And because mathematical proof reveals an insight into "the way things have to be" we realise that the Pythagorean theorem would have to be true in any possible world we could imagine. For example, aliens on other planets would at some stage of their technological evolution undoubtedly independently discover their own version of the Pythagorean theorem. The great mathematician Carl Friedrich Gauss suggested that the diagram of the Pythagorean theorem should be drawn on the Siberian tundra so that Martian observers would recognise that there was intelligent life on Earth. The outlines of the shapes were to be ten-mile-wide strips of pine forest. The interiors of the shapes were to be giant fields of yellow wheat.

We can feel certain about the universal truth of mathematical theorems because they are derived — in a sequence of logical steps — from simple *axioms*. Axioms can be considered the foundation stones of mathematics. They are simple propositions which are considered as being "obviously true". For example, the axioms of classical geometry were defined by the Greek mathematician Euclid. These five axioms are:

1. It is possible to draw a straight line from any point to any other point.
2. It is possible to extend a straight line indefinitely.
3. It is possible to draw a circle with any centre and any radius.
4. All right angles are equal to one another.
5. Parallel lines never meet — no matter how long they are.

Though these axioms might appear trivially simple, all of classical geometry (including the Pythagorean theorem) can be derived by logical reasoning (building up) from these five axioms. In fact, it is the simplicity of the axioms which gives them their strength: the truth of these axioms appears intuitively obvious. And it is the obvious truth of its axioms which provides mathematics with its universal certainty.

However, it was known that the last of Euclid's five axioms — the *parallel postulate* — was not quite as intuitively obvious as the other four axioms. Attempts to prove the parallel postulate from the other four axioms failed. Did the parallel postulate necessarily have to be true?

Euclidean geometry is also called *plane geometry* because it assumes that the geometry is being constructed on a flat surface. However, in the 19th century it was realised that geometry could also be performed on curved surfaces, e.g., the surface of a sphere. In that case, the parallel postulate does not hold: parallel lines can eventually meet. Lines which are parallel on one part of the sphere might converge to a point. As an example, the north-south lines of longitude on the surface of the Earth are parallel at the Equator but converge to a point at the North and South Poles.

The resultant form of geometry — which can deal with curved surfaces — is called *non-Euclidean geometry*. In the early years of the 20th century, the real-world application of non-Euclidean geometry was revealed when Einstein's theory of general relativity showed that space itself had curvature, so only a non-Euclidean geometry

could correctly describe space.

So the introduction of non-Euclidean geometry showed that our certainty of mathematics is only as secure as our certainty of the axioms on which mathematics is based. Suddenly, mathematics seemed less than secure. As John Barrow says in his book *Pi in the Sky*: "The discovery that Euclidean geometry was not a unique, inevitable, and absolute truth about the world came therefore as a stunning blow. Its impact was far-reaching and irreversible. It undermined absolutist views about human knowledge across a vast spectrum of human thinking. Prior to the coming of non-Euclidean geometry, there was a unity, a confidence, and a certainty to our knowledge of the world. Afterwards, the one unassailable truth about the nature of the physical world had been eroded and so, along with it, had centuries of confidence in the existence and knowability of unassailable truths about the universe. How are the mighty fallen."

The Barber of Seville

In the early years of the 20th century, there was a great deal of interest in a number of logical paradoxes which threatened to undermine the foundations of mathematics. As an example, Epimenides — a Greek philosopher of the sixth century — once said: "All Cretans are liars". This might appear rather a racist comment, however, it should be mentioned that Epimenides was from Crete himself. So what are we to make of Epimenides' statement? If all Cretans really are liars, then Epimenides is a liar himself. In which case, we should not believe his statement. Therefore, Epimenides might be a truthful Cretan. In which case, all Cretans are liars, etc.

The liar's paradox also featured in a 1967 episode of *Star Trek* (<http://tinyurl.com/liarsparadox>). Captain Kirk and the crew manage to defeat an android simply by telling it "I am lying". The android finds this so illogical (if he is lying, then he must be telling the truth) that its circuits blow and smoke pours out of its head.

The liar's paradox is not written in the language of mathematics, it is written in English which is a language not notable for its logical consistency. Hence, this paradox is considered to be nothing more than a linguistic oddity, and not a threat to mathematics. However, other paradoxes were discovered which were phrased in the language of mathematics, and these paradoxes posed more serious problems. One of these paradoxes is known as the paradox of the Barber of Seville: "A man of Seville is shaved by the Barber of Seville if and only if the man does not shave himself. Does the Barber shave himself?"

This paradox is slightly more complex than the previous liar's paradox. It refers to the mathematical structure known as a *set*, which is a collection of objects. The paradox considers the set of all men who do not shave themselves (and are therefore shaved by the barber):

Should the barber be in the set? In other words, does the barber shave himself? If we assume the barber does **not** shave himself, then we should put him in the set. But if we put him in the set, then the barber **should** shave himself

because the barber shaves all the men in the set.

So if the barber shaves himself, then he does not shave himself. But if the barber does **not** shave himself, then he **does** shave himself.

Hence, this is another paradox. But unlike the previous liar's paradox — which was expressed in the English language — sets are mathematical structures which can be expressed mathematically. So the tale of the Barber of Seville represents a true mathematical paradox.

This paradox was discovered by the English philosopher and logician Bertrand Russell in 1903, and it is called *Russell's paradox*. Russell was so disturbed by mathematical paradoxes that he embarked on a project aimed at restoring perfect certainty to mathematics.

Russell started writing a book. A very, very, long book.

Principia Mathematica

Although mathematicians believed they were completely rigorous in their approach, Russell realised that this was not the case. Often, mathematicians used terms which had not been rigorously defined, or used reasoning — perhaps unconsciously — which was logically inconsistent. Russell decided that what was needed was to derive all of mathematics using pure logic. Nothing would be left to chance. There would be no room for differing interpretations, or human emotion. Essentially, the whole process could be performed by a computer, relentlessly building-up endless theorems and printing out the results.

However, as there was a shortage of computers in the first decade of the 20th century, the task fell solely on the shoulders of Russell and his occasional collaborator Alfred Whitehead. After 360 pages of writing, their first major result was definitively proved: $1+1=2$

It might seem rather excessive to spend such a long time to prove such an apparently trivial result, but it revealed Russell's determination to build mathematics on a solid logical foundation and thereby eliminate all paradoxes and contradictions.

After almost ten years of work, the first volume of Russell's magnum opus *Principia Mathematica* was released in 1910. The book was so large that Russell and Whitehead had to transport the book to their publisher's office in a wheelbarrow. Two further volumes followed in 1912 and 1913.

Unfortunately, the writing of the *Principia* required an almost obsessive approach, with no room for creativity or inspiration. Russell remarked that the mental effort had irretrievably drained his mental abilities. Talking of his experience, Russell said: "The effort was so severe that at the end we both turned aside from mathematical logic with a kind of nausea."

Russell was not the only one working to eliminate uncertainty from mathematics. At the start of the 20th century, the German mathematician David Hilbert was regarded as being the greatest mathematician in the world. According to John Barrow in his book about the history of mathematics, *Pi in the Sky*: "There is virtually no part of mathematics to which he did not make profound original contributions." In 1895, Hilbert became a professor of mathematics at the University of Göttingen where he was to spend his entire career. During his time there, the University of Göttingen became the world's leading centre of mathematics.

Here is a photograph of David Hilbert:

In 1900, at the International Congress of Mathematicians in Paris, Hilbert presented a list of 23 unsolved problems in mathematics which he considered to be the most important questions of the time. The list proved to be remarkably prescient and influential, and the attempts to solve the 23 problems were to dominate 20th century mathematics.

However, the true motivation behind Hilbert's set of problems was an attempt to place the science of mathematics on a surer footing. Remember, at the time, in the early 20th century, the whole edifice of mathematics appeared to be threatened by the presence of paradoxes — statements which can be both true and false at the same time. This appeared to undermine the status of mathematics as the source of all truth. According to Hilbert: "The present state of affairs is intolerable. Just think, the definitions and deductive methods which everyone learns, teaches and uses in mathematics, the paragon of truth and certitude, lead to absurdities! If mathematical thinking is defective, where are we to find truth and certitude?"

The second of Hilbert's 23 problems proved to be particularly interesting from the point-of-view of uncertainty. Hilbert challenged mathematicians to prove that mathematics was *complete*, in other words, **they had to prove that there were no true theorems in mathematics which could not be proved to be true**. This is the definition of mathematical completeness. If there was any statement which was true — but could not be proved to be true using mathematics — then that would appear to seriously limit the ability of mathematics to reveal truths about the world.

However, Hilbert's program to ensure the certainty and completeness of mathematics was about to be derailed in spectacular fashion.

Gödel's incompleteness theorem

Let us now return to Vienna. We have read how the paintings of Gustav Klimt "seemed to reject the fashionable notion that science and mathematics would provide us with complete knowledge founded on **absolute provable truth**." Indeed, one of the students in the University of Vienna at that time presented the greatest challenge to the notion of provable truth.

Kurt Gödel became interested in mathematical logic while studying as an undergraduate at the university. One year after completing his doctorate, in 1931 while he was still living in Vienna, he published the work for which he is most famous. Indeed, it is the work which sent shockwaves throughout mathematics and many other fields far removed from mathematical logic. Gödel solved Hilbert's second problem by showing that some mathematical statements exist which are true, but which cannot be proved to be true. This meant that mathematics was not *complete*: there are some things you cannot prove using mathematics. This effectively proved the death knell of David Hilbert's program to eliminate uncertainty from mathematics.

This result is known as *Gödel's incompleteness theorem*.

So, how did Gödel arrive at his result? The method was actually very similar to the liar's paradox which we considered earlier. If you remember, the liar's paradox essentially consisted of the English language sentence "This sentence is false". If the sentence is false, then the sentence must be true. But if the sentence is true, then the

sentence must be false. Hence the contradiction.

However, as was explained in the discussion about the liar's paradox, English is a language with poorly-defined rules, and it is not a mathematical language. As such, no sentence phrased in English can pose a threat to mathematics. I can basically say whatever I like in English. If I say "Mathematics is flawed" then that poses no actual threat to mathematics.

But Gödel's brilliant stroke of genius was to show how any statement could be converted into a mathematical statement. He achieved this translation by using a code. The code converted a statement into a single whole number (usually a very large whole number). The whole number is called the *Gödel number*. The code worked on the basis that any number can be calculated by multiplying prime numbers together in one — **and only one** — way. For example, $51 = 3 \times 17$. Because there is only one way of calculating a number in this manner, that meant that there is a one-to-one relationship between a string of prime numbers and a unique Gödel number. If each prime number is then taken as representing a symbol in a statement, then this allows a statement to be converted into a Gödel number.

This conversion meant that any statement **about** mathematics could then be imported **into** mathematics. Most importantly, this allowed a mathematical statement to refer to itself. This is how Gödel achieved that ...

Gödel considered the liar's paradox, and wondered if it had a corresponding equivalent in mathematics. But instead of considering the statement "This sentence is false", Gödel considered the statement "This statement cannot be proved to be true". More precisely, Gödel considered the statement "The statement with Gödel number x cannot be proved to be true". What Gödel then did was to encode **that entire statement** into a Gödel number, and replace the letter x in the statement with that Gödel number. In that way, the statement forms a strange kind of loop, looping back to refer to itself. And the end result is that the final statement refers to itself and so does, indeed, end up representing the statement "This statement cannot be proved to be true".

Let us now consider that statement "This statement cannot be proved to be true". If that statement is false, then we **can** prove it to be true — a contradiction. But if the statement is true, then we have a true statement which we cannot prove!

So either way — if the statement is true or the statement is false — mathematics is in trouble. By converting the statement into a mathematical form using his coding approach, Gödel revealed that a statement could exist which was either a contradiction (a paradox), or else there existed a true statement which could never be proved to be true.

Essentially, Gödel's result showed that all the work done by Russell and Whitehead in their *Principia Mathematica* was doomed. It was simply never possible to prove all theorems by building up from axioms — the method proposed by Russell and Whitehead. *Principia Mathematica* aimed to create a mathematics which was perfectly consistent and complete. It now emerged that all that work was for nothing. Gödel had showed that there could never be **complete** certainty in mathematics, because mathematics itself was not complete.

In his book *Impossibility*, John Barrow presents a very nice analogy to incompleteness: "If all truths in a logical system can be deduced from its axioms, it is called **complete**. As an illustration, consider a board game like chess or Go. Incompleteness would mean that there were configurations of pieces on the board that could not have been reached from the starting layout by following the rules of the game."

Douglas Hofstadter wrote an extraordinary Pulitzer Prize-winning book about the incompleteness theorem entitled *Gödel, Escher, Bach*. In an extract from that book, Hofstadter describes the impact of the incompleteness theorem on the general public: "Modern readers may not be as nonplussed by this as readers of 1931 were, since in the interim our culture has absorbed Gödel's theorem, along with the conceptual revolutions of relativity and quantum mechanics, and their philosophically disorienting messages have reached the public, even if cushioned by several layers of translation (and usually obfuscation). There is a general mood of expectation, these days, of 'limitative' results — but back in 1931, this came as a bolt from the blue."

Towards the end of his life, Gödel unfortunately became quite paranoid. In 1947, Gödel applied for American citizenship to join his good friend Einstein in Princeton. Einstein was to appear at the hearing as a character witness for Gödel.

On the night before the hearing, Gödel became quite distressed when he believed he had found a logical loophole in the constitution which would enable a dictatorship to be created in America. Einstein only just managed to calm him down enough in order to appear at the hearing, and he told Gödel not to mention the loophole under any circumstance.

The next day, the hearing seemed to go smoothly. The judge was impressed by Einstein's testimony as character witness. In summing up, the judge turned to Gödel and noted that, up to this point, Gödel had held German citizenship. The judge noted that Germany had been under an evil dictatorship, something that was "simply not possible in America". On hearing the word "dictatorship", Gödel burst into life and started explaining to the judge why he has wrong and, what, what was more, "I can prove it!". It took the efforts of both Einstein and the judge to

calm Gödel down, and he was eventually awarded American citizenship, joining Einstein at the Institute for Advanced Study.

The uncertain century

In Chapter One, it was described how the end of the 19th century was a period of great achievement, and there was great optimism and certainty about continued progress in science. However, once the 20th century arrived, discoveries in science and mathematics (quantum mechanics and Gödel's theorem) seemed to undermine this certainty, and it is uncanny how this loss of confidence seemed to mirror a loss of direction in other areas of human endeavour.

We might regard David Hilbert's effort to formalise mathematics as a last-gasp attempt to ensure certainty and stability in a world on the brink of chaos. As David Leavitt says (in his biography of Alan Turing): "It is hard not to read into Hilbert's program an attempt, through mathematics, to ward off the coming nightmare, just as it is hard not to read into Kurt Gödel's subsequent derailing of that program both the death knell of prewar idealism and the advent of a bloody, off-kilter epoch in which the prevailing metaphors would be of chaos and night, not order and morning. Hilbert hoped to establish once and for all the security of the mathematical landscape (and by extension, the security of Europe)."

However, it was those other citizens of Vienna — Hitler and Stalin — who were to have the greatest influence on the 20th century. Once aimed solely at the good of mankind, science was turned to the creation of weapons. During the First World War, the Jewish director of Berlin's Institute for Chemistry, Fritz Haber, turned his attention to the creation of chemical weapons. He developed a mathematical formula — known as *Haber's law* — which gave the relationship between the concentration of a poisonous gas and how long the gas had to be breathed to achieve death.

Haber was awarded the Nobel Prize for Chemistry in 1918.

Progress in science and technology was being warped so that it was no longer the servant of humanity. Instead, science became the enemy of millions. Haber became the first director of the corporation which produced the poisonous gas Zyklon B, later responsible for the deaths of millions in the gas chambers during the Second World War.

Meanwhile, in America, the greatest physics project of all time — which at its peak was greater than the entire American automobile industry — was devoted not to the benefit of mankind but to the development of the ultimate weapon of mass destruction: the atomic bomb.

Finally, in Chapter One it was described how the iron steamship the Great Eastern was built in the 19th century and became the largest passenger ship ever built. The ship laid the first telegraph cable across the Atlantic, and became a symbol of the confidence and certainty of the era. However, the record of the largest passenger ship was beaten early in the 20th century by a steamship whose selling-point was certainty: the perfect certainty of safety and security.

That ship was the Titanic.

Welcome to the uncertain century.

5

THE COASTLINE OF BRITAIN

In 1961, Edward Lorenz was a mathematician and meteorologist working at MIT. He was attempting to use a computer for the first time as a tool for long-range weather prediction. In theory, the computer seemed an ideal tool for weather forecasting, capable of performing endless repetitive calculations, applying Newton's deterministic laws of motion to millions of small pockets of air. In this way, it was supposed that the weather could be predicted in much the same way as the motion of the planets could be predicted with great accuracy.

In order to create his simulation of the movement of air in the atmosphere, Lorenz had constructed a simple model based on *convection*. Convection occurs when a volume of air is heated from below. As far as the weather is concerned, this is the situation when the Sun heats the ground and the air immediately above the ground becomes warm. Warm air is less dense than cold air, so this warm air rises to the higher levels of the atmosphere where it cools. This cooled air then descends again to replace the newly-warmed air at ground level. Hence, over time a circular convection current is formed.

