclusion remains true even if further errors occur, if whatever computational algorithm that is used produces small backward error, as might be asserted if, say, a final residual satisfies  $\|\mathbf{r}\|_2 \leq \mathcal{O}(\epsilon) \|\mathbf{b}\|_2$ . This situation changes substantially if the right-hand side is changed to

$$b_k = (-1)^k(k - 1)(100 - k)/10,000,$$

which only introduces a sign variation in  $\mathbf{b}$ . In this case,  $\kappa_2(A, \hat{\mathbf{x}}) \approx \kappa_2(A)$ , and the components of the computed solution can be expected to lose about 4 significant digits purely on the basis of errors that are made in the initial representation. Additional errors made in the course of the computation can hardly be expected to improve this situation.

## 38.2 Triangular Linear Systems

Systems of linear equations for which the unknowns may be solved for one at a time in sequence may be reordered to produce linear systems with triangular coefficient matrices. Such systems can be solved both with remarkable accuracy and remarkable efficiency. Triangular systems are the archetype for easily solvable systems of linear equations; as such, they often constitute an intermediate goal for strategies of solving linear systems.

### Definitions:

A linear system of equations  $T\mathbf{x} = \mathbf{b}$  with  $T \in \mathbb{C}^{n \times n}$  (representing  $n$  equations in  $n$  unknowns) is a **triangular system** if  $T = [t_{ij}]$  is either an **upper triangular matrix** ( $t_{ij} = 0$  for  $i > j$ ) or a **lower triangular matrix** ( $t_{ij} = 0$  for  $i < j$ ).

**Facts:** [Hig96], [GV96]

1. [GV96, pp. 88–90]

**Algorithm 1:** Row-oriented forward-substitution for solving lower triangular system

Input:  $L \in \mathbb{R}^{n \times n}$  with  $\ell_{ij} = 0$  for  $i < j$ ;  $\mathbf{b} \in \mathbb{R}^n$

Output: solution vector  $\mathbf{x} \in \mathbb{R}^n$  that satisfies  $L\mathbf{x} = \mathbf{b}$

$$x_1 \leftarrow b_1 / \ell_{1,1}$$

For  $k = 2 : n$

$$x_k \leftarrow (b_k - L_{k,1:k-1} \cdot x_{1:k-1}) / \ell_{k,k}$$

end

2. [GV96, pp. 88–90]

**Algorithm 2:** Column-oriented back-substitution for solving upper triangular system

Input:  $U \in \mathbb{R}^{n \times n}$  with  $u_{ij} = 0$  for  $i > j$ ;  $\mathbf{b} \in \mathbb{R}^n$

Output: solution vector  $\mathbf{x} \in \mathbb{R}^n$  that satisfies  $U\mathbf{x} = \mathbf{b}$

For  $k = n$  down to 2 by steps of  $-1$

$$x_k \leftarrow b_k / u_{k,k}$$

$$b_{1:k-1} \leftarrow b_{1:k-1} - x_k U_{1:k-1,k}$$

end

$$x_1 \leftarrow b_1 / u_{1,1}$$

3. Algorithm 1 involves as a core calculation, dot products of portions of coefficient matrix rows with corresponding portions of the emerging solution vector. This can incur a performance penalty for large  $n$  from accumulation of dot products using a scalar recurrence. A “column-oriented” reformulation may have better performance for large  $n$ . Algorithm 2 is a “column-oriented” formulation for solving upper triangular systems.

4. The solution of triangular systems using either Algorithm 1 or 2 is *componentwise backward stable*. In particular the computed result,  $\tilde{\mathbf{x}}$ , produced either by Algorithm 1 or 2 in solving a triangular system,  $T\mathbf{x} = \mathbf{b}$ , will be the exact result of a perturbed system  $(T + \delta T)\tilde{\mathbf{x}} = \mathbf{b}$ , where  $|\delta T| \leq \frac{n\epsilon}{1-n\epsilon}|T|$  and  $\epsilon$  is the unit roundoff error.
5. The error in the solution of a triangular system,  $T\mathbf{x} = \mathbf{b}$ , using either Algorithm 1 or 2 satisfies

$$\frac{\|\tilde{\mathbf{x}} - \hat{\mathbf{x}}\|_\infty}{\|\hat{\mathbf{x}}\|_\infty} \leq \frac{n\epsilon \operatorname{cond}(T, \hat{\mathbf{x}})}{1 - n\epsilon (\operatorname{cond}(T) + 1)}.$$

6. If  $T = [t_{ij}]$  is a lower triangular matrix satisfying  $|t_{ii}| \geq |t_{ij}|$  for  $j \leq i$ , the computed solution to the linear system  $T\mathbf{x} = \mathbf{b}$  produced by either Algorithm 1 or the variant of Algorithm 2 for lower triangular systems satisfies

$$|\hat{x}_i - \tilde{x}_i| \leq \frac{2^i n\epsilon}{1 - n\epsilon} \max_{j \leq i} |\tilde{x}_j|,$$

where  $\tilde{x}_i$  are the components of the computed solution,  $\tilde{\mathbf{x}}$ , and  $\hat{x}_i$  are the components of the exact solution,  $\hat{\mathbf{x}}$ . Although this bound degrades exponentially with  $i$ , it shows that early solution components will be computed to high accuracy relative to those components already computed.

### Examples:

1. Use Algorithm 2 to solve the triangular system

$$\begin{bmatrix} 1 & 2 & -3 \\ 0 & 2 & -6 \\ 0 & 0 & 3 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}.$$

$k = 3$  step: Solve for  $x_3 = 1/3$ . Update right-hand side:

$$\begin{bmatrix} 1 & 2 \\ 0 & 2 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} - (1/3) \begin{bmatrix} -3 \\ -6 \\ 3 \end{bmatrix} = \begin{bmatrix} 2 \\ 3 \\ 0 \end{bmatrix}.$$

$k = 2$  step: Solve for  $x_2 = 3/2$ . Update right-hand side:

$$\begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix} [x_1] = \begin{bmatrix} 2 \\ 3 \\ 0 \end{bmatrix} - (3/2) \begin{bmatrix} 2 \\ 2 \\ 0 \end{bmatrix} = \begin{bmatrix} -1 \\ 0 \\ 0 \end{bmatrix}.$$

$k = 1$  step: Solve for  $x_1 = -1$ .

2. ([Hig96, p. 156]) For  $\epsilon > 0$ , consider  $T = \begin{bmatrix} 1 & 0 & 0 \\ \epsilon & \epsilon & 0 \\ 0 & 1 & 1 \end{bmatrix}$ . Then  $T^{-1} = \begin{bmatrix} 1 & 0 & 0 \\ -1 & \frac{1}{\epsilon} & 0 \\ 1 & -\frac{1}{\epsilon} & 1 \end{bmatrix}$ , and so  $\operatorname{cond}(T) = 5$ , even though

$$\kappa_\infty(T) = 2(2 + \frac{1}{\epsilon}) \approx \frac{2}{\epsilon} + \mathcal{O}(1).$$

Thus, linear systems having  $T$  as a coefficient matrix will be solved to high relative accuracy, independent of both right-hand side and size of  $\epsilon$ , despite the poor conditioning of  $T$  (as measured by  $\kappa_\infty$ ) as  $\epsilon$  becomes small. However, note that

$$\operatorname{cond}(T^T) = 1 + \frac{2}{\epsilon} \quad \text{and} \quad \kappa_\infty(T^T) = (1 + \epsilon) \frac{2}{\epsilon} \approx \frac{2}{\epsilon} + \mathcal{O}(1).$$

So, linear systems having  $T^T$  as a coefficient matrix may have solutions that are sensitive to perturbations and indeed,  $\text{cond}(T^T, \mathbf{x}) \approx \text{cond}(T^T)$  for any right-hand side  $\mathbf{b}$  with  $b_3 \neq 0$  yielding solutions that are sensitive to perturbations for small  $\epsilon$ .

### 38.3 Gauss Elimination and LU Decomposition

Gauss elimination is an elementary approach to solving systems of linear equations, yet it still constitutes the core of the most sophisticated of solution strategies. In the  $k^{\text{th}}$  step, a transformation matrix,  $M_k$ , (a ‘‘Gauss transformation’’) is designed so as to introduce zeros into  $A$  — typically into a portion of the  $k^{\text{th}}$  column — without harming zeros that have been introduced in earlier steps. Typically, successive applications of Gauss transformations are interleaved with row interchanges. Remarkably, this reduction process can be viewed as producing a decomposition of the coefficient matrix  $A = NU$ , where  $U$  is a triangular matrix and  $N$  is a row permutation of a lower triangular matrix.

**Definitions:**

For each index  $k$ , a **Gauss vector** is a vector in  $\mathbb{C}^n$  with the leading  $k$  entries equal to zero:  $\ell_k = [0, \dots, 0, \underbrace{\ell_{k+1}, \dots, \ell_n}_k]^T$ . The entries  $\ell_{k+1}, \dots, \ell_n$  are **Gauss multipliers** and the associated matrix

$$M_k = I - \ell_k \mathbf{e}_k^T$$

is called a **Gauss transformation**.

For the pair of indices  $(i, j)$ , with  $i \leq j$  the associated **permutation matrix**,  $\Pi_{i,j}$  is an  $n \times n$  identity matrix with the  $i^{\text{th}}$  row and  $j^{\text{th}}$  row interchanged. Note that  $\Pi_{i,i}$  is the identity matrix.

A matrix  $U \in \mathbb{C}^{m \times n}$  is in **row-echelon form** if (1) the first nonzero entry of each row has a strictly smaller column index than all nonzero entries having a strictly larger row index and (2) zero rows occur at the bottom. The first nonzero entry in each row of  $U$  is called a **pivot**. Thus, the determining feature of row echelon form is that pivots occur to the left of all nonzero entries in lower rows.

A matrix  $A \in \mathbb{C}^{m \times n}$  has an **LU decomposition** if there exists a unit lower triangular matrix  $L \in \mathbb{C}^{m \times m}$  ( $L_{i,j} = 0$  for  $i < j$  and  $L_{i,i} = 1$  for all  $i$ ) and an upper triangular matrix  $U \in \mathbb{C}^{m \times n}$  ( $U_{i,j} = 0$  for  $i > j$ ) such that  $A = LU$ .

**Facts:** [GV96]

- Let  $\mathbf{a} \in \mathbb{C}^n$  be a vector with a nonzero component in the  $r^{\text{th}}$  entry,  $a_r \neq 0$ . Define the Gauss vector,  $\ell_r = [0, \dots, 0, \underbrace{a_{r+1}, \dots, a_n}_r]^T$ . The associated Gauss transformation  $M_r = I - \ell_r \mathbf{e}_r^T$  introduces zeros into the last  $n - r$  entries of  $\mathbf{a}$ :

$$M_r \mathbf{a} = [a_1, \dots, a_r, 0, \dots, 0]^T.$$

- If  $A \in \mathbb{C}^{m \times n}$  with  $\text{rank}(A) = \rho \geq 1$  has  $\rho$  leading principal submatrices nonsingular,  $A_{1:r,1:r}$ ,  $r = 1, \dots, \rho$ , then there exist Gauss transformations  $M_1, M_2, \dots, M_\rho$  so that

$$M_\rho M_{\rho-1} \cdots M_1 A = U$$

with  $U$  upper triangular. Each Gauss transformation  $M_r$  introduces zeros into the  $r^{\text{th}}$  column.

- Gauss transformations are unit lower triangular matrices. They are invertible, and for the Gauss transformation,  $M_r = I - \ell_r \mathbf{e}_r^T$ ,

$$M_r^{-1} = I + \ell_r \mathbf{e}_r^T.$$

4. If Gauss vectors  $\ell_1, \ell_2, \dots, \ell_{n-1}$  are given with

$$\ell_1 = \begin{Bmatrix} 0 \\ \ell_{21} \\ \ell_{31} \\ \vdots \\ \ell_{n1} \end{Bmatrix}, \quad \ell_2 = \begin{Bmatrix} 0 \\ 0 \\ \ell_{32} \\ \vdots \\ \ell_{n2} \end{Bmatrix}, \quad \dots, \quad \ell_{n-1} = \begin{Bmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ \ell_{n,n-1} \end{Bmatrix},$$

then the product of Gauss transformations  $M_{n-1}M_{n-2} \cdots M_2M_1$  is invertible and has an explicit inverse

$$(M_{n-1}M_{n-2} \cdots M_2M_1)^{-1} = I + \sum_{k=1}^{n-1} \ell_k \mathbf{e}_k^T = \begin{bmatrix} 1 & 0 & \cdots & 0 & 0 \\ \ell_{21} & 1 & & & 0 \\ \ell_{31} & \ell_{32} & \ddots & & 0 \\ \vdots & & & 1 & 0 \\ \ell_{n1} & \ell_{n2} & \cdots & \ell_{n,n-1} & 1 \end{bmatrix}.$$

5. If  $A \in \mathbb{C}^{m \times n}$  with  $\text{rank}(A) = \rho$  has  $\rho$  leading principal submatrices nonsingular,  $A_{1:r,1:r}$ ,  $r = 1, \dots, \rho$ , then  $A$  has an  $LU$  decomposition:  $A = LU$ , with  $L$  unit lower triangular and  $U$  upper triangular. The  $(i, j)$  entry of  $L$ ,  $L_{i,j}$  with  $i > j$  is the Gauss multiplier used to introduce a zero into the corresponding  $(i, j)$  entry of  $A$ . If, additionally,  $\rho = m$ , then the  $LU$  decomposition is unique.
6. Let  $\mathbf{a}$  be an arbitrary vector in  $\mathbb{C}^n$ . For any index  $r$ , there is an index  $\mu \geq r$ , a permutation matrix  $\Pi_{r,\mu}$ , and a Gauss transformation  $M_r$  so that

$$M_r \Pi_{r,\mu} \mathbf{a} = [a_1, \dots, a_{r-1}, a_\mu, \underbrace{0, \dots, 0}_{n-r}]^T.$$

The index  $\mu$  is chosen so that  $a_\mu \neq 0$  out of the set  $\{a_r, a_{r+1}, \dots, a_n\}$ . If  $a_r \neq 0$ , then  $\mu = k$  and  $\Pi_{r,\mu} = I$  is a possible choice; if each element is zero,  $a_r = a_{r+1} = \cdots = a_n = 0$ , then  $\mu = k$ ,  $\Pi_{r,\mu} = I$ , and  $M_r = I$  is a possible choice.

7. For every matrix  $A \in \mathbb{C}^{m \times n}$  with  $\text{rank}(A) = \rho$ , there exists a sequence of  $\rho$  indices  $\mu_1, \mu_2, \dots, \mu_\rho$  with  $i \leq \mu_i \leq m$  for  $i = 1, \dots, \rho$  and Gauss transformations  $M_1, M_2, \dots, M_\rho$  so that

$$M_\rho \Pi_{\rho,\mu_\rho} M_{\rho-1} \Pi_{\rho-1,\mu_{\rho-1}} \cdots M_1 \Pi_{1,\mu_1} A = U$$

with  $U$  upper triangular and in row echelon form. Each pair of transformations  $M_r \Pi_{r,\mu_r}$  introduces zeros below the  $r^{\text{th}}$  pivot.

8. For  $r < i < j$ ,  $\Pi_{i,j} M_r = \tilde{M}_r \Pi_{i,j}$ , where  $\tilde{M}_r = I - \tilde{\ell}_r \mathbf{e}_r^T$  and  $\tilde{\ell}_r = \Pi_{i,j} \ell_r$  (i.e., the  $i$  and  $j$  entries of  $\ell_r$  are interchanged to form  $\tilde{\ell}_r$ ).
9. For every matrix  $A \in \mathbb{C}^{m \times n}$  with  $\text{rank}(A) = \rho$ , there is a row permutation of  $A$  that has an  $LU$  decomposition:  $PA = LU$ , with a permutation matrix  $P$ , unit lower triangular matrix  $L$ , and an upper triangular matrix  $U$  that is in row echelon form.  $P$  can be chosen as  $P = \Pi_{\rho,\mu_\rho} \Pi_{\rho-1,\mu_{\rho-1}} \cdots \Pi_{1,\mu_1}$  from (7), though in general there can be many other possibilities as well.
10. Reduction of  $A$  with Gauss transformations (or equivalently, calculation of an  $LU$  factorization) must generally incorporate row interchanges. As a practical matter, these row interchanges commonly are chosen so as to bring the largest magnitude entry within the column being reduced up into the pivot location. This strategy is called “partial pivoting.” In particular, if zeros are to be introduced into the  $k^{\text{th}}$  column below the  $r^{\text{th}}$  row (with  $r \leq k$ ), then one seeks an index  $\mu_r$  such that  $r \leq \mu_r \leq m$  and  $|A_{\mu_r,k}| = \max_{r \leq i \leq m} |A_{i,k}|$ . When  $\mu_1, \mu_2, \dots, \mu_\rho$  in (7) are chosen in this way, the reduction process is called “Gaussian Elimination with Partial Pivoting” (GEPP) or, within the context of factorization, the permuted  $LU$  factorization (PLU).

11. [GV96, p. 115]

**Algorithm 1:** GEPP/PLU decomposition of a rectangular matrix (outer product)

Input:  $A \in \mathbb{R}^{m \times n}$   
Output:  $L \in \mathbb{R}^{m \times m}$  (unit lower triangular matrix)  
 $U \in \mathbb{R}^{m \times n}$  (upper triangular matrix - row echelon form)  
 $P \in \mathbb{R}^{m \times m}$  (permutation matrix) so that  $PA = LU$   
( $P$  is represented with an index vector  $\mathbf{p}$  such that  $\mathbf{y} = P\mathbf{z} \Leftrightarrow y_j = z_{p_j}$ )  
 $L \leftarrow I_m; U \leftarrow 0 \in \mathbb{R}^{m \times n};$   
 $\mathbf{p} = [1, 2, 3, \dots, m]$   
 $r \leftarrow 1;$   
For  $k = 1$  to  $n$   
Find  $\mu$  such that  $r \leq \mu \leq m$  and  $|A_{\mu,k}| = \max_{r \leq i \leq m} |A_{i,k}|$   
If  $A_{\mu,k} \neq 0$ , then  
Exchange  $A_{\mu,k:n} \leftrightarrow A_{r,k:n}$ ,  $L_{\mu,1:r-1} \leftrightarrow L_{r,1:r-1}$ , and  $p_\mu \leftrightarrow p_r$   
 $L_{r+1:m,r} \leftarrow A_{r+1:m,k} / A_{r,k}$   
 $U_{r,k:n} \leftarrow A_{r,k:n}$   
For  $i = r + 1$  to  $m$   
For  $j = k + 1$  to  $n$   
 $A_{i,j} \leftarrow A_{i,j} - L_{i,r} U_{r,j}$   
 $r \leftarrow r + 1$

12. [GV96, p. 115]

**Algorithm 2:** GEPP/PLU decomposition of a rectangular matrix (gaxpy)

Input:  $A \in \mathbb{R}^{m \times n}$   
Output:  $L \in \mathbb{R}^{m \times m}$  (unit lower triangular matrix),  
 $U \in \mathbb{R}^{m \times n}$  (upper triangular matrix - row echelon form), and  
 $P \in \mathbb{R}^{m \times m}$  (permutation matrix) so that  $PA = LU$   
( $P$  is represented with an index vector  $\boldsymbol{\pi}$  that records row interchanges  
 $\pi_r = \mu$  means row  $r$  and row  $\mu > r$  were interchanged)  
 $L \leftarrow I_m \in \mathbb{R}^{m \times m}; U \leftarrow 0 \in \mathbb{R}^{m \times n};$  and  $r \leftarrow 1;$   
For  $j = 1$  to  $n$   
 $\mathbf{v} \leftarrow A_{1:m,j}$   
If  $r > 1$ , then  
for  $i = 1$  to  $r - 1$ ,  
Exchange  $v_i \leftrightarrow v_{\pi_i}$   
Solve the triangular system,  $L_{1:r-1,1:r-1} \cdot \mathbf{z} = \mathbf{v}_{1:r-1};$   
 $U_{1:r-1,j} \leftarrow \mathbf{z};$   
Update  $\mathbf{v}_{r:m} \leftarrow \mathbf{v}_{r:m} - L_{r:m,1:r-1} \cdot \mathbf{z};$   
Find  $\mu$  such that  $|v_\mu| = \max_{r \leq i \leq m} |v_i|$   
If  $v_\mu \neq 0$ , then  
 $\pi_r \leftarrow \mu$   
Exchange  $v_\mu \leftrightarrow v_r$   
For  $i = 1$  to  $r - 1$ ,  
Exchange  $L_{\mu,i} \leftrightarrow L_{r,i}$   
 $L_{r+1:m,r} \leftarrow \mathbf{v}_{r+1:m} / v_r$   
 $U_{r,j} \leftarrow v_r$   
 $r \leftarrow r + 1$

13. The condition for skipping reduction steps ( $A_{\mu,k} \neq 0$  in Algorithm 1 and  $v_\mu \neq 0$  in Algorithm 2) indicates deficiency of column rank and the potential for an infinite number of solutions. These

conditions are sensitive to rounding errors that may occur in the calculation of those columns and as such, GEPP/PLU is applied for the most part in full column rank settings ( $\text{rank}(A) = n$ ), guaranteeing that no zero pivots are encountered and that no reduction steps are skipped.

14. Both Algorithms 1 and 2 require approximately  $\frac{2}{3}\rho^3 + \rho m(n - \rho) + \rho n(m - \rho)$  arithmetic operations. Algorithm 1 involves as a core calculation the updating of a submatrix having ever diminishing size. For large matrix dimension, the contents of this submatrix,  $A_{r+1:m, k+1:n}$ , may be widely scattered through computer memory and a performance penalty can occur in gathering the data for computation (which can be costly relative to the number of arithmetic operations that must be performed). Algorithm 2 is a reorganization that avoids excess data motion by delaying updates to columns until the step within which they have zeros introduced. This forces modifications to the matrix entries to be made just one column at a time and the necessary data motion can be more efficient.
15. Other strategies for avoiding the adverse effects of small pivots exist. Some are more aggressive than partial pivoting in producing the largest possible pivot, others are more restrained.

“Complete pivoting” uses both row and column permutations to bring in the largest possible pivot: If zeros are to be introduced into the  $k^{\text{th}}$  column in row entries  $r + 1$  to  $m$ , then one seeks indices  $\mu$  and  $\nu$  such that  $r \leq \mu \leq m$  and  $k < \nu \leq n$  such that  $|A_{\mu, \nu}| = \max_{\substack{r \leq i \leq m \\ k < j \leq n}} |A_{i, j}|$ . Gauss elimination with complete pivoting produces a unit lower triangular matrix  $L \in \mathbb{R}^{m \times m}$ , an upper triangular matrix  $U \in \mathbb{R}^{m \times n}$ , and two permutation matrices,  $P$  and  $Q$ , so that  $PAQ = LU$ .

“Threshold pivoting” identifies pivot candidates in each step that achieve a significant (pre-determined) fraction of the magnitude of the pivot that would have been used in that step for partial pivoting: Consider all  $\hat{\mu}$  such that  $r \leq \hat{\mu} \leq m$  and  $|A_{\hat{\mu}, k}| \geq \tau \cdot \max_{r \leq i \leq m} |A_{i, k}|$ , where  $\tau \in (0, 1)$  is a given threshold. This allows pivots to be chosen on the basis of other criteria such as influence on sparsity while still providing some protection from instability.  $\tau$  can often be chosen quite small ( $\tau = 0.1$  or  $\tau = 0.025$  are typical values).