Lorenz used three simple equations to model this convection current. While Lorenz's equations predicted that the system would always tend to form a simple circular current, they also revealed that this stability was deceptive. The equations also showed that sometimes — in a completely unpredictable way — the direction of circulation could slow down and then reverse.

This was a remarkable discovery. It had always been assumed that complex or unpredictable behaviour could only arise from a complicated system. You would certainly not expect random behaviour to be generated by a simple deterministic equation (an equation is deterministic as you can be completely certain of the output of the equation for a particular input). However, Lorenz's discovery showed that very simple equations can generate behaviour which appears random.

In order to illustrate this principle, Professor Ian Stewart in his book *Does God Play Dice?* presents a very simple mathematical expression: $2x^2-1$. We will discover how a simple expression such as this can produce complex behaviour which appears random.

Pick a fractional value between 0 and 1 and substitute that value for x in the expression (use your calculator — there should be an x^2 button on your calculator which makes the calculation of $2x^2-1$ a simple process). As an example, we will start with the value 0.9. You will calculate the result of the expression as being 0.62. This then becomes your new value of x . So repeat the process, this time substituting your new value of 0.62 for x in the expression. You will find you get -0.2312. Repeat this process several times and you will get the following sequence:

0.9
0.62
-0.2312
-0.8930931
0.5952306
-0.2914009
-0.8301709
0.3783676
-0.7136758
0.0186665
-0.9993031
0.9972134

Here is a plot of the sequence extended to 40 numbers:

The values and the plot appears completely random! This is bizarre: a simple, deterministic equation has generated behaviour which appears completely random. Certainly, if you encountered this sort of behaviour in Nature then you would probably assume that there was some complex mechanism underlying it, such as the interactions of a large population of animals. You would not imagine that such randomness could be generated by something as simple as $2x^2-1$.

But still, at least this appears like a predictable process. We have a simple equation, and as long as we know the starting value we should be able to plot the rest of the sequence with perfect accuracy. If the weather really does behave like this, then it appears we have discovered the secret of accurate long-term weather forecasting!

However, one day when he was comparing two plots of output data which were supposedly generated by the same input data, Lorenz got a shock. The two plots were very similar at first, but diverged after a few values until the two graphs became completely different. Lorenz was baffled. These plots were not hand drawn, they were computer-generated so there should be no room for error. If you give a computer the same data, and perform the same calculation repeatedly you should always get the same result. Computers are entirely predictable. This result seemed to challenge everything we know about how computers function.

Because of the predictable behaviour of computers, Lorenz immediately suspected his input data had to be different in the two circumstances. When he examined the second sequence he saw he had set the value at the start of the sequence to be 0.506. He had copied this value from the first sequence. However, when he examined the first sequence he found the values there actually had six decimal places: 0.506127. In order to save time, Lorenz had not bothered to copy all the decimal places — he did not think they were important.

Lorenz was surely justified in thinking these extra numbers — just one part in a thousand — were not important. You would certainly not expect small features like a tiny gust of wind to be able to have a huge effect on the large-scale weather pattern. But this appeared to be the case. Lorenz looked at the two graphs and, almost immediately, knew his quest to predict the weather was doomed to failure.

The butterfly effect

In order to duplicate Lorenz's discovery, let us return to our simple expression $2x^2-1$. Our first graph of values was generated from a starting value of 0.9. This time let us start with a very slightly different value of 0.9001. You might not imagine such a tiny difference — just one part in a thousand, as with Lorenz's experiment — would have much effect. In fact, you might expect this tiny variation to be barely visible on a graph.

As before, you might like to calculate some of the values using your calculator, this time starting with 0.9001. I have calculated the first twelve numbers for you, but you might like to check:

0.9001
 0.62036
 -0.2303068
 -0.8939174
 0.5981768
 -0.2843688
 -0.8382687
 0.405389

-0.6713194
-0.0986603
-0.9805322
0.9228871

And here is a plot of the sequence again extended to 40 numbers:

The graph appears very similar to the first graph (which was calculated starting with the value 0.9), but let us superimpose the first graph over the top of this second graph (the first graph is shown by the dotted line):

At the start, you will see that the two graphs are in very close agreement. However, after approximately ten points the two graphs start to diverge. After fifteen points the two graphs look completely different — despite starting with almost identical values.

This extreme sensitivity to initial conditions is a property of all deterministic systems which behave in this chaotic manner. This behaviour is called *chaos*.

Returning to Edward Lorenz's attempt to predict the weather, we find that if we knew the precise position and velocity of every tiny pocket of air at any one time, then we could produce long-term weather forecasts of perfect accuracy. However, for all practical purposes, it is simply impossible to obtain this perfect knowledge. We would have to know the value of all variables with perfect accuracy, to an effectively infinite number of decimal places. As we have seen in our experiment with $2x^2-1$, any slight error — no matter how small — would be magnified over time to produce huge later errors in our forecasts.

Even the tiniest fluttering of a butterfly's wings would affect the state of the current weather by a small amount, and that effect would become magnified over time. Lorenz called this principle the *butterfly effect*, the principle that a butterfly flapping its wings in China could potentially cause a hurricane next month in New York.

Lorenz was well aware of the implications of this discovery for long-range weather forecasting: "When our results concerning the instability of nonperiodic flow are applied to the atmosphere, which is ostensibly nonperiodic, they indicate that prediction of the sufficiently distant future is impossible by any method, unless the present conditions are known exactly. In view of the inevitable inaccuracy and incompleteness of weather observations, precise very-long-range forecasting would seem to be non-existent."

In Chapter Two we considered the uncertainty due to quantum mechanics and found that — at the very base of

Nature — there was a fundamental uncertainty. Randomness seems built into the very fabric of Nature at a low level. However, the uncertainty we encounter due to chaos is a very different kind of uncertainty.

The processes which produce chaos are completely deterministic (unlike the case with quantum mechanics). Every pocket of air in the atmosphere moves in a perfectly deterministic manner according to Newtonian laws. **There is no randomness in this situation**, there is only the illusion of randomness. Chaos is produced by simple deterministic equations creating behaviour that appears random. From the point of view of this book, we have found another source of uncertainty, but this uncertainty is generated by a very unlikely source: determinism.

What is more, while the fundamental uncertainty of quantum mechanics only becomes significant at very small scales (for example, attempting to determine the velocity and momentum of a particle), we encounter the uncertainty of chaos at the far larger human-scale. Every time you feel turbulence in an airplane, or watch a flag flapping in the breeze, or simply look at the clouds drifting across the sky, you encounter the uncertainty of chaos. As James Gleick says in his book *Chaos*: "Twentieth-century science will be remembered for just three things: relativity, quantum mechanics, and chaos. Of the three, the revolution in chaos applies to the universe we see and touch, to objects at human scale."

Strange attractors

Lorenz's three simple equations had just three variables — x , y , and z — which denoted the current state of the system at any particular time, plus two fixed parameters: σ (which represented the viscosity of the fluid) and ρ (which represented the temperature difference between the top and bottom of the volume of air). These fixed parameters would be set to particular values before the simulation was run in order to obtain an interesting output.

In order to examine how the convection system developed over time, Lorenz took the x , y , and z values (which represented the state of the system at any particular time) and plotted a single point in a three-dimensional space, the coordinate of the point being the value (x, y, z) . As the system developed over time, this single point moved in the three-dimensional space and plotted a curve. The resulting diagram is shown below (although it is a two-dimensional diagram, it is actually a rendering of a three-dimensional plot):

This method — by which the state of a system is represented by a single point moving in a multi-dimensional space — is a common approach in physics and engineering. The space is called a *phase space*.

This diagram is the most famous diagram in the history of chaos research, appearing in Lorenz's groundbreaking 1962 paper on chaos.^[7] You can clearly see the diagram has two lobes. Depending on which lobe the point is currently orbiting, this determines whether the convection current is circulating clockwise or anticlockwise. If the point switches to orbiting the opposite lobe, then that represents a reversal in the direction of the convection current. These type of diagrams, which show the evolution of the state of a chaotic system over time, are called *strange attractors*. Strange attractors are objects which live in phase space. This particular diagram is called the *Lorenz attractor*.

These diagrams are called "attractors" because whatever random state a system might be in initially, the effect of chaos will always be to drag the state of that system towards the attractor. For example, in the case of a volume of air being heated from below, no matter what random configuration the air molecules are in initially, the effect of chaos is to create circular convection currents. Thus the state of the system is dragged towards the Lorenz attractor as if experiencing a "strange attraction". Hence, ironically, chaos operates to create structure, and that structure is the strange attractor.

The most important feature of the Lorenz attractor diagram is that the point never writes over the same point twice — the point continually writes a new curve through space, showing that the system is never in the same state twice. Hence, the system never repeats — it continually creates new convection patterns in a completely unpredictable way.

Strange attractors are therefore infinitely detailed: no matter how much you zoom in on them, you will always find more detail. This infinite detailing causes the extreme sensitivity to initial conditions in chaotic systems: even the slightest difference in position, the slightest movement from one pixel to the next, can have a huge effect on the later state of the system. Even the tiniest fluttering of a butterfly's wings can move the point on the attractor which represents the current weather — thus modifying the long-term behaviour of the weather.

Structures which have this kind of infinite detail are called *fractals*. According to Ian Stewart: "It is now customary to define a strange attractor to be one that is fractal." Fractals are the geometry of chaos, and they are found throughout Nature.

Fractals

The French mathematician Benoit Mandelbrot was a scientific maverick who discovered the geometry of chaos, a geometry which we encounter throughout the natural world.

In 1960, Mandelbrot was working in the Thomas J. Watson Research Center, the pure research wing of IBM which was located 38 miles north of New York City. The scientists were effectively sheltered there, able to pursue whichever obscure research topic took their interest. IBM's philosophy was that if they got enough highly-intelligent people together in a single location then surely some great ideas would emerge which would benefit the company. Five Nobel Prize winners were to come out of the facility.

Legend has it that Mandelbrot became interested in unconventional forms of geometry when he wanted to obtain a value for the length of the coastline of Britain. On examining several encyclopedias, he found they all gave different values for the length. Mandelbrot realised that there was no single correct value for the length: it depended on how the length was measured. To be precise, it depended on the length of your measuring rod. If you imagine a giant measuring rod several miles in length, it would not be able to get into all the bays and inlets of the coast. Alternatively, a measuring rod only a few metres in length would be able to do a better job of measuring around all the bays. Hence, the shorter rod would measure a greater length for the coast of Britain than the longer rod.

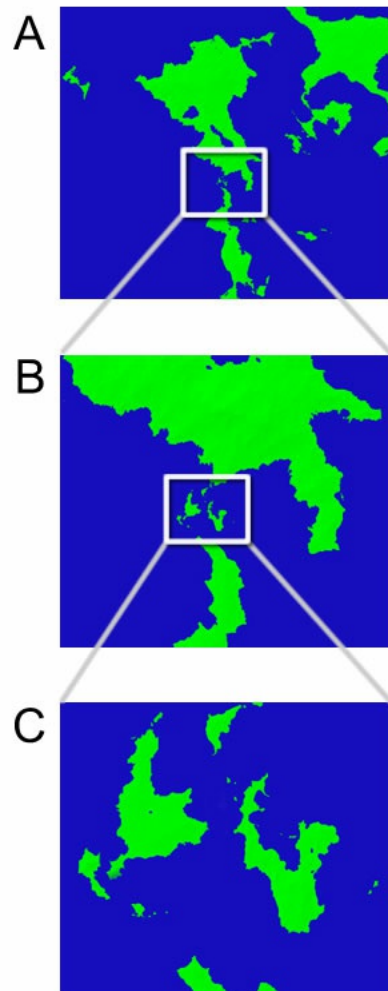

But which measurement should we accept as the accurate measurement of the length of the coast of Britain? You might intuitively accept the longer measurement — obtained with the shorter ruler — as the correct measurement. However, if we further reduce the length of our measuring rod so that it is only a few inches in length, we will find we get an even longer measurement (as we can now get our ruler into the smallest nooks and crannies of the coast). So it appears that the smaller our ruler, the longer our measurement of the length of the coast. So, remarkably, it emerges that there is no "correct" measurement of the length of the coast of Britain: the value is completely dependent on the length of the measuring ruler.

It would appear that — as we zoom into the coastline — we find an ever increasing range of detail. The further we zoom, the more detail we find. And it appears that we could keep zooming into the coastline without limit: our measurement for the length of the coast would just keep getting larger.

In order to see this peculiar property of the coastline, examine the next set of three images. The images show an area of coast at three increasing levels of zoom. A smaller rectangular area of image A is expanded to form the

entirety of image B. Hence, image B is a zoomed version of image A. Similarly, a smaller rectangular area of image B is expanded to form the entirety of image C. Hence, image C is a zoomed version of image B.

If you examine image C you will see that the general characteristics of the coast — with its rocky bays and inlets — looks very much the same as the coast in image A. No matter how far you zoom into a coast, it looks very much the same. We could even imagine zooming down to the level of small rock pools — the basic shapes would still be similar. So the coastline looks similar at small and large scales.

As another similar example, consider a small rock — only a couple of inches high — which might be found on a mountain:

and compare that rock to the mountain on which the rock was found (in this case, Camelback Mountain near Phoenix, Arizona):

The similarity is clear. And you could even zoom further into the small rock and find a miniature rugged landscape which resembles a microscopic mountain range. So there is a similarity across scale between small rocks and large mountains just like there is a similarity of the coastline at small and large scales.

So there can be a similarity between a large object, and the smaller objects which comprise the large object. This is called *self-similarity*, and it is a common property of many natural objects.

Benoit Mandelbrot realised that these objects possessed a symmetry. But this was not the same kind of symmetry seen in normal geometric objects. Conventional symmetry meant an object looked the same when it was reflected in a mirror, or turned upside down. Mandelbrot realised that self-similarity resulted in a symmetry when an object was examined at different scales: if you zoomed into an object, it still looked the same.

So we have seen that coastlines and rocks have self-similarity, but self-similarity can also be found in living objects. In the following diagram of a tree, you will see that each branch, and each twig, of the tree resembles the tree in its entirety. Hence, if you were to snap off a branch, it would resemble a small tree. And if you snapped a few twigs off that branch, it would again resemble a small tree.

So trees — and many other plants — possess self-similarity in abundance. In the following diagram, an example of a fern leaf is also shown, the leaf being composed of 30 segments. You will see that each of those 30 segments resembles the entire fern leaf. And each of those segments can be further subdivided into 30 sub-segments which

each resemble the entire fern leaf:

In order to see how Nature uses simple mechanisms to produce these strange zoomable structures, consider the following transformation:

What this simple transformation does is replace a straight line with a line with a triangular kink in the middle. In order to see how this transformation can be applied, consider the following four shapes:

Shape A shows a simple triangle. In shape B, we have used the previous transformation to replace each straight line of the triangle with a line with a triangular kink in it. Similarly, to generate shape C we have applied the transformation again to shape B, replacing each of its straight lines with a line with a triangular kink in it. Shape D is generated in a similar manner from shape C. This transformation could be applied repeatedly — continuing to infinity — producing an ever more elaborate final shape. This shape is called the *Koch snowflake*.

We could imagine the jagged edge of the Koch snowflake as representing a coastline: you can keep on zooming forever. So we find that by applying very simple construction rules repeatedly, Nature can produce structures of infinite complexity. Mandelbrot named these structures *fractals*.

As was considered in the previous chapter, classical geometry was defined two thousand years ago by the Greek mathematician Euclid. Euclidean geometry is based on straight lines, and regular geometric shapes such as circles, spheres, triangles, and cones. For most school pupils, this is the only type of geometry they will ever study. However, when we look around and consider the natural world, this is not the geometry we see. As Benoit Mandelbrot said in his book *The Fractal Geometry of Nature*: "Clouds are not spheres, mountains are not cones, coastlines are not circles, and bark is not smooth, nor does lightning travel in a straight line." The true geometry of Nature is fractal geometry, not Euclidean geometry.

Just as chaos results from simple rules which produce endlessly complex behaviour, so fractals result from simple rules which produce endlessly complex structures. Just as chaos is the true language for describing the behaviour of Nature, so fractals are the true language for describing the structure of Nature.

The Mandelbrot set

In discovering how Nature manages to produce these wonderfully intricate fractals, we have seen that simple processes are continuously applied in an iterative manner. In a similar example from mathematics, we might

consider the *Mandelbrot set*, which is an incredibly beautiful, infinitely detailed fractal which is produced by a very simple formula.

Benoit Mandelbrot discovered the Mandelbrot set by considering complex numbers, which we first encountered in Chapter Two in the discussion of Schrödinger's wavefunction. If you remember, a complex number has two parts: a *real* part (which is a conventional real number) and an *imaginary* part. The imaginary part is based on the square root of -1. This is rather strange because you might realise that the square of no conventional number can be a negative number. So how can -1 have a square root? Well, we don't worry about that — we just symbolise the square root of -1 by the letter *i*. The imaginary part of a complex number then consists of a number multiplying *i*. Hence, an example of a complex number might be: $6 + 3i$.