16. If  $\hat{P} \in \mathbb{R}^{m \times m}$ ,  $\hat{L} \in \mathbb{R}^{m \times m}$ , and  $\hat{U} \in \mathbb{R}^{m \times n}$  are the computed permutation matrix and  $LU$  factors from either Algorithm 1 or 2 on  $A \in \mathbb{R}^{m \times n}$ , then

$$\hat{L}\hat{U} = \hat{P}(A + \delta A) \quad \text{with} \quad |\delta A| \leq \frac{2n\epsilon}{1-n\epsilon} |\hat{L}||\hat{U}|$$

and for the particular case that  $m = n$  and  $A$  is nonsingular, if an approximate solution,  $\hat{\mathbf{x}}$ , to  $A\mathbf{x} = \mathbf{b}$  is computed by solving the two triangular linear systems,  $\hat{L}\mathbf{y} = \hat{P}\mathbf{b}$  and  $\hat{U}\hat{\mathbf{x}} = \mathbf{y}$ , then  $\hat{\mathbf{x}}$  is the exact solution to a perturbed linear system:

$$(A + \delta A)\hat{\mathbf{x}} = \mathbf{b} \quad \text{with} \quad |\delta A| \leq \frac{2n\epsilon}{1-n\epsilon} \hat{P}^T |\hat{L}||\hat{U}|.$$

Furthermore,  $|L_{i, j}| \leq 1$  and  $|U_{i, j}| \leq 2^{i-1} \max_{k \leq i} |A_{k, j}|$ , so

$$\|\delta A\|_{\infty} \leq \frac{2^n n^2 \epsilon}{1 - n\epsilon} \|A\|_{\infty}.$$

### Examples:

- Using Algorithm 1, find a permuted LU factorization of

$$A = \begin{bmatrix} 1 & 1 & 2 & 2 \\ 2 & 2 & 4 & 6 \\ -1 & -1 & -1 & 1 \\ 1 & 1 & 3 & 1 \end{bmatrix}.$$

Setup:	$\mathbf{p} = [1\ 2\ 3\ 4], r \leftarrow 1$
$k = 1$ step:	$\mu \leftarrow 2, \mathbf{p} = [2\ 1\ 3\ 4]$
	Permuted A: $\begin{bmatrix} 2 & 2 & 4 & 6 \\ 1 & 1 & 2 & 3 \\ -1 & -1 & -2 & 1 \\ 1 & 1 & 3 & 1 \end{bmatrix}$
LU snapshot:	$L = \begin{bmatrix} 1 & 0 & 0 & 0 \\ \frac{1}{2} & 1 & 0 & 0 \\ -\frac{1}{2} & 0 & 1 & 0 \\ \frac{1}{2} & 0 & 0 & 1 \end{bmatrix}$ and $U = \begin{bmatrix} 2 & 2 & 4 & 6 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$ .
	Updated $A_{2:4,2:4}$ : $\begin{bmatrix} 0 & 0 & -1 \\ 0 & 1 & 4 \\ 0 & 1 & -2 \end{bmatrix}$
	$r \leftarrow 2$
$k = 2$ step:	$\mu \leftarrow 2,  A_{2,2}  = \max_{2 \leq i \leq 4}  A_{i,2}  = 0$
$k = 3$ step:	$\mu \leftarrow 3, \mathbf{p} = [2\ 3\ 1\ 4],  A_{3,3}  = \max_{2 \leq i \leq 4}  A_{i,3}  = 1$
	Permuted $A_{2:4,3:4}$ : $\begin{bmatrix} 1 & 4 \\ 0 & -1 \\ 1 & -2 \end{bmatrix}$
LU snapshot:	$L = \begin{bmatrix} 1 & 0 & 0 & 0 \\ -\frac{1}{2} & 1 & 0 & 0 \\ \frac{1}{2} & 0 & 1 & 0 \\ \frac{1}{2} & 1 & 0 & 1 \end{bmatrix}$ and $U = \begin{bmatrix} 2 & 2 & 4 & 6 \\ 0 & 0 & 1 & 4 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$ .
	Updated $A_{3:4,4}$ : $\begin{bmatrix} -1 \\ -6 \end{bmatrix}$
	$r \leftarrow 3$
$k = 4$ step:	$\mu \leftarrow 4, \mathbf{p} = [2\ 3\ 4\ 1],  A_{4,4}  = \max_{3 \leq i \leq 4}  A_{i,4}  = 6$
	Permuted $A_{2:4,3:4}$ : $\begin{bmatrix} -6 \\ -1 \end{bmatrix}$
LU snapshot:	$L = \begin{bmatrix} 1 & 0 & 0 & 0 \\ -\frac{1}{2} & 1 & 0 & 0 \\ \frac{1}{2} & 1 & 1 & 0 \\ \frac{1}{2} & 0 & \frac{1}{6} & 1 \end{bmatrix}$ and $U = \begin{bmatrix} 2 & 2 & 4 & 6 \\ 0 & 0 & 1 & 4 \\ 0 & 0 & 0 & -6 \\ 0 & 0 & 0 & 0 \end{bmatrix}$ .

The permutation matrix associated with  $\mathbf{p} = [2\ 3\ 4\ 1]$  is

$$P = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{bmatrix}$$

and

$$PA = \begin{bmatrix} 2 & 2 & 4 & 6 \\ -1 & -1 & -1 & 1 \\ 1 & 1 & 3 & 1 \\ 1 & 1 & 2 & 2 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ -\frac{1}{2} & 1 & 0 & 0 \\ \frac{1}{2} & 1 & 1 & 0 \\ \frac{1}{2} & 0 & \frac{1}{6} & 1 \end{bmatrix} \begin{bmatrix} 2 & 2 & 4 & 6 \\ 0 & 0 & 1 & 4 \\ 0 & 0 & 0 & -6 \\ 0 & 0 & 0 & 0 \end{bmatrix} = L \cdot U.$$

2. Using Algorithm 2, solve the system of linear equations

$$\begin{bmatrix} 1 & 3 & 1 \\ 2 & 2 & -1 \\ 2 & -1 & 0 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 1 \\ -3 \\ 3 \end{bmatrix}.$$

Phase 1: Find permuted LU decomposition.

$r \leftarrow 1$

---

$$j = 1 \text{ step: } \mathbf{v} \leftarrow \begin{bmatrix} 1 \\ 2 \\ 2 \end{bmatrix}, \pi_1 \leftarrow \mu = 2. \text{ Permuted } \mathbf{v}: \begin{bmatrix} 2 \\ 1 \\ 2 \end{bmatrix}$$

$$LU \text{ snapshot: } \pi = [2] \quad L = \begin{bmatrix} 1 & 0 & 0 \\ \frac{1}{2} & 1 & 0 \\ 1 & 0 & 1 \end{bmatrix} \quad \text{and} \quad U = \begin{bmatrix} 2 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

$r \leftarrow 2$

---

$$j = 2 \text{ step: } \mathbf{v} \leftarrow \begin{bmatrix} 3 \\ 2 \\ -1 \end{bmatrix}, \text{ Permuted } \mathbf{v}: \begin{bmatrix} 2 \\ 3 \\ -1 \end{bmatrix}.$$

$$\text{Solve } \mathbf{1} \cdot \mathbf{z} = 2. U_{1,2} \leftarrow \mathbf{z} = [2].$$

$$\begin{bmatrix} v_2 \\ v_3 \end{bmatrix} \leftarrow \begin{bmatrix} 2 \\ -3 \end{bmatrix} = \begin{bmatrix} 3 \\ -1 \end{bmatrix} - \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix} [2]$$

$$\pi_2 \leftarrow \mu = 3. L_{3,2} \leftarrow -\frac{2}{3} \text{ and } U_{2,2} \leftarrow -3$$

$$LU \text{ snapshot: } \pi = [2, 3] \quad L = \begin{bmatrix} 1 & 0 & 0 \\ 1 & 1 & 0 \\ \frac{1}{2} & -\frac{2}{3} & 1 \end{bmatrix} \quad \text{and} \quad U = \begin{bmatrix} 2 & 2 & 0 \\ 0 & -3 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

$r \leftarrow 3$

---

$$j = 3 \text{ step: } \mathbf{v} \leftarrow \begin{bmatrix} 1 \\ -1 \\ 0 \end{bmatrix}, \text{ Permuted } \mathbf{v}: \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}, \text{ Solve } \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix} \cdot \mathbf{z} = \begin{bmatrix} -1 \\ 0 \end{bmatrix},$$

$$\begin{bmatrix} U_{1,3} \\ U_{2,3} \end{bmatrix} \leftarrow \mathbf{z} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}, v_3 \leftarrow 2\frac{1}{6} = 1 - [\frac{1}{2}, -\frac{2}{3}] \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

$$\pi_3 \rightarrow 3 \text{ and } U_{3,3} \leftarrow 2\frac{1}{6}$$

$$LU \text{ snapshot: } \pi = [2, 3, 3] \quad L = \begin{bmatrix} 1 & 0 & 0 \\ 1 & 1 & 0 \\ \frac{1}{2} & -\frac{2}{3} & 1 \end{bmatrix} \quad \text{and} \quad U = \begin{bmatrix} 2 & 2 & -1 \\ 0 & -3 & 1 \\ 0 & 0 & 2\frac{1}{6} \end{bmatrix}.$$

The permutation matrix associated with  $\pi$  is  $P = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix}$  and

$$PA = \begin{bmatrix} 2 & 2 & -1 \\ 2 & -1 & 0 \\ 1 & 3 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 1 & 1 & 0 \\ \frac{1}{2} & -\frac{2}{3} & 1 \end{bmatrix} \begin{bmatrix} 2 & 2 & -1 \\ 0 & -3 & 1 \\ 0 & 0 & 2\frac{1}{6} \end{bmatrix} = L \cdot U.$$

Phase 2: Solve the lower triangular system  $L\mathbf{y} = P\mathbf{b}$ .

$$\begin{bmatrix} 1 & 0 & 0 \\ 1 & 1 & 0 \\ \frac{1}{2} & -\frac{2}{3} & 1 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \\ y_3 \end{bmatrix} = \begin{bmatrix} -3 \\ 3 \\ 1 \end{bmatrix} \Rightarrow y_1 = -3, y_2 = 6, y_3 = 6\frac{1}{2}.$$

Phase 3: Solve the upper triangular system  $U\mathbf{x} = \mathbf{y}$ .

$$\begin{bmatrix} 2 & 2 & -1 \\ 0 & -3 & 1 \\ 0 & 0 & 2\frac{1}{6} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} -3 \\ 6 \\ 6\frac{1}{2} \end{bmatrix} \Rightarrow x_1 = 1, x_2 = -1, x_3 = 3.$$

### 38.4 Orthogonalization and QR Decomposition

The process of transforming an arbitrary linear system into a triangular system may also be approached by systematically introducing zeros into the coefficient matrix with unitary transformations: Given a system  $A\mathbf{x} = \mathbf{b}$ , find unitary matrices  $V_1, V_2, \dots, V_\ell$  such that  $V_\ell \dots V_2 V_1 A = T$  is triangular; calculate  $\mathbf{y} = V_\ell \dots V_2 V_1 \mathbf{b}$ ; solve the triangular system  $T\mathbf{x} = \mathbf{y}$ .

There are two different types of rudimentary unitary transformations that are described here: Householder transformations and Givens transformations.

**Definitions:**

Let  $\mathbf{v} \in \mathbb{C}^n$  be a nonzero vector. The matrix  $H = I - \frac{2}{\|\mathbf{v}\|_2^2} \mathbf{v}\mathbf{v}^*$  is called a **Householder transformation** (or **Householder reflector**). In this context,  $\mathbf{v}$ , is called a **Householder vector**.

For  $\theta, \vartheta \in [0, 2\pi)$ , let  $G(i, j, \theta, \vartheta)$  be an  $n \times n$  identity matrix modified so that the  $(i, i)$  and  $(j, j)$  entries are replaced by  $c = \cos(\theta)$ , the  $(i, j)$  entry is replaced by  $s = e^{i\vartheta} \sin(\theta)$ , and the  $(j, i)$  entry is replaced by  $-\bar{s} = -e^{-i\vartheta} \sin(\theta)$ :

$$G(i, j, \theta, \vartheta) = \begin{bmatrix} 1 & \dots & 0 & \dots & 0 & \dots & 0 \\ \vdots & \ddots & \vdots & & \vdots & & \vdots \\ 0 & \dots & c & \dots & s & \dots & 0 \\ \vdots & & \vdots & \ddots & \vdots & & \vdots \\ 0 & \dots & -\bar{s} & \dots & c & \dots & 0 \\ \vdots & & \vdots & & \vdots & \ddots & \vdots \\ 0 & \dots & 0 & \dots & 0 & \dots & 1 \end{bmatrix}.$$

$G(i, j, \theta, \vartheta)$  is called a **Givens transformation** (or **Givens rotation**).

**Facts:** [GV96]

1. Householder transformations are unitary matrices.
2. Let  $\mathbf{a} \in \mathbb{C}^n$  be a nonzero vector. Define  $\mathbf{v} = \text{sign}(a_1)\|\mathbf{a}\|\mathbf{e}_1 + \mathbf{a}$  with  $\mathbf{e}_1 = [1, 0, \dots, 0]^T \in \mathbb{C}^n$ . Then the Householder transformation  $H = I - \frac{2}{\|\mathbf{v}\|_2^2} \mathbf{v}\mathbf{v}^*$  satisfies

$$H\mathbf{a} = \alpha\mathbf{e}_1 \quad \text{with} \quad \alpha = -\text{sign}(a_1)\|\mathbf{a}\|.$$

3. [GV96, pp. 210–213]

**Algorithm 3:** Householder QR Factorization:

Input: matrix  $A \in \mathbb{C}^{m \times n}$  with  $m \geq n$

Output: the QR factorization  $A = QR$ , where the upper triangular part of  $R$  is stored in the upper triangular part of  $A$

$Q = I_m$

For  $k = 1 : n$

$\mathbf{x} = A_{k:m,k}$

$\mathbf{v}_k = \text{sign}(x_1)\|\mathbf{x}\|\mathbf{e}_1 + \mathbf{x}$ , where  $\mathbf{e}_1 \in \mathbb{C}^{m-k+1}$

$\mathbf{v}_k = \mathbf{v}_k / \|\mathbf{v}_k\|$

$A_{k:m,k:n} = (I_{m-k+1} - 2\mathbf{v}_k\mathbf{v}_k^*)A_{k:m,k:n}$

$Q_{1:k-1,k:m} = Q_{1:k-1,k:m}(I_{m-k+1} - 2\mathbf{v}_k\mathbf{v}_k^*)$

$Q_{k:m,k:m} = Q_{k:m,k:m}(I_{m-k+1} - 2\mathbf{v}_k\mathbf{v}_k^*)$

4. [GV96, p. 215] A Givens rotation is a unitary matrix.
5. [GV96, pp. 216–221] For any scalars  $x, y \in \mathbb{C}$ , there exists a Givens rotation  $G \in \mathbb{C}^{2 \times 2}$  such that

$$G \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} c & s \\ -\bar{s} & c \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} r \\ 0 \end{bmatrix},$$

where  $c, s$ , and  $r$  can be computed via

- If  $y = 0$  (includes the case  $x = y = 0$ ), then  $c = 1, s = 0, r = x$ .
  - If  $x = 0$  ( $y$  must be nonzero), then  $c = 0, s = \text{sign}(\bar{y}), r = |y|$ .
  - If both  $x$  and  $y$  are nonzero, then  $c = |x|/\sqrt{|x|^2 + |y|^2},$   
 $s = \text{sign}(x)\bar{y}/\sqrt{|x|^2 + |y|^2}, r = \text{sign}(x)\sqrt{|x|^2 + |y|^2}.$
6. [GV96, pp. 226–227]

**Algorithm 4:** Givens QR Factorization

Input: matrix  $A \in \mathbb{C}^{m \times n}$  with  $m \geq n$

Output: the QR factorization  $A = QR$ , where the upper triangular part of  $R$  is stored in the upper triangular part of  $A$

$Q = I_m$

For  $k = 1 : n$

For  $i = k + 1 : m$

$[x, y] = [A_{kk}, A_{ik}]$

Compute  $G = \begin{bmatrix} c & s \\ -\bar{s} & c \end{bmatrix}$  via Fact 5.

$\begin{bmatrix} A_{k,k:n} \\ A_{i,k:n} \end{bmatrix} = G \begin{bmatrix} A_{k,k:n} \\ A_{i,k:n} \end{bmatrix}$

$[Q_{1:m,k}, Q_{1:m,i}] = [Q_{1:m,k}, Q_{1:m,i}]G^*$

7. [GV96, p. 212] In many applications, it is not necessary to compute  $Q$  explicitly in Algorithm 3 and Algorithm 4. See also [TB97, p. 74] for details.
8. [GV96, pp. 225–227] If  $A \in \mathbb{R}^{m \times n}$  with  $m \geq n$ , then the cost of Algorithm 3 without explicitly computing  $Q$  is  $2n^2(m - n/3)$  flops and the cost of Algorithm 4 without explicitly computing  $Q$  is  $3n^2(m - n/3)$  flops.
9. [Mey00, p. 349] Algorithm 3 and Algorithm 4 are numerically stable for computing the QR factorization.

**Examples:**

1. We shall use Givens rotations to transform  $A = \begin{bmatrix} 1 & 1 \\ 1 & 2 \\ 1 & 3 \end{bmatrix}$  to upper triangular form, as in Algorithm 4.

First, to annihilate the element in position (2,1), we use Fact 5 with  $(x, y) = (1, 1)$  and obtain  $c = s = 1/\sqrt{2}$ ; hence:

$$A^{(1)} = G_1 A = \begin{bmatrix} 0.7071 & 0.7071 & 0 \\ -0.7071 & 0.7071 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 1 & 2 \\ 1 & 3 \end{bmatrix} = \begin{bmatrix} 1.4142 & 2.1213 \\ 0 & 0.7071 \\ 1 & 3 \end{bmatrix}.$$

Next, to annihilate the element in position (3,1), we use  $(x, y) = (1.4142, 1)$  in Fact 5 and get

$$A^{(2)} = G_2 A^{(1)} = \begin{bmatrix} 0.8165 & 0 & 0.5774 \\ 0 & 1 & 0 \\ -0.5774 & 0 & 0.8165 \end{bmatrix} A^{(1)} = \begin{bmatrix} 1.7321 & 3.4641 \\ 0 & 0.7071 \\ 0 & 1.2247 \end{bmatrix}.$$

Finally, we annihilate the element in position (3,2) using  $(x, y) = (.7071, 1.2247)$ :

$$A^{(3)} = G_3 A^{(2)} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0.5000 & 0.8660 \\ 0 & -0.8660 & 0.5000 \end{bmatrix} A^{(2)} = \begin{bmatrix} 1.7321 & 3.4641 \\ 0 & 1.4142 \\ 0 & 0 \end{bmatrix}.$$

As a result,  $R = A^{(3)}$  and  $\widehat{R}$  consists of the first two rows of  $A^{(3)}$ . The matrix  $Q$  can be computed as the product  $G_1^T G_2^T G_3^T$ .

2. We shall use Householder reflections to transform  $A$  from Example 1 to upper triangular form as in Algorithm 3. First, let  $\mathbf{a} = A_{:,1} = [1 \ 1 \ 1]^T$ ,  $\gamma_1 = -\sqrt{3}$ ,  $\widehat{\mathbf{a}} = [-\sqrt{3} \ 0 \ 0]^T$ , and  $\mathbf{u}_1 = [0.8881 \ 0.3251 \ 0.3251]^T$ ; then

$$A^{(1)} = (I - 2\mathbf{u}_1 \mathbf{u}_1^T) A = A - \mathbf{u}_1 \overbrace{\begin{bmatrix} 3.0764 & 5.0267 \end{bmatrix}}^{2\mathbf{u}_1^T A} = \begin{bmatrix} -1.7321 & -3.4641 \\ 0 & 0.3660 \\ 0 & 1.3660 \end{bmatrix}.$$

Next,  $\gamma_2 = -\|A_{2:3,2}^{(1)}\|_2$ ,  $\mathbf{u}_2 = [0 \ 0.7934 \ 0.6088]^T$ , and

$$A^{(2)} = (I - 2\mathbf{u}_2 \mathbf{u}_2^T) A^{(1)} = A^{(1)} - \mathbf{u}_2 \overbrace{\begin{bmatrix} 0 & 2.2439 \end{bmatrix}}^{2\mathbf{u}_2^T A^{(1)}} = \begin{bmatrix} -1.7321 & -3.4641 \\ 0 & -1.4142 \\ 0 & 0 \end{bmatrix}.$$

Note that  $R = A^{(2)}$  has changed sign as compared with Example 1. The matrix  $Q$  can be computed as  $(I - 2\mathbf{u}_1 \mathbf{u}_1^T)(I - 2\mathbf{u}_2 \mathbf{u}_2^T)$ . Therefore, we have full information about the transformation if we store the vectors  $\mathbf{u}_1$  and  $\mathbf{u}_2$ .

## 38.5 Symmetric Factorizations

Real symmetric matrices ( $A = A^T$ ) and their complex analogs, Hermitian matrices (Chapter 8), are specified by roughly half the number of parameters than general  $n \times n$  matrices, so one could anticipate benefits that take advantage of this structure.

### Definitions:

An  $n \times n$  matrix,  $A$ , is **Hermitian** if  $A = A^* = \bar{A}^T$ .

$A \in \mathbb{C}^{n \times n}$  is **positive-definite** if  $\mathbf{x}^* A \mathbf{x} > 0$  for all  $\mathbf{x} \in \mathbb{C}^n$  with  $\mathbf{x} \neq 0$ .

The **Cholesky decomposition** (or **Cholesky factorization**) of a positive-definite matrix  $A$  is  $A = G G^*$  with  $G \in \mathbb{C}^{n \times n}$  lower triangular and having positive diagonal entries.

**Facts:** [Hig96], [GV96]

1. A positive-definite matrix is Hermitian. Note that the similar but weaker assertion for a matrix  $A \in \mathbb{R}^{n \times n}$  that “ $\mathbf{x}^T A \mathbf{x} > 0$  for all  $\mathbf{x} \in \mathbb{R}^n$  with  $\mathbf{x} \neq 0$ ” does not imply that  $A = A^T$ .

- If  $A \in \mathbb{C}^{n \times n}$  is positive-definite, then  $A$  has an  $LU$  decomposition,  $A = LU$ , and the diagonal of  $U$ ,  $\{u_{11}, u_{22}, \dots, u_{nn}\}$ , has strictly positive entries.
- If  $A \in \mathbb{C}^{n \times n}$  is positive-definite, then the  $LU$  decomposition of  $A$  satisfies  $A = LU$  with  $U = DL^*$  and  $D = \text{diag}(U)$ . Thus,  $A$  can be written as  $A = LDL^*$  with  $L$  unit lower triangular and  $D$  diagonal with positive diagonal entries. Furthermore,  $A$  has a Cholesky decomposition  $A = GG^*$  with  $G \in \mathbb{C}^{n \times n}$  lower triangular. Indeed, if

$$\widehat{D} = \text{diag}(\{\sqrt{u_{11}}, \sqrt{u_{22}}, \dots, \sqrt{u_{nn}}\})$$

then  $\widehat{D}\widehat{D} = D$  and  $G = L\widehat{D}$ .