One of the most useful features of complex numbers is that they can be represented geometrically. It is possible to plot complex numbers on a two-dimensional graph with the real part being plotted along the horizontal *x* axis, and the imaginary part being plotted up the vertical *y* axis. This is called the *complex plane*. Hence, in the complex plane, the real axis is horizontal, and the imaginary axis is vertical.

An image of the Mandelbrot set can be produced very simply. Consider a point in the complex plane, and the complex number represented by that point. You then apply a simple iterative process which involves taking the square of the number and adding the original number. You then square the result, and add the original number again. This process is performed several times. If the resultant number stays low (within a certain limit) then the point **is** in the Mandelbrot set, and the associated pixel is coloured black. However, if after a number of iterations the resultant number shoots off to a very large value, the point is **not** in the Mandelbrot set. In that case, instead of colouring the pixel black, the pixel is assigned a colour based on how many iterations were performed.

This can be coded as a very simple computer program (I have done it myself several times). You can also get various apps on your mobile phone and tablet to explore the Mandelbrot set. These allow you to zoom into the image very simply by using two fingers to pinch and zoom. As you zoom into the set, the full beauty of the Mandelbrot set is revealed. I believe the best app on an iOS device is called "Frax". On my Android tablet I used the free "Fractoid" app (very simple to use and well worth getting) to generate the following images of the Mandelbrot set.

The first image shows the full Mandelbrot set, featuring the characteristic large black blobs. You will notice a very small white rectangle has been drawn on the top border of the set. This is magnified in the lower image, so you can see how increasing levels of detail emerge as you zoom in. You will notice how this magnified image resembles the earlier image of a fractal fern, perhaps giving a clue as to how Nature produces fractal structures by repeatedly applying simple iterative processes.

The following two images were obtained using the Fractoid app, zooming in to various areas of the Mandelbrot set. I hope they give you an impression of the beauty of the Mandelbrot set. In the first image you might be able to identify areas which resemble turbulence in a fluid (such as smoke rising):

Fractal dimensions

When we consider a fractal border, such as the Koch snowflake, we find that as we zoom in to the fractal the border gets fractionally longer. This is a similar principle to the idea that if we measure the coastline of Britain with progressively shorter rulers we get an ever increasing value for the length of the coast. The conventional measurement of length clearly has no validity when measuring a fractal coastline, so Mandelbrot realised that another form of measurement was required: the *dimension*.

This is a surprise as we do not usually think of the number of dimensions of an object as a value of measurement. However, a square is a two-dimensional object, and a cube is a three-dimensional object, so the number of dimensions an object possesses is clearly a property of that object — just like its width and height.

Mandelbrot asked a simple question: what is the dimension of a ball of string? The answer is not as obvious as you might assume. From a great distance, the ball appears as a tiny point, and would therefore have zero dimensions. If we move closer to the ball of string, it appears as a sphere and therefore has three dimensions. However, if we actually consider the material of which the ball is made — the string — then we can consider it as only having a length: a one dimensional object. So the number of dimensions of the ball of string is dependent on your point of view, a number from zero to three.

So returning to the theme of this book, once again the old notion of certainty in mathematics has taken a blow. From considering objects as having a clear observer-independent number of dimensions, we now find that the number of dimensions is uncertain — dependent on the observer. Mandelbrot — a mathematician — was even so bold as to suggest a connection with developments about uncertainty in physics: "The notion that a numerical result

should depend on the relation of object to observer is in the spirit of physics in this century and is even an exemplary illustration of it."

So a ball of string can be considered as having zero dimensions when viewed from far away, or three dimensions when viewed up close. But what about intermediate distances? What about values between zero and three dimensions? Mandelbrot came up with a remarkable new concept: fractional dimensions. He suggested we could consider an object as having 2.7 dimensions, for example, or 1.55 dimensions.

So how do we calculate how many dimensions a fractal has? Mandelbrot realised that the number of dimensions of a self-similar object (such as a fractal) could be calculated by a simple formula:

$$D = \frac{\log(N)}{\log(Z)}$$

where N is the total number of self-similar pieces in the fractal, and Z is the zoom factor. The formula basically reveals how many more self-similar pieces of the fractal do we see as we zoom out (as if we are zooming out of a coastline to reveal more detail).

In order to see how the formula works, let us consider one of the simplest self-similar objects: a square. Yes, surprisingly a square is a self-similar object as it can be divided into a number of smaller squares, each exactly the same shape (but not the same scale) as the larger square. Imagine we zoom out of a square by a factor of two, thus revealing more detail:

It can be seen that each side of the resultant larger square is twice as long (because of the zoom factor). However, it can also be seen that the larger square actually contains four self-similar smaller squares. So, from Mandelbrot's formula, we can calculate the dimension of the square as:

$$D = \frac{\log(4)}{\log(2)} = 2$$

So the formula states that a square has two dimensions: it is a two-dimensional object, which is the result we would expect.

Now let us use the formula to calculate the number of dimensions of a cube (yes, a cube is also a self-similar object as it is composed of a number of smaller cubes). As before, imagine we zoom out by a factor of two, revealing more detail:

As before, it can be seen that each side of the resultant larger cube is twice as long (because of the zoom factor). However, this time the resultant cube contains eight self-similar smaller cubes. So, according to Mandelbrot's formula, the number of dimensions of a cube is:

$$D = \frac{\log(8)}{\log(2)} = 3$$

So the formula states that a cube has three dimensions: it is a three-dimensional object, which is the result we would expect.

If we repeat this process for a straight line (yes, a line is also a self-similar object as it can be thought of as being composed of many smaller lines) then the formula tells us that a line has one dimension — which is again the value we would expect.

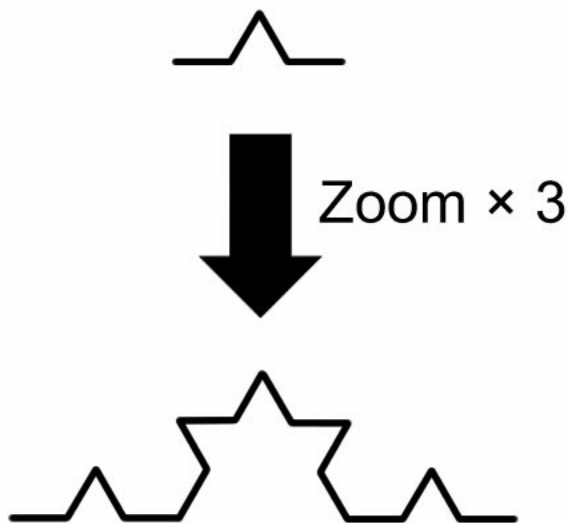

So when we consider the classical Euclidean shapes of the line, the square, and the cube, we find they all have an integer (whole number) dimensionality. But what do we find when we consider the dimensionality of a fractal? As an example, let us calculate the dimensionality of the Koch snowflake fractal which we considered earlier.

Remember how the Koch snowflake fractal was generated by a triangular line with a "kink" in the middle:

This type of kinky line which is used to form a fractal is called a *generator*.

Now let us zoom out of the Koch snowflake fractal in order to see more detail, but this time let us zoom out by a factor of three:

You will see that as we zoom out of the generator, more detail (the "coastline") starts to emerge. However, although we have zoomed-out by a factor of three, you will see that the second zoomed-out image is now composed of four of the initial generator shapes. So, from Mandelbrot's formula, we can calculate the dimension of the Koch snowflake as:

$$D = \frac{\log(4)}{\log(3)} = 1.26$$

So the formula is telling us that the Koch snowflake is an object with 1.26 dimensions!

It might seem bizarre to consider a structure as having 1.26 dimensions. Perhaps think of the Koch snowflake as being "rougher" than a line — which has a dimensionality of one — but not filling the entire two dimensional plane

like a square would do (a square having two dimensions). So, on that basis, we might expect the dimensionality of a Koch snowflake to lie somewhere between 1 and 2.

When Mandelbrot considered the fractal coastline of Great Britain he found it had a dimensionality of approximately 1.24. In contrast, the coastline of South Africa — which is nearly circular — has a dimensionality of approximately one. It is clear that the rougher the fractal shape, the higher its dimensionality.

Mandelbrot was therefore finally able to answer his question "How long is the coastline of Britain?" with an answer presented in the only measure which made sense: the fractal dimension.

As we find fractal structures throughout the natural world here on Earth, we should perhaps not be so surprised to discover that the entire universe itself appears to have a self-similar fractal shape. Stars group together to form galaxies, galaxies group into clusters, and clusters group together into superclusters. There is some symmetry over scale here — just as in a fractal. In fact, the universe has been measured as being fractal on scales up to 350 million light years, with a fractal dimension of 1.2.

At the mercy of chaos

In this chapter we have seen how chaotic behaviour can emerge in simple mathematical systems, and also in natural systems such as the weather. The common theme in these systems is that a simple nonlinear process (as we have seen, the process could be as simple as $2x^2-1$) is iterated several times before the chaos emerges. If we now extend our study to consider human populations, with their complex behaviours and their millions of daily interactions, we should not be surprised to find chaotic behaviour emerging.

It was Benoit Mandelbrot (again) who first detected the signs of mathematical chaos in the behaviour of the stock market. When Mandelbrot was considering the behaviour of cotton prices over the previous century, he recognised a degree of self-similarity: the seemingly random jumps in price over a day resembled the shape of the jumps in price over a year. There was symmetry over scale. There was order within the disorder — the trademark of mathematical chaos.

However, this chaotic jumping of prices was contrary to conventional economics theory. According to orthodox economic theory (which I was taught as an undergraduate many moons ago — and I was dissatisfied with it then), prices should reach a steady equilibrium when supply of a product matches the demand for that product. But if equilibrium is the natural state of affairs, then how come markets are so turbulent?

As Mandelbrot says in his book *The (Mis)Behaviour of Markets*: "To me, all the power and wealth of the New York Stock Exchange or a London currency-dealing room are abstract; they are analogous to physical systems of turbulence in a sunspot or eddies in a river."

In his book, Mandelbrot firstly describes the conventional approach to predicting the behaviour of the financial markets: "There are many ways of handling risk. In the financial markets, the oldest is the simplest: 'fundamental' analysis. If a stock is rising, seek the cause in a study of the company behind it, or of the industry and economy around it. 'Because' is the key word here. The price of a stock, bond, derivative, or currency moves 'because' of some event or fact that more often than not comes from outside the market. World wheat prices rise because a heat wave desiccates Kansas or Ukraine. The dollar sinks because talk of war raises oil prices. Financial newspapers thrive on it; they sell news and rank the importance of all the 'because's. The implicit assumption in all this: if one knows the cause, one can forecast the event and manage the risk. Would it were so simple. In the real world, causes are usually obscure. The precise market mechanism that links news to price, cause to effect, is mysterious and seems inconsistent."

Mandelbrot then goes on to explain why it is simply not possible to find simple causes — the "because's" — of complex market behaviour. He does this by explaining how a financial market is a nonlinear dynamic system which is effectively impossible to model and analyse accurately. Mandelbrot considered the interactions in a simulation of two groups of investors who behave differently: "In computer simulations by economists in Belgium, the two groups start interacting in unexpected ways, and price bubbles and crashes arise spontaneously. The market switches from a well-behaved linear system in which one factor adds predictably to the next, to a chaotic nonlinear system in which factors interact and yield the unexpected."

This switch from linearity to nonlinearity is crucial. A linear system can be broken into individual elements — "black boxes" — and the behaviour of the entire system can be analysed by considering the behaviour of each individual element. This is not possible with a nonlinear system which cannot be broken-down in the same way. Instead, it is only possible to analyse the system as a whole — a far more complex task.

The financial crisis of 2008 (which Mandelbrot considers in later versions of his book) is often blamed on the misselling of subprime mortgages in the United States. However, this implies that we can break down the market

into individual units (one of those units being the selling of mortgages) and place the blame for the crisis on one particular unit — as if the selling of mortgages was the "cause" of the crash. But this is simply not the case in a nonlinear system. A nonlinear system cannot be subdivided. Its individual units cannot be considered in isolation. No single unit can be considered as being the cause of the overall behaviour.

A recent news story was that a 90-year-old famous man had "died from pneumonia". But, of course, he did not die of pneumonia: he died from being 90 years old. When you are 90 years old, even a common cold can kill you. But the true cause of death would not be the cold — it would be your age. To try to isolate one particular cause is to miss the bigger picture, it is to fail to see that the real problem lies with the entire nonlinear system (yes, a human body is another example of a nonlinear system). Once again, individual units cannot be considered in isolation.

As we saw with the weather, a butterfly flapping its wings in China could potentially cause a hurricane next month in New York. So it is in the financial markets: a trader waking up late one morning could cause a crash on Wall Street in three months time. To blame the selling of subprime mortgages is to miss the point: it can never be possible to identify a single cause and try to isolate that cause to eliminate the possibility of market chaos. The possibility of chaos is always latent in the system and can never be eliminated — it is built into the design of the system. It is an inherent property of nonlinear systems.

We have created a monster.

So just as we can never eliminate the possibility of storms from the weather, we can never eliminate the possibility of chaos in our financial markets. All we can do is try to insulate ourselves from the financial storms when they do eventually come. As Mandelbrot says: "For centuries, shipbuilders have put care into the design of their hulls and sails. They know that, in most cases, the sea is moderate. But they also know that typhoons arise and hurricanes happen. They design not just for the 95 percent of sailing days when the weather is clement, but also for the other 5 percent, when storms blow and their skill is tested. The financiers and investors of the world are, at the moment, like mariners who heed no weather warnings."

In this respect, humanity is at the mercy from the nonlinear systems it has created. But the system of financial markets is not the nonlinear system which poses the greatest threat for the stability of humanity. The complex military network around the world poses the greatest threat. When nations arm themselves, they might feel they are acting responsibly as they have created a strong defence against possible aggression. But all they are really doing is adding to the complexity of the existing worldwide military nonlinear system. They are simply making a bad situation worse. The die is cast — even before war breaks out. Mankind is no longer in control of the situation — there is only an illusion of control. The weather might appear calm for an extended period of time, but, from now on, mankind is at the mercy of chaos. And the butterfly effect tells us that there is always the possibility that a tiny disturbance will be responsible for a terrible storm. This principle was illustrated perfectly in Sarajevo in 1914 when a single assassin's bullet killed Archduke Franz Ferdinand of Austria and instigated the tragedy of the First World War.

According to the BBC TV programme about chaos entitled *High Anxieties* (available on YouTube): "When World War One broke out, the world was still determined to believe in a Newtonian world where even the complexities of human affairs **could** be predicted, and the war **would** be over by Christmas. They all wheeled out their artillery confident that reality could be made to follow their plans. After all, the same mathematics which predicted the orbits of the planets also governed the firing of artillery. The mathematics of ballistics told them exactly where the shells would land. The tragedy of the war was that no matter what carnage unfolded, they believed there was not only a science of ballistics, but a science of war: a way of predicting how many men per mile of front would win the objective. They thought if they understood the science of war they could control its outcome — they could simply overpower the chaos. In the end, they weren't fighting each other. Both sides were fighting the chaos of reality. In the end, the chaos defeated them all, and ten million men died."

6

HOLLYWOOD

Hollywood is the town where dreams become reality. We are told that every waitress wants to be an actress, every limo driver has written a screenplay. And dreams become reality in Hollywood movies as well. No one would pay to watch a purely realistic movie of dreary office jobs, or being stuck in interminable traffic jams. So movies portray escapism: an artificial reality, a synthetic universe of musicals, adventure, and imaginative science fiction. The advances in computer-generated imagery (CGI) have made it more cost effective to produce entire alien worlds in a computer rather than construct them in a studio. If you watch a Hollywood movie you know you will be transported into another, better — but completely artificial — universe.

The director James Cameron was well-aware of the importance of creating a convincing artificial world when he created the alien planet Pandora for his movie *Avatar*: "You've got to compete head-on with these other epic works of fantasy and fiction, the Tolkiens, and the Star Wars, and the Star Treks. People want a persistent alternate reality to invest themselves in and they want the detail that makes it rich and worth their time. They want to live somewhere else. Like Pandora."

However, we are not only transported to another world when we enter a movie theatre. Modern consumer society is based on creating artificial reality. Enter a modern shopping mall, which may have a dreary exterior, and you might find yourself entirely enclosed in an artificial retail environment which resembles a glamorous European catwalk. Go to a swimming pool and you might find yourself in a synthetic environment which resembles a tropical island. Go to Las Vegas and you might well find yourself in a simulation of anywhere on Earth. Play an immersive video game and you might well find yourself in a simulation of anywhere in the universe.

In 1981, the French philosopher Jean Baudrillard wrote a short book entitled *Simulacra and Simulation* which explored the idea of modern life being a simulation. Baudrillard picked the particular example of Disneyland as an extreme example of a completely immersive artificial reality. The zero-crime zero-litter policy of Disneyland is an attempt to generate an improved version of reality in much the same way that a Hollywood movie provides escapism. As Baudrillard says: "Disneyland is a perfect model of all the entangled orders of simulacra. It is first of all a play of illusions and phantasms: the Pirates, the Frontier, the Future World, etc. This imaginary world is supposed to ensure the success of the operation. But what attracts the crowds the most is without a doubt the social microcosm, the religious, miniaturized pleasure of real America, of its constraints and joys. One parks outside and stands in line inside, one is altogether abandoned at the exit."