- [GV96, p. 144] The Cholesky decomposition of a positive-definite matrix  $A$  can be computed directly:

**Algorithm 1:** Cholesky decomposition of a positive-definite matrix

Input:  $A \in \mathbb{C}^{n \times n}$  positive definite

Output:  $G \in \mathbb{C}^{n \times n}$  (lower triangular matrix so that  $A = GG^*$ )

$G \leftarrow 0 \in \mathbb{C}^{n \times n}$ ;

For  $j = 1$  to  $n$

$\mathbf{v} \leftarrow A_{j:n,j}$

    for  $k = 1$  to  $j - 1$ ,

$\mathbf{v} \leftarrow \mathbf{v} - \overline{G_{j,k}} G_{j:n,k}$

$G_{j:n,j} \leftarrow \frac{1}{\sqrt{v_1}} \mathbf{v}$

- Algorithm 1 requires approximately  $n^3/3$  floating point arithmetic operations and  $n$  floating point square roots to complete (roughly half of what is required for an  $LU$  decomposition).
- If  $A \in \mathbb{R}^{n \times n}$  is symmetric and positive-definite and Algorithm 1 runs to completion producing a computed Cholesky factor  $\widehat{G} \in \mathbb{R}^{n \times n}$ , then

$$\widehat{G}\widehat{G}^T = A + \delta A \quad \text{with} \quad |\delta A| \leq \frac{(n+1)\epsilon}{1-(n+1)\epsilon} |\widehat{G}| |\widehat{G}^T|.$$

Furthermore, if an approximate solution,  $\hat{\mathbf{x}}$ , to  $A\mathbf{x} = \mathbf{b}$  is computed by solving the two triangular linear systems  $\widehat{G}\mathbf{y} = \mathbf{b}$  and  $\widehat{G}^T\hat{\mathbf{x}} = \mathbf{y}$ , and a scaling matrix is defined as  $\Delta = \text{diag}(\sqrt{a_{ii}})$ , then the scaled error  $\Delta(\mathbf{x} - \hat{\mathbf{x}})$  satisfies

$$\frac{\|\Delta(\mathbf{x} - \hat{\mathbf{x}})\|_2}{\|\Delta\mathbf{x}\|_2} \leq \frac{\kappa_2(H)\epsilon}{1 - \kappa_2(H)\epsilon},$$

where  $A = \Delta H \Delta$ . If  $\kappa_2(H) \ll \kappa_2(A)$ , then it is quite likely that the entries of  $\Delta\hat{\mathbf{x}}$  will have mostly the same magnitude and so the error bound suggests that all entries of the solution will be computed to high relative accuracy.

- If  $A \in \mathbb{C}^{n \times n}$  is Hermitian and has all leading principal submatrices nonsingular, then  $A$  has an  $LU$  decomposition that can be written as  $A = LU = LDL^*$  with  $L$  unit lower triangular and  $D$  diagonal with real diagonal entries. Furthermore, the number of positive and negative entries of  $D$  is equal to the number of positive and negative eigenvalues of  $A$ , respectively (the *Sylvester law of inertia*).
- Note that it may not be prudent to compute the  $LU$  (or  $LDL^T$ ) decomposition of a Hermitian indefinite matrix  $A$  without pivoting, yet the use of pivoting will likely eliminate the advantages symmetry might offer. An alternative is a block  $LDL^T$  decomposition that incorporates a diagonal pivoting strategy (see [GV96] for details).

**Examples:**

1. Calculate the Cholesky decomposition of the  $3 \times 3$  Hilbert matrix,

$$A = \begin{bmatrix} 1 & \frac{1}{2} & \frac{1}{3} \\ \frac{1}{2} & \frac{1}{3} & \frac{1}{4} \\ \frac{1}{3} & \frac{1}{4} & \frac{1}{5} \end{bmatrix}.$$

---

Setup:	$G \leftarrow \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$
<hr/>	
$j = 1$ step:	$\mathbf{v} \leftarrow [1, \frac{1}{2}, \frac{1}{3}]^T$
$G$ snapshot:	$G = \begin{bmatrix} 1 & 0 & 0 \\ \frac{1}{2} & 0 & 0 \\ \frac{1}{3} & 0 & 0 \end{bmatrix}$
<hr/>	
$j = 2$ step:	$\mathbf{v} \leftarrow \begin{bmatrix} \frac{1}{3} \\ \frac{1}{4} \end{bmatrix} - \frac{1}{2} \begin{bmatrix} \frac{1}{2} \\ \frac{1}{3} \end{bmatrix} = \begin{bmatrix} \frac{1}{12} \\ \frac{1}{12} \end{bmatrix}$
$G$ snapshot:	$G = \begin{bmatrix} 1 & 0 & 0 \\ \frac{1}{2} & \frac{1}{2\sqrt{3}} & 0 \\ \frac{1}{3} & \frac{1}{2\sqrt{3}} & 0 \end{bmatrix}$
<hr/>	
$j = 3$ step:	$\mathbf{v} \leftarrow \frac{1}{5} - \left(\frac{1}{3}\right)^2 - \left(\frac{1}{2\sqrt{3}}\right)^2 = \frac{1}{180} = \left(\frac{1}{6\sqrt{5}}\right)^2$
$G$ snapshot:	$G = \begin{bmatrix} 1 & 0 & 0 \\ \frac{1}{2} & \frac{1}{2\sqrt{3}} & 0 \\ \frac{1}{3} & \frac{1}{2\sqrt{3}} & \frac{1}{6\sqrt{5}} \end{bmatrix}$

### 39.1 Basic Concepts

---

(See Chapter 5 for additional information.)

#### Definitions:

Given a vector  $\mathbf{b} \in \mathbb{R}^m$  and a matrix  $A \in \mathbb{R}^{m \times n}$  with  $m > n$ , the **least squares problem** is to find a vector  $\mathbf{x}_0 \in \mathbb{R}^n$  that minimizes the Euclidean length of the difference between  $A\mathbf{x}$  and  $\mathbf{b}$ :

$$\text{Problem LS: Find } \mathbf{x}_0 \text{ satisfying } \|\mathbf{b} - A\mathbf{x}_0\|_2 = \min \|\mathbf{b} - A\mathbf{x}\|_2.$$

Such an  $\mathbf{x}_0$  is called a **least squares solution**.

For any vector  $\mathbf{x}$  the vector  $\mathbf{r} = \mathbf{r}(\mathbf{x}) = \mathbf{b} - A\mathbf{x}$  is the **residual vector**. The residual of a least squares solution is denoted by  $\mathbf{r}_0$ . The least squares problem is **consistent** if  $\mathbf{b} \in \text{range}(A)$ .

A **basic solution**,  $\mathbf{x}_{0B}$ , is a least squares solution with at least  $n - \text{rank}(A)$  zero components. The **minimum-norm least squares solution**,  $\mathbf{x}_{0M}$ , is the least squares solution of minimum Euclidean norm.

In a **weighted least squares problem**, we are also given weights  $w_i \geq 0$  for  $i = 1, \dots, m$ , and the objective is to minimize  $\|W(\mathbf{b} - A\mathbf{x})\|_2$ , where  $W = \text{diag}(w_1, \dots, w_m)$ . This is an important special case of the **generalized least squares problem**:

$$\text{Problem GLS: Let } A\mathbf{x} + B\mathbf{v} = \mathbf{b}, \text{ where } B \in \mathbb{R}^{m \times p} \text{ with } p \leq m. \\ \text{Find } \mathbf{x}_G, \mathbf{v}_G \text{ such that } \|\mathbf{v}\|_2 \text{ is minimized.}$$

Note that  $B\mathbf{v}$  plays the role of the residual vector.

In the **total least squares problem**, we allow for errors both in the vector  $\mathbf{b}$  and in the matrix  $A$ :

**Problem TLS:** Let  $(A + E)\mathbf{x} + \mathbf{r} = \mathbf{b}$ , where  $E \in \mathbb{R}^{m \times n}$  with  $n \leq m$ .  
Find  $\mathbf{x}_T$  such that  $\|(E, \mathbf{r})\|_F$  is minimized.

$\|\cdot\|_F$  denotes the Frobenius norm.

In this chapter,  $A_{i,\cdot}$  and  $A_{\cdot,j}$  denote the vectors given by the elements in the  $i$ th row and  $j$ th column of matrix  $A$ , respectively. Similarly,  $A_{k:l,\cdot}$  (or  $A_{\cdot,k:l}$ ) is the submatrix consisting of rows (or columns)  $k$  through  $l$  of  $A$ .

In the examples in this chapter, the computation is done with about 16 digits accuracy, but the displayed results are rounded to fewer digits.

### Facts:

(See, e.g., Chapters 1 and 2 in [Bjo96].)

1. If  $m > n = \text{rank}(A)$ , then the least squares solution  $\mathbf{x}_0$  is analytically equivalent to the solution to the *normal equations*  $A^T A \mathbf{x} = A^T \mathbf{b}$ .
2. If the least squares problem is consistent, then  $\mathbf{r}_0 = \mathbf{0}$ .
3. The least squares solution is unique if  $m \geq n$  and  $A$  has full rank.
4. If the system is underdetermined ( $m < n$ ) or if  $A$  is rank deficient, then the solution to Problem LS is not unique. Also, a basic solution is not unique.
5. The minimum-norm least squares solution  $\mathbf{x}_{0M}$  is always unique.
6. If  $m > n = \text{rank}(A)$ , then the least squares solution can be written as  $\mathbf{x}_0 = A^\dagger \mathbf{b}$ , where the matrix  $A^\dagger$  is the Moore–Penrose generalized inverse or pseudoinverse of  $A$ . (See Section 5.7.) In general,  $A^\dagger$  produces the minimum-norm solution:  $\mathbf{x}_{0M} = A^\dagger \mathbf{b}$ .
7. If  $B$  is nonsingular, then  $\mathbf{x}_G$  minimizes  $\|B^{-1}(\mathbf{b} - A\mathbf{x})\|_2$ .
8. If the covariance matrix for  $\mathbf{b}$  has the Cholesky factorization  $\text{Cov}(\mathbf{b}) = C^T C$ , then  $\mathbf{x}_G$  is the *best linear unbiased estimate* (BLUE) in the general linear model with  $B = C^T$ .
9. If  $\text{Cov}(\mathbf{b})$  has full rank, then  $\mathbf{x}_G$  is the solution to the least squares problem  $\min \|C^{-T}(\mathbf{b} - A\mathbf{x})\|_2$ .
10. In particular, if  $\text{Cov}(\mathbf{b}) = \sigma^2 I$ , then  $\mathbf{x}_G = \mathbf{x}_0$  and  $\text{Cov}(\mathbf{x}_0) = \sigma^2 (A^T A)^{-1}$ .
11. An English translation of the original work on least squares problems by C. F. Gauss is available in [Gau95].

### Examples:

1. Consider problem LS with  $m = 3$  and  $n = 2$ :

$$\min \left\| \begin{bmatrix} 1 & 1 \\ 1 & 2 \\ 1 & 3 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} - \begin{bmatrix} 0.75 \\ 1.13 \\ 1.39 \end{bmatrix} \right\|_2.$$

The associated normal equations and the least squares solution are

$$\begin{bmatrix} 3 & 6 \\ 6 & 14 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 3.27 \\ 7.18 \end{bmatrix}, \quad \mathbf{x}_0 = \begin{bmatrix} 0.45 \\ 0.32 \end{bmatrix}.$$

The residual vector corresponding to  $\mathbf{x}_0$  is

$$\mathbf{r}_0 = \mathbf{r}(\mathbf{x}_0) = \mathbf{b} - A\mathbf{x}_0 = \begin{bmatrix} -0.02 \\ 0.04 \\ -0.02 \end{bmatrix},$$

and  $A^T \mathbf{r}_0 = \mathbf{0}$ .

2. If we use the weights  $w_1 = 10$  and  $w_2 = w_3 = 1$ , the problem is changed to

$$\min \left\| \begin{bmatrix} 10 & 10 \\ 1 & 2 \\ 1 & 3 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} - \begin{bmatrix} 7.5 \\ 1.13 \\ 1.39 \end{bmatrix} \right\|_2$$

whose least squares solution and corresponding residual are

$$\mathbf{x}_0 = \begin{bmatrix} 0.41838 \\ 0.33186 \end{bmatrix}, \quad \mathbf{r}_0 = \begin{bmatrix} -0.00024 \\ 0.04790 \\ -0.02395 \end{bmatrix}.$$

Note that the first component of  $\mathbf{r}_0$  is reduced when  $w_1$  is increased from 1 to 10.

## 39.2 Least Squares Data Fitting

---

### Definitions:

Given  $m$  data points  $(t_i, y_i)$ ,  $i = 1, \dots, m$ , and  $n$  linearly independent functions  $f_j$ ,  $j = 1, \dots, n$  (with  $m > n$ ), find the linear combination

$$F(\mathbf{x}, t) = \sum_{j=1}^n x_j f_j(t)$$

that minimizes the sum of squared residuals  $y_i - F(\mathbf{x}, t_i)$  at the data points:

$$\min_{\mathbf{x}} \sum_{i=1}^m (y_i - F(\mathbf{x}, t_i))^2.$$

The coefficients  $x_i$  are the components of the least squares solution to  $\min \|\mathbf{b} - A\mathbf{x}\|_2$ , where the columns  $A_{:,j}$  of  $A$  are samples of  $f_j$  at  $t_i$  and the elements of  $\mathbf{b}$  are the values  $y_i$ :

$$A_{ij} = f_j(t_i), \quad b_i = y_i, \quad i = 1, \dots, m \quad j = 1, \dots, n.$$

The solution  $F(\mathbf{x}_0, t)$  is said to fit the data in the least squares sense.

### Facts:

(See, e.g., Chapter 4 in [Bjo96].)

1. The fit can be made more robust to outliers by solving a weighted least squares problem  $\min \|W(\mathbf{b} - A\mathbf{x})\|_2$  with  $W = \text{diag}(w_1, \dots, w_m)$ ,  $w_i = \psi(r_i) = \psi(b_i - A_{i,:}\mathbf{x})$ ;  $\psi$  being a convex function. This problem is usually solved by an iteratively reweighted least squares algorithm.
2. In orthogonal distance fitting, instead of minimizing the residuals one minimizes the orthogonal distances between the fitting function  $F$  and the data points. Important examples are fitting of a circle, an arc, or an ellipse to data points.

### Examples:

1. Given  $f_1(t) = 1$  and  $f_2(t) = t$ , find the least squares fit to the data points  $(1, 0.75)$ ,  $(2, 1.13)$ , and  $(3, 1.39)$ . We get the  $A$ ,  $\mathbf{b}$ , and  $\mathbf{x}_0$  from Example 1 in section 39.1, and

$$F(\mathbf{x}_0, t) = 0.45 + 0.32t.$$

If the third data point is changed to  $(3, 13.9)$ , then the least squares solution changes to  $\mathbf{x}_0 = (-7.890, 6.575)^T$ , and the least squares fit becomes  $F(\mathbf{x}_0, t) = -7.890 + 6.575t$ ; this illustrates the sensitivity to outliers.

### 39.3 Geometric and Algebraic Aspects

#### Definitions:

The columns of  $A \in \mathbb{R}^{m \times n}$  span the **range of  $A$** , while the **nullspace** or **kernel** of  $A$  is the set of solutions to the homogeneous system  $A\mathbf{x} = \mathbf{0}$ :

$$\text{range}(A) = \{\mathbf{z} = A\mathbf{x} \mid \mathbf{x} \in \mathbb{R}^n\}, \quad \ker(A) = \{\mathbf{x} \in \mathbb{R}^n \mid A\mathbf{x} = \mathbf{0}\}.$$

The four **fundamental subspaces** associated with Problem LS are  $\text{range}(A)$ ,  $\ker(A^T)$ ,  $\ker(A)$ , and  $\text{range}(A^T)$ . (See Section 2.4 for more information.)

#### Facts:

The first three facts can be found in [Str88, Sec. 2.4]; the remaining facts are discussed in [Bjo96, Chap. 1].  $p$  denotes the rank of  $A$ :  $p = \text{rank}(A)$ .

1. If  $p = n < m$ , then the vector  $\mathbf{0}$  of all zeros is the only element in  $\ker(A)$ .
2. The spaces  $\text{range}(A)$  and  $\ker(A^T)$  are subspaces of  $\mathbb{R}^m$  with dimensions  $p$  and  $m-p$ , respectively. The two spaces are orthogonal complements, i.e.,  $\mathbf{y}^T \mathbf{z} = 0$  for any pair  $(\mathbf{y} \in \text{range}(A), \mathbf{z} \in \ker(A^T))$ , and  $\text{range}(A) \oplus \ker(A^T) = \mathbb{R}^m$ .
3. The spaces  $\ker(A)$  and  $\text{range}(A^T)$  are subspaces of  $\mathbb{R}^n$  with dimensions  $n-p$  and  $p$ , respectively. The two spaces are orthogonal complements.
4. The least squares residual vector  $\mathbf{r}_0 = \mathbf{b} - A\mathbf{x}_0$  is an element in  $\ker(A^T)$ . Combining this with the definition of  $\mathbf{r}$ , we get the so-called **augmented system** associated with Problem LS:

$$\begin{bmatrix} I & A \\ A^T & 0 \end{bmatrix} \begin{bmatrix} \mathbf{r} \\ \mathbf{x} \end{bmatrix} = \begin{bmatrix} \mathbf{b} \\ \mathbf{0} \end{bmatrix}.$$

If  $p = n$ , then the augmented system is nonsingular and the solution components are  $\mathbf{r}_0$  and  $\mathbf{x}_0$ .

5. The vector  $A\mathbf{x}_0$  is the orthogonal projection of  $\mathbf{b}$  onto  $\text{range}(A)$ .
6. The vector  $\mathbf{r}_0$  is the orthogonal projection of  $\mathbf{b}$  onto  $\ker(A^T)$ .
7. If  $p < n$ , then the columns in  $A$  can be reordered such that  $A\Pi = [\tilde{A} \quad \hat{A}]$ , where  $\Pi$  is a permutation matrix and the submatrix  $\tilde{A}$  has  $p$  columns,  $\text{range}(A) = \text{range}(\tilde{A})$ . The permutation is not unique.
8. The orthogonal projectors onto  $\text{range}(A)$  and  $\ker(A)$  are given by  $AA^\dagger$  and  $I - A^\dagger A$ , respectively.

#### Examples:

1. The Figure 39.1 illustrates Facts 5 and 6 in the case  $m = 3, n = p = 2$ .

FIGURE 39.1

2. For the problem in Example 1 in Section 39.1, both  $\text{range}(A)$  and  $\ker(A^T)$  are subspaces of  $\mathbb{R}^3$  given by, respectively,

$$\text{range}(A) = \alpha \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + \beta \begin{bmatrix} 1 \\ 2 \\ 3 \end{bmatrix}, \quad \ker(A^T) = \gamma \begin{bmatrix} 1 \\ -2 \\ 1 \end{bmatrix},$$

with  $\alpha, \beta, \gamma \in \mathbb{R}$ .

3. Fact 4 can be used to derive the normal equations:

$$\mathbf{r} = \mathbf{b} - A\mathbf{x} \in \ker(A^T) \Rightarrow A^T(\mathbf{b} - A\mathbf{x}) = \mathbf{0}.$$

## 39.4 Orthogonal Factorizations

(See Section 5.5 and Section 38.4 for additional information on orthogonal factorizations.)

### Definitions:

The real matrix  $Q$  is **orthogonal** if it is square and satisfies  $Q^T Q = I$ .

A **QR factorization** of a matrix  $A \in \mathbb{R}^{m \times n}$  with  $m \geq n$  has the form

$$A = QR = Q \begin{bmatrix} \widehat{R} \\ 0 \end{bmatrix} = \widehat{Q} \widehat{R},$$

where  $Q \in \mathbb{R}^{m \times m}$  is orthogonal,  $R \in \mathbb{R}^{m \times n}$ ,  $\widehat{R} \in \mathbb{R}^{n \times n}$  is upper triangular, and  $\widehat{Q} = Q_{:,1:n}$ . The form  $A = \widehat{Q}\widehat{R}$  is the so-called “reduced” (or “skinny”) QR factorization.

The **singular value decomposition** (SVD) of  $A \in \mathbb{R}^{m \times n}$  has the form

$$A = U \Sigma V^T,$$

where  $U \in \mathbb{R}^{m \times m}$  and  $V \in \mathbb{R}^{n \times n}$  are orthogonal matrices and  $\Sigma = \text{diag}(\sigma_1, \dots, \sigma_r) \in \mathbb{R}^{m \times n}$  has diagonal elements

$$\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_r \geq 0, \quad r = \min\{m, n\}.$$

Letting  $\mathbf{u}_j$  and  $\mathbf{v}_j$  denote the  $j$ th column in  $U$  and  $V$ , respectively, we can write

$$A = \sum_{j=1}^r \sigma_j \mathbf{u}_j \mathbf{v}_j^T.$$

For  $k < r$  the matrix  $\sum_{j=1}^k \sigma_j \mathbf{u}_j \mathbf{v}_j^T$  is called the **truncated SVD** approximation to  $A$ . (See Sections 5.6, 17, and 45 for more information about the singular value decomposition.)

### Facts:

Except for Facts 1 and 8 see [Bjo96, Chap. 1]. Also see Section 39.5.

- [Str88, Chap. 3]. A QR factorization preserves rank:  $\text{rank}(R) = \text{rank}(\widehat{R}) = \text{rank}(A)$ .
- A QR factorization is not unique, but two factorizations  $Q_1 R_1$  and  $Q_2 R_2$  always satisfy  $\widehat{R}_1 = D \widehat{R}_2$ , where  $D$  is diagonal with  $D_{ii} = \pm 1$ .
- The triangular factor  $\widehat{R}$  and the upper triangular Cholesky factor  $C$  for the normal equations matrix  $A^T A$  always satisfy  $\widehat{R} = \widetilde{D} C$ , where  $\widetilde{D}$  is diagonal with  $\widetilde{D}_{ii} = \pm 1$ .
- If  $A$  has full rank and has the QR factorization  $A = QR$ , then  $\mathbf{x}_0$  can be found by back substitution in the upper triangular system  $\widehat{R} \mathbf{x} = Q_{:,1:n}^T \mathbf{b}$ .