Baudrillard is making the point that visitors to Disneyland mistakenly perceive Main Street in Disneyland as being an accurate — though improved — copy of a Main Street in a real American town outside the gates of Disneyland. Whereas, the truth is that old-fashioned perfect Main Street simply does not exist in modern America. So Disneyland is not a copy of anything: Disneyland is a completely original reality. It is not accurate to call Disneyland an "artificial reality" because that would infer that it was a copy of a reality that actually existed. No, in Disneyland (and in our modern consumer culture) **the simulation has become the reality**. It is literally the American dream. Baudrillard referred to this artificial reality, which has no basis or resemblance to actual reality, as *hyperreality*.

When we watch a Hollywood movie, we become entirely immersed in its alternate reality. We might become so emotionally involved in the movie that we even cry at a sad moment. However, we would rarely cry at the start of the movie — we would only cry near the end of the movie, because it takes a full two hours for us to become emotionally involved to the point at which we care about the characters on the screen. At that point, the artificial reality has become our genuine reality. We might even forget there is a real world outside the movie theatre. As with Disneyland, the simulation has become the reality.

And that is when things become really interesting ...

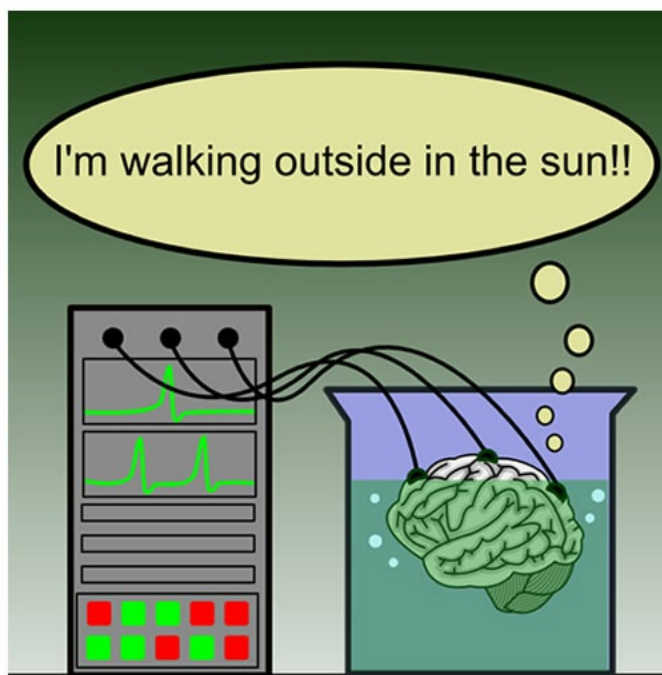

The Matrix

It is rather ironic that it was a Hollywood blockbuster movie which presented the work of Jean Baudrillard to the mass market. *The Matrix* was a science fiction movie released in 1999 which became something of a sensation,

becoming the biggest-selling DVD of all time. About eight minutes into the movie, the character of Keanu Reeves takes a book down from a shelf. The book is hollow. It is a fake book, a simulation. In its hollow compartment it contains some computer disks. The book is none other than Baudrillard's *Simulacra and Simulation*. From this early statement of intent, it is clear this movie is going to be — in the words of the producers — an "intellectual action movie". [8]

In *The Matrix*, Keanu Reeves plays a computer hacker called Neo who is informed that the world in which he lives is unreal — a computer simulation. The illusion is being created by intelligent machines which now rule the Earth. Humans are being kept in a subdued state to provide heat and electrical activity as an energy source for the machines. The humans float in vats, while the illusory Matrix world is transmitted into their brains in order to subdue and pacify them. The simulation, of the world as it existed in 1999, is so accurate that it is indistinguishable from the real thing.

This idea that we might be living in a simulated reality caused quite a stir at the time, though it is far from an original idea. The idea dates back as far as 1641 when the French philosopher René Descartes suggested the possibility that the entire world was merely an illusion created by an evil demon. In that case, Descartes suggested that all sensations might be inserted directly into the mind, and even the human body might be an illusion. In the modern era, a computer-based version of the evil demon was provided by the American philosopher Hilary Putnam. Putnam proposed what is known as the brain-in-a-vat thought experiment. Putnam suggested that an evil mad scientist might have extracted your brain and was keeping it alive in a vat of liquid. All sensory neurons of your brain were connected to an external computer which was supplying an accurate simulation of an external world. The disembodied brain would have no idea of its predicament, and would probably be blissfully happy.

It would appear that there is no way of knowing whether we are brains-in-a-vat or if we are living in the Matrix, with our bodies suspended in fluid, our brains connected to a supercomputer. Might this impose fundamental limitations on our certainty?

However, there are weaknesses in these theories. In an article entitled *Why Make a Matrix? And Why You Might Be In One*, Oxford philosopher Nick Bostrom argues that there would be no obvious motive for an advanced civilisation to imprison our bodies in fluid. In the movie *The Matrix*, the human bodies are used to provide power, but as Bostrom points out: "Human brains may be many things, but efficient batteries they are not." Presumably, the human would have to feed as well, which would entail some form of energy input to the comatose human. The energy which could be generated by the entrapped humans could never be more than the energy supplied to the humans. The scenario might have made more sense if the humans were being used for food (after all, we feed cattle to supply food for ourselves, but we only get back a quarter of the energy present in the food which we feed to the

cattle). But machine overlords would have no reason or desire to eat humans — I presume future computers would not have a digestive system!

And why should the advanced civilisation (or mad scientist) go to all the trouble of generating a simulated reality when the human brains could be kept subdued merely by the use of drugs? Basically, why bother creating the Matrix?

No, the whole brain-in-a-vat scenario in which we are suspended in a gloopy substance appears to make no sense. But there is another form of simulated reality which is more interesting, and which is being taken more seriously by the scientific community.

Simulacron-3

In 1964, the second book by science fiction author Daniel F. Galouye was published. The book was called *Simulacron-3*. It really was quite a remarkably foresighted work, and has been called a "virtual reality novel from a time before virtual reality". Not only was the novel ahead of its time in terms of technology, its style was also highly-influential, being called the first "cyberpunk" novel.

In *Simulacron-3* we meet our main protagonist Douglas Hall who is a computer developer specialising in the construction of simulated computer societies (Hall's field of expertise is described as "simulelectronics"). Individual computer-generated "people" are programmed to model human behaviour. The purpose of these simulations was to discover the behaviour of communities in order to guide government policy, and also to provide feedback to marketers.

Hall describes the computer-generated "people" who populate the simulation: "We can electronically simulate a social environment. We can populate it with subjective analogs — reactional identity units. By manipulating the environment, by prodding the ID units, we can estimate behaviour in hypothetical situations."

Although these ID units behave like humans, we would imagine that they are merely unthinking automatons — just states in computer memory — and are certainly not conscious like you and me. Well, *Simulacron-3* takes this scenario a step further to imagine that these computer generated citizens are, indeed, conscious: "The reaction entities weren't merely ingenious circuits in a simulelectronic complex, but instead were real, living, thinking personalities. They actually existed. In a solipsistic world, perhaps, but never suspecting that their past experiences were synthetic, that their universe wasn't a good, solid, firm, materialistic one."

You might find this a bold assertion — that mere states in a computer can become conscious — but we understand so little about the nature of consciousness that this is certainly not beyond the bounds of possibility. If something acts like a human, maybe it thinks like a human? There is a wonderful quote from one of the characters in *Simulacron-3*: "You can hardly stuff people into machines without starting to wonder about the basic nature of both machines and people."

So here we have an example of a simulated reality which exists merely as states in a computer. People are programmed into existence. Crucially, this is in contrast to the Matrix scenario, or the brain-in-a-vat scenario. In both of those scenarios an actual human brain in suspension is required.

This type of computer-based simulation is very similar to the type of artificial life simulations which are currently very popular such as *The Sims* which is the best-selling PC game of all time. In *The Sims*, virtual people go about their daily activities oblivious to the fact that they are being observed by the game player who retains complete control over the environment. The virtual people have individual personalities and experience desires and fears. There is no obvious goal to the lives of these "people" except to entertain the game player.

Again, as with the case of the brain-in-a-vat thought experiment, this seems to have implications for certainty and uncertainty. As Descartes realised back in the 17th century, if you cannot be certain as to whether or not you are in a simulation, then **you cannot be certain of anything**. This is because you are effectively isolated from reality. Only the simulation programmers would live in the real world: you would be merely living in an illusion of reality. It might appear to you that "the cat is on the mat", but in reality there is no cat and no mat: they would be states in a computer program. This type of general uncertainty — in which you can no longer be certain of anything — is called *Cartesian uncertainty* (called "Cartesian" after "Descartes"). [9]

The Thirteenth Floor

From this discussion, it would appear that the only people who would actually be living in reality — and could

therefore say that "the cat is on the mat" with certainty — would be the simulation programmers. But is that really the case? In order to find out, let us now return to *Simulacron-3*, because the story is about to take a surprising twist.

We left Douglas Hall in charge of development of the total environment simulator called *Simulacron-3*. Expectations were high for the impending launch of this revolutionary product. However, a series of unusual and unnerving incidents makes Hall doubt the reality of his own world. Events reach a startling conclusion when Hall is driving in the desert one night and encounters a most unusual sight: "The road ended a hundred feet away. On each side of the strip, the very earth itself dropped off into an impenetrable barrier of stygian blackness. Out there were no stars, no moonlight — only the nothingness within nothingness that might be found beyond the darkest infinity."

Hall realises that his own universe is nothing more than a simulated reality generated by a computer at a higher level of reality to his own world. The road disappears because it has not yet been generated by the simulating computer (probably for reasons of computational economy). Hence, there are now three levels of reality: the simulated reality generated by Hall's computer, the reality in which Hall find himself, and the highest level of reality which is simulating Hall's world.

But the possible number of levels of reality is clearly not just limited to three levels. In 1999, the movie *The Thirteenth Floor* was released which was based on the novel *Simulacron-3*.[\[10\]](#) The plot of *The Thirteenth Floor* follows the plot of *Simulacron-3* fairly closely, but the number of possible levels of reality is increased from three to thirteen (hence the title).

With so many possible different levels of reality, we might imagine those levels as different floors of a tall building: press a button to get to a higher or lower floor:

It is surely this analogy which lead to the title of the movie *The Thirteenth Floor*.

Of course, the number of possible levels is not limited to thirteen levels: we could consider an infinity of levels. And, I believe, it is this move to consider a possible infinity of levels which is crucial in understanding the true principle behind fundamental uncertainty.

As we shall now see ...

7

LEVELS OF INFINITY

This is the final chapter of this book.

Regular readers of my books will know I like to present some of my own ideas in the final chapter, and this book is no exception.

In this chapter we will be discovering what I feel is the true underlying reason behind all of the uncertainties we have considered in this book, the real reason why uncertainty can never be completely eliminated in our universe.

But we are going to start our discussion in rather a surprising place ...

The location is a mental hospital, in the town of Halle in Germany. The year is 1918. One of the patients in the mental hospital, Georg Cantor, is suffering catastrophic mental and physical collapse. But what was killing Cantor was no usual illness.

Cantor was dying from mathematics.

Counting to infinity

We need to start at the beginning.

Georg Cantor was born in St. Petersburg in 1845. His family moved to Germany when Cantor was eleven. At school, Cantor showed a great talent for mathematics, and he went on to study mathematics at the University of Berlin.

Here is a photograph of Georg Cantor:

In 1874, Cantor published the work for which he is now most famous. Cantor's discovery concerned the mind-blowing concept of infinity. Infinity is a number which has a magnitude which has no end. The symbol for infinity is based on the ancient Egyptian design of the *Ouroboros*, representing a snake eating its own tail:

Incredibly, Cantor revealed that there can be infinities of different sizes — which implies that there can be a number larger than infinity!

So how can it be possible to create an infinity of a larger size than another infinity? Indeed, how can it be possible to measure the size of something which is infinite? Cantor realised the answer to these questions lay in the process of **counting**.

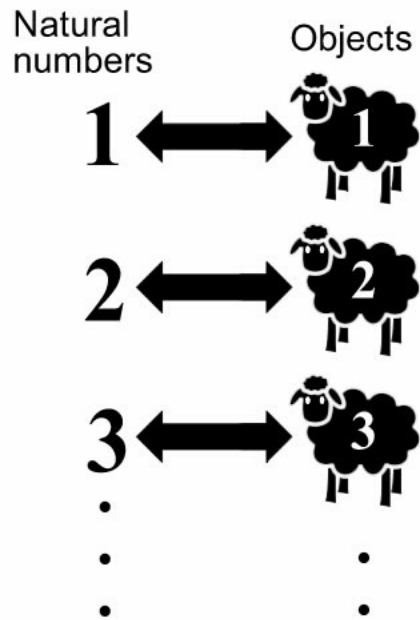

How do we determine the number of objects in a group? The answer is that we have to count the objects. Even if we suspect we have an infinite number of objects, the only way we can determine the number of objects is to count those objects. Counting lies at the heart of determining whether or not we have an infinite number of objects.

But what do we actually do when we count? The act of counting seems so natural, so intuitive, that perhaps we do not even think what we are doing when we count a number of objects. We will have to analyse the process of counting in more detail.

Imagine that you are a shepherd, and you want to determine the number of sheep in your field. Obviously, you need to count those sheep:

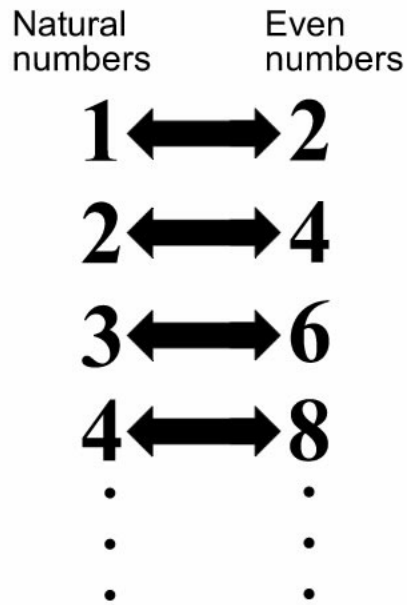

When we count our sheep we might point at the first sheep and say "one", then point to the second sheep and say "two", and so on until we have counted all the sheep. As you can see on the previous diagram, what we are actually doing when we perform this pointing and numbering operation is to create a one-to-one correspondence between each sheep and a unique number (the numbers are shown on the side of the sheep in the previous diagram). So the act of counting in fact involves the pairing of objects and numbers, as shown in the following diagram:

The numbers which are used for counting operations — the positive integers, 1, 2, 3, etc. — are called the *natural numbers*. It is clear that the natural numbers extend to infinity, i.e., the list of natural numbers does not have an end.

Based on this principle of counting, Cantor created a definition of a type of infinity. Cantor defined a *countable infinity* as being an infinity in which there exists a one-to-one correspondence between the list of objects and the natural numbers. According to Cantor's definition, it is clear that if there was an infinity of sheep in a field then that would represent a countable infinity of sheep because it would be possible to create a correspondence between each sheep and a unique natural number (as shown in the previous diagram). In theory, a shepherd could count all the sheep in a countable infinity of sheep (if the shepherd had infinite time).

Now let us consider the infinite list of even numbers: 2, 4, 6, 8, etc. It is easy to count all of those numbers by the usual counting method, i.e., creating a one-to-one correspondence between the even numbers and the list of natural numbers. This is easily done when it is realised that each even number is double the value of a corresponding natural number:

This reveals that the infinite number of even numbers is also a countable infinity — by Cantor's definition (they can be put into a one-to-one correspondence with the natural numbers). Hence, because both of these types of infinity were countable infinities and could be put into a one-to-one correspondence with each other, Cantor stated that they were both the same size of infinity. As an example, if the numbers in these lists were attached to sheep, then both of these infinite lists could be counted by a shepherd in a field — given infinite time.

Other examples of countable infinities include the list of the odd numbers, the list of the squares of the natural numbers, and the list of fractions (with a natural number on the top and bottom of the fraction).

Cantor believed this countable infinity was the most fundamental type of infinity. He named this type of infinity by the first letter of the Hebrew alphabet, \aleph , which is pronounced *aleph*. Cantor also added the subscript zero to the aleph symbol — \aleph_0 — because he believed it represented the smallest type of infinity. Hence, Cantor's countable infinity is called *aleph-zero* or *aleph-nought*.

Now let us consider the situation when we add a number — say the number 0 — to our list of natural numbers. You can see from the following diagram that there will still be a one-to-one correspondence with the list of natural numbers. In other words, both infinities will still be the same size:

It might be naively imagined that by adding a number to an infinite list (as we have just done) would result in a

list with a length larger than infinity. However, we have just shown that the resulting list is the same size as the original list — they are both countable infinities. As John Barrow explains in *The Infinite Book*: "At first you might think that making bigger infinities is child's play. Suppose you have an infinite collection of numbers: 1, 2, 3, ... Just add one more thing to it. Isn't that bigger? Unfortunately not. Adding one or two — or even infinity — to infinity still leaves infinity."