5. If  $Q$  has not been saved, then we can use forward and back substitution to solve the seminormal equations:  $\widehat{R}^T \widehat{R} \mathbf{x} = A^T \mathbf{b}$ . For reasons of numerical stability, this must be followed by one step of iterative refinement; the complete process is called the *corrected seminormal equations* method.
6. Let  $\text{rank}(A) = p \leq n \leq m$  and  $A = QR$ . The columns in  $Q_{:,1:p}$  and  $Q_{:,p+1:m}$  are orthonormal bases of  $\text{range}(A)$  and  $\ker(A^T)$ , respectively.
7. Let  $A = U \Sigma V^T$ . Then  $p = \text{rank}(A)$  is equal to the number of strictly positive singular values:  $\sigma_1 \geq \dots \geq \sigma_p > 0$ ,  $\sigma_{p+1} = \dots = \sigma_{\min\{m,n\}} = 0$ . The columns in  $U_{:,1:p}$  and  $U_{:,p+1:m}$  are orthonormal bases of  $\text{range}(A)$  and  $\ker(A^T)$ , respectively, and the columns in  $V_{:,1:p}$  and  $V_{:,p+1:m}$  are orthonormal bases of  $\text{range}(A^T)$  and  $\ker(A)$ , respectively.
8. [GV96, Chap. 12]. The TLS solution can be computed as follows: compute the SVD of the coefficient matrix  $A$  augmented with the right-hand side  $\mathbf{b}$ , i.e.,  $[A, \mathbf{b}] = \widetilde{U} \widetilde{\Sigma} \widetilde{V}^T$ . If the smallest singular value  $\widetilde{\sigma}_{n+1}$  is simple, and if  $\beta = \widetilde{V}_{n+1,n+1} \neq 0$ , then

$$\mathbf{x}_T = -\beta^{-1} \widetilde{V}_{1:n,n+1}, \quad E_T = -\widetilde{\sigma}_{n+1} \widetilde{U}_{:,n+1} \widetilde{V}_{1:n,n+1}^T, \quad \mathbf{r}_T = -\widetilde{\sigma}_{n+1} \beta \widetilde{U}_{:,n+1}.$$

### Examples:

1. For the problem from Example 1 in Section 39.1, we find  $[A, \mathbf{b}] = \widetilde{U} \widetilde{\Sigma} \widetilde{V}^T$  with

$$\widetilde{\Sigma} = \text{diag} \begin{bmatrix} 4.515 \\ 0.6198 \\ 0.0429 \end{bmatrix}, \quad \widetilde{U}_{:,3} = \begin{bmatrix} 0.4248 \\ -0.8107 \\ 0.4029 \end{bmatrix}, \quad \widetilde{V}_{:,3} = \begin{bmatrix} 0.3950 \\ 0.2796 \\ -0.8751 \end{bmatrix}.$$

Thus,

$$\mathbf{x}_T = \begin{bmatrix} 0.4513 \\ 0.3195 \end{bmatrix}, \quad E_T = \begin{bmatrix} -0.0072 & -0.0051 \\ 0.0137 & 0.0097 \\ -0.0068 & -0.0048 \end{bmatrix}, \quad \mathbf{r}_T = \begin{bmatrix} -0.015939 \\ 0.030421 \\ -0.015118 \end{bmatrix}.$$

In Example 1 in section 39.1 we found  $\mathbf{x}_0 = [0.4500 \quad 0.3200]^T$ . The difference between  $\mathbf{x}_0$  and  $\mathbf{x}_T$  is small because the problem is almost consistent and  $A$  is well conditioned; see Section 39.6. The elements in  $\mathbf{r}_T$  are about 80% of the elements in  $\mathbf{r}_0$  given in Example 1 in Section 39.1.

## 39.5 Least Squares Algorithms

---

### Definitions:

By least squares algorithms we mean algorithms for computing the least squares solution efficiently and stably on a computer. The algorithms should take into account the size of the matrix and, if applicable, also its structure.

### Facts:

For real systems the following facts can be found in, e.g., [Bjo96], [Bjo04], and [LH95].

1. The algorithm which is least sensitive to the influence of rounding errors is based on the QR factorization of  $A$ :
  - (a) Compute the reduced QR factorization  $A = \widehat{Q}\widehat{R}$ .
  - (b) Compute the vector  $\beta = \widehat{Q}^T \mathbf{b}$  (can be computed during the QR factorization algorithm without forming  $\widehat{Q}$  explicitly).
  - (c) Compute  $\mathbf{x} = \widehat{R}^{-1} \beta$  via back substitution.

The use of this algorithm was first suggested in [Gol65].

2. If  $A$  is well conditioned, the normal equations can be used instead:
  - (a) Compute the normal equation system  $M = A^T A$  and  $\mathbf{d} = A^T \mathbf{b}$ .
  - (b) Compute the Cholesky factorization  $M = C^T C$  and  $\mathbf{y} = C^{-T} \mathbf{d}$  (the vector  $\mathbf{y}$  can be computed during the Cholesky algorithm).
  - (c) Compute  $\mathbf{x} = C^{-1} \mathbf{y}$  via back substitution.
3. If  $A$  or  $A^T A$  is a Toeplitz matrix, use an algorithm that utilizes this structure to obtain the computational complexity  $O(mn)$ .
4. If  $A$  is large and sparse, use a sparse QR factorization algorithm that avoids storing the matrix  $Q$ . If solving a system with the same  $A$  but a different right-hand side, use the corrected seminormal equations.
5. Alternatively, if  $A$  is large and sparse, it may be preferable to use the augmented system approach because it may lead to less fill-in. Then a symmetric indefinite solver, such as the  $LDL^T$  factorization, must be used, cf. [GV96, Sec. 4.4].
6. If  $A$  is large and the matrix-vector multiplications with  $A$  and  $A^T$  can be computed easily, then use the conjugate gradient algorithm on the normal equations. Several implementations are available; CGLS is the classical formulation; LSQR is more accurate for ill-conditioned matrices.

## 39.6 Sensitivity

---

### Definitions:

For  $A \in \mathbb{R}^{m \times n}$  with  $p = \text{rank}(A) \leq \min(m, n)$  the **condition number** for the least squares problem is given by  $\kappa(A) = \sigma_1 / \sigma_p$ , where  $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_p > 0$  are the nonzero singular values of  $A$ .

Let  $\mathbf{x}_{0M}$  and  $\tilde{\mathbf{x}}_{0M}$  denote the minimum-norm least squares solutions to the problems  $\min \|\mathbf{b} - A\mathbf{x}\|_2$  and  $\min \|\tilde{\mathbf{b}} - \tilde{A}\mathbf{x}\|_2$ , the latter being a perturbation of the former. Define the quantities

$$\delta_A = \|\tilde{A} - A\|_2, \quad \delta_b = \|\tilde{\mathbf{b}} - \mathbf{b}\|_2, \quad \eta = \frac{\delta_A}{\sigma_p} = \kappa(A) \frac{\delta_A}{\|A\|_2}.$$

### Facts:

(See, e.g., [Bjo96, Sec. 1.4] or [LH95, Chap. 9].)

1. If  $\eta < 1$ , then the rank is not changed by the perturbation  $\text{rank}(\tilde{A}) = \text{rank}(A)$ .
2. If  $\eta < 1$ , then the relative perturbation in  $\tilde{\mathbf{x}}_{0M}$  is bounded as

$$\frac{\|\tilde{\mathbf{x}}_{0M} - \mathbf{x}_{0M}\|_2}{\|\mathbf{x}_{0M}\|_2} \leq \frac{\kappa(A)}{1 - \eta} \left( \frac{\delta_A}{\|A\|_2} + \frac{\delta_b + \eta \|\mathbf{r}_0\|_2}{\|A\|_2 \|\mathbf{x}_{0M}\|_2} \right) + \eta, \quad \mathbf{r}_0 = \mathbf{b} - A\mathbf{x}_{0M}.$$

If  $\text{rank}(A) = n$ , then the last term  $\eta$  is omitted. If the problem is consistent, i.e.,  $\mathbf{r}_0 = \mathbf{0}$ , then the relative error can be expected to grow linearly with  $\kappa$ . For  $\mathbf{r}_0 \neq \mathbf{0}$  the contribution  $\eta \|\mathbf{r}_0\|_2$  and the definition of  $\eta$  show that the relative error may grow as  $\kappa(A)^2$ .

3. The condition number for the normal equations matrix is  $\kappa(A^T A) = \kappa(A)^2$ . Due to the finite computer precision, information may be lost when the normal equations are formed; see, e.g., [Bjo96, Sec. 2.2] and Example 2 below.
4. *Component-wise perturbation theory* applies when component-wise perturbation bounds are available for the errors in  $A$  and  $\mathbf{b}$ ; if

$$|\tilde{A} - A| \leq \epsilon |A| \quad \text{and} \quad |\tilde{\mathbf{b}} - \mathbf{b}| \leq \epsilon |\mathbf{b}|,$$

where the absolute values and inequalities are interpreted componentwise, then

$$|\tilde{\mathbf{x}} - \mathbf{x}| = \epsilon |A^\dagger| (|\mathbf{b}| + |A| |\mathbf{x}|) + \epsilon |(A^T A)^{-1}| |E^T| |\mathbf{r}|$$

and

$$\|\tilde{\mathbf{x}} - \mathbf{x}\|_\infty \leq \epsilon \left\| |A^\dagger| (|A| |\mathbf{x}| + |\mathbf{b}|) \right\|_\infty + \epsilon \left\| |(A^T A)^{-1}| |A^T| |\mathbf{r}| \right\|_\infty.$$

See [Bjo96, Secs. 1.4.5–6] for further references about component-wise perturbation analysis and *a posteriori* error estimation.

### Examples:

1. We consider the problem from Example 1 in Section 39.1 and two perturbed versions of it,

$$A = \begin{bmatrix} 1 & 1 \\ 1 & 2 \\ 1 & 3 \end{bmatrix}, \quad \mathbf{b} = \begin{bmatrix} 0.75 \\ 1.13 \\ 1.39 \end{bmatrix}, \quad \tilde{A} = \begin{bmatrix} 0.8 & 1.1 \\ 0.95 & 2 \\ 1.1 & 2.95 \end{bmatrix}, \quad \tilde{\mathbf{b}} = \begin{bmatrix} 0.79 \\ 1.23 \\ 1.30 \end{bmatrix}.$$

The matrix has full rank, so the least squares solution is unique (and equal to the minimum-norm least squares solution). The vectors

$$\mathbf{x}_0 = \begin{bmatrix} 0.4500 \\ 0.3200 \end{bmatrix}, \quad \tilde{\mathbf{x}}_1 = \begin{bmatrix} 0.5967 \\ 0.2550 \end{bmatrix}, \quad \tilde{\mathbf{x}}_2 = \begin{bmatrix} 0.8935 \\ 0.1280 \end{bmatrix}$$

are the minimizers of  $\|\mathbf{b} - A\mathbf{x}\|_2$ ,  $\|\tilde{\mathbf{b}} - A\mathbf{x}\|_2$ , and  $\|\tilde{\mathbf{b}} - \tilde{A}\mathbf{x}\|_2$ , respectively.

The matrix has condition number  $\kappa(A) = 6.793$ , and  $\eta = \kappa(A) \|\tilde{A} - A\|_2 / \|A\|_2 = 0.4230 < 1$ . The relative errors and their upper bounds are

$$\frac{\|\tilde{\mathbf{x}}_1 - \mathbf{x}_0\|_2}{\|\mathbf{x}_0\|_2} = 0.291 \leq \kappa(A) \frac{\|\tilde{\mathbf{b}} - \mathbf{b}\|_2}{\|A\|_2 \|\mathbf{x}_0\|_2} = 0.423$$

$$\frac{\|\tilde{\mathbf{x}}_2 - \mathbf{x}_0\|_2}{\|\mathbf{x}_0\|_2} = 0.875 \leq \frac{1}{1 - \eta} \left( \eta + \kappa(A) \frac{\|\tilde{\mathbf{b}} - \mathbf{b}\|_2 + \eta \|\mathbf{b} - A\mathbf{x}_0\|_2}{\|A\|_2 \|\mathbf{x}_0\|_2} \right) = 1.575.$$

2. Consider the following matrix  $A$  and the corresponding normal equation matrix:

$$A = \begin{bmatrix} 1 & 1 \\ \delta & 0 \\ 0 & \delta \end{bmatrix}, \quad A^T A = \begin{bmatrix} 1 + \delta^2 & 1 \\ 1 & 1 + \delta^2 \end{bmatrix}.$$

If  $|\delta| \leq \sqrt{\epsilon}$  (where  $\epsilon$  is the machine precision), then the quantity  $1 + \delta^2$  is represented by 1 on the computer and, therefore, the computed  $A^T A$  is singular. If we use Householder transformations to compute the QR factorization, we get  $R = \begin{bmatrix} -1 & -1 \\ 0 & \delta\sqrt{2} \end{bmatrix}$ , so information about  $\delta$  is preserved.

## 39.7 Up- and Downdating of QR Factorization

### Definitions:

Given  $A \in \mathbb{R}^{m \times n}$  with  $m > n$  and its QR factorization, as well as a row vector  $\mathbf{a}^T$  with  $\mathbf{a} \in \mathbb{R}^n$ , **updating** of the factorization means computing the QR factorization of the augmented matrix  $\begin{bmatrix} A \\ \mathbf{a}^T \end{bmatrix} = \tilde{A} = \tilde{Q}\tilde{R}$  from the QR factors of  $A$ . Similarly, **downdating** means computing the QR factors of  $A$  from those of  $\tilde{A}$ . Up- and downdating algorithms require only  $O(mn)$  flops (compared to the  $O(mn^2)$  flops of recomputing the QR factors).

**Facts:**

The following facts can be found in Chapter 3 of [Bjo96].

1. The matrix  $R$  can be updated to  $\tilde{R}$  without knowledge of  $Q$  by means a sequence of  $n$  Givens transformations  $G_1, \dots, G_n$ .
2. The updating of  $Q$  to  $\tilde{Q}$  then takes the form

$$\tilde{Q} = \begin{bmatrix} Q & 0 \\ 0 & I \end{bmatrix} G_1^T \dots G_n^T.$$

3. Downdating of  $\tilde{R}$  to  $R$  requires the first row  $\tilde{Q}_{1,:}$  of  $\tilde{Q}$ . Let  $\tilde{G}_1, \dots, \tilde{G}_{m-n}$  be Givens rotations such that  $\hat{R} = G_{m-n} \dots G_1 (\tilde{R} \tilde{Q}_{1,:}^T)$  is upper triangular. Then  $R = \hat{R}_{2:n+1,2:n}$ .
4. If  $\tilde{Q}$  is not available, then its first row  $\tilde{Q}_{1,:}$  can be computed by the LINPACK/ Saunders algorithm or via hyperbolic rotations. If  $A$  is available, the corrected seminormal equations provide a more accurate algorithm.
5. Up- and downdating algorithms are also available for the cases where a column is appended to or deleted from  $A$ .
6. Up- and downdating of the Cholesky factor under a rank-one modification  $\tilde{M} = M \pm \mathbf{a} \mathbf{a}^T$  is analytically equivalent to updating  $R$  from the QR factorization. In the downdating case the matrix  $\tilde{M}$  must be positive (semi)definite.

**Examples:**

1. Let

$$A = \begin{bmatrix} 1 & 1 \\ 1 & 2 \\ 1 & 3 \end{bmatrix} = QR = \begin{bmatrix} 0.5774 & -0.7071 & -0.4082 \\ 0.5774 & 0 & 0.8165 \\ 0.5774 & 0.7071 & -0.4082 \end{bmatrix} \begin{bmatrix} 1.732 & 3.464 \\ 0 & 1.414 \\ 0 & 0 \end{bmatrix}.$$

If  $\mathbf{a}^T = (1 \ 4)$ , then

$$\tilde{A} = \begin{bmatrix} 1 & 1 \\ 1 & 2 \\ 1 & 3 \\ 1 & 4 \end{bmatrix} = \tilde{Q} \tilde{R} \quad \text{with} \quad \tilde{R} = \begin{bmatrix} 2 & 5 \\ 0 & 2.236 \\ 0 & 0 \\ 0 & 0 \end{bmatrix}.$$

The updated factor  $\tilde{R}$  is computed by augmenting  $R$  with  $\mathbf{a}^T$  and applying two left Givens rotations  $G_1$  and  $G_2$  to row pairs (1,4) and (2,4), respectively:

$$\begin{bmatrix} R \\ \mathbf{a}^T \end{bmatrix} = \begin{bmatrix} 1.732 & 3.464 \\ 0 & 1.414 \\ 0 & 0 \\ 1 & 4 \end{bmatrix} \xrightarrow{G_1} \begin{bmatrix} 2 & 5 \\ 0 & 1.414 \\ 0 & 0 \\ 0 & 1.732 \end{bmatrix} \xrightarrow{G_2} \begin{bmatrix} 2 & 5 \\ 0 & 2.236 \\ 0 & 0 \\ 0 & 0 \end{bmatrix}.$$

## 39.8 Damped Least Squares

---

**Definitions:**

The **damped least squares** solution is the solution to the problem  $(A^T A + \alpha I) \mathbf{x} = A^T \mathbf{b}$ , where  $\alpha > 0$  and  $A$  and  $\mathbf{b}$  are real. Damped least squares is also known as **ridge regression** and **Tikhonov** (or **Phillips**) **regularization**.

**Facts:**

(See, e.g., [Han98] for further details.)

1. The two formulations

$$\min\{\|\mathbf{b} - A\mathbf{x}\|_2^2 + \alpha\|\mathbf{x}\|_2^2\} \quad \text{and} \quad \min\left\|\begin{bmatrix} \mathbf{b} \\ \mathbf{0} \end{bmatrix} - \begin{bmatrix} A \\ \sqrt{\alpha} I \end{bmatrix} \mathbf{x}\right\|_2$$

are analytically equivalent.

2. The damping (controlled by the parameter  $\alpha$ ) reduces the variance of the solution, at the cost of introducing bias.
3. If  $\text{Cov}(\mathbf{b}) = I$ , then the covariance matrix for the damped least squares solution  $\mathbf{x}_\alpha$  is

$$\text{Cov}(\mathbf{x}_\alpha) = (A^T A + \alpha I)^{-1} A^T A (A^T A + \alpha I)^{-1} = V \Sigma^2 (\Sigma^2 + \alpha I)^{-2} V^T,$$

where  $\Sigma$  and  $V$  are from the SVD of  $A$ . Hence,

$$\|\text{Cov}(\mathbf{x}_\alpha)\|_2 = \max_i \{\sigma_i^2 / (\sigma_i^2 + \alpha)^2\} \leq (4\alpha)^{-1},$$

while  $\|\text{Cov}(\mathbf{x}_0)\|_2 = \|(A^T A)^{-1}\|_2 = \sigma_n^{-2}$ , which can be much larger.

4. The expected value of  $\mathbf{x}_\alpha$  is

$$\mathcal{E}(\mathbf{x}_\alpha) = (A^T A + \alpha I)^{-1} A^T A \mathbf{x}_0,$$

which introduces a bias because  $\mathcal{E}(\mathbf{x}_\alpha) \neq \mathcal{E}(\mathbf{x}_0)$  when  $\alpha > 0$ .

5. The damped least squares problem can take the more general form

$$\min\{\|\mathbf{b} - A\mathbf{x}\|_2^2 + \alpha\|B\mathbf{x}\|_2^2\} \quad \Leftrightarrow \quad (A^T A + \alpha B^T B) \mathbf{x} = A^T \mathbf{b},$$

where  $\|B \cdot\|_2$  defines a (semi)norm. The solution to this problem is unique when the nullspaces of  $A$  and  $B$  intersect trivially.

6. [Han98, Chap. 7]. Some algorithms for computing  $\alpha$  are the discrepancy principle, generalized cross validation, and the L-curve criterion.

**Examples:**

1. Let  $\delta = 10^{-5}$  and consider the matrix and vectors

$$A = \begin{bmatrix} 1 & 1 \\ 1 & 1 + \delta \\ 1 & 1 + 2\delta \end{bmatrix}, \quad \mathbf{x}_0 = \begin{bmatrix} 1 \\ 1 \end{bmatrix}, \quad \mathbf{b} = A \mathbf{x}_0, \quad \tilde{\mathbf{b}} = \mathbf{b} + \begin{bmatrix} 0 \\ 0 \\ \delta \end{bmatrix}.$$

Obviously  $\mathbf{x}_0$  is the least squares solution to  $A\mathbf{x} + \mathbf{r} = \mathbf{b}$  with  $\mathbf{r}_0 = \mathbf{0}$ . The minimizer of  $\|\tilde{\mathbf{b}} - A\mathbf{x}\|_2$  is  $\tilde{\mathbf{x}}_0 = (0.5 \ 1.5)^T$ , showing that for this problem the least squares solution is very sensitive to perturbations (the condition number is  $\kappa(A) = 2.4 \cdot 10^5$ ). Using  $\alpha = 10^{-8}$ , we obtain the damped least squares solutions

$$\mathbf{x}_\alpha = \begin{bmatrix} 0.999995 \\ 1.000005 \end{bmatrix} \quad \text{and} \quad \tilde{\mathbf{x}}_\alpha = \begin{bmatrix} 0.995 \\ 1.005 \end{bmatrix}.$$

Comparing the damped and the undamped least squares solutions  $\tilde{\mathbf{x}}_\alpha$  and  $\tilde{\mathbf{x}}_0$  to the perturbed least squares problem, we see that  $\tilde{\mathbf{x}}_\alpha$  is a better approximation to the unperturbed solution  $\mathbf{x}_0$  than  $\tilde{\mathbf{x}}_0$ .

## 39.9 Rank Revealing Decompositions

### Definitions:

A **rank revealing decomposition** is a two-sided orthogonal decomposition of the form

$$A = U \widehat{R} V^T = U \begin{bmatrix} R \\ 0 \end{bmatrix} V^T,$$

where  $U$  and  $V$  are orthogonal, and  $R$  is upper triangular and reveals the (numerical) rank of  $A$  in the size of its diagonal elements.

The **numerical rank**  $k_\tau$  of  $A$ , with respect to the threshold  $\tau$ , is defined as

$$k_\tau = \min \text{rank}(A + E) \quad \text{subject to} \quad \|E\|_2 \leq \tau.$$

### Facts:

(See, e.g., [Bjo96, Sec. 1.7.3–6], [Han98, Sec. 2.2], and [Ste98, Chap. 5].)

- [GV96, p. 73] The numerical rank  $k_\tau$  is equal to the number of singular values greater than  $\tau$ , i.e.,  $\sigma_{k_\tau} > \tau \geq \sigma_{k_\tau+1}$ .
- The singular value decomposition is rank revealing with the middle matrix  $R = \Sigma$ . The SVD is difficult to update.
- If  $A$  is exactly rank deficient with  $\text{rank}(A) = p$ , then there always exists a **pivoted QR factorization**  $A \Pi = Q \widehat{R}$  with  $\widehat{R}$  of the form

$$\widehat{R} = \begin{bmatrix} R_{11} & R_{12} \\ 0 & 0 \end{bmatrix}, \quad R_{11} \in \mathbb{R}^{p \times p}, \quad \text{rank}(\widehat{R}) = \text{rank}(R_{11}) = p,$$

and a **complete orthogonal decomposition** of the form  $A = U \widehat{R} V^T$ , where

$$\widehat{R} = \begin{bmatrix} R_{11} & 0 \\ 0 & 0 \end{bmatrix}, \quad R_{11} \in \mathbb{R}^{p \times p}, \quad \text{rank}(\widehat{R}) = \text{rank}(R_{11}) = p.$$

The pseudoinverse of  $A$  is  $A^\dagger = V_{:,1:p} R_{11}^{-1} U_{:,1:p}^T$ .

- A basic solution can be computed from the pivoted QR factorization as  $\mathbf{x}_{0B} = \Pi R_{11}^{-1} Q_{:,1:p}^T \mathbf{b}$ . The minimum-norm least squares solution is given in terms of the complete orthogonal decomposition as  $\mathbf{x}_{0M} = V_{:,1:p} R_{11}^{-1} U_{:,1:p}^T \mathbf{b}$ .
- The **rank revealing QR (RRQR) decomposition** is a pivoted QR factorization  $A \Pi = Q \widehat{R}$  such that

$$\sigma_i / c_i \leq \sigma_i(R_{1:i,1:i}) \leq \sigma_i \leq \|R_{1:i,1:i}\|_2 \leq c_i \sigma_i, \quad i = 1, \dots, n,$$

where  $\sigma_i$  is the  $i$ th singular value of  $A$ ,

$$c_i = \sqrt{i(n-i) + \min(i, n-i)},$$

and  $\sigma_i(R_{1:i,1:i})$  denotes the smallest singular value of  $R_{1:i,1:i}$ . The RRQR factorization can be used to estimate the numerical rank  $k_\tau$ . The RRQR factorization is not unique.