On that basis, here we see the result of adding the number one to our infinite list, expressed as a mathematical equation:

$$\aleph_0 + 1 = \aleph_0$$

According to conventional arithmetic, we are then free to subtract infinity from both sides of that equation, which leaves us with the nonsensical and paradoxical result:

$$1=0$$

Because the application of conventional arithmetic to infinity results in paradoxes such as this, for a long time it was believed that infinity had no place in mathematics. It took the genius of Georg Cantor to realise that infinity could be used in mathematics as long as his new approach to handling infinities — called *transfinite arithmetic* — was used. [\[11\]](#)

The number larger than infinity

Now let us consider how Cantor used his transfinite arithmetic to create a number larger than infinity.

Cantor started by considering the infinite list of the *real numbers*. But what are the "real" numbers? And what is their connection with the "real" world?

Well, so far we have only considered the natural numbers, the positive whole numbers. But the real world of physics is not generally described by discrete numbers. The real world is described by values which are continuous and can take absolutely any value — not just whole numbers. To describe the real world, we will need to consider the "real" numbers. As Roger Penrose says in his book *The Emperor's New Mind*: "Real numbers are called 'real' because they seem to provide the magnitudes needed for the measurement of distance, angle, time, energy, temperature, or of numerous other geometrical and physical quantities."

Instead of discrete whole numbers, the real world is often described by decimal numbers (numbers with decimal points), often with an infinitely long string of decimal places. As an example, the very common value of π which appears often in the real-world (for example, describing circles) is defined by the number three followed by an infinite string of digits after the decimal point:

$$\pi = 3.14159265358979323846 \dots$$

These types of numbers — which can potentially include an infinite string of decimal places — are called the real numbers.

Cantor then asked a rather peculiar question: "How many real numbers are there?" It is clear that there is going to be an infinite list of real numbers, just as there is an infinite list of natural numbers. It might be imagined that the two lists would be the same length, but is that necessarily the case?

To determine if the two lists were the same length, Cantor applied the usual method of counting the elements in the lists, i.e., establishing a one-to-one correspondence with the natural numbers. As an example, let us consider an attempt to count all of the real numbers between 0 and 1. Because real numbers can be specified with infinite precision (an infinite number of digits after the decimal point) there will be an infinite number of real numbers between 0 and 1. So here is an attempt to create a one-to-one correspondence between the natural numbers and the infinite list of all the real numbers between 0 and 1:

Natural numbers		Real numbers
1	↔	0. 2 83634085...
2	↔	0.9 7 4395783...
3	↔	0.32 1 884673...
4	↔	0.675 8 54320...
5	↔	0.1183 3 8438...
6	↔	0.94732 6 113...
⋮		⋮
⋮		⋮
⋮		⋮

At this point, Cantor presented an ingenious method which has become known as the *diagonal slash* method. You will see that the first real number has an ellipse drawn around its first digit after the decimal point, the second real number has an ellipse drawn around its second digit after the decimal point, and so on. We could then take all of the digits with ellipses drawn around them and create a new real number with them in the order in which they appear, which creates the number 0.271836...

Now we get to the clever part of Cantor's method. Let us alter each digit of our new real number by either adding or subtracting one to each digit. Hence, our number 0.271836... might become 0.362927... (you will see that each digit in the new number has been altered from the original number). The crucial result is that this new number we have generated must be different from all of the real numbers in our list because its first digit will differ from the first digit of the first real number in the list, and its second digit will differ from the second digit of the second real number in the list, and so on. In other words, this new real number we have generated cannot appear anywhere in the infinite list of real numbers. So our attempt to construct a list of all the real numbers between 0 and 1 cannot have been complete.

Cantor had shown that the infinite list of real numbers cannot be counted. Amazingly, this result revealed that the number of real numbers is greater than the number of natural numbers — Cantor had discovered a number greater than infinity!

You can see Cantor's diagonal slash method inscribed on the right of his memorial in Halle:

(Unfortunately, you will also see that some wag with a piece of chalk has added that Cantor's equation is equal to 7 — which is most certainly not correct!)

However, the mathematics establishment was highly-resistant to Cantor's ideas about infinity. In particular, Cantor found a determined opponent in Leopold Kronecker, a highly-conservative professor at the University of Berlin which was the centre of mathematics in the mid 19th century. Kronecker believed that only the natural numbers (the positive integers) had a role to play in mathematics — even to the point of attempting to outlaw the use of negative numbers! According to a famous quote by Kronecker: "God created the natural numbers, all else is the work of man".

Kronecker did everything in his power to exclude Cantor's ideas about infinity from mathematics, calling it "mathematical insanity". Cantor slowly became paranoid — but with good reason. Kronecker was highly-influential, and blocked Cantor's ideas from being published in mathematical journals.

Cantor suffered his first nervous breakdown in the spring of 1884. But this was not entirely due to the persecution of Kronecker. Cantor's mental problems were at least partly due to his continued fascination with infinity, trying to attain an understanding of concepts which perhaps cannot be fully captured by the human mind. John Barrow describes Cantor's struggles in his book about the history of mathematics *Pi in the Sky*: "He retreated from mathematics, recognizing that his intense concentration upon particular mathematical questions was beginning to affect his mental equilibrium."

Cantor suffered a series of breakdowns over the following years, forced to recover in mental hospitals. This resulted in Cantor losing his job at the university. Cantor tragically became a broken man and ended his life in a sanatorium, a decline at least partly due to his obsession with the mind-altering concept of infinity.

Levels of infinity

So Cantor had discovered an infinity larger than aleph-zero. Cantor called this new, larger infinity \aleph_1 (*aleph-one*). But Cantor also showed that the levels of infinity do not stop at that point. Using a generalisation of his diagonal slash method, Cantor showed that there would always be a number which was not contained in any infinite list. In other words, **there is always an infinity greater than any infinity.** [12]

It is now known that there are an infinite number of different types of infinity, with each successive infinity being infinitely larger than the previous type of infinity. This results in a tower of ever larger infinities:

What does this remind you of? Think back to where we have seen a similar image to this before in this book. **This is surely reminiscent of the infinite levels of reality described in the earlier description of the movie *The Thirteenth Floor*:**

Wow — that seems like rather a random connection. But might there be a deep reason behind that connection?

Well, imagine your universe is represented by Cantor's aleph-zero (\aleph_0). Maybe this number could represent the number of particles in the universe, for example. In that case it would represent an infinite number of particles, and so your universe would seem infinite: a never-ending vast expanse, the only thing that could possibly exist. It would

seem impossible to imagine anything could exist beyond infinity, anything beyond that infinite universe.

Now imagine you are an inhabitant of a computer-simulated reality, perhaps at the lowest level of reality in the movie *The Thirteenth Floor*. Again, your universe would appear infinite in expanse, and, again, it would seem impossible to imagine anything could exist beyond your infinite — but simulated — universe.

However, in both cases, there would be a completely different infinite universe above you, in a "higher realm" so to speak. In Cantor's aleph-zero universe, there would be the aleph-one infinitely-large universe immediately above you. And in the simulated universe, there would be an infinitely-large universe immediately above you, a higher-level of reality, occupied by the programmers of the simulation in which you reside.

So there appears to be some intriguing parallels between the two scenarios. This is something we should explore further.

And maybe we might even uncover a link to fundamental uncertainty, the true reason why there will always be fundamental uncertainty in the universe ...

Cantor, Gödel, ... and Turing

In Chapter Four, it was described how, in 1900, David Hilbert listed 23 problems in mathematics which needed to be solved to place mathematics on a surer footing. In a continuation of his program, Hilbert presented three more unsolved problems at an international conference in 1928. The third of these problems is the one which interests us, and it was called the *decision problem*.

If you remember, in Chapter Four it was explained how mathematical statements can be either true or false, and the aim of mathematicians is to prove the truth of statements. Throughout history, mathematicians have used their creativity and instincts to develop ingenious proofs.

David Hilbert wanted to take all the guesswork (and ingenuity and creativity) out of that process of developing proofs. Wouldn't it be great, thought Hilbert, if there existed a step-by-step list of instructions which mathematicians could follow every time they wanted to prove a statement to be true. Mathematics would no longer be reliant on the skills and creativity of mathematicians. That would go a long way to eliminating the uncertainty from mathematics. Could a step-by-step method be developed which could reliably prove all true statements? That was called the "decision problem".

It was the English mathematician Alan Turing who, in 1936, discovered a solution to the decision problem. Roger Penrose provided a clear explanation of Turing's method in his popular book *The Emperor's New Mind*. The following description is based on Penrose's explanation in his book, and even uses the same data.

Remember, we are attempting to find a step-by-step series of instructions — or *algorithm* — which a mathematician could use to solve any problem. Therefore, Alan Turing proposed a very general computing device which could take data as input, and could also take a particular program (algorithm) as input. The computing device could then apply that program to process the input data, producing an output.

We now call Alan Turing's simple computing device a *Turing machine*, and the Turing machine design forms the basis for almost all modern computers. For this reason, Alan Turing is often considered to be the inventor of the modern general-purpose digital computer.

Both the input data and the input program of the Turing machine could take the form of single number. The following diagram shows a table with all possible inputs along the horizontal top line, and all the possible computer programs down the vertical line. The elements of the table then represent the outputs of the particular computer program after processing that particular input:

		Input data									
		0	1	2	3	4	5	6	7	8	...
Computer program number 	0	0	0	0	0	0	0	0	0	0	...
	1	0	0	0	0	0	0	0	0	0	...
	2	1	1	1	1	1	1	1	1	1	...
	3	0	2	0	2	0	2	0	2	0	...
	4	1	1	1	1	1	1	1	1	1	...
	5	0	0	0	0	0	0	0	0	0	...
	6	0	0	1	0	2	0	3	0	4	...
	7	0	1	2	3	4	5	6	7	8	...
	8	0	1	0	0	1	0	0	0	1	...
⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	
⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	

The horizontal rows then represent all possible *computable sequences*. As Roger Penrose describes, a computable sequence is a sequence whose successive numbers can be produced by a particular computer program. Therefore, every computable sequence of natural numbers must appear somewhere in the table.

Alan Turing then did something inspired: he applied Cantor's diagonal slash method to the numbers in the table. You can see on the previous diagram that a circle has been drawn around all of the diagonal elements. Turing then followed the method of Cantor by modifying each of those diagonal elements. As Roger Penrose explains, this modification method is clearly a computable procedure (it could be performed by a computer), so the effect of this is to produce a new computable sequence. However, crucially, because this new computable sequence has been generated by Cantor's diagonal slash method, **it is bound to be different from every other computable sequence in the table**. But the table was supposed to contain every possible computable sequence. As Roger Penrose states: "This is manifestly a contradiction".

The implication of this contradiction is that our initial premise was incorrect: it is not possible to compute a table of all computable sequences. There are limitations on the abilities of computers: there are some things computers can never compute. These are now called *uncomputable* functions.

So Alan Turing had discovered another limitation on our ability to understand the world, another source of uncertainty. In that respect, Turing's result is really just the computerized equivalent of Gödel's incompleteness theorem. Turing solved the "decision problem" by showing that there could never be a step-by-step algorithm to decide whether every mathematical statement was either true or false. Hence, there are some true statements which can never be shown to be true by any step-by-step method. And that necessarily implies Gödel's incompleteness theorem: there are true statements which can never be proved to be true.

So the uncertainties revealed by Turing and Gödel are equivalent. And the underlying principle seems to be Cantor's diagonal slash method. Roger Penrose considers this in his book, also including Russell's paradox: "These similarities are not accidental. There is a strong thread of historical connection between the three. Turing found his argument after studying the work of Gödel. Gödel himself was well aware of the Russell paradox. All these arguments have their origins in Cantor's 'diagonal slash' method."

It is clear that Cantor's diagonal slash method lies at the heart of uncertainty. In the following final section of this book, let us now explore why that is the case. And, in the process, let us discover why uncertainty is fundamental in the universe.

The only certainty is uncertainty

So far in this chapter, we have discovered a fundamental connection between different types of uncertainty. We have seen how Cantor's diagonal slash method underlies the uncertainties discovered by Gödel and Turing. What is more, earlier in this chapter it was revealed how Cantor's "tower of infinities" resembled the stack of simulated realities in the movie *The Thirteenth Floor*. What is the connection? And what is the significance of Cantor's diagonal slash method?

The solution is perhaps best understood by considering the simulated universes example. In the previous chapter, the simulated universe of *Simulacron-3* was described. If you were living in such a simulated universe, it would be impossible to detect. In other words, there would be a fundamental limitation on your possible knowledge, a restriction in your ability to know all possible truths about your world — which might remind you of the results of Gödel and Turing.

What would be the origin of this limitation on knowledge? Well, in order to discover all the truths about your world, you would use all the tools available to you. You would use your eyes, and observational instruments such as telescopes, and particle accelerators. And you would also use all the computational tools available to you, such as your brain, and computers. But here is where the limitation arises: **all of those tools available to you are components of the universe they are trying to analyse**. A telescope is part of the universe, your eyes are part of the universe, your brain is part of the universe. So you can only use those tools to reveal truths which are **internal** to the universe — you cannot reveal truths **ABOUT** the universe, as though you were external to the universe.

So this is the reason for the uncertainty in a simulated universe: you cannot use the tools inside a simulated universe to reveal truths about the higher-level universe of the simulators. And, at this point, Cantor's diagonal slash argument has its impact. Even though the universe in which you reside is infinite, the diagonal slash argument reveals that there is always the possibility of a higher-level reality above you. In fact, it reveals the possibility of an infinite tower of infinite realities above you.

In fact, no matter which level you find yourself in that tower of simulated universes, you could never be certain that you were the highest level. Even at the level of the supposed simulation programmers there would always be uncertainty as to whether there was a level above.

And, as we have seen, it is the diagonal slash method of Cantor which results in the uncertainties described by Gödel and Turing. The diagonal slash method reveals the existence of uncomputable sequences or unknowable truths — a higher realm of knowledge which is beyond our grasp.

The diagonal slash method introduces fundamental limitations on our knowledge, which leads to fundamental uncertainty.

This principle was a recurring theme of Douglas Hofstadter's book *Gödel, Escher, Bach*. Hofstadter considers the limitations on our knowledge introduced by Gödel, and realises that the only way to obtain knowledge of all truths about our world — or any system in which we were contained — would be to transcend that system: to somehow move outside that system. Hofstadter actually becomes quite metaphysical in style when he talks about this, and introduces concepts from Zen Buddhism: "Zen is a system and cannot be its own metasystem; there is always something outside of Zen, which cannot be fully understood or described within Zen."

It has also been suggested that this principle might place limitations on our ability to understand our brains or consciousness. Catherine Loveday presents this viewpoint in her *Book of the Brain*: "So the human brain is complex — but is it clever enough to understand itself? Philosophers have debated this paradox for centuries, with some claiming that a system can only ever understand another system that is less complex than itself. They argue that human beings will never fully understand their own brains and that to do so is like trying to smell your own nose. As one pharmaceutical worker is memorably quoted as saying: 'If the human brain were simple enough for us to understand, we would be too simple to understand it.'" [\[13\]](#)

In that quote, Catherine Loveday says that the principle behind fundamental uncertainty is like "trying to smell your own nose". That is a perfect example of a fundamental limitation. And limitations introduce uncertainty: what does your nose smell like? You are uncertain. Does it smell bad? You are uncertain about a truth about your system. It might be a true statement that your nose smells bad, but you cannot prove it — just like the uncertainties of Gödel and Turing. I could tell you if your nose smells bad, but I am outside your system.

It would appear that because our thought processes are confined within the object they are trying to analyse — our brain — then that imposes another limitation on our knowledge, another source of uncertainty. In that case, the only way to eliminate the uncertainty would be to transcend the system: to somehow move outside our brains. Even Albert Einstein once expressed a similar idea when he said: "No problem can be solved from the same level of consciousness that created it."

This principle — that uncertainty arises because we are part of the universe we are trying to analyse — was presented by Stephen Hawking in a 2002 lecture entitled *Gödel and the End of Physics*. Hawking presented the following insight: "In the standard approach to the philosophy of science, physical theories live rent free in a

Platonic heaven of ideal mathematical models. That is, a model can be arbitrarily detailed and can contain an arbitrary amount of information without affecting the universes they describe. **But we are not angels, who view the universe from outside. Instead, we and our models are both part of the universe we are describing.** Thus a physical theory is self-referencing, like in Gödel's theorem. One might therefore expect it to be either inconsistent or incomplete. The theories we have so far are both inconsistent and incomplete."

I have placed in bold Hawking's quote: "**But we are not angels, who view the universe from outside. Instead, we and our models are both part of the universe we are describing.**" Hawking then goes on to explain that we should therefore expect our theories of the universe to be "inconsistent and incomplete" — leading to fundamental uncertainty.

The only certainty is uncertainty.