- The **URV decomposition** is a two-sided orthogonal decomposition  $A = U \widehat{R} V^T$ , such that, for  $k = 1, \dots, n$ ,

$$\sigma_i \check{c}_k \leq \sigma_i(R_{1:i,1:i}) \leq \sigma_i, \quad i = 1, \dots, k$$

and

$$\sigma_i \leq \sigma_{i-k}(R_{k+1:n,k+1:n}) \leq \sigma_i / \check{c}_k, \quad i = k+1, \dots, n,$$

where

$$\check{c}_k = \left( 1 - \frac{\|R_{k+1:n,k+1:n}\|_2^2}{\sigma_k(R_{1:i,1:i})^2 - \|R_{k+1:n,k+1:n}\|_2^2} \right)^{1/2}.$$

There is also a ULV decomposition with a lower triangular middle matrix; both can be used to estimate the numerical rank of  $A$ .

7. The RRQR, URV, and ULV decompositions can be updated, at slightly more cost than the QR factorization.

### Examples:

1. The rank of  $A$  is revealed by the zero element in the (3,3) position of  $R$ :

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 2 & 3 & 4 \\ 3 & 4 & 5 \\ 4 & 5 & 6 \end{bmatrix} = QR \quad \text{with} \quad R = \begin{bmatrix} 5.477 & 7.303 & 9.129 \\ 0 & 0.816 & 1.633 \\ 0 & 0 & 0 \end{bmatrix}.$$

Here the QR factorization is rank revealing ( $U = Q$  and  $V = I$ ).

2. Pivoting must be used to ensure that a QR factorization is rank revealing. The “standard column pivoting” often works well in connection with Householder transformations; here the pivot column in each stage is chosen to maximize the norm of the leading column of the submatrix  $A_{k:m,k:n}^{(k)}$  to be reduced. Example:

$$A = \begin{bmatrix} 4 & 2 & 2 \\ 2 & 1 & 2 \\ 0 & 0 & 1 \end{bmatrix},$$

$$A^{(1)} = H_1 A = \begin{bmatrix} -4.4721 & -2.2361 & -2.6833 \\ 0 & 0 & 0.8944 \\ 0 & 0 & 1 \end{bmatrix},$$

$$A^{(1)}\Pi = \begin{bmatrix} -4.4721 & -2.6833 & -2.2361 \\ 0 & 0.8944 & 0 \\ 0 & 1 & 0 \end{bmatrix}, \quad \Pi = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix},$$

$$\hat{R} = A^{(2)} = H_2 A^{(1)}\Pi = \begin{bmatrix} -4.4721 & -2.6833 & -2.2361 \\ 0 & -1.3416 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

3. The standard column pivoting strategy is not guaranteed to reveal the numerical rank; hence, the development of the RRQR and URV decompositions.

### 40.1 Introduction

---

Let  $A$  be an  $n$  by  $n$  nonsingular matrix and  $\mathbf{b}$  be an  $n$ -vector. As discussed in Chapter 38, Matrix Factorizations and Direct Solution of Linear Systems, the solution of the system of linear equations  $A\mathbf{x} = \mathbf{b}$  using Gaussian elimination requires  $O(n^3)$  operations, which typically include additions, subtractions, multiplications, and divisions. The solution also requires  $O(n^2)$  words of storage. The computational complexity is based on the assumption that every element of the matrix has to be stored and operated on. However, linear systems that arise in many scientific and engineering applications can be large; that is,  $n$  can be large. It is not uncommon for  $n$  to be over hundreds of thousands or even millions. Fortunately, for these linear systems, it is often the case that most of the elements in the matrix  $A$  will be zero.

Following is a simple example that illustrates where the zero elements come from. Consider the Laplace equation defined on a unit square:

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0.$$

Assume that  $u$  is known along the boundary. Suppose the square domain is discretized into a  $(k+2)$  by  $(k+2)$  mesh with evenly spaced mesh points, as shown in Figure 40.1. Also suppose that the mesh points are labeled from 0 to  $k+1$  in the  $x$  and  $y$  directions. For  $0 \leq i \leq k+1$ , let the variables in the  $x$  direction be denoted by  $x_i$ . Similarly, for  $0 \leq j \leq k+1$ , let the variables in the  $y$  direction be denoted by  $y_j$ . The solution at  $(x_i, y_j)$  will be denoted by  $u_{i,j} = u(x_i, y_j)$ . To solve the Laplace equation numerically, the partial derivatives at  $(x_i, y_j)$  will be approximated, for example, using second-order centered difference approximations:

$$\begin{aligned}\frac{\partial^2 u}{\partial x^2} \Big|_{(x_i, y_j)} &\approx \frac{u_{i-1,j} - 2u_{i,j} + u_{i+1,j}}{h^2}, \\ \frac{\partial^2 u}{\partial y^2} \Big|_{(x_i, y_j)} &\approx \frac{u_{i,j-1} - 2u_{i,j} + u_{i,j+1}}{h^2},\end{aligned}$$

FIGURE 40.1 Discretization of a unit square.

where  $h = \frac{1}{k+1}$  is the spacing between two mesh points in each direction. Here, it is assumed that  $u_{0,j}$ ,  $u_{k+1,j}$ ,  $u_{i,0}$ ,  $u_{i,k+1}$  are given by the boundary condition, for  $1 \leq i, j \leq k$ . Using the difference approximations, the Laplace equation at each mesh point  $(x_i, y_j)$ ,  $1 \leq i, j \leq k$ , is approximated by the following linear equation:

$$u_{i-1,j} + u_{i,j-1} - 4u_{i,j} + u_{i+1,j} + u_{i,j+1} = 0, \quad \text{for } 1 \leq i, j \leq k.$$

This leads to a system of  $k^2$  by  $k^2$  linear equations in  $k^2$  unknowns. The solution to the linear system provides the approximate solution  $u_{i,j}$ ,  $1 \leq i, j \leq k$ , at the mesh points. Note that each equation has at most five unknowns. Thus, the coefficient matrix of the linear system, which is  $k^2$  by  $k^2$  and has  $k^4$  elements, has at most  $5k^2$  nonzero elements. It is therefore crucial, for the purpose of efficiency (both in terms of operations and storage), to take advantage of the zero elements as much as possible when solving the linear system. The goal is to compute the solution without storing and operating on most of the zero elements of the matrix. This chapter will discuss some of techniques for exploiting the zero elements in Gaussian elimination.

Throughout this chapter, the matrices are assumed to be real. However, most of the discussions are also applicable to complex matrices, with the exception of those on real symmetric positive definite matrices. The discussions related to real symmetric positive definite matrices are applicable to Hermitian positive definite matrices (which are complex but not symmetric).

## 40.2 Sparse Matrices

---

### Definitions:

A matrix  $A$  is **sparse** if substantial savings in either operations or storage can be achieved when the zero elements of  $A$  are exploited during the application of Gaussian elimination to  $A$ .

The number of nonzero elements in a matrix  $A$  is denoted by  $nmz(A)$ .

### Facts: [DER89], [GL81]

1. Let  $A$  be an  $n$  by  $n$  sparse matrix. It often takes much less than  $n^2$  words to store the nonzero elements in  $A$ .
2. Let  $T$  be an  $n$  by  $n$  sparse triangular matrix. The number of operations required to solve the triangular system of linear equations  $T\mathbf{x} = \mathbf{b}$  is  $O(nmz(T))$ .

3. The *compressed row storage* (CRS) scheme is another possibility of storing the nonzero elements of a sparse matrix. It is very similar to the CCS scheme, except that the nonzero elements are stored by rows.
4. Let  $A = [a_{i,j}]$  be an  $n$  by  $n$  sparse matrix. Let  $\mathbf{b} = [b_i]$  and  $\mathbf{c} = [c_i]$  be  $n$ -vectors. The following algorithm computes the product  $\mathbf{c} = \mathbf{A}\mathbf{b}$ , with the assumption that the nonzero elements of  $A$  are stored using the CRS scheme.

**for**  $i = 1, 2, \dots, n$  **do**

$c_i \leftarrow 0$

**for**  $s = \text{ROWPTR}(i), \text{ROWPTR}(i) + 1, \dots, \text{ROWPTR}(s + 1) - 1$  **do**

$c_i \leftarrow c_i + \text{VAL}(s)b_{\text{IND}(s)}$ .

5. Let  $A = [a_{i,j}]$  be an  $n$  by  $n$  sparse matrix. Let  $\mathbf{b} = [b_i]$  and  $\mathbf{c} = [c_i]$  be  $n$ -vectors. The following algorithm computes the product  $\mathbf{c} = \mathbf{A}\mathbf{b}$ , with the assumption that the nonzero elements of  $A$  are stored using the CCS scheme.

**for**  $i = 1, 2, \dots, n$  **do**

$c_i \leftarrow 0$

**for**  $i = 1, 2, \dots, n$  **do**

**for**  $s = \text{COLPTR}(i), \text{COLPTR}(i) + 1, \dots, \text{COLPTR}(s + 1) - 1$  **do**

$c_{\text{IND}(s)} \leftarrow c_{\text{IND}(s)} + \text{VAL}(s)b_i$ .

### 40.3 Sparse Matrix Factorizations

---

Mathematically, computing a triangular factorization of a sparse matrix using Gaussian elimination is really no different from that of a dense matrix. However, the two are very different algorithmically. Sparse triangular factorizations can be quite complicated because of the need to preserve the zero elements as much as possible.

#### Definitions:

Let  $A$  be a sparse matrix. An element of a sparse matrix  $A$  is a **fill element** if it is zero in  $A$  but becomes nonzero during Gaussian elimination.

The **sparsity structure** of a matrix  $A = [a_{i,j}]$  refers to the set  $\text{Struct}(A) = \{(i, j) : a_{i,j} \neq 0\}$ .

Consider applying Gaussian elimination to a matrix  $A$  with row and column pivoting:

$$A = P_1 M_1 P_2 M_2 \cdots P_{n-1} M_{n-1} U Q_{n-1} \cdots Q_2 Q_1,$$

where  $P_i$  and  $Q_i$  ( $1 \leq i \leq n - 1$ ), are, respectively, the row and column permutations due to pivoting,  $M_i$  ( $1 \leq i \leq n - 1$ ) is a Gauss transformation (see Chapter 38), and  $U$  is the upper triangular factor. Let  $L = M_1 + M_2 + \cdots + M_{n-1} - (n - 2)I$ , where  $I$  is the identity matrix. Note that  $L$  is a lower triangular matrix. The matrix  $F = L + U - I$  is referred to as the **fill matrix**.

The matrix  $A$  is said to have a **zero-free diagonal** if all the diagonal elements of  $A$  are nonzero. The zero-free diagonal is also known as a **maximum transversal**.

No **exact numerical cancellation** between two numbers  $u$  and  $v$  means that  $u + v$  (or  $u - v$ ) is nonzero regardless of the values of  $u$  and  $v$ .

**Facts:** [DER89], [GL81]

In the following discussion,  $A$  is a sparse nonsingular matrix and  $F$  is its fill matrix.

1. [Duf81], [DW88] There exists a (row) permutation matrix  $P_r$  such that  $P_r A$  has a zero-free diagonal. Similarly, there exists a (column) permutation matrix  $P_c$  such that  $AP_c$  has a zero-free diagonal.

2. It is often true that there are more nonzero elements in  $F$  than in  $A$ .
3. The sparsity structure of  $F$  depends on the sparsity structure of  $A$ , as well as the pivot sequence needed to maintain numerical stability in Gaussian elimination. This means that  $\text{Struct}(F)$  is known only during numerical factorization. As a result, the storage scheme cannot be created in advance to accommodate the fill elements that occur during Gaussian elimination.
4. If  $A$  is symmetric and positive definite, then pivoting for numerical stability is not needed during Gaussian elimination. Assume that exact numerical cancellations do not occur during Gaussian elimination. Then  $\text{Struct}(A) \subseteq \text{Struct}(F)$ .
5. Let  $A$  be symmetric and positive definite. Assume that exact numerical cancellations do not occur during Gaussian elimination. Then  $\text{Struct}(F)$  is determined solely by  $\text{Struct}(A)$ . This implies that  $\text{Struct}(F)$  can be computed before any numerical factorization proceeds. Knowing  $\text{Struct}(F)$  in advance allows a storage scheme to be set up prior to numerical factorization.
6. [GN85] Suppose that  $A$  is a nonsymmetric matrix. Consider applying Gaussian elimination to a matrix  $A$  with partial pivoting:

$$A = P_1 M_1 P_2 M_2 \cdots P_{n-1} M_{n-1} U,$$

where  $P_i$  ( $1 \leq i \leq n - 1$ ), is a row permutation due to pivoting,  $M_i$  ( $1 \leq i \leq n - 1$ ) is a Gauss transformation, and  $U$  is the upper triangular factor. Let  $F$  denote the corresponding fill matrix; that is,  $F = M_1 + M_2 + \cdots + M_{n-1} + U - (n - 1)I$ . The matrix product  $A^T A$  is symmetric and positive definite and, hence, has a Cholesky factorization  $A^T A = L_C L_C^T$ . Assume that  $A$  has a zero-free diagonal. Then  $\text{Struct}(F) \subseteq \text{Struct}(L_C + L_C^T)$ . This result holds for *every* legitimate sequence of pivots  $\{P_1, P_2, \dots, P_{n-1}\}$ . Thus,  $\text{Struct}(L_C)$  and  $\text{Struct}(L_C^T)$  can serve as *upper bounds* on  $\text{Struct}(L)$  and  $\text{Struct}(U)$ , respectively. When  $A$  is irreducible, then  $\text{Struct}(L_C^T)$  is a *tight* bound on  $\text{Struct}(U)$ : for a given  $(i, j) \in \text{Struct}(L_C^T)$ , there is an assignment of numerical values to the nonzero elements of  $A$  so that  $U_{i,j}$  is nonzero; this is referred to as an *one-at-time* result [GN93]. However,  $\text{Struct}(L_C)$  is *not* a tight bound on  $\text{Struct}(L)$ . A tight bound on  $\text{Struct}(L)$  can be found in [GN87] and [GN93].

**Examples:**

Some of the properties of sparse matrices, such as zero-free diagonals and reducible/irreducible matrices, depend only on the sparsity structures of the matrices; the actual values of the nonzero elements are irrelevant. As a result, for the examples illustrating such properties, only the sparsity structures will be taken into consideration. The numerical values will not be shown. Nonzero elements will be indicated by  $\times$ .

1. Following is an example of a reducible matrix:

$$A = \begin{bmatrix} \times & \times & \times & \times & \times & & \times & & & \\ & & & & \times & \times & \times & \times & & \\ & \times & \times & & \times & & & & & \\ & \times & & \times & & \times & & \times & \times & \\ & \times & \times & & \times & & & \times & & \\ \times & \times & \times & \times & & \times & & \times & \times & \\ & \times & & \times & & & & \times & & \\ \times & & & \times & & & & \times & \times & \\ & & & & & & & & & \times \end{bmatrix}.$$

The matrix  $A$  can be put into a block upper triangular form using the following permutations:

$$\pi_r = [2, 4, 7, 1, 9, 6, 8, 5, 3, 10],$$

$$\pi_c = [8, 6, 4, 7, 1, 3, 9, 5, 2, 10].$$

Here,  $\pi_r(i) = j$  means that row  $i$  of the permuted matrix comes from row  $j$  of the original matrix. Similarly,  $\pi_c(i) = j$  means that column  $i$  of the permuted matrix comes from column  $j$  of the original matrix. When  $\pi_r$  and  $\pi_c$  are applied to the identity matrix (separately), the corresponding permutation matrices are obtained:

$$P_r = \begin{bmatrix} & \times & & & & & & & & \\ & & \times & & & & & & & \\ & & & \times & & & & & & \\ \times & & & & & & & & & \\ & & & & \times & & & & & \\ & & & & & \times & & & & \\ & & & & & & \times & & & \\ & & \times & & & & & & & \\ & & & \times & & & & & & \\ & & & & & & & \times & & \\ & & & & & & & & \times & \\ & & & & & & & & & \times \end{bmatrix}, P_c = \begin{bmatrix} & & & & \times & & & & & \\ & & & & & \times & & & & \\ & & & & & & \times & & & \\ & & & & & & & \times & & \\ & & & & & & & & \times & \\ \times & & & & & & & & & \\ & \times & & & & & & & & \\ & & \times & & & & & & & \\ & & & \times & & & & & & \\ & & & & \times & & & & & \\ & & & & & \times & & & & \\ & & & & & & \times & & & \\ & & & & & & & \times & & \\ & & & & & & & & \times & \\ & & & & & & & & & \times \end{bmatrix}.$$

The permuted matrix  $P_r A P_c$  is shown below:

$$P_r A P_c = \begin{bmatrix} \times & & & & & & & & & \\ & \times & \times & & & & \times & \times & & \\ & & & & & & & & & \\ & & \times & \times & \times & & \times & \times & & \times \\ & & \times & \times & \times & & \times & & \times & \times \\ & & & & & \times & & \times & \times & \times \\ & & & & & & \times & & \times & \times \\ & & & & & & & \times & \times & \times \\ & & & & & & \times & & \times & \times \\ & & & & & & & & & \times \end{bmatrix}.$$

The block triangular form has four  $1 \times 1$  blocks, one  $2 \times 2$  block, and one  $4 \times 4$  block on the diagonal.

- The advantage of the block triangular form is that only the diagonal blocks have to be factored in the solution of a linear system. As an example, suppose that  $A$  is lower block triangular:

$$A = \begin{bmatrix} A_{1,1} & & & \\ A_{2,1} & A_{2,2} & & \\ \vdots & \vdots & \ddots & \\ A_{m,1} & A_{m,2} & \dots & A_{m,m} \end{bmatrix}.$$

Here,  $m$  is the number of blocks on the diagonal of  $A$ . Consider the solution of the linear system  $A\mathbf{x} = \mathbf{b}$ . Suppose that  $\mathbf{b}$  and  $\mathbf{x}$  are partitioned according to the block structure of  $A$ :

$$\mathbf{b} = \begin{bmatrix} \mathbf{b}_1 \\ \mathbf{b}_2 \\ \vdots \\ \mathbf{b}_m \end{bmatrix} \quad \text{and} \quad \mathbf{x} = \begin{bmatrix} \mathbf{x}_1 \\ \mathbf{x}_2 \\ \vdots \\ \mathbf{x}_m \end{bmatrix} .$$

Then the solution can be obtained using a block substitution scheme:

$$A_{k,k}\mathbf{x}_k = \mathbf{b}_k - \sum_{i=1}^{k-1} A_{k,i}\mathbf{x}_i, \quad \text{for } 1 \leq k \leq m.$$

Note that only the diagonal blocks  $A_{k,k}$ ,  $1 \leq k \leq m$  have to be factored; Gaussian elimination does not have to be applied to the entire matrix  $A$ . This can result in substantial savings in storage and operations.

3. In this example, the matrix  $A$  has zero elements on the diagonal:

$$A = \begin{bmatrix} & & & \times & \times & \times & \times \\ & & \times & & & & \times \\ & & \times & \times & & \times & \times \\ & \times & & \times & \times & \times & \times \\ \times & & & & \times & \times & \times \\ \times & & & & \times & & \times \\ & \times & \times & & & \times & \times \\ & \times & \times & \times & \times & \times & \\ & & & \times & & \times & \\ \times & \times & & \times & & & \times \end{bmatrix} .$$

The following permutation matrix  $P$ , when applied to the columns of  $A$ , will produce a matrix with a zero-free diagonal:

$$P = \begin{bmatrix} & & & & & \times \\ & & & \times & & \\ & \times & & & \times & \\ & & \times & & & \\ \times & & & & & \times \\ & \times & & & & \\ & & \times & & & \\ & & & \times & & \\ & & & & \times & \end{bmatrix} .$$

The sparsity structure of the permuted matrix is shown below:

$$AP = \begin{bmatrix} \times & & \times & \times & & & \times & & & & \\ & \times & & & & & & \times & & & \\ & \times & \times & \times & & & & \times & & & \\ \times & & & \times & \times & & & & \times & & \\ \times & & \times & & \times & \times & \times & & & \times & \\ \times & & & \times & \times & \times & & & & & \\ & \times & \times & & \times & & \times & \times & & & \\ \times & \times & \times & \times & & & & & \times & \times & \\ & & & & \times & & & & & \times & \\ & & & & & \times & \times & & \times & \times & \end{bmatrix}.$$

The permutation matrix  $P$  is obtained by applying the following permutation  $\pi$  to the columns of the identity matrix:

$$\pi = [7, 4, 8, 5, 9, 2, 10, 3, 6, 1].$$

Again,  $\pi(i) = j$  means that column  $i$  of the permuted matrix comes from column  $j$  of the original matrix.

4. Consider the following matrix:

$$A = \begin{bmatrix} 10 & 0 & 1 & 0 & 1 & 0 & 0 \\ 1 & 10 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 10 & 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 10 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 10 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 & 10 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 10 \end{bmatrix},$$

which is diagonal dominant. The matrix can be factored without pivoting for stability. The triangular factors are given below:

$$L = \begin{bmatrix} 1 & & & & & & & \\ \frac{1}{10} & 1 & & & & & & \\ 0 & 0 & 1 & & & & & \\ 0 & 0 & \frac{1}{10} & 1 & & & & \\ 0 & \frac{1}{10} & \frac{1}{1000} & 0 & 1 & & & \\ \frac{1}{10} & 0 & -\frac{1}{100} & 0 & -\frac{10}{991} & 1 & & \\ 0 & 0 & 0 & 0 & \frac{100}{991} & \frac{1}{99199} & 1 & \end{bmatrix}, U = \begin{bmatrix} 10 & 0 & 1 & 0 & 1 & 0 & 0 \\ & 10 & -\frac{1}{10} & 0 & \frac{9}{10} & 0 & 0 \\ & & 10 & 0 & 0 & 1 & 0 \\ & & & 10 & 0 & -\frac{1}{10} & 1 \\ & & & & \frac{991}{100} & -\frac{1}{1000} & 1 \\ & & & & & \frac{99199}{9910} & \frac{10}{991} \\ & & & & & & \frac{981980}{99199} \end{bmatrix}.$$

Note that  $A$  has 18 nonzero elements, whereas  $L + U$  has 26 nonzero elements, showing that there are more nonzero elements in the fill matrix than in  $A$ .

5. Consider the matrix  $A$  in the previous example. Suppose  $\hat{A} = [\hat{a}_{i,j}]$  is obtained from  $A$  by swapping the (1, 1) and (2, 1) elements:

$$\hat{A} = \begin{bmatrix} 1 & 0 & 1 & 0 & 1 & 0 & 0 \\ 10 & 10 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 10 & 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 10 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 10 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 & 10 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 10 \end{bmatrix}.$$

When Gaussian elimination with partial pivoting is applied to  $\hat{A}$ , rows 1 and 2 will be interchanged at step 1 of the elimination since  $|\hat{a}_{2,1}| > |\hat{a}_{1,1}|$ . It can be shown that no more interchanges are needed in the subsequent steps. The triangular factors are given by

$$\hat{L} = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ \frac{1}{10} & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{1}{10} & 1 & 0 & 0 & 0 \\ 0 & -1 & \frac{1}{10} & 0 & 1 & 0 & 0 \\ \frac{1}{10} & 1 & -\frac{1}{10} & 0 & -\frac{10}{109} & 1 & 0 \\ 0 & 0 & 0 & 0 & \frac{10}{1099} & \frac{10}{10999} & 1 \end{bmatrix}, \hat{U} = \begin{bmatrix} 10 & 10 & 0 & 0 & 1 & 0 & 0 \\ 0 & -1 & 1 & 0 & \frac{9}{10} & 0 & 0 \\ 0 & 0 & 10 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 10 & 0 & -\frac{1}{10} & 1 \\ 0 & 0 & 0 & 0 & \frac{109}{10} & -\frac{1}{10} & 1 \\ 0 & 0 & 0 & 0 & 0 & \frac{10999}{1090} & \frac{10}{109} \\ 0 & 0 & 0 & 0 & 0 & 0 & \frac{108980}{10999} \end{bmatrix}.$$

Even though  $A$  (in the previous example) and  $\hat{A}$  have the same sparsity structures, their fill matrices have different numbers of nonzero elements. For  $\hat{A}$ , there are 27 nonzero elements in the fill matrix of  $\hat{A}$ . While this example is small, it illustrates that the occurrence of fill elements in Gaussian elimination generally depends on both the sparsity structure and the values of the nonzero elements of the matrix.