We have seen throughout this book how many of the greatest minds in science and mathematics have been repelled by the notion of fundamental uncertainty. Einstein was so repelled by the idea that he constructed endless thought experiments to argue with Niels Bohr. Bertrand Russell tried to eliminate uncertainty from mathematics by writing three huge volumes of the *Principia Mathematica*. In the end, though, Bell's theorem proved that Einstein was wrong, and Kurt Gödel's incompleteness theorem proved that Russell was wasting his time. Some of the greatest minds have been made to look rather foolish in their attempts to eliminate fundamental uncertainty. However, it has been shown time and time again that science only advances when fundamental uncertainty is firstly recognised and then accepted.

So when we discover some apparent fundamental uncertainty in Nature — as in quantum mechanics, for example — we should not be surprised, or throw up our arms in horror or denial. Instead, we should welcome uncertainty.

After all, it is what makes life interesting.

FURTHER READING

A great selection this time, including some of the best popular science books ever written:

Gödel, Escher, Bach by Douglas R. Hofstadter

One of the finest non-fiction books ever written. A story of "strange loops" — including Gödel's incompleteness theorem. A book in which the form is as important as the content.

Chaos by James Gleick

The book which introduced chaos theory to the general public.

Does God Play Dice? by Ian Stewart

Another great book on chaos. More technical and less-wordy than Gleick's book.

Hunting the Hidden Dimension

An excellent NOVA documentary on fractals, available on YouTube.

Quantum by Manjit Kumar

A very detailed account of the development of quantum mechanics, and the arguments between the key figures.

The (Mis)Behaviour of Markets by Benoit Mandelbrot

If you have investments on the stock market, this is a book you cannot afford to ignore.

Pi in the Sky by John D. Barrow

An ambitious attempt to find the meaning of mathematics. Includes the tragic story of Georg Cantor.

Impossibility by John D. Barrow

Examining the limits of science, including the effect of Gödel's incompleteness theorem.

The Newtonian Casino (published as *The Eudaemonic Pie* in the USA) by Thomas Bass

The account of how Norman Packard and Doyne Farmer defeated the casinos of Las Vegas by using their knowledge of Newtonian mechanics.

The Simulation Argument by Nick Bostrom

<http://www.simulation-argument.com/>

Plenty of articles on the theme that we might be living in the Matrix.

NOTES

[1] Interestingly, the development of the first mechanical computer, the laws of probability, and the invention of the game of roulette are all associated with the French mathematician Blaise Pascal.

[2] Another visionary quote from Lord Kelvin in 1895 was that "Heavier than air flying machines are impossible."

[3] The type of matrix which can be used for these quantum operations is called an *Hermitian* matrix.

[4] The great British mathematical physicist, Paul Dirac, later showed that Heisenberg's matrix mechanics and Schrödinger's wave mechanics were mathematically equivalent.

[5] The physical process behind the so-called "collapse of the wavefunction" is often presented as a great mystery, as something almost mystical. However, if you have read my first book you will know that great strides have been taken in understanding the process as a form of *environmental decoherence*.

[6] 1913: *When Hitler, Trotsky, Tito, Freud and Stalin all lived in the same place*, BBC News, <http://tinyurl.com/viennapeople>

[7] Edward Lorenz, *Deterministic Nonperiodic Flow*, Journal of the Atmospheric Sciences, 1962.

[8] In fact, the producers of the movie, the Wachowskis, asked Keanu Reeves to read *Simulacra and Simulation* as preparation for his role. The book is completely impenetrable — I doubt Reeves thanked the Wachowskis for their decision. Baudrillard has since said that *The Matrix* misunderstands and distorts his work.

[9] If we cannot trust our senses, then Descartes reasoned that we could only trust the contents of our own minds. Hence his famous dictum *cogito, ergo sum* ("I think, therefore I am").

[10] *The Thirteenth Floor* was released just a few months after *The Matrix* was released, and so made nothing like the same impact. *The Thirteenth Floor* features an astonishingly convincing simulated reality of Los Angeles in the 1930s. You would swear it was real ...

[11] The readers of my fifth book who used conventional arithmetic to express reservations about the sum of all the natural numbers being equal to one twelfth should remember this fact: **you cannot use conventional arithmetic when dealing with infinity.**

[12] Cantor actually considered the power set of any infinite set, and showed that it must have a greater number of members. For details of how Cantor did that, see this document by Professor Raymond Flood:

PREFACE

This book is an introduction to the principles of particle physics, the physics which deals with atoms and the smallest elements of the universe. The book will emphasise the underlying principles, rather than just listing the particles (and their properties) in a rather encyclopaedic manner. I believe it is much more valuable to gain an understanding of the principles involved.

For example, we will be discovering the principle which explains why material objects feel solid to the touch, but you can't touch a ray of light. We will be discovering the real reason why positive and negative electric charge attract each other (clue: it has to do with symmetry).

I must admit, this book is perhaps more challenging than my previous books. I do think many popular science books underestimate the intelligence of their readers.

I am firmly of the conviction that if a reader is having difficulty understanding a concept then it is not because a concept is hard — it is because it is being badly explained. In this book, care is taken to describe each step simply and clearly.

Once again, thank you for your support.

*"The road to a knowledge of the stars
leads through the atom."*

- SIR ARTHUR EDDINGTON, 1928

1

THE INVESTIGATOR

At the start of the 19th century, the land of Australia was still an unexplored country. The coastal areas had been mapped by various earlier Europeans (predominantly the Dutch, who named the country "New Holland"). However, due to the size of the continent, it was not certain if these coastal areas were connected as part of a single island, or if Australia was composed of many islands.

In July 1801, an expedition to Australia from Britain was due to set sail on the ship the *Investigator*. The main aim of the mission was to determine if Australia was a connected land mass, but, as a secondary aim, the expedition also aimed to study the flora and fauna of the island.

The expedition chose the Scottish botanist Robert Brown to be its resident naturalist. Brown, the son of a strict church minister, had learnt botany while studying in Edinburgh University where he had taken frequent trips to the Highlands of Scotland to collect and classify rare plants.

The *Investigator* set sail on the 18th July. It arrived in King George Sound in Western Australia six months later. As part of its voyage, the ship had to traverse the treacherous Great Barrier Reef (then called the Labyrinth). The ship eventually performed the first ever circumnavigation of Australia, thus establishing it as a continent.

During the voyage, Brown discovered approximately 2000 species of plants, almost all of which were previously unknown to science. When he returned to London three and a half years later, his reputation as a botanist of note was secured.

Brown's reputation was established on his talent for examining his Australian plant specimens in the smallest detail. In order to achieve this, Brown became skilled at microscopy. Brown realised that the study of microscopic pollen grains could be used as a method to classify plants.

It was while he was using a microscope to examine some of these pollen grains suspended in water that Brown observed something rather peculiar. The pollen grains were seen to move in a jittery, random motion. This random motion was given the name *Brownian motion* (named after Robert Brown), but its origin was to remain a mystery for almost a century.

At this point, our tale takes an unexpected turn. We rejoin our tale in 1905 — the "miracle year" of Albert Einstein.

At the time, the existence of atoms was still in doubt: there had never been a direct observation of the behaviour of atoms. The stage was set for Einstein who, in one of his remarkable acts of intuition, speculated that the motion of the pollen grains might be due to the random motion of water molecules. He realised that a pollen grain was so small that — purely by chance — there would occasionally be significantly more water molecules buffeting one side of the pollen than the other. The resultant motion has been compared to a giant inflatable balloon being bounced around randomly by a crowd in a football stadium.

Einstein crushed the mathematics and realised that this effect would result in precisely the random dance of the pollen which was first observed by Robert Brown almost a century earlier.

This atomic explanation of Brownian motion represented the first directly observable effect of the kinetic theory of atoms, and is regarded as the first conclusive evidence of the existence of atoms. From now on, there could be no doubt about it: atoms were real.

And that unlikely chain of events is the story of how the atom was discovered — it all started on Robert Brown's expedition to Australia on board the *Investigator*.

Rutherford's atom

Ernest Rutherford was born in the rural South Island of New Zealand in 1871, the fourth of twelve children. He grew up on a farm, herding cows and riding horseback. It was this adventurous, pioneering spirit and enthusiasm for discovery which propelled Rutherford to become the greatest experimental physicist of his era. Rutherford has been called "the Newton of atomic physics".

Rutherford had an uncanny instinct for designing ingenious experiments using primitive equipment which revealed the structure of the atom. As Richard Rhodes says in his book *The Making of the Atomic Bomb*, Rutherford "won the atom. He found its constituent parts and named them. With string and sealing wax, he made the atom real."

Rutherford won a scholarship to Cambridge University to work in the Cavendish Laboratory under the leadership of J. J. Thomson. Thomson had been performing experiments with the recently-invented cathode ray tube. The cathode ray tube consists of an electrically negatively-charged heated filament called a *cathode*, facing a positively-charged *anode*. All the components are contained in a vacuum in a sealed glass tube:

As the temperature of the cathode increased, it had been found that a stream of particles left the cathode, attracted to the positively-charged anode. If these particles hit a fluorescent screen, they made a small spot of light on the screen (this is how a cathode ray tube forms the main tube on old CRT televisions). Thomson discovered these particles could be deflected by electrically-charged plates, attracted to the positive plate, and their path could also be bent by a magnetic field. He named these particles *electrons*, the first atomic particle to be identified.

It was shown experimentally that the part of the atom which was left behind when these electrons were emitted was heavier, and was positively-charged. With this in mind, Thomson developed a model of the atom as a big lump of positively-charged material into which electrons were evenly distributed. This was called the "plum pudding"

model (because the electrons were like raisins evenly distributed inside a pudding).

However, one of Rutherford's experiments soon revealed that this plum pudding model was incorrect.

By 1907, Rutherford had moved to Manchester University. In Manchester, Rutherford performed experiments involving recently-discovered radioactivity. He enlisted the help of Hans Geiger who had developed a device which could detect individual particles of radiation. Rutherford performed an experiment in which these particles (produced by radioactive radium) were fired at thin gold foils. He found some of the particles were deflected as they passed through the foil, but, more mysteriously, he found that some of the particles appeared not to get through the foil at all — they just vanished. Almost as an afterthought, Rutherford placed a detector in front of the foil instead of behind it, and he discovered — to his great surprise — that some of the particles were being reflected back from the foil.

Rutherford was amazed at this discovery: "It was quite the most incredible event that has ever happened to me in my life. It was almost as incredible as if you fired a 15-inch shell at a piece of tissue paper and it came back and hit you. On consideration I realised that this scattering backwards must be the result of a single collision, and when I made the calculations I saw that it was impossible to get anything of that order of magnitude unless you took a system in which the greatest part of the mass of the atom was concentrated in a minute nucleus."

This meant that Thomson's plum pudding model was wrong. Instead, it meant that atoms had a hard centre, a positively-charged *nucleus*.

Rutherford proposed a model of the atom which consisted of electrons orbiting a nucleus composed of positively-charged *protons*. The electrons were held in orbit due to their electrical attraction to the protons. This arrangement resembled a small Solar System, and was called the *Rutherford model* or *planetary model*.

However, the mass of atoms was about twice the mass which would be expected if the nucleus was composed of just protons. Rutherford proposed that the nucleus also contained other particles called *neutrons*, each neutron being approximately the same mass as a proton. These particles were called neutrons because they were electrically neutral. The existence of neutrons was confirmed in 1932.

Atoms are made out of these three particles: electrons, protons, and neutrons. As an example, the following diagram shows Rutherford's planetary model of a carbon atom. It is composed of six negatively-charged electrons orbiting a nucleus which is composed of six positively-charged protons and six neutrons:

The death spiral of the electron

However, it was known that there was a problem with this planetary model. Just as in the case of a planet in the Solar System, eventually the orbit loses energy and the planet would crash into the Sun. A very similar scenario was predicted with this model of the atom. Newton had shown that any object moving in a circle is undergoing an acceleration (a deviation from its natural straight-line path), and according to Maxwell's theory of electromagnetism, any electrically-charged particle will lose energy in the form of radiation if it is accelerated. The electron would

inevitably lose energy and crash into the nucleus in a thousandth of a billionth of a second.

Robert Oerter describes this rather disastrous scenario in his book about particle physics called *The Theory of Almost Everything*: "An electron in such an orbit would have to emit electromagnetic radiation, thereby losing energy, which would send it into a 'death spiral', which could not end until the electron reached the nucleus. With all the negatively charged electrons in the nucleus cancelling out the positive nuclear charge, there would be no electric repulsion keeping the nuclei at atomic distances from each other. In a fraction of a second a house would collapse to the size of a grain of sand."

So what was holding the electrons in their orbit? A solution was proposed by Rutherford's most eminent student, Niels Bohr.

In 1912, Bohr came to Manchester from Cambridge specifically to work under Rutherford. Bohr was concerned about the stability of Rutherford's atom. Rutherford had correctly discovered that electrons orbit the nucleus, but he provided no explanation as to what kept them in orbit. Bohr believed an answer was to be found from the new physics of quantum theory. Bohr was aware of the previous discovery of Max Planck that the energy radiated from a hot body was composed of "quantized" chunks of energy (described in my previous book). This seemed to indicate a new physics beyond classical physics. Bohr suggested that the energy of the orbiting electrons was not continuous, but was instead only allowed specific quantized values. This would result in electrons only being able to occupy specific "allowed" orbits. This restriction on electron energy would prevent the electrons from spiralling into the nucleus.

Bohr's theory resulted in a stable atom. Also, Bohr's theory predicted that radiation of certain specific energies would be emitted by the atom when an electron jumped between these allowed orbits. This prediction of specific energy levels perfectly matched the clearly-defined spectral lines emitted by heated materials.

So Bohr appeared to have found a solution. But it was a rather unsatisfactory solution in that it was a mix of the old classical physics (an atom was still being modelled as an electron spinning around the nucleus in just the same way that Newtonian physics predicted the orbit of planets around the Sun), and the new quantum theory.

A more elegant explanation was provided by the French physicist Louis de Broglie (pronounced "de Broy") in 1923. De Broglie was aware of Einstein's earlier explanation of the photoelectric effect (covered in my previous books) which suggested that a light wave was actually composed of particles called *photons*. Hence, there appeared to be a strange duality between waves and particles. De Broglie made the brave and inspired suggestion that this duality also worked in the other direction: that any particle also had a wavelike nature.

One consequence of this idea was that it provided an ingenious explanation of why electrons were held in their orbits around the nucleus. We find the solution if we no longer consider an electron as being an orbiting particle — like the Earth orbiting the Sun — but instead consider it as being a wave around the nucleus. We could imagine that only a whole number of wavelengths could be allowed around the nucleus: if this was not the case, the wave would not join up with itself when it returned to its starting point and it would interfere destructively with itself.

Different electron orbits represented a different number of whole wavelengths. Electrons could jump between orbits, but only by emitting or absorbing a photon of a fixed ("quantized") amount of energy. This model also implied that there would always be a minimum energy possessed by the electron (called the *ground state*) corresponding to the lowest frequency wave (analogous to the fundamental frequency of a wave on a string).

Hence, this wavelike model of the electron meant the death spiral of the electron into the nucleus could be avoided. And this is essentially the principle by which atoms achieve their size, and prevents houses collapsing into a grain of sand!

What is a particle?

Before we reach the end of this introductory chapter, there is a question which you might well be wondering. The question is: what are particles actually made from?

In order to answer this question, we have to examine particles at the highest level of detail. However, we certainly cannot use a conventional microscope to look at particles. That is because visible light has a wavelength between 4×10^{-7} metres and 7×10^{-7} metres, while atoms are much smaller, approximately 10^{-10} metres across. This is important, because it is not possible to see any object which is smaller than the wavelength of the light which illuminates the object. Hence, it is never going to be possible to see an atom with a conventional microscope.

However, the wavelength associated with a particle is inversely proportional to the energy of that particle. In other words, particles with more energy have shorter wavelengths (according to the previously-discussed theory of Louis de Broglie) and can therefore be used to probe smaller distances. As an example, the wavelength of an electron can be up to 100,000 times smaller than the wavelength of a photon (a particle of light), a principle which gave birth to electron microscopy.

In a modern particle accelerator, it is possible to achieve observations using particles with far higher energy than those used in an electron microscope. Using wavelengths as small as 10^{-16} metres it was possible to detect the existence of the smallest known particles. However, as accelerator energies have increased, with wavelengths now down as small as 10^{-18} metres, no smaller structure has been found in these particles. It would appear that these are *elementary particles* in that they are truly fundamental having no internal structure — no constituent parts. It is simply not possible to break them down into smaller units.

So how big is an elementary particle? As the energy of particle accelerators has increased, these particles appear to be smaller than anything we can detect. In fact, it is believed that these particles have no actual size: they should be considered as infinitely small pointlike particles. It might be said that they have no *spatial extent* — they do not extend into space. Essentially, they are not made of anything! Which makes a kind of sense: if they were made of any material, it would be possible to split that material into two parts to create smaller particles. In which case, the original particles would not be elementary (as they could be split into two "more fundamental" particles).

By this logical argument, it would appear that a truly elementary particle would **have** to be pointlike, or else it could not be considered to be truly elementary.