6. Consider the example in the last two examples again. Note that  $A$  has a zero-free diagonal. Both  $A$  and  $\hat{A}$  have the same sparsity structure. The sparsity structure of  $A^T A$  is the same as that of  $\hat{A}^T \hat{A}$ :

$$A^T A = \begin{bmatrix} \times & \times & \times & & \times & \times \\ \times & \times & & & \times & \times \\ \times & & \times & \times & \times & \times \\ & & \times & \times & & \times \\ \times & \times & \times & & \times & \times \\ \times & & \times & & \times & \\ & \times & \times & \times & \times & \times \end{bmatrix}.$$

(Again,  $\times$  denotes a nonzero element.) The Cholesky factor  $L_C$  of the symmetric positive definite matrix  $A^T A$  has the form:

$$L_C = \begin{bmatrix} \times & & & & & & \\ \times & \times & & & & & \\ \times & \times & \times & & & & \\ & & \times & \times & & & \\ \times & \times & \times & \times & \times & & \\ \times & \times & \times & \times & \times & \times & \\ & \times & \times & \times & \times & \times & \times \end{bmatrix}.$$

Note that  $\text{Struct}(L) \neq \text{Struct}(\hat{L})$ , but  $\text{Struct}(L) \subset \text{Struct}(L_C)$  and  $\text{Struct}(\hat{L}) \subset \text{Struct}(L_C)$ . Similarly,  $\text{Struct}(U) \neq \text{Struct}(\hat{U})$ , but  $\text{Struct}(U) \subset \text{Struct}(L_C^T)$  and  $\text{Struct}(\hat{U}) \subset \text{Struct}(L_C^T)$ . This example illustrates that when  $A$  has a zero-free diagonal the sparsity structure of the Cholesky factor of  $A^T A$  indeed contains the sparsity structure of  $L$  (or  $U^T$ ), irrespective of the choice of the pivot sequence.

7. It is shown in an earlier example that fill elements do occur in Gaussian elimination of sparse matrices. In order to allow for these fill elements during Gaussian elimination, the simple storage schemes (CCS or CRS) may not be sufficient. More sophisticated storage schemes are often needed. The choice of a storage scheme depends on the choice of the factorization algorithm. There are many implementations of sparse Gaussian elimination, such as *profile methods*, *left-looking methods*, *right-looking methods*, and *frontal/multifrontal methods* [DER89], [GL81]. Describing these implementations is beyond the scope of this chapter. Following is a list of pointers to some of the implementations.
  - (a) Factorization of sparse symmetric positive definite matrices: [NP93], [RG91].
  - (b) Factorization of sparse symmetric indefinite matrices: [AGL98], [DR83], [DR95], [Duf04], [Liu87a], [Liu87b].
  - (c) Factorization of sparse nonsymmetric matrices: [DEG<sup>+</sup>99], [Duf77], [DR96], [GP88].

## 40.4 Modeling and Analyzing Fill

---

A key component of sparse Gaussian elimination is the exploitation of the sparsity structure of the given matrix and its triangular factors. Graphs are useful in understanding and analyzing how fill elements are introduced in sparse Gaussian elimination. Some basic graph-theoretical tools and results are described in this section. Others can be found in [EL92], [GL81], [GL93], [GNP94], [Liu86], [Liu90], and [Sch82].

In this and the next sections, all graphs (bipartite graphs, directed graphs, and undirected graphs) are simple. That is, loops and multiple edges are not allowed. More information on graphs can be found in Chapter 28 (graphs), Chapter 29 (digraphs), and Chapter 30 (bipartite graphs).

### Definitions:

Consider a sparse nonsymmetric matrix  $A = [a_{i,j}]$ . Let  $R = \{r_1, r_2, \dots, r_n\}$  be a set of “row” vertices associated with the rows of  $A$ . Similarly, let  $C = \{c_1, c_2, \dots, c_n\}$  be a set of “column” vertices associated with the columns of  $A$ . The **bipartite graph** or **bigraph** of  $A$ , denoted by  $H(A) = (R, C, E)$ , can be associated with the sparsity structure of  $A$ . There is an edge  $\{r_i, c_j\} \in E$  if and only  $a_{i,j} \neq 0$ .

Let  $A = [a_{i,j}]$  be a sparse nonsymmetric matrix. Suppose that  $A$  has a zero-free diagonal, and assume that the pivots are always chosen from the diagonal. Then the sparsity structure of  $A$  can be represented by a **directed graph** or **digraph**, denoted by  $\Gamma(A) = (X, E)$ . Here,  $X = \{x_1, x_2, \dots, x_n\}$ , with  $x_i$ ,  $1 \leq i \leq n$ , representing column  $i$  and row  $i$  of  $A$ . There is a directed edge or arc  $(x_i, x_j) \in E$  if and only if  $a_{i,j} \neq 0$ , for  $i \neq j$ . (The nonzero elements on the diagonal of  $A$  are not represented.)

Suppose  $A = [a_{i,j}]$  is symmetric and positive definite, and assume that the pivots are always chosen from the diagonal. Then an **undirected graph** or **graph** (when the context is clear)  $G(A) = (X, E)$  can be used to represent the sparsity structure of  $A$ . Let  $X = \{x_1, x_2, \dots, x_n\}$ , with  $x_i$  representing row  $i$  and column  $i$  of  $A$ . There is an (undirected) edge  $\{x_i, x_j\} \in E$  if and only if  $a_{i,j} \neq 0$  (and, hence,  $a_{j,i} \neq 0$ ), for  $i \neq j$ . (The nonzero elements on the diagonal of  $A$  are not represented.)

A **path** in a graph (which can be a bigraph, digraph, or undirected graph) is a sequence of *distinct* vertices  $(x_{s_1}, x_{s_2}, \dots, x_{s_t})$  such that there is an edge between every pair of consecutive vertices. For bigraphs and undirected graphs,  $\{x_{s_p}, x_{s_{p+1}}\}$ ,  $1 \leq p \leq t-1$ , is an (undirected) edge. For digraphs, the path is a directed path, and  $(x_{s_p}, x_{s_{p+1}})$ ,  $1 \leq p \leq t-1$ , is an arc.

Let  $A$  be an  $n$  by  $n$  matrix. After  $k$  ( $1 \leq k \leq n$ ) steps of Gaussian elimination, the matrix remaining to be factored is the trailing submatrix that consists of the elements in the last  $(n-k)$  rows and the last

$(n - k)$  columns of  $A$ . The graph (bipartite, digraph, or undirected graph) associated with this  $(n - k)$  by  $(n - k)$  trailing matrix is the  $k$ -th **elimination graph**.

**Facts:**

1. [PM83] Let  $H^{(0)}, H^{(1)}, H^{(2)}, \dots, H^{(n)}$  be the sequence of elimination bigraphs associated with the Gaussian elimination of a sparse nonsymmetric matrix  $A = [a_{i,j}]$ . The initial bigraph  $H^{(0)}$  is the bigraph of  $A$ . Each elimination bigraph can be obtained from the previous one through a simple transformation. Suppose that the nonzero element  $a_{s,t}$  is chosen as the pivot at step  $k$ ,  $1 \leq k \leq n$ . Then the edge corresponding to  $a_{s,t}$ ,  $\{r_s, c_t\}$ , is removed from  $H^{(k-1)}$ , together with all the edges incident to  $r_s$  and  $c_t$ . To obtain the next elimination bigraph  $H^{(k)}$  from the modified  $H^{(k-1)}$ , an edge  $\{r, c\}$  is added if there is a path  $(r, c_t, r_s, c)$  in the original  $H^{(k-1)}$  and if  $\{r, c\}$  is not already in  $H^{(k-1)}$ . The new edges added to create  $H^{(k)}$  correspond to the fill elements introduced when  $a_{s,t}$  is used to eliminate row  $s$  and column  $t$ . The bigraph  $H^{(k)}$  represents the sparsity structure of the matrix remaining to be factored after row  $s$  and column  $t$  are eliminated.
2. [RT78] Let  $A$  be a sparse nonsymmetric matrix. Suppose that  $A$  has a zero-free diagonal and assume that pivots are restricted to the diagonal. Then Gaussian elimination can be modeled using elimination digraphs. Let  $\Gamma^{(0)}, \Gamma^{(1)}, \Gamma^{(2)}, \dots, \Gamma^{(n)}$  be the sequence of elimination digraphs. The initial digraph  $\Gamma^{(0)}$  is the digraph of  $A$ . Each elimination digraph can be obtained from the previous one through a simple transformation. Without loss of generality, assume that Gaussian elimination proceeds from row/column 1 to row/column  $n$ . Consider step  $k$ ,  $1 \leq k \leq n$ . Vertex  $x_k$  is removed from  $\Gamma^{(k-1)}$ , together with all the arcs of the form  $(x_k, u)$  and  $(v, x_k)$ , where  $u$  and  $v$  are vertices in  $\Gamma^{(k-1)}$ . To obtain the next elimination digraph  $\Gamma^{(k)}$  from the modified  $\Gamma^{(k-1)}$ , an arc  $(r, c)$  is added if there is a directed path  $(r, x_k, c)$  in the original  $\Gamma^{(k-1)}$  and if  $(r, c)$  is not already in  $\Gamma^{(k-1)}$ . The new arcs added to create  $\Gamma^{(k)}$  correspond to the fill elements introduced by Gaussian elimination at step  $k$ . The digraph  $\Gamma^{(k)}$  represents the sparsity structure of the matrix remaining to be factored after  $k$  steps of Gaussian elimination.
3. [Ros72] For a symmetric positive definite matrix  $A$ , the elimination graphs associated with Gaussian elimination can be represented by (undirected) graphs. Let the elimination graphs be denoted by  $G^{(0)}, G^{(1)}, G^{(2)}, \dots, G^{(n)}$ . The initial graph  $G^{(0)}$  is the graph of  $A$ . Each elimination graph can be obtained from the previous one through a simple transformation. Without loss of generality, assume that Gaussian elimination proceeds from row/column 1 to row/column  $n$ . Consider step  $k$ ,  $1 \leq k \leq n$ . Vertex  $x_k$  is removed from  $G^{(k-1)}$ , together with all its incident edges. To obtain the next elimination graph  $G^{(k)}$  from the modified  $G^{(k-1)}$ , an (undirected) edge  $\{r, c\}$  is added if there is a path  $(r, x_k, c)$  in the original  $G^{(k-1)}$  and if  $\{r, c\}$  is not already in  $G^{(k-1)}$ . The new edges added to create  $G^{(k)}$  correspond to the fill elements introduced by Gaussian elimination at step  $k$ . The graph  $G^{(k)}$  represents the sparsity structure of the matrix remaining to be factored after  $k$  steps of Gaussian elimination.
4. [GL80b], [RTL76] Consider an  $n$  by  $n$  symmetric positive definite matrix  $A$ . Let  $G = (X, E)$  be the (undirected) graph of  $A$  and let  $X = \{x_1, x_2, \dots, x_n\}$ . Denote the Cholesky factor of  $A$  by  $L$ . For  $i > j$ , the  $(i, j)$  element of  $L$  is nonzero if and only there is a path  $(x_i, x_{s_1}, x_{s_2}, \dots, x_{s_t}, x_j)$  in  $G$  such that  $s_p < j (< i)$ , for  $1 \leq p \leq t$ . Such a path is sometimes referred to as a *fill path*. Note that  $t$  can be zero, which corresponds to  $\{x_i, x_j\} \in E$ .

**Examples:**

1. As one may observe, the operations involved in the generation of the elimination bigraphs, digraphs, and graphs are very similar. Thus, only one example will be illustrated here. Consider the nonsymmetric matrix  $A = [a_{i,j}]$  in Figure 40.3. The bigraph  $H$  of  $A$  is depicted in Figure 40.4. Suppose that  $a_{1,1}$  is used to elimination row 1 and column 1. After the first step of Gaussian elimination, the remaining matrix is shown in Figure 40.5. Following the recipe given above, the edges  $\{r_1, c_1\}$ ,  $\{r_1, c_3\}$ ,  $\{r_1, c_6\}$ ,  $\{r_4, c_1\}$ , and  $\{r_7, c_1\}$  are to be removed from the bigraph  $H$  in Figure 40.4. Then  $r_1$

$$A = \begin{bmatrix} \times & & \times & & \times & & \\ & & & \times & & & \\ \times & & & & \times & \times & \\ & \times & & & & & \times \\ & & \times & & & \times & \times \\ \times & & & & \times & & \end{bmatrix}.$$

FIGURE 40.3 A sparse nonsymmetric matrix  $A$ .

FIGURE 40.4 The bigraph of the matrix  $A$  in Figure 40.3.

$$A' = \begin{bmatrix} & & \times & & & & \\ & \times & & & & & \\ & + & \times & \times & + & & \\ \times & & & & & & \times \\ & \times & & & \times & \times & \\ & + & & \times & + & & \end{bmatrix}.$$

FIGURE 40.5 The remaining matrix after the first step of Gaussian elimination on the matrix  $A$  in Figure 40.3.

and  $c_1$  are also removed from the bigraph  $H$ . The new bigraph is obtained by adding to  $H$  the following edges:

- (a)  $\{r_4, c_3\}$  (because of the path  $(r_4, c_1, r_1, c_3)$  in the original  $H$ ).
- (b)  $\{r_4, c_6\}$  (because of the path  $(r_4, c_1, r_1, c_6)$  in the original  $H$ ).
- (c)  $\{r_7, c_3\}$  (because of the path  $(r_7, c_1, r_1, c_3)$  in the original  $H$ ).
- (d)  $\{r_7, c_6\}$  (because of the path  $(r_7, c_1, r_1, c_6)$  in the original  $H$ ).

The new bigraph is shown in Figure 40.6, in which the new edges are shown as dashed lines. Note that the new bigraph is exactly the bigraph of  $A'$ .

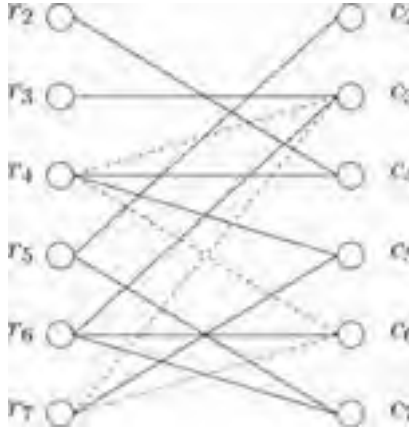

FIGURE 40.6 The bigraph of the matrix  $A'$  in Figure 40.5.

2. Let  $A = [a_{i,j}]$  be a symmetric and positive definite matrix:

$$A = \begin{bmatrix} \times & & & & & & & & \times \\ & \times & \times & & \times & & & & \\ \times & \times & \times & & & & & & \\ & & & \times & \times & & \times & & \\ \times & & & \times & \times & \times & \times & & \\ & & & & \times & \times & & \times & \\ & & & & \times & & \times & & \\ \times & & & & & \times & \times & \times & \end{bmatrix}.$$

Assume that exact numerical cancellations do not occur. Then the sparsity structure of the Cholesky factor  $L = [\ell_{i,j}]$  of  $A$  is given below:

$$L = \begin{bmatrix} \times & & & & & & & & \\ & \times & & & & & & & \\ \times & \times & \times & & & & & & \\ & & & \times & & & & & \\ \times & + & \times & \times & & & & & \\ & & & & \times & \times & & & \\ & & & & \times & + & + & \times & \\ \times & + & + & \times & + & \times & & \times & \end{bmatrix}.$$

The symbol  $+$  represents a fill element. The (undirected) graph  $G$  of  $A$  is shown in Figure 40.7. There are several fill paths in  $G$ . The fill path  $(x_5, x_2, x_3, x_1, x_8)$  corresponds to the fill element  $\ell_{8,5}$  in  $L$ . Another example is the fill path  $(x_7, x_4, x_5, x_6)$ , which corresponds to the fill element  $\ell_{7,6}$  in  $L$ .

FIGURE 40.7 An example illustrating fill paths.

## 40.5 Effect of Reorderings

Let  $A$  be a sparse nonsingular matrix. As noted above, the occurrence of fill elements in Gaussian elimination generally depends on the values of the nonzero elements in  $A$  (which affect the choice of pivots if numerical stability is a concern) and the sparsity structure of  $A$ . This section will consider some techniques that will help preserve the sparsity structure in the factorization of  $A$ .

### Definitions:

Let  $A$  be a sparse matrix. Suppose that  $G$  is a graph associated with  $A$  as described in the previous section; the graph can be a bipartite graph, directed graph, or undirected graph, depending on whether  $A$  is nonsymmetric or symmetric and whether the pivots are chosen to be on the diagonal. The **fill graph**  $G^F$  of  $A$  is  $G$ , together with all the additional edges corresponding to the fill elements that occur during Gaussian elimination.

An **elimination ordering** (or **elimination sequence**) for the rows (or columns) of a matrix is a bijection  $\alpha : \{1, 2, \dots, n\} \rightarrow \{1, 2, \dots, n\}$ . It specifies the order in which the rows (or columns) of the matrix are eliminated during Gaussian elimination.

A **perfect elimination ordering** is an elimination ordering that does not produce any fill elements during Gaussian elimination.

Consider an  $n$  by  $n$  sparse matrix  $A$ . Let  $f_i$  and  $\ell_i$  be the column indices of the *first* and *last* nonzero elements in row  $i$  of  $A$ , respectively. The **envelope** of  $A$  is the set

$$\{(i, j) : f_i \leq j \leq \ell_i, \text{ for } 1 \leq i \leq n\}.$$

That is, all the elements between the first and last nonzero elements of every row are in the envelope. The **profile** of a matrix is the number of elements in the envelope.

**Facts:**

The problem of reordering a sparse matrix is combinatorial in nature. The facts stated below are some of fundamental ones. Others can be found, for example, in [GL81] and [Gol04].

1. [GL81] An elimination ordering for the rows/columns of the matrix corresponds to a permutation of the rows/columns.
2. [DER89], [GL81] The choice of an elimination ordering will affect the number of fill elements in the triangular factors.
3. [GL81], [Ros72] When  $A$  is sparse symmetric positive definite, an elimination ordering  $\alpha$  can be determined by analyzing the sparsity structure of  $A$ . Equivalently,  $\alpha$  can be obtained by analyzing the sequence of elimination graphs. The elimination ordering provides a symmetric permutation of  $A$ . Let  $P$  denote the permutation matrix corresponding to  $\alpha$ . Let  $G^F$  be the fill graph of the matrix  $PAP^T$ . There exists a perfect elimination ordering for  $G^F$  and  $G^F$  is a chordal graph.
4. [Yan81] For sparse symmetric positive definite matrices, finding the optimal elimination ordering (i.e., an elimination ordering that minimizes the number of fill elements in the Cholesky factor) is NP-complete. This implies that almost all reordering techniques are heuristic in nature.
5. [DER89] When  $A$  is a sparse nonsymmetric matrix, the elimination orderings for the rows and columns of  $A$  have to be chosen to preserve the sparsity structure and to maintain numerical stability.
6. [GN85] Suppose that  $A$  is a sparse nonsymmetric matrix. If partial pivoting (by rows) is used to maintain numerical stability, then an elimination ordering for the columns of  $A$  can be chosen to preserve the sparsity structure.

**Examples:**

1. Consider the following two diagonally dominant matrices:

$$A = \begin{bmatrix} 7 & 1 & -1 & 1 & -1 \\ -1 & 7 & 0 & 0 & 0 \\ 1 & 0 & 7 & 0 & 0 \\ -1 & 0 & 0 & 7 & 0 \\ 1 & 0 & 0 & 0 & 7 \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} 7 & 0 & 0 & 0 & 1 \\ 0 & 7 & 0 & 0 & -1 \\ 0 & 0 & 7 & 0 & 1 \\ 0 & 0 & 0 & 7 & -1 \\ -1 & 1 & -1 & 1 & 7 \end{bmatrix}.$$

Applying Gaussian elimination to  $A$  produces the following triangular factors:

$$A = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ -\frac{1}{7} & 1 & 0 & 0 & 0 \\ \frac{1}{7} & -\frac{1}{50} & 1 & 0 & 0 \\ -\frac{1}{7} & \frac{1}{50} & -\frac{1}{51} & 1 & 0 \\ \frac{1}{7} & -\frac{1}{50} & \frac{1}{51} & -\frac{1}{52} & 0 \end{bmatrix} \begin{bmatrix} 7 & 1 & -1 & 1 & -1 \\ 0 & \frac{50}{7} & -\frac{1}{7} & \frac{1}{7} & -\frac{1}{7} \\ 0 & 0 & \frac{357}{50} & -\frac{7}{50} & \frac{7}{50} \\ 0 & 0 & 0 & \frac{364}{51} & -\frac{7}{51} \\ 0 & 0 & 0 & 0 & \frac{371}{52} \end{bmatrix}.$$

Applying Gaussian elimination to  $B$ , on the other hand, produces the following triangular factors:

$$B = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ -\frac{1}{7} & \frac{1}{7} & -\frac{1}{7} & \frac{1}{7} & 1 \end{bmatrix} \begin{bmatrix} 7 & 0 & 0 & 0 & 1 \\ 0 & 7 & 0 & 0 & -1 \\ 0 & 0 & 7 & 0 & 1 \\ 0 & 0 & 0 & 7 & -1 \\ 0 & 0 & 0 & 0 & \frac{53}{7} \end{bmatrix}.$$

The two matrices  $A$  and  $B$  have the *same* numbers of nonzero elements, but their respective triangular factors have *very different* numbers of fill elements. In fact, the triangular factors of  $B$

have *no* fill elements. Note that  $B$  can be obtained by permuting the rows and columns of  $A$ . Let  $P$  be the following permutation matrix:

$$P = \begin{bmatrix} 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \end{bmatrix}.$$

Then  $B = PAP^T$ ; that is,  $B$  is obtained by *reversing* the order of the rows and columns. This example illustrates that permuting the rows and columns of a sparse matrix may have a drastic effect on the sparsity structures of the triangular factors in Gaussian elimination.