This type of behaviour, and this strange type of argument, might appear completely bizarre and counter-intuitive. How on earth is it possible to have objects which cannot be broken into smaller objects? How on earth is it possible to have objects which have no spatial extent? The problem is that we are only used to operating in the human-scale ("macroscopic") world, and things work very differently at that vastly larger scale: all objects can be broken into smaller objects, all of these composite objects take up volume in space, etc.

However, at the fundamental scale of elementary particles, the world works very differently, and in very counter-intuitive ways. Another counter-intuitive fact about elementary particles is that all particles of a particular type are identical. For example, all electrons are exactly the same, as if they are perfect copies (we will discover the implications of this later in the book when we consider the Pauli exclusion principle). Again, this has no analogy in our macroscopic world. In our macroscopic world, we always have the option of "delving deeper", to sub-analyse an object to discover distinguishing details. For example, if we want to distinguish two identical models of car, we might divide the car into its constituent parts, and then consider the cars' number plates. Hence, all macroscopic objects can be distinguished. However, when we are dealing with elementary particles, we no longer have access to any lower distinguishing level. This is a clear sign that we are dealing with the lowest level of reality.

When dealing with these fundamental concepts, we have to make the effort to break away from our human-scale, macroscopic preconceptions about how things behave, and how objects are structured. Because only then will we have a chance of understanding the elementary structure of Nature.

This book will consider the structure of the atom, and is essentially divided into three parts. The first part might be described as a study of "the forces which hold the atom apart" (in this chapter we have already seen how energy quantization prevents the electrons from spiralling into the nucleus). The second part of the book might be described as a study of "the forces which pull the atom together", in which we will examine the fundamental forces which hold the electrons and the atomic nucleus together. And the third part of the book considers the balance which arises between these two opposing forces: the forces which hold the atom apart, and the forces which pull the atom together.

It is by considering this concept of "balance" in this third part of the book that we will find a remarkable similarity between the forces which hold the atom together and the forces which hold the universe together. We will discover that the very large and the very small have much in common.

2

ADVENTURES IN THE MATRIX

When Ernest Rutherford gave an interview to the *London Daily Herald* in 1933, he tried to explain how small the atom was: "If everyone in the world spent twelve hours a day placing individual atoms into a single thimble, a century would elapse before it was filled."

At first glance, the intended message of Rutherford's quote appears clear: atoms are inconceivably small. However, there is another possible interpretation because, of course, all sizes are relative. The alternative interpretation is that humans (and thimbles, for that matter) are inconceivably huge.

In similar fashion, whenever I hear the usual quote that humans are insignificantly small in relation to the size of the universe, I get mildly irritated. Because, of course, on the atomic scale (which is a much more sensible standard scale of size) human beings are cosmos-straddling giants. A typical human contains 7,000,000,000,000,000,000,000,000 atoms. We are certainly not "insignificantly small" by that definition.

In fact, it is this extraordinarily huge size of human beings (and our experimental apparatus) which causes us such great difficulty as we attempt to explore the atomic world, because much of the true behaviour of atoms becomes hidden from our eyes. Instead, all we ever consider is phenomena in which the individual behaviour of atoms is "averaged out". Most notably, the peculiar quantum mechanical behaviour of individual atoms is obscured as we only ever consider systems which are composed of billions of atoms. However, if we really want to obtain an accurate picture of the behaviour of individual atoms, it is precisely this quantum mechanical behaviour which we need to capture.

And so, this chapter presents a brief introduction to quantum mechanics, describing the actual techniques used by physicists in order to construct an accurate model of the atom.

Basic matrix operations

Central to this discussion of quantum mechanics will be the mathematical object known as a *matrix*. You might have been introduced to matrices ("matrices" is the plural of "matrix") in your mathematics class in school, and you might have suspected that you would never use such an obscure piece of mathematics in your everyday life. Well, unless you found employment in some fields of science and engineering then you might have been correct. However, in this book you will finally get a chance to use your skills as you discover just how useful matrices really are.

The discussion will show why matrices are so central to quantum mechanics, and why solving problems in quantum mechanics involves solving a problem described by matrices. You will get much more out of the rest of the book if you ensure you understand the concepts in this section. I will be asking you to perform some important matrix calculations later in this book. You won't believe what we can achieve!

A matrix is a square (or rectangular) grid of numbers. Here is an example of a 2×2 matrix (it has two rows and two columns):

$$\begin{bmatrix} 2 & 4 \\ 7 & 3 \end{bmatrix}$$

We might ask how matrix multiplication (the multiplication of two matrices) might be achieved. For example, how could we multiply the following two matrices:

$$\begin{bmatrix} 2 & 4 \\ 7 & 3 \end{bmatrix} \times \begin{bmatrix} 5 & 6 \\ 1 & 5 \end{bmatrix}$$

We can multiply these two matrices by the following sequence of steps.

First, consider the first row of the first matrix and the first column of the second matrix (shown in the two dashed ellipses in the following diagram). Take the first number in the first row of the first matrix (which is 2) and multiply it by the first number in the first column of the second matrix (which is 5). This gives us our first intermediate result of 10 (we must remember this). Then take the second number in the first row of the first matrix (which is 4) and multiply it by the second number in the first column of the second matrix (which is 1). This gives us our second intermediate result of 4.

We add our two intermediate results (10 and 4) together to get the answer 14, and that number goes in the first position in our result matrix:

$$\begin{bmatrix} 2 & 4 \\ 7 & 3 \end{bmatrix} \times \begin{bmatrix} 5 & 6 \\ 1 & 5 \end{bmatrix} = \begin{bmatrix} 14 & \\ & \end{bmatrix}$$

To calculate the next entry in our answer matrix, once again we have to consider the first row of our first matrix, but now we consider the second column of the second matrix. We perform a similar series of steps to the first case, but this time we need to calculate $(2 \times 6) + (4 \times 5)$ to give an answer of 32:

$$\begin{bmatrix} 2 & 4 \\ 7 & 3 \end{bmatrix} \times \begin{bmatrix} 5 & 6 \\ 1 & 5 \end{bmatrix} = \begin{bmatrix} 14 & 32 \\ & \end{bmatrix}$$

We continue in a similar fashion until we have filled all the positions in our result matrix. So here is the answer of our matrix multiplication:

$$\begin{bmatrix} 2 & 4 \\ 7 & 3 \end{bmatrix} \times \begin{bmatrix} 5 & 6 \\ 1 & 5 \end{bmatrix} = \begin{bmatrix} 14 & 32 \\ 38 & 57 \end{bmatrix}$$

You might want to check the steps yourself to make sure it is the correct answer. $(7 \times 5) + (3 \times 1) = 38$ and $(7 \times 6) +$

$(3 \times 5) = 57$.

One vitally important feature about matrix multiplication is that it is *noncommutative*. Conventional multiplication is commutative in that it does not matter in which order the numbers are multiplied, the answer will be the same. For example, 7×5 will give the same result as 5×7 . However, matrix multiplication is noncommutative in that the ordering does matter. If the ordering of the matrices is reversed, the answer will be different. You might want to check this by considering the previous example, but this time placing the second matrix before the first matrix. When the multiplication is performed, you should get a different answer:

$$\begin{bmatrix} 5 & 6 \\ 1 & 5 \end{bmatrix} \times \begin{bmatrix} 2 & 4 \\ 7 & 3 \end{bmatrix} = \begin{bmatrix} 52 & 38 \\ 37 & 19 \end{bmatrix}$$

So this is something very important which I want you to remember as we will be returning to this point several times in this book: **matrix multiplication is noncommutative**. You get a different result for your multiplication when you reverse the ordering of the matrices.

Vectors

The mathematical construction known as a *vector* is closely associated with matrices. A vector is a line of a specified length which has a definite direction — essentially it is an arrow. In three-dimensional space, we could imagine a vector extending outwards from the origin of our coordinate system, as is the case with the dashed arrow in the following diagram:

You will see that the dashed arrow (the vector) points to a point in space which is a distance x along the horizontal axis, and is a distance y along the vertical axis, and a distance z along the axis which is coming out of the page. You can see that this vector could actually point to any position in space, as long as we have the (x, y, z) coordinates of the position. Hence, three coordinates are enough to define this vector, and we could list those coordinates in matrix form as a matrix which has only one column:

$$\begin{bmatrix} x \\ y \\ z \end{bmatrix}$$

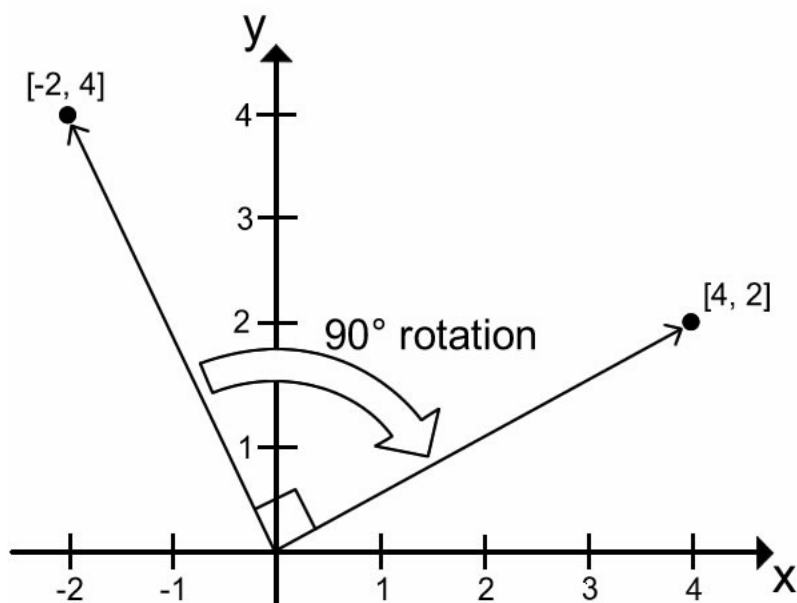

A vector is therefore essentially just a matrix, and so we can perform matrix multiplication by multiplying a vector by a matrix. As we shall see, the result of the multiplication will be another vector. Hence, a matrix can be used for **transforming** a vector into another vector.

Here is an example of a matrix multiplication being used to transform a vector which has just two coordinates $[-2, 4]$ (as an example, a vector drawn on a flat sheet of paper would only have two coordinates: x and y):

$$\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \times \begin{bmatrix} -2 \\ 4 \end{bmatrix} = \begin{bmatrix} 4 \\ 2 \end{bmatrix}$$

The result vector is calculated in the usual method. The first entry is $(0 \times -2) + (1 \times 4)$ which is 4, and that goes in the first position in the result vector. The second entry would be $(-1 \times -2) + (0 \times 4) = 2$.

So what is the result of this transformation? A vector with the coordinates $[-2, 4]$ has been transformed into a vector $[4, 2]$. Let us plot these two positions on a graph:

You will see from the graph that the result of this matrix multiplication is to rotate the vector about the origin by 90 degrees.

This ability of matrices to perform transformations is an incredibly useful property. As we shall now discover, this is the reason matrices are used in quantum mechanics.

The quantum measurement

We only have to consider the implications of quantum mechanics when we are dealing with the smallest parts of Nature, which are particles. True, the rules which apply to particles inevitably apply to larger objects as well, but the counter-intuitive behaviour of quantum mechanics gets "averaged out" as we move up the scale from individual particles to macroscopic ("human scale") objects composed of trillions of particles. We simply don't have to deal with the quantum rules directly in our everyday lives.

However, in this book we are interested in the behaviour of particles, so a good understanding of quantum mechanical behaviour is going to be crucial.

I considered the logic of quantum mechanics in my first book, hopefully trying to convey the impression that there is a clear and consistent underlying logic to quantum mechanical behaviour (even though the "weirdness" of quantum mechanics is often stressed elsewhere). It was stated how quantum mechanics is important whenever we want to extract some information about the state of a system. That is just a grand way of saying that quantum mechanics is all about measurement. When we talk about "measurement" you might have an impression of someone using a tape measure, but, really, measurement is a much more general concept. Whenever we detect an object, for example, we are measuring the position of the object and determining that it resides in a particular location. In fact, in the most general case, we might consider "measurement" to be any interaction between particles (because that interaction has the ability to pin down the position of a particle).

In my first book, I described the principles of measurement at the quantum scale in very simple terms:

1. Before we measure certain properties of a particle (e.g., position, momentum) the particle behaves as though it has **all possible values** for that property.
2. After we have performed the measurement, we find the particle property takes only one of the possible values at random. It is fundamentally impossible to predict which value the property will take.

And those two simple principles, basically, are the underlying principles of quantum measurement. Hence, they are the underlying principles of quantum mechanics itself. It is really not so difficult or weird!

With these two principles in mind, I presented a useful analogy to quantum measurement: a roulette wheel. Before the measurement is taken, we might imagine the ball spinning around the wheel to be in all possible states, certainly it has the potential to take all possible states. In this pre-measurement phase, we might consider the system to be in a *superposition* state (i.e., all possible states). However, when the measurement is taken, the ball occupies only one clearly-defined state. The number of the slot indicates the value of the measurement. It is fundamentally impossible to predict which slot the ball will end up in. In other words, it is fundamentally impossible to predict the outcome of a measurement in advance: quantum mechanics can only give you the probability of a certain outcome.

As an example of these principles in practice, my first book described the famous *double-slit experiment*. According to Richard Feynman: "The double-slit experiment has in it the heart of quantum mechanics. In reality, it contains the only mystery of quantum mechanics."

In the double-slit experiment, a light source is in front of a board. Two narrow slits are cut into the board. Light can only pass through these two slits, and the light which passes through the two slits illuminates a screen behind the board. The two light rays from the two slits meet at the screen. Due to the wavelike nature of light — and the resultant constructive and destructive interference — this results in a characteristic pattern of dark and light bands projected onto the screen (for details, see my first book).

This all makes sense, and is in agreement with the classical (i.e., non-quantum) view of waves. Indeed, this effect can even be seen in water waves passing through two slits.

However, the real surprise happens when the intensity of the light is reduced to such an extent that only one particle (one photon) is emitted at a time. In other words, at any point in time there is only a single photon travelling from the light source, through one of the two slits (we do not know which slit), before hitting the screen behind the board. Over time, these individual photons build up a pattern on the screen. Amazingly, the pattern on the screen still exhibits the dark and light interference bands. It appears that the photon is interfering with itself! In fact, **it appears that the photon is passing through both slits at once.**

As amazing as this result might appear, it is in line with the simple principles of quantum mechanics I described earlier in this section. Before we make a measurement of a particle's position (i.e., before we localise the particle by making it hit a screen) the particle behaves as if it has all possible values, as if it is passing through both slits at the same time. At this point, the particle is in a superposition state of all possible values.

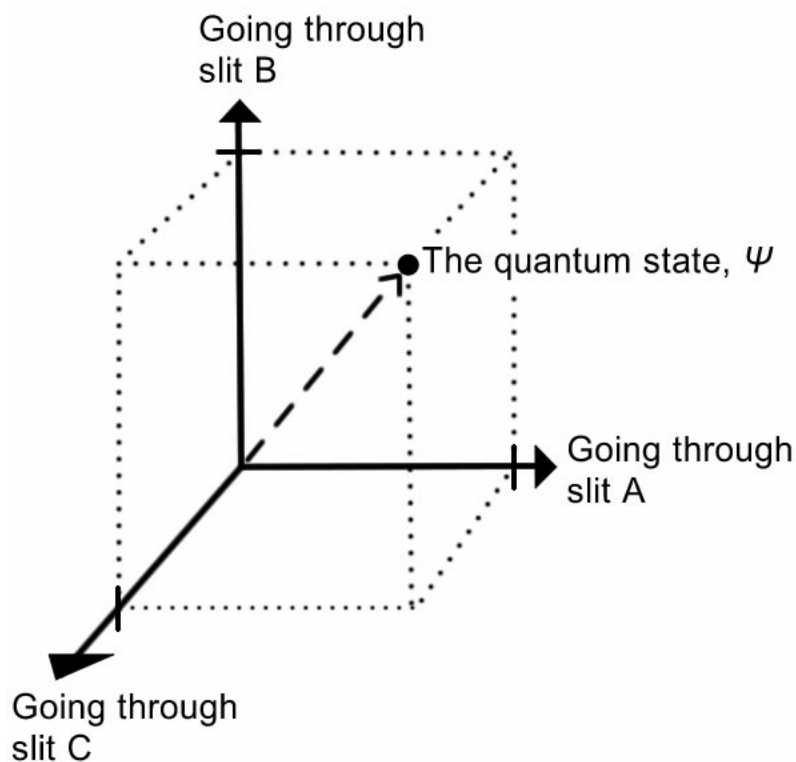

But, you might argue, one particle is only making one dot on the screen. Surely this means that the particle is truly only going through one slot? If we could install detectors on each slit, surely we might be able to detect which slit the particle is actually passing through? If we try this approach, true enough, we discover the particle appearing to only travel through one slot — **but this makes the interference pattern on the screen disappear!** By detecting the

particle, we are effectively localising it, and forcing it to appear in only one position. The act of measurement takes the particle out of its superposition state. Again, this agrees with the principles of quantum mechanics I described earlier in this section: after we have performed the measurement, we find the particle property takes only one of the possible values at random.