2. A popular way to preserve the sparsity structure of a sparse matrix during Gaussian elimination is to find elimination orderings so that the nonzero elements in the permuted matrix are near the diagonal. This can be accomplished, for example, by permuting the matrix so that it has a small envelope or profile. The Cuthill–McKee algorithm [CM69] and the reverse Cuthill–McKee algorithms [Geo71], [LS76] are well-known heuristics for producing reorderings that reduce the profile of a sparse symmetric matrix. The permuted matrix can be factored using the *envelope* or *profile* method [GL81], which is similar to the factorization methods for band matrices. The storage scheme for the profile method is very simple. The permuted matrix is stored by rows. If the symmetric matrix is positive definite, then for every row of the permuted matrix, all the elements between the first nonzero element and the diagonal elements are stored. It is easy to show that the fill elements in the triangular factor can only occur inside the envelope of the lower triangular part of the permuted matrix.
3. Although the profile method is easy to implement, it is not designed to reduce the number of fill elements in Gaussian elimination. The nested dissection algorithm [Geo73], which is based on a divide-and-conquer idea, is a well-known heuristic for preserving the sparsity structure. Let  $A$  be a symmetric positive definite matrix, and let  $G = (X, E)$  be the (undirected) graph of  $A$ . Without loss of generality, assume that  $G$  is connected. Let  $S \subseteq X$ . Suppose that  $S$  is removed from  $G$ . Also assume that all edges incident to every vertex in  $S$  are removed from  $G$ . Denote the remaining graph by  $G(X - S)$ . If  $S$  is chosen so that  $G(X - S)$  contains one or more disconnected components, then the set  $S$  is referred to as a *separator*. Consider the following reordering strategy: renumber the vertices of the disconnected components of  $G(X - S)$  first, and renumber of the vertices of  $S$  last. Now pick vertex  $x$  in one component and vertex  $y$  in another component. The renumbering scheme ensures that there is *no* fill path between  $x$  and  $y$  in  $G$ . This is a heuristic way to limit the creation of fill elements. The renumbering corresponds to a symmetric permutation of the rows and columns of the matrix. Consider the example in Figure 40.8. The removal of the vertices in  $S$  (together with the incident edges) divides the mesh into two joint meshes (labeled  $G_1$  and  $G_2$ ). Suppose that the mesh points in  $G_1$  are renumbered before those in  $G_2$ . Then the matrix on the right in Figure 40.8 shows the sparsity structure of the permuted matrix. Note the block structure of the permuted matrix. The blocks  $A_1$  and  $A_2$  correspond to mesh points in  $G_1$  and  $G_2$ , respectively. The block  $A_S$  corresponds to the mesh points in  $S$ . The nonzero elements in the off-diagonal blocks  $C_1/C_2$  correspond to the edges between  $G_1/G_2$  and  $S$ . The unlabeled blocks are entirely zero. This is referred to as the “dissection” strategy. When the strategy is applied recursively to the disconnected components, more zero (but smaller) blocks will be created in  $A_1$  and  $A_2$ . The resulting reordering is called a “nested dissection” ordering. It can be shown that, when the nested dissection algorithm is applied to a  $k$  by  $k$  mesh (like the example in the Introduction), the number of nonzero elements in the Cholesky factor will be  $O(k^2 \log k)$  and the number of operations required to compute the Cholesky factor will be  $O(k^3)$ . Incidentally, for the  $k$  by  $k$  mesh, it has been proved that the number of nonzero elements in the Cholesky factor and the number of operations required to compute the triangular factorization are at least  $O(k^2 \log k)$  and  $O(k^3)$ , respectively [HMR73], [Geo73]. Thus, nested

FIGURE 40.8 An example of the dissection strategy.

dissection orderings can be optimal asymptotically. In recent years, higher quality nested dissection orderings have been obtained for general sparse symmetric matrices by using more sophisticated graph partitioning techniques to generate the separators [HR98], [PSL90], [Sch01].

4. The nested dissection algorithm is a “top-down” algorithm since it identifies the vertices (i.e., rows/columns) to be reordered last. The minimum degree algorithm [TW67] is a “bottom-up” algorithm. It is a heuristic that is best described using the elimination graphs. Let  $G^{(0)}$  be the (undirected) graph of a sparse symmetric positive definite matrix. The minimum degree algorithm picks the vertex  $x_m$  with the *smallest* degree (i.e., the smallest number of incident edges) to be eliminated; that is,  $x_m$  is to be reordered as the first vertex. Then  $x_m$ , together with all the edges incident to  $x_m$ , are eliminated from  $G^{(0)}$  to generate the next elimination graph  $G^{(1)}$ . This process is repeated until all the vertices are eliminated. The order in which the vertices are eliminated is a minimum degree ordering. Note that if several vertices have the minimum degree in the current elimination graph, then ties have to be broken. It is well known that the quality of a minimum degree ordering can be influenced by the choice of the tie-breaking strategy [BS90]. Several efficient implementations of the minimum degree algorithm are available [ADD96], [GL80b], [GL80a], [Liu85]. An excellent survey of the minimum degree algorithm can be found in [GL89].
5. The minimum deficiency algorithm [TW67] is another bottom-up strategy. It is similar to the minimum degree algorithm, except that the vertex whose elimination would introduce the *fewest* fill elements will be eliminated at each step. In general, the minimum deficiency algorithm is much more expensive to implement than the minimum degree algorithm. This is because the former one needs the *look-ahead* to predict the number of fill elements that would be introduced. However, inexpensive approximations to the minimum deficiency algorithms have been proposed recently [NR99], [RE98].
6. For a sparse nonsymmetric matrix  $A = [a_{i,j}]$ , there are analogs of the minimum degree and minimum deficiency algorithms. The Markowitz scheme [Mar57] is the nonsymmetric version of the minimum degree algorithm for sparse nonsymmetric matrices. Recall that  $nnz(A_{i,1:n})$  is the number of nonzero elements in row  $i$  of  $A$  and  $nnz(A_{1:n,j})$  is the number of nonzero elements in column  $j$  of  $A$ . For each nonzero  $a_{i,j}$  in  $A$ , define its “Markowitz” cost to be the product  $[nnz(A_{i,1:n}) - 1][nnz(A_{1:n,j}) - 1]$ , which would be the number of nonzero elements in the rank-1 update if  $a_{i,j}$  were chosen as pivot. At each step of Gaussian elimination, the nonzero element that has the *smallest* Markowitz cost will be chosen as the pivot. After the elimination, the Markowitz costs of all the nonzero elements, including the fill elements, are updated to reflect the change in

the sparsity structure before proceeding to the next step. If  $A$  is symmetric and positive definite, and if pivots are chosen from the diagonal, then the Markowitz scheme is the same as the minimum degree algorithm.

7. The Markowitz scheme for sparse nonsymmetric matrices attempts to preserve the sparsity structure by minimizing the number of nonzero elements introduced into the triangular factors at each step of Gaussian elimination. The resulting pivots may not lead to a numerically stable factorization. For example, the magnitude of a pivot may be too small compared to the magnitudes of the other nonzero elements in the matrix. To enhance numerical stability, a modified Markowitz scheme is often used. Denote the matrix to be factored by  $A = [a_{i,j}]$ . Let  $s = \max\{|a_{i,j}| : a_{i,j} \neq 0\}$ . Let  $\tau$  be a given tolerance; e.g.,  $\tau$  can be 0.01 or 0.001. Without loss of generality, consider the first step of Gaussian elimination of  $A$ . Instead of considering all nonzero elements in  $A$ , let  $C = \{a_{i,j} : |a_{i,j}| \geq \tau s\}$ . Thus,  $C$  is the subset of nonzero elements whose magnitudes are larger than or equal to  $\tau s$ ; it is the set of candidate pivots. Then the pivot search is limited to applying the Markowitz scheme to the nonzero elements in  $C$ . This is a compromise between preserving sparsity and maintaining numerical stability. The two parameters  $\tau$  and  $s$  are usually fixed throughout the entire Gaussian elimination process. The modified scheme is often referred to as the *threshold pivoting* scheme [Duf77].
8. As noted earlier, if Gaussian elimination with partial pivoting is used to factor a sparse nonsymmetric matrix  $A$ , then the columns may be permuted to preserve sparsity. Suppose that  $A$  has a zero-free diagonal, and let  $L_C$  be the Cholesky factor of the symmetric positive definite matrix  $A^T A$ . Since  $\text{Struct}(L) \subseteq \text{Struct}(L_C)$  and  $\text{Struct}(U) \subseteq \text{Struct}(L_C^T)$ , a possibility is to make sure that  $L_C$  is sparse. In other words, one can choose a permutation  $P_{L_C}$  for  $A^T A$  to reduce the number of nonzero elements in the Cholesky factor of  $P_{L_C}^T (A^T A) P_{L_C}$ . Note that  $P_{L_C}^T (A^T A) P_{L_C} = (A P_{L_C})^T (A P_{L_C})$ . Thus,  $P_{L_C}$  can be applied to the columns of  $A$  [GN85], [GN87].

Given an  $n$  by  $n$  nonsingular matrix  $A$  and an  $n$ -vector  $\mathbf{b}$ , the linear system  $A\mathbf{x} = \mathbf{b}$  can always be solved for  $\mathbf{x}$  by Gaussian elimination. The work required is approximately  $2n^3/3$  operations (additions, subtractions, multiplications, and divisions), and, in general,  $n^2$  words of storage are required. This is often acceptable if  $n$  is of moderate size, say  $n \leq 1000$ , but for much larger values of  $n$ , say,  $n \approx 10^6$ , both the work and storage for Gaussian elimination may become prohibitive.

Where do such large linear systems arise? They may occur in many different areas, but one important source is the numerical solution of partial differential equations (PDEs). Solutions to PDEs can be approximated by replacing derivatives by finite difference quotients. For example, to solve the equation

$$\frac{\partial}{\partial x} \left( a(x, y, z) \frac{\partial u}{\partial x} \right) + \frac{\partial}{\partial y} \left( a(x, y, z) \frac{\partial u}{\partial y} \right) + \frac{\partial}{\partial z} \left( a(x, y, z) \frac{\partial u}{\partial z} \right) = f(x, y, z) \quad \text{in } \Omega$$
$$u = g \quad \text{on boundary of } \Omega,$$

on a three-dimensional region  $\Omega$ , where  $a$ ,  $f$ , and  $g$  are given functions with  $a$  bounded away from 0, one might first divide the region  $\Omega$  into small subregions of width  $h$  in each direction, and then replace each partial derivative by a centered difference approximation; e.g.,

$$\frac{\partial}{\partial x} \left( a \frac{\partial u}{\partial x} \right) (x, y, z) \approx \frac{1}{h^2} [a(x + h/2, y, z)(u(x + h, y, z) - u(x, y, z)) - a(x - h/2, y, z)(u(x, y, z) - u(x - h, y, z))],$$

with similar approximations for  $\partial/\partial y(a\partial u/\partial y)$  and  $\partial/\partial z(a\partial u/\partial z)$ . If the resulting finite difference approximation to the differential operator is set equal to the right-hand side value  $f(x_i, y_j, z_k)$  at each of the interior mesh points  $(x_i, y_j, z_k)$ ,  $i = 1, \dots, n_1$ ,  $j = 1, \dots, n_2$ ,  $k = 1, \dots, n_3$ , then this gives a system of  $n = n_1 n_2 n_3$  linear equations for the  $n$  unknown values of  $u$  at these mesh points. If  $u_{ijk}$  denotes the approximation to  $u(x_i, y_j, z_k)$ , then the equations are

$$\begin{aligned} \frac{1}{h^2} [ & a(x_i + h/2, y_j, z_k)(u_{i+1,j,k} - u_{ijk}) - a(x_i - h/2, y_j, z_k)(u_{ijk} - u_{i-1,j,k}) \\ & + a(x_i, y_j + h/2, z_k)(u_{i,j+1,k} - u_{ijk}) - a(x_i, y_j - h/2, z_k)(u_{ijk} - u_{i,j-1,k}) \\ & + a(x_i, y_j, z_k + h/2)(u_{i,j,k+1} - u_{ijk}) - a(x_i, y_j, z_k - h/2)(u_{ijk} - u_{i,j,k-1}) ] \\ & = f(x_i, y_j, z_k). \end{aligned}$$

The formula must be modified near the boundary of the region, where known boundary values are added to the right-hand side. Still the result is a system of linear equations for the unknown interior values of  $u$ . If  $n_1 = n_2 = n_3 = 100$ , then the number of equations and unknowns is  $100^3 = 10^6$ .

Notice, however, that the system of linear equations is *sparse*; each equation involves only a few (in this case seven) of the unknowns. The actual form of the system matrix  $A$  depends on the numbering of equations and unknowns. Using the *natural ordering*, equations and unknowns are ordered first by  $i$ , then  $j$ , then  $k$ . The result is a *banded* matrix, whose bandwidth is approximately  $n_1 n_2$ , since unknowns in any  $z$  plane couple only to those in the same and adjacent  $z$  planes. This results in some savings for Gaussian elimination. Only entries inside the band need be stored because these are the only ones that *fill in* (become nonzero, even if originally they were zero) during the process. The resulting work is about  $2(n_1 n_2)^2 n$  operations, and the storage required is about  $n_1 n_2 n$  words. Still, this is too much when  $n_1 = n_2 = n_3 = 100$ . Different orderings can be used to further reduce fill in, but another option is to use iterative methods.

Because the matrix is so sparse, matrix-vector multiplication is very cheap. In the above example, the product of the matrix with a given vector can be accomplished with just  $7n$  multiplications and  $6n$  additions. The nonzeros of the matrix occupy only  $7n$  words and, in this case, they are so simple that they hardly need be stored at all. If the linear system  $Ax = b$  could be solved iteratively, using only matrix-vector multiplication and, perhaps, solution of some much simpler linear systems such as diagonal or sparse triangular systems, then a tremendous savings might be achieved in both work and storage.

This section describes how to solve such systems iteratively. While iterative methods are appropriate for sparse systems like the one above, they also may be useful for *structured systems*. If matrix-vector multiplication can be performed rapidly, and if the structure of the matrix is such that it is not necessary to store the entire matrix but only certain parts or values in order to carry out the matrix-vector multiplication, then iterative methods may be faster and require less storage than Gaussian elimination or other methods for solving  $Ax = b$ .

## 41.1 Krylov Subspaces and Preconditioners

### Definitions:

An **iterative method** for solving a linear system  $Ax = b$  is an algorithm that starts with an initial guess  $x_0$  for the solution and successively modifies that guess in an attempt to obtain improved approximate solutions  $x_1, x_2, \dots$

The **residual** at step  $k$  of an iterative method for solving  $Ax = b$  is the vector  $r_k \equiv b - Ax_k$ , where  $x_k$  is the approximate solution generated at step  $k$ . The initial residual is  $r_0 \equiv b - Ax_0$ , where  $x_0$  is the initial guess for the solution.

The **error** at step  $k$  is the difference between the true solution  $A^{-1}b$  and the approximate solution  $x_k$ :  $e_k \equiv A^{-1}b - x_k$ .

A **Krylov space** is a space of the form  $\text{span}\{q, Aq, A^2q, \dots, A^{k-1}q\}$ , where  $A$  is an  $n$  by  $n$  matrix and  $q$  is an  $n$ -vector. This space will be denoted as  $K_k(A, q)$ .

A **preconditioner** is a matrix  $M$  designed to improve the performance of an iterative method for solving the linear system  $A\mathbf{x} = \mathbf{b}$ . Linear systems with coefficient matrix  $M$  should be easier to solve than the original linear system, since such systems will be solved at each iteration.

The matrix  $M^{-1}A$  (for **left preconditioning**) or  $AM^{-1}$  (for **right preconditioning**) or  $L^{-1}AL^{-*}$  (for **Hermitian preconditioning**, when  $M = LL^*$ ) is sometimes referred to as the **preconditioned iteration matrix**.

Another name for a preconditioner is a **splitting**; that is, if  $A$  is written in the form  $A = M - N$ , then this is referred to as a splitting of  $A$ , and iterative methods based on this splitting are equivalent to methods using  $M$  as a preconditioner.

A **regular splitting** is one for which  $M$  is nonsingular with  $M^{-1} \geq 0$  (elementwise) and  $M \geq A$  (elementwise).

**Facts:**

The following facts and general information on Krylov spaces and preconditioners can be found, for example, in [Axe95], [Gre97], [Hac94], [Saa03], and [Vor03].

1. An iterative method may obtain the exact solution at some stage (in which case it might be considered a direct method), but it may still be thought of as an iterative method because the user is interested in obtaining a good approximate solution before the exact solution is reached.
2. Each iteration of an iterative method usually requires one or more matrix-vector multiplications, using the matrix  $A$  and possibly its Hermitian transpose  $A^*$ . An iteration may also require the solution of a preconditioning system  $M\mathbf{z} = \mathbf{r}$ .
3. The residual and error vector at step  $k$  of an iterative method are related by  $\mathbf{r}_k = A\mathbf{e}_k$ .
4. All of the iterative methods to be described in this chapter generate approximate solutions  $\mathbf{x}_k$ ,  $k = 1, 2, \dots$ , such that  $\mathbf{x}_k - \mathbf{x}_0$  lies in the Krylov space  $\text{span}\{\mathbf{z}_0, C\mathbf{z}_0, \dots, C^{k-1}\mathbf{z}_0\}$ , where  $\mathbf{z}_0$  is the initial residual, possibly multiplied by a preconditioner, and  $C$  is the preconditioned iteration matrix.
5. The *Jacobi*, *Gauss-Seidel*, and *SOR (successive overrelaxation)* methods use the simple iteration

$$\mathbf{x}_k = \mathbf{x}_{k-1} + M^{-1}(\mathbf{b} - A\mathbf{x}_{k-1}), \quad k = 1, 2, \dots,$$

with different preconditioners  $M$ . For the Jacobi method,  $M$  is taken to be the diagonal of  $A$ , while for the Gauss-Seidel method,  $M$  is the lower triangle of  $A$ . For the SOR method,  $M$  is of the form  $\omega^{-1}D - L$ , where  $D$  is the diagonal of  $A$ ,  $-L$  is the strict lower triangle of  $A$ , and  $\omega$  is a relaxation parameter. Subtracting each side of this equation from the true solution  $A^{-1}\mathbf{b}$ , we find that the error at step  $k$  is

$$\mathbf{e}_k = (I - M^{-1}A)\mathbf{e}_{k-1} = \dots = (I - M^{-1}A)^k\mathbf{e}_0.$$

Subtracting each side of this equation from  $\mathbf{e}_0$ , we find that  $\mathbf{x}_k$  satisfies

$$\begin{aligned} \mathbf{e}_0 - \mathbf{e}_k = \mathbf{x}_k - \mathbf{x}_0 &= [I - (I - M^{-1}A)^k]\mathbf{e}_0 \\ &= \left[ \sum_{j=1}^k \binom{k}{j} (-1)^{j-1} (M^{-1}A)^{j-1} \right] \mathbf{z}_0, \end{aligned}$$

where  $\mathbf{z}_0 = M^{-1}A\mathbf{e}_0 = M^{-1}\mathbf{r}_0$ . Thus,  $\mathbf{x}_k - \mathbf{x}_0$  lies in the Krylov space

$$\text{span}\{\mathbf{z}_0, (M^{-1}A)\mathbf{z}_0, \dots, (M^{-1}A)^{k-1}\mathbf{z}_0\}.$$

6. Standard *multigrid methods* for solving linear systems arising from partial differential equations are also of the form  $\mathbf{x}_k = \mathbf{x}_{k-1} + M^{-1}\mathbf{r}_{k-1}$ . For these methods, computing  $M^{-1}\mathbf{r}_{k-1}$  involves restricting the residual to a coarser grid or grids, solving (or iterating) with the linear system on those grids, and then prolonging the solution back to the finest grid.

**FIGURE 41.1** Convergence of iterative methods for the problem given in the introduction with  $a(x, y, z) = 1 + x + 3yz$ ,  $h = 1/50$ . Jacobi (dashed), Gauss–Seidel (dash-dot), and SOR with  $\omega = 1.9$  (solid).

### Applications:

- Figure 41.1 shows the convergence of the Jacobi, Gauss–Seidel, and SOR (with  $\omega = 1.9$ ) iterative methods for the problem described at the beginning of this chapter, using a mildly varying coefficient  $a(x, y, z) = 1 + x + 3yz$  on the unit cube  $\Omega = [0, 1] \times [0, 1] \times [0, 1]$  with homogeneous Dirichlet boundary conditions,  $u = 0$  on  $\partial\Omega$ . The right-hand side function  $f$  was chosen so that the solution to the differential equation would be  $u(x, y, z) = x(1 - x)y^2(1 - y)z(1 - z)^2$ . The region was discretized using a  $50 \times 50 \times 50$  mesh, and the natural ordering of nodes was used, along with a zero initial guess.

## 41.2 Optimal Krylov Space Methods for Hermitian Problems

Throughout this section, we let  $A$  and  $b$  denote the already preconditioned matrix and right-hand side vector, and we assume that  $A$  is Hermitian. Note that if the original coefficient matrix is Hermitian, then this requires Hermitian positive definite preconditioning (preconditioner of the form  $M = LL^*$  and preconditioned matrix of the form  $L^{-1}AL^{-*}$ ) in order to maintain this property.

### Definitions:

The **Minimal Residual (MINRES)** algorithm generates, at each step  $k$ , the approximation  $\mathbf{x}_k$  with  $\mathbf{x}_k - \mathbf{x}_0 \in K_k(A, \mathbf{r}_0)$  for which the 2-norm of the residual,  $\|\mathbf{r}_k\| \equiv \langle \mathbf{r}_k, \mathbf{r}_k \rangle^{1/2}$ , is minimal.

The **Conjugate Gradient (CG)** algorithm for Hermitian positive definite matrices generates, at each step  $k$ , the approximation  $\mathbf{x}_k$  with  $\mathbf{x}_k - \mathbf{x}_0 \in K_k(A, \mathbf{r}_0)$  for which the  $A$ -norm of the error,  $\|\mathbf{e}_k\|_A \equiv \langle \mathbf{e}_k, A\mathbf{e}_k \rangle^{1/2}$ , is minimal. (Note that this is sometimes referred to as the  $A^{1/2}$ -norm of the error, e.g., in Chapter 37 of this book.)

The **Lanczos** algorithm for Hermitian matrices is a short recurrence for constructing an orthonormal basis for a Krylov space.

**Facts:**

The following facts can be found in any of the general references [Axe95], [Gre97], [Hac94], [Saa03], and [Vor03].

1. The Lanczos algorithm [Lan50] is implemented as follows:

**Lanczos Algorithm.** (For Hermitian matrices  $A$ )

Given  $\mathbf{q}_1$  with  $\|\mathbf{q}_1\| = 1$ , set  $\beta_0 = 0$ . For  $j = 1, 2, \dots$ ,

$$\tilde{\mathbf{q}}_{j+1} = A\mathbf{q}_j - \beta_{j-1}\mathbf{q}_{j-1}. \text{ Set } \alpha_j = \langle \tilde{\mathbf{q}}_{j+1}, \mathbf{q}_j \rangle, \quad \bar{\mathbf{q}}_{j+1} \leftarrow \tilde{\mathbf{q}}_{j+1} - \alpha_j \mathbf{q}_j.$$

$$\beta_j = \|\bar{\mathbf{q}}_{j+1}\|, \quad \mathbf{q}_{j+1} = \bar{\mathbf{q}}_{j+1}/\beta_j.$$

2. It can be shown by induction that the Lanczos vectors  $\mathbf{q}_1, \mathbf{q}_2, \dots$  produced by the above algorithm are orthogonal. Gathering the first  $k$  vectors together as the columns of an  $n$  by  $k$  matrix  $Q_k$ , this recurrence can be written succinctly in the form

$$AQ_k = Q_k T_k + \beta_k \mathbf{q}_{k+1} \xi_k^T,$$

where  $\xi_k \equiv (0, \dots, 0, 1)^T$  is the  $k$ th unit vector and  $T_k$  is the tridiagonal matrix of recurrence coefficients:

$$T_k \equiv \begin{pmatrix} \alpha_1 & \beta_1 & & & \\ \beta_1 & \ddots & \ddots & & \\ & \ddots & \ddots & \beta_{k-1} & \\ & & & \beta_{k-1} & \alpha_k \end{pmatrix}.$$

The above equation is sometimes written in the form

$$AQ_k = Q_{k+1} \underline{T}_k,$$

where  $\underline{T}_k$  is the  $k + 1$  by  $k$  matrix whose top  $k$  by  $k$  block is  $T_k$  and whose bottom row is zero except for the last entry which is  $\beta_k$ .

3. If the initial vector  $\mathbf{q}_1$  in the Lanczos algorithm is taken to be  $\mathbf{q}_1 = \mathbf{r}_0/\|\mathbf{r}_0\|$ , then the columns of  $Q_k$  span the Krylov space  $K_k(A, \mathbf{r}_0)$ . Both the MINRES and CG algorithms take the approximation  $\mathbf{x}_k$  to be of the form  $\mathbf{x}_0 + Q_k \mathbf{y}_k$  for a certain vector  $\mathbf{y}_k$ . For the MINRES algorithm,  $\mathbf{y}_k$  is the solution of the  $k + 1$  by  $k$  least squares problem

$$\min_{\mathbf{y}} \|\beta \xi_1 - \underline{T}_k \mathbf{y}\|,$$

where  $\beta \equiv \|\mathbf{r}_0\|$  and  $\xi_1 \equiv (1, 0, \dots, 0)^T$  is the first unit vector. For the CG algorithm,  $\mathbf{y}_k$  is the solution of the  $k$  by  $k$  tridiagonal system

$$T_k \mathbf{y} = \beta \xi_1.$$

4. The following algorithms are standard implementations of the CG and MINRES methods.

**Conjugate Gradient Method (CG).**

(For Hermitian Positive Definite Problems)

Given an initial guess  $\mathbf{x}_0$ , compute  $\mathbf{r}_0 = \mathbf{b} - A\mathbf{x}_0$  and set  $\mathbf{p}_0 = \mathbf{r}_0$ . For  $k = 1, 2, \dots$ ,

Compute  $A\mathbf{p}_{k-1}$ .

Set  $\mathbf{x}_k = \mathbf{x}_{k-1} + a_{k-1}\mathbf{p}_{k-1}$ , where  $a_{k-1} = \frac{(\mathbf{r}_{k-1}, \mathbf{r}_{k-1})}{(\mathbf{p}_{k-1}, A\mathbf{p}_{k-1})}$ .

Compute  $\mathbf{r}_k = \mathbf{r}_{k-1} - a_{k-1}A\mathbf{p}_{k-1}$ .

Set  $\mathbf{p}_k = \mathbf{r}_k + b_{k-1}\mathbf{p}_{k-1}$ , where  $b_{k-1} = \frac{(\mathbf{r}_k, \mathbf{r}_k)}{(\mathbf{r}_{k-1}, \mathbf{r}_{k-1})}$ .

**Minimal Residual Algorithm (MINRES).** (For Hermitian Problems)

Given  $\mathbf{x}_0$ , compute  $\mathbf{r}_0 = \mathbf{b} - A\mathbf{x}_0$  and set  $\mathbf{q}_1 = \mathbf{r}_0 / \|\mathbf{r}_0\|$ .

Initialize  $\xi = (1, 0, \dots, 0)^T$ ,  $\beta = \|\mathbf{r}_0\|$ . For  $k = 1, 2, \dots$ ,

Compute  $\mathbf{q}_{k+1}$ ,  $\alpha_k \equiv T(k, k)$ , and  $\beta_k \equiv T(k+1, k) \equiv T(k, k+1)$  using the Lanczos algorithm.

Apply rotations  $F_{k-2}$  and  $F_{k-1}$  to the last column of  $T$ ; that is,

$$\begin{pmatrix} T(k-2, k) \\ T(k-1, k) \end{pmatrix} \leftarrow \begin{pmatrix} c_{k-2} & s_{k-2} \\ -\bar{s}_{k-2} & c_{k-2} \end{pmatrix} \begin{pmatrix} 0 \\ T(k-1, k) \end{pmatrix}, \text{ if } k > 2,$$

$$\begin{pmatrix} T(k-1, k) \\ T(k, k) \end{pmatrix} \leftarrow \begin{pmatrix} c_{k-1} & s_{k-1} \\ -\bar{s}_{k-1} & c_{k-1} \end{pmatrix} \begin{pmatrix} T(k-1, k) \\ T(k, k) \end{pmatrix}, \text{ if } k > 1.$$

Compute the  $k^{\text{th}}$  rotation,  $c_k$  and  $s_k$ , to annihilate the  $(k+1, k)$  entry of  $T$ :

$$c_k = |T(k, k)| / \sqrt{|T(k, k)|^2 + |T(k+1, k)|^2}, \bar{s}_k = c_k T(k+1, k) / T(k, k).$$

Apply  $k^{\text{th}}$  rotation to  $\xi$  and to last column of  $T$ :

$$\begin{pmatrix} \xi(k) \\ \xi(k+1) \end{pmatrix} \leftarrow \begin{pmatrix} c_k & s_k \\ -\bar{s}_k & c_k \end{pmatrix} \begin{pmatrix} \xi(k) \\ 0 \end{pmatrix}.$$

$$T(k, k) \leftarrow c_k T(k, k) + s_k T(k+1, k), \quad T(k+1, k) \leftarrow 0.$$

Compute  $\mathbf{p}_{k-1} = [\mathbf{q}_k - T(k-1, k)\mathbf{p}_{k-2} - T(k-2, k)\mathbf{p}_{k-3}] / T(k, k)$ , where undefined terms are zero for  $k \leq 2$ .

Set  $\mathbf{x}_k = \mathbf{x}_{k-1} + a_{k-1}\mathbf{p}_{k-1}$ , where  $a_{k-1} = \beta\xi(k)$ .

5. In exact arithmetic, both the CG and the MINRES algorithms obtain the exact solution in at most  $n$  steps, since the affine space  $\mathbf{x}_0 + K_n(A, \mathbf{r}_0)$  contains the true solution.

FIGURE 41.2 Convergence of MINRES (solid) and CG (dashed) for the problem given in the introduction with  $a(x, y, z) = 1 + x + 3yz$ ,  $h = 1/50$ .

**Applications:**

- Figure 41.2 shows the convergence (in terms of the 2-norm of the residual) of the (unpreconditioned) CG and MINRES algorithms for the same problem used in the previous section. Note that the 2-norm of the residual decreases monotonically in the MINRES algorithm, but not in the CG algorithm. Had we instead plotted the  $A$ -norm of the error, then the CG convergence curve would have been below that for MINRES.

### 41.3 Optimal and Nonoptimal Krylov Space Methods for Non-Hermitian Problems

In this section, we again let  $A$  and  $\mathbf{b}$  denote the already preconditioned matrix and right-hand side vector. The matrix  $A$  is assumed to be a general nonsingular  $n$  by  $n$  matrix.

**Definitions:**

The **Generalized Minimal Residual (GMRES)** algorithm generates, at each step  $k$ , the approximation  $\mathbf{x}_k$  with  $\mathbf{x}_k - \mathbf{x}_0 \in K_k(A, \mathbf{r}_0)$  for which the 2-norm of the residual is minimal.

The **Full Orthogonalization Method (FOM)** generates, at each step  $k$ , the approximation  $\mathbf{x}_k$  with  $\mathbf{x}_k - \mathbf{x}_0 \in K_k(A, \mathbf{r}_0)$  for which the residual is orthogonal to the Krylov space  $K_k(A, \mathbf{r}_0)$ .

The **Arnoldi algorithm** is a method for constructing an orthonormal basis for a Krylov space that requires saving all of the basis vectors and orthogonalizing against them at each step.

The **restarted GMRES algorithm**,  $\text{GMRES}(j)$ , is defined by simply restarting GMRES every  $j$  steps, using the latest iterate as the initial guess for the next GMRES cycle. Sometimes partial information from the previous GMRES cycle is retained and used after the restart.

The **non-Hermitian (or two-sided) Lanczos algorithm** uses a pair of three-term recurrences involving  $A$  and  $A^*$  to construct **biorthogonal** bases for the Krylov spaces  $K_k(A, \mathbf{r}_0)$  and  $K_k(A^*, \hat{\mathbf{r}}_0)$ , where  $\hat{\mathbf{r}}_0$  is a given vector with  $\langle \mathbf{r}_0, \hat{\mathbf{r}}_0 \rangle \neq 0$ . If the vectors  $\mathbf{v}_1, \dots, \mathbf{v}_k$  are the basis vectors for  $K_k(A, \mathbf{r}_0)$ , and  $\mathbf{w}_1, \dots, \mathbf{w}_k$  are the basis vectors for  $K_k(A^*, \hat{\mathbf{r}}_0)$ , then  $\langle \mathbf{v}_i, \mathbf{w}_j \rangle = 0$  for  $i \neq j$ .

In the **BICG** (biconjugate gradient) method, the approximate solution  $\mathbf{x}_k$  is chosen so that the residual  $\mathbf{r}_k$  is orthogonal to  $K_k(A^*, \hat{\mathbf{r}}_0)$ .

In the QMR (quasi-minimal residual) algorithm, the approximate solution  $\mathbf{x}_k$  is chosen to minimize a quantity that is related to (but not necessarily equal to) the residual norm.

The CGS (conjugate gradient squared) algorithm constructs an approximate solution  $\mathbf{x}_k$  for which  $\mathbf{r}_k = \varphi_k^2(A)\mathbf{r}_0$ , where  $\varphi_k(A)$  is the  $k$ th degree polynomial constructed in the BiCG algorithm; that is, the BiCG residual at step  $k$  is  $\varphi_k(A)\mathbf{r}_0$ .

The BiCGSTAB algorithm combines CGS with a one or more step residual norm minimizing method to smooth out the convergence.

### Facts:

1. The Arnoldi algorithm [Arn51] is implemented as follows:

**Arnoldi Algorithm.**

Given  $\mathbf{q}_1$  with  $\|\mathbf{q}_1\| = 1$ . For  $j = 1, 2, \dots$ ,

$\tilde{\mathbf{q}}_{j+1} = A\mathbf{q}_j$ . For  $i = 1, \dots, j$ ,  $h_{ij} = \langle \tilde{\mathbf{q}}_{j+1}, \mathbf{q}_i \rangle$ ,  $\tilde{\mathbf{q}}_{j+1} \leftarrow \tilde{\mathbf{q}}_{j+1} - h_{ij}\mathbf{q}_i$ .

$h_{j+1,j} = \|\tilde{\mathbf{q}}_{j+1}\|$ ,  $\mathbf{q}_{j+1} = \tilde{\mathbf{q}}_{j+1}/h_{j+1,j}$ .

2. Unlike the Hermitian case, if  $A$  is non-Hermitian then there is no known algorithm for finding the optimal approximations from successive Krylov spaces, while performing only  $O(n)$  operations per iteration. In fact, a theorem due to Faber and Manteuffel [FM84] shows that for most non-Hermitian matrices  $A$  there is no short recurrence that generates these optimal approximations for successive values  $k = 1, 2, \dots$ . Hence, the current options for non-Hermitian problems are either to perform extra work ( $O(nk)$  operations at step  $k$ ) and use extra storage ( $O(nk)$  words to perform  $k$  iterations) to find optimal approximations from the successive Krylov subspaces or to settle for nonoptimal approximations. The (full) GMRES (generalized minimal residual) algorithm [SS86] finds the approximation for which the 2-norm of the residual is minimal, at the cost of this extra work and storage, while other non-Hermitian iterative methods (e.g., BiCG [Fle75], CGS [Son89], QMR [FN91], BiCGSTAB [Vor92], and restarted GMRES [SS86], [Mor95], [DeS99]) generate nonoptimal approximations.
3. Similar to the MINRES algorithm, the GMRES algorithm uses the Arnoldi iteration defined above to construct an orthonormal basis for the Krylov space  $K_k(A, \mathbf{r}_0)$ .

If  $Q_k$  is the  $n$  by  $k$  matrix with the orthonormal basis vectors  $\mathbf{q}_1, \dots, \mathbf{q}_k$  as columns, then the Arnoldi iteration can be written simply as

$$AQ_k = Q_k H_k + h_{k+1,k} \mathbf{q}_{k+1} \xi_k^T = Q_{k+1} \underline{H}_k.$$

Here  $H_k$  is the  $k$  by  $k$  upper Hessenberg matrix with  $(i, j)$  entry equal to  $h_{ij}$ , and  $\underline{H}_k$  is the  $k+1$  by  $k$  matrix whose upper  $k$  by  $k$  block is  $H_k$  and whose bottom row is zero except for the last entry, which is  $h_{k+1,k}$ .

If  $\mathbf{q}_1 = \mathbf{r}_0/\|\mathbf{r}_0\|$ , then the columns of  $Q_k$  span the Krylov space  $K_k(A, \mathbf{r}_0)$ , and the GMRES approximation is taken to be of the form  $\mathbf{x}_k = \mathbf{x}_0 + Q_k \mathbf{y}_k$  for some vector  $\mathbf{y}_k$ . To minimize the 2-norm of the residual, the vector  $\mathbf{y}_k$  is chosen to solve the least squares problem

$$\min_{\mathbf{y}} \|\beta \xi_1 - \underline{H}_k \mathbf{y}\|, \quad \beta \equiv \|\mathbf{r}_0\|.$$

The GMRES algorithm [SS86] can be implemented as follows:

**Generalized Minimal Residual Algorithm (GMRES).**  
 Given  $\mathbf{x}_0$ , compute  $\mathbf{r}_0 = \mathbf{b} - A\mathbf{x}_0$  and set  $\mathbf{q}_1 = \mathbf{r}_0 / \|\mathbf{r}_0\|$ .  
 Initialize  $\xi = (1, 0, \dots, 0)^T$ ,  $\beta = \|\mathbf{r}_0\|$ . For  $k = 1, 2, \dots$ ,  
 Compute  $\mathbf{q}_{k+1}$  and  $h_{i,k} \equiv H(i, k)$ ,  $i = 1, \dots, k+1$ , using the Arnoldi algorithm.  
 Apply rotations  $F_1, \dots, F_{k-1}$  to the last column of  $H$ ; that is,  
 For  $i = 1, \dots, k-1$ ,

$$\begin{pmatrix} H(i, k) \\ H(i+1, k) \end{pmatrix} \leftarrow \begin{pmatrix} c_i & s_i \\ -\bar{s}_i & c_i \end{pmatrix} \begin{pmatrix} H(i, k) \\ H(i+1, k) \end{pmatrix}.$$

Compute the  $k^{\text{th}}$  rotation,  $c_k$  and  $s_k$ , to annihilate the  $(k+1, k)$  entry of  $H$ :  
 $c_k = |H(k, k)| / \sqrt{|H(k, k)|^2 + |H(k+1, k)|^2}$ ,  $\bar{s}_k = c_k H(k+1, k) / H(k, k)$ .  
 Apply  $k^{\text{th}}$  rotation to  $\xi$  and to last column of  $H$ :

$$\begin{pmatrix} \xi(k) \\ \xi(k+1) \end{pmatrix} \leftarrow \begin{pmatrix} c_k & s_k \\ -\bar{s}_k & c_k \end{pmatrix} \begin{pmatrix} \xi(k) \\ 0 \end{pmatrix}$$

$$H(k, k) \leftarrow c_k H(k, k) + s_k H(k+1, k), \quad H(k+1, k) \leftarrow 0.$$

If residual norm estimate  $\beta|\xi(k+1)|$  is sufficiently small, then  
 Solve upper triangular system  $H_{k \times k} \mathbf{y}_k = \beta \xi_{k \times 1}$ .  
 Compute  $\mathbf{x}_k = \mathbf{x}_0 + Q_k \mathbf{y}_k$ .

4. The (full) GMRES algorithm described above may be impractical because of increasing storage and work requirements, if the number of iterations needed to solve the linear system is large. In this case, the restarted GMRES algorithm or one of the algorithms based on the non-Hermitian Lanczos process may provide a reasonable alternative. The BiCGSTAB algorithm [Vor92] is often among the most effective iteration methods for solving non-Hermitian linear systems. The algorithm can be written as follows:

**BiCGSTAB.**

Given  $\mathbf{x}_0$ , compute  $\mathbf{r}_0 = \mathbf{b} - A\mathbf{x}_0$  and set  $\mathbf{p}_0 = \mathbf{r}_0$ . Choose  $\hat{\mathbf{r}}_0$  such that  $\langle \mathbf{r}_0, \hat{\mathbf{r}}_0 \rangle \neq 0$ .  
 For  $k = 1, 2, \dots$ ,

Compute  $A\mathbf{p}_{k-1}$ .

Set  $\mathbf{x}_{k-1/2} = \mathbf{x}_{k-1} + a_{k-1}\mathbf{p}_{k-1}$ , where  $a_{k-1} = \frac{\langle \mathbf{r}_{k-1}, \hat{\mathbf{r}}_0 \rangle}{\langle A\mathbf{p}_{k-1}, \hat{\mathbf{r}}_0 \rangle}$ .

Compute  $\mathbf{r}_{k-1/2} = \mathbf{r}_{k-1} - a_{k-1}A\mathbf{p}_{k-1}$ .

Compute  $A\mathbf{r}_{k-1/2}$ .

Set  $\mathbf{x}_k = \mathbf{x}_{k-1/2} + \omega_k \mathbf{r}_{k-1/2}$ , where  $\omega_k = \frac{\langle \mathbf{r}_{k-1/2}, A\mathbf{r}_{k-1/2} \rangle}{\langle A\mathbf{r}_{k-1/2}, A\mathbf{r}_{k-1/2} \rangle}$ .

Compute  $\mathbf{r}_k = \mathbf{r}_{k-1/2} - \omega_k A\mathbf{r}_{k-1/2}$ .

Compute  $\mathbf{p}_k = \mathbf{r}_k + b_k(\mathbf{p}_{k-1} - \omega_k A\mathbf{p}_{k-1})$ , where  $b_k = \frac{a_{k-1}}{\omega_k} \frac{\langle \mathbf{r}_k, \hat{\mathbf{r}}_0 \rangle}{\langle \mathbf{r}_{k-1}, \hat{\mathbf{r}}_0 \rangle}$ .

5. The non-Hermitian Lanczos algorithm can break down if  $\langle \mathbf{v}_i, \mathbf{w}_i \rangle = 0$ , but neither  $\mathbf{v}_i$  nor  $\mathbf{w}_i$  is zero. In this case **look-ahead** strategies have been devised to skip steps at which the Lanczos vectors are undefined. See, for instance, [PTL85], [Nac91], and [FN91]. These look-ahead procedures are used in the QMR algorithm.
6. When  $A$  is Hermitian and  $\hat{\mathbf{r}}_0 = \mathbf{r}_0$ , the BiCG method reduces to the CG algorithm, while the QMR method reduces to the MINRES algorithm.
7. The question of which iterative method to use is, of course, an important one. Unfortunately, there is no straightforward answer. It is problem dependent and may depend also on the type of machine being used. If matrix-vector multiplication is very expensive (e.g., if  $A$  is dense and has no special properties to enable fast matrix-vector multiplication), then full GMRES is probably the method of choice because it requires the fewest matrix-vector multiplications to reduce the residual norm to a desired level. If matrix-vector multiplication is not so expensive or if storage becomes a problem for full GMRES, then a restarted GMRES algorithm, some variant of the QMR method, or some variant of BiCGSTAB may be a reasonable alternative. With a sufficiently good preconditioner, each of these iterative methods can be expected to find a good approximate solution quickly. In fact, with a sufficiently good preconditioner  $M$ , an even simpler iteration method such as  $\mathbf{x}_k = \mathbf{x}_{k-1} + M^{-1}(\mathbf{b} - A\mathbf{x}_{k-1})$  may converge in just a few iterations, and this avoids the cost of inner products and other things in the more sophisticated Krylov space methods.

### Applications:

**FIGURE 41.3** Convergence of full GMRES (solid), restarted GMRES (restarted every 10 steps) (dashed), QMR (dotted), and BiCGSTAB (dash-dot) for a problem from neutron transport. For GMRES (full or restarted), the number of matrix-vector multiplications is the same as the number of iterations, while for QMR and BiCGSTAB, the number of matrix-vector multiplications is *twice* the number of iterations.

1. To illustrate the behavior of iterative methods for solving non-Hermitian linear systems, we have taken a simple problem involving the Boltzmann transport equation in one dimension:

$$\mu \frac{\partial \psi}{\partial x} + \sigma_T \psi - \sigma_s \phi = f, \quad x \in [a, b], \quad \mu \in [-1, 1],$$

where

$$\phi(x) = \frac{1}{2} \int_{-1}^1 \psi(x, \mu') d\mu',$$

with boundary conditions

$$\psi(b, \mu) = \psi_b(\mu), \quad -1 \leq \mu < 0,$$

$$\psi(a, \mu) = \psi_a(\mu), \quad 0 < \mu \leq 1.$$

The difference method used is described in [Gre97], and a test problem from [ML82] was solved. Figure 41.3 shows the convergence of full GMRES, restarted GMRES (restarted every 10 steps), QMR, and BiCGSTAB. One should keep in mind that each iteration of the QMR algorithm requires *two* matrix-vector multiplications, one with  $A$  and one with  $A^*$ . Still, the QMR approximation at iteration  $k$  lies in the  $k$ -dimensional affine space  $\mathbf{x}_0 + \text{span}\{\mathbf{r}_0, A\mathbf{r}_0, \dots, A^{k-1}\mathbf{r}_0\}$ . Each iteration of the BiCGSTAB algorithm requires *two* matrix-vector multiplications with  $A$ , and the approximate solution generated at step  $k$  lies in the  $2k$ -dimensional affine space  $\mathbf{x}_0 + \text{span}\{\mathbf{r}_0, A\mathbf{r}_0, \dots, A^{2k-1}\mathbf{r}_0\}$ . The full GMRES algorithm finds the optimal approximation from this space at step  $2k$ . Thus, the GMRES residual norm at step  $2k$  is guaranteed to be less than or equal to the BiCGSTAB residual norm at step  $k$ , and each requires the *same* number of matrix-vector multiplications to compute.

## 41.4 Preconditioners

---

### Definitions:

An **incomplete Cholesky decomposition** is a preconditioner for a Hermitian positive definite matrix  $A$  of the form  $M = LL^*$ , where  $L$  is a sparse lower triangular matrix. The entries of  $L$  are chosen so that certain entries of  $LL^*$  match those of  $A$ . If  $L$  is taken to have the same sparsity pattern as the lower triangle of  $A$ , then its entries are chosen so that  $LL^*$  matches  $A$  in the positions where  $A$  has nonzeros.

A **modified incomplete Cholesky decomposition** is a preconditioner of the same form  $M = LL^*$  as the incomplete Cholesky preconditioner, but the entries of  $L$  are modified so that instead of having  $M$  match as many entries of  $A$  as possible, the preconditioner  $M$  has certain other properties, such as the same row sums as  $A$ .

An **incomplete LU decomposition** is a preconditioner for a general matrix  $A$  of the form  $M = LU$ , where  $L$  and  $U$  are sparse lower and upper triangular matrices, respectively. The entries of  $L$  and  $U$  are chosen so that certain entries of  $LU$  match the corresponding entries of  $A$ .

A **sparse approximate inverse** is a sparse matrix  $M^{-1}$  constructed to approximate  $A^{-1}$ .

A **multigrid** preconditioner is a preconditioner designed for problems arising from partial differential equations discretized on grids. Solving the preconditioning system  $Mz = r$  entails *restricting* the residual to coarser grids, performing relaxation steps for the linear system corresponding to the same differential operator on the coarser grids, and *prolonging* solutions back to finer grids.