At this point, we start to realise why all our work on matrices and vectors was worthwhile. In order to see why that is the case, we have to realise that a particle in a superposition state is really in a combination of all possible states. And we can represent a combination by a vector.

In order to see how we can do this, let's expand the double-slit experiment into a triple-slit experiment. In other words, we get our knife out and cut another slit in the board so that the particle can now pass through three slits in the board instead of just two slits.

Before the particle hits the screen and is detected, we have to consider the particle as being in a superposition state, which means we now have to consider the particle is passing through all three slits. The state of the particle is therefore in a combination of three states: "Going through slit A", "Going through slit B", and "Going through slit C". In the following diagram, I hope you can see how this superposition state of the particle can be represented as a vector (the dashed arrow) which is composed of all three possible states:

You will notice that this superposition state of the particle is referred to as the quantum state, and is denoted by the Greek letter Ψ (pronounced "sigh"). This is the standard notation used to denote the quantum state of a particle.

So this explains how vectors are a perfect mathematical tool for representing quantum states. Please note that the vectors in the previous diagram no longer represent the three coordinate axes of space. No, the three vectors are now purely a mathematical abstraction representing the three possible states of the particle. This type of vector space which is used for representing quantum states is called a *Hilbert space* (after the great German mathematician David Hilbert).

So what happens when we make a measurement? Well, the particle is pulled out of its superposition (multi-valued) state into a single well-defined state. For example, when we try to detect the position of the particle in our triple-slit experiment, we find it only passing through one slit. As you will see in the following diagram, in state vector terms this is represented by a rotation of the quantum state vector from its previous superposition state to one of the well-defined single states (in this case, going through slit B):

And what have we already seen are very useful tools for rotating vectors? Yes, matrices! (Remember earlier in this chapter we showed how matrix multiplication can rotate a vector). So all our work with matrices was not wasted. We will now see that matrices are the key tool for analysing what happens when we make a quantum measurement.

However, the way we use matrices to predict the possible outcomes of measurements is rather different from this rotational model. The next section describes the procedure which really lies at the heart of all quantum mechanical measurements.

You just need to know the magic word ...

The magic word: "Eigen"

You will find in quantum mechanics that a particular word crops up time and time again. It is a German word, emphasising that Germany led the world in the development of quantum mechanics in the early decades of the 20th century. The word is "eigen", and — in the German style — you will find the word added before another word to make a compound word, such as "eigenstate", "eigenvector", or "eigenvalue".

Apparently in German, the correct translation of "eigen" is "personal" or "idiosyncratic". However, when I see the word "eigen" I think of only one word, and that word is "allowed".

As an example, an *eigenvalue* is the value you will measure when you perform a measurement or observation on a quantum system. Only a few, certain values can possibly result from your measurement: you will find you will only measure one of a few "allowed" values.

As an example, in the previously-described triple-slit experiment, when we perform a quantum measurement on the particle (i.e., measuring its position to detect which slit it went through) we will obtain one of only three possible values: slit A, slit B, or slit C. In other words, only three possible values are allowed. These would represent the eigenvalues of the system.

Remember the analogy I presented earlier of a ball spinning round a roulette wheel? I said that before the measurement is taken, the ball spinning around the wheel represents the multi-valued superposition state. However,

after the measurement is taken, the ball only occupies one clearly-defined slot. The numbers on these clearly defined slots represent the allowed eigenvalues we will measure.

So how do we calculate our possible eigenvalues? Firstly, we have to decide what property we want to measure, because different properties have different eigenvalues. Each different measurable property value (called an *observable*) is associated with a different matrix operation. And that particular matrix operation is achieved by using a particular *operator matrix* (sometimes simply called an *operator*). For example, if you want to know the possible energies which a particle can have, you would use the energy operator matrix. Or, if you want to know the possible values for a particle's momentum, you would use the momentum operator matrix.

This use of a particular operator in order to produce a measurable value emphasises the importance of the observer in quantum mechanics. It is as though the very act of observation creates the measured value. Before the operator is applied, it is meaningless to talk of the value of a property of a particle.

So, when we have selected a suitable operator matrix, what happens next? Well, it turns out that the operator matrix contains within it all the information we need, but we have to extract that information in a rather unusual manner. Remember that the possible states of the particle (e.g., "slit A", "slit B", etc.) can be represented by vectors in a vector space. These vectors are called *eigenvectors* (i.e., the "allowed" states after measurement). So how are eigenvectors and eigenvalues related? The relationship is quite peculiar, but it is vitally important: **The result of multiplying an eigenvector by the operator matrix results in the same eigenvector — but multiplied by a number. And that number happens to be the eigenvalue we measure.**

This method is represented in the following diagram:

The diagram shows the following equation with arrows pointing to the components:

$$\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \times \begin{bmatrix} 0 \\ 1 \end{bmatrix} = -1 \times \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

Labels and arrows in the diagram:

- "Operator matrix" with an arrow pointing to the first matrix.
- "The same eigenvector" with two arrows pointing to the second matrix and the final matrix.
- "The measured eigenvalue" with an arrow pointing to the scalar "-1".

Take some time to ensure you understand the previous diagram. This eigenvalue/eigenvector approach is the **absolutely central** method for analysing quantum mechanical measurements. An actual example will be presented later in this chapter.

For a particular operator matrix, only a few very specific eigenvectors can successfully satisfy this requirement. So a particular operator matrix defines a set of possible eigenvectors. And, as each eigenvector is associated with just one particular measurable eigenvalue, this means that a particular operator matrix gives us the complete set of possible measurements we will find. As Leonard Susskind and Art Friedman say in their book *Quantum Mechanics*: "An operator is a way of packaging up states along with their eigenvalues, which are the possible results of measuring those states."

Crucially, the noncommutative property of matrices (which we considered earlier in this chapter) is known to have important consequences for the ordering in which measurements are taken in quantum mechanics. The

Heisenberg uncertainty principle is a consequence because the order in which you take measurements is important: if you measure a particle's momentum first, and then its position, you will get a different result if you performed the measurements in the opposite order. This is due to matrix multiplication — which lies at the heart of quantum mechanical measurements — being noncommutative: the order does matter.

So this is a very mathematical approach to producing "allowed" eigenvalues. But is there a more intuitive approach? Well, yes there is. Where previously have we encountered "allowed" values before? Remember back to the work of Louis de Broglie in the previous chapter who suggested that only an integer (whole number) of wavelengths could be allowed in the orbit of an electron around the nucleus. This meant that the energy of the electron could not be continuously variable, but had to be divided into discrete chunks. In other words, only certain energy levels were allowed. Well, these allowed values of energy precisely correspond to the allowed eigenvalues of energy for the electron.

It has been shown that the eigenvalue approach to finding allowed values, and the "whole number of wavelengths" approach to finding allowed values are mathematically equivalent. In fact, in 1926 Erwin Schrödinger first presented his famous Schrödinger wave equation in a paper entitled *Quantization as an Eigenvalue Problem*.

The following diagram shows how allowed energy states are related to the number of whole wavelengths:

So next time you might be having difficulty in imagining the "allowed" eigenvalues produced by a matrix calculation, just imagine the problem in terms of an allowed number of integer wavelengths instead.

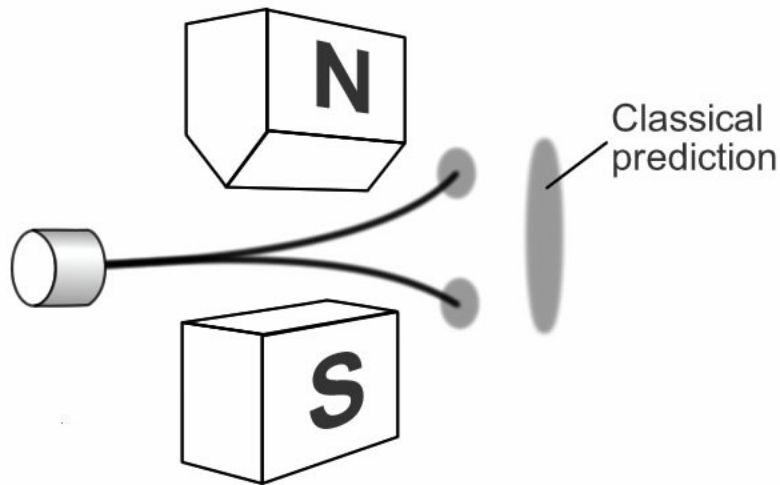

This wavelike nature of the quantum state means the quantum state (or quantum state vector) is frequently referred to as the *wavefunction*. Personally, I generally find it easier to think in terms of a quantum state as a vector, and that is the approach I have followed in this book. But just bear in mind that the two terms both refer to the same thing.

Certainly, this wave-based approach hopefully gives you more of a feel as to how discrete eigenvalues can emerge as the only allowed values for a property. And it is these discrete (rather than continuous) values which we find at the lowest level of Nature, and it is these "chunks" — the *quanta* — which give quantum theory its name.

Spin

In 1921, Otto Stern and Walther Gerlach performed an experiment in Frankfurt which revealed a new property of particles. The experiment is now known as the *Stern-Gerlach experiment*. In the experiment, Stern and Gerlach sent a beam of particles through a magnetic field. They observed that the particles were deflected, and left two distinct

marks on a screen. In order to explain this, it was proposed that the particle might be spinning about an axis. After all, a moving charge generates a magnetic field, so this would result in the particle behaving as if it was a bar magnet. If the particles turned into bar magnets, then this would explain the observed magnetic deflection.

However, there was a problem with this picture of a spinning particle. If we imagine the particles as spinning around an axis, then we would imagine this axis to be randomly-oriented when the particles were emitted from the gun. We would certainly expect the effect of the magnetic field to deflect the particles, but we would expect this to result in a smooth smearing of the particles when they hit the screen (see the "classical prediction" in the previous diagram). However, this is not what happens. When the particles hit the screen, they cluster into two clearly-defined groups.

This clustering into two groups suggests that when we measure the spin of a particle along a particular axis (such as north-south in the previous example) then only two results are possible. Imagine the curled fingers of your right hand representing the direction of spin of the particle:

SPIN UP

Thumb aligned with direction of motion

SPIN DOWN

Thumb opposite to direction of motion

As you can see from the previous diagram, we can understand the two possible states of the particle by using our right hand with our fingers curled up and our thumb pointed out. In this way, the curling of the fingers forms a *spin vector* representing the rotation of the particle. As you can see from the diagram, if our thumb is directed in the direction of motion of the particle then that represents "spin up". Alternatively, if our thumb points in the opposite direction to the direction of motion, that represents "spin down". When we measure the particle, these are the only two possibilities we will encounter.

So this reminds us of eigenvalues: only two values are **allowed**: spin up or spin down. It is as if our quantum roulette wheel has only two slots into which the particle can land. So we come to the conclusion that the spin of a particle is an example of quantum mechanical behaviour.

So if spin is quantum mechanical in nature, let us use our knowledge of eigenvalues and eigenvectors to express spin in a useful mathematical form.

Firstly, we can see that there are two possible states of spin: "spin up" and "spin down". These will be our two "allowed" eigenvector states, and we can represent these by the two vectors:

$$\text{Spin up: } \begin{bmatrix} 1 \\ 0 \end{bmatrix} \quad \text{Spin down: } \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

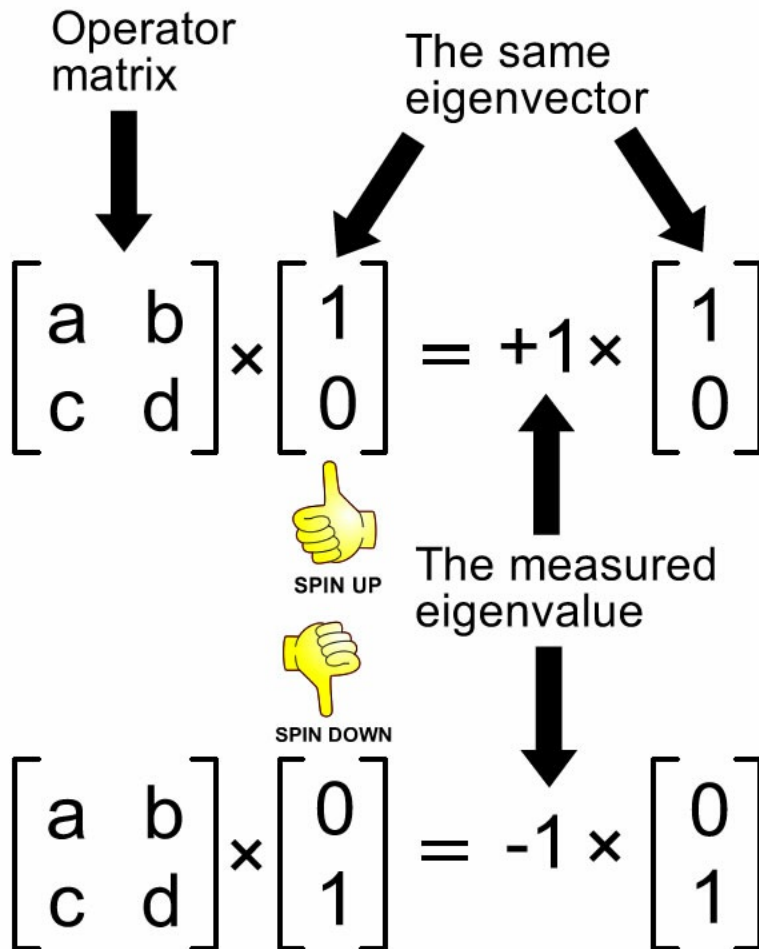

Now, what about the value we actually measure when we make a measurement? In other words, what values

would we expect for our eigenvalues? Logically, we would expect to measure a value of +1 for spin up, and -1 for spin down.

And that is all the information we need. We are now in a position to derive the all-important operator matrix which describes the spin of a particle. Let us represent the operator matrix we need to find by:

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix}$$

We are now left with the task of finding the values of a , b , c , and d . How do we do that? Well, using our knowledge of eigenvalues and eigenvectors, we know that the operator matrix must satisfy the two conditions for "spin up" and "spin down":

These two conditions can only be satisfied if $a=1$, $b=0$, $c=0$, and $d=-1$. Hence, the operator matrix which describes spin is:

$$\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$$

(You might want to check that this operator matrix satisfies both of the two previous eigenvalue/eigenvector operations.)

So this is great! This single operator matrix contains all the information we need to describe both of the possible spin states about an axis, and the spin values we can measure.

However, there are two more axes about which we could measure spin, and the operator matrices for these additional axes can be found in a similar fashion.^[1] The set of the three operator matrices which describe spin about the three axes (x, y, and z) are called the *Pauli spin matrices* (named after Wolfgang Pauli):

The Pauli Spin Matrices

$$\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \quad \begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix} \quad \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$$

where i is the square root of -1 (if you multiply i with i you get -1).

So that is very satisfying. From our knowledge of quantum mechanics we have been able to derive the matrices which are used to describe the behaviour of particle spin, and we will be encountering these Pauli spin matrices again later in this book.

However, we produced these matrices merely by observing the behaviour of particles. It would be so much better (and rather amazing) if we could derive these matrices from basic principles.

Well, that is precisely what we shall do in the next chapter.

But ... what is spin?

We have covered a lot of important ground in this chapter, and at quite a pace. But we have managed to get to this point without ever specifying what, precisely, is meant by the spin of a particle. According to most popular science books, there is apparently little doubt that particle spin has nothing to do with actual physical rotation of the particle.

Well, sorry, I can't accept that. I can't help thinking that if you repeat a statement often enough then eventually it becomes a kind of fact which gets copied and repeated and nobody ever gets round to checking it, so it takes on a life of its own.

It is time for a correction.

In the Stern-Gerlach experiment described earlier this chapter, you will remember that particles deflected in a magnetic field behaved **precisely** as if they were actually physically spinning, the spinning particles turning into miniature bar magnets. This was the initial motivation for suggesting that particles have spin and, indeed, provided the motivation for the term "spin". Indeed, no one disputes that these particles possess the property of angular momentum. So why do so many authors appear to suggest that there is no physical rotation? It appears that this is because spin does not behave in the same way as the classical notion of spin with which we are all acquainted. When a measurement is made of quantum spin, the angular momentum of a particle is quantized into chunks of Planck's constant, h . As we have seen, we interpret this as either "spin up" or "spin down" for the particle, which is

obviously not the case for a classically spinning object.

So on the basis of these quantum peculiarities, should we conclude that the particle is not actually physically spinning, or should we instead conclude that this is precisely the sort of behaviour we should expect in quantum mechanics?

I firmly believe we should come to the latter conclusion.

Firstly, when we measure the spin of a particle, some might be surprised that the act of observation appears to force the particle to choose between either "spin up" or "spin down". But this type of observer effect is found throughout quantum mechanics, and we should surely not be surprised by it. In fact, it would have been much more surprising if we had **not** found an observer effect! It would have been much more surprising if had found particle spin operating according to classical rules when we moved down to the quantum level.

Admittedly, particle spin is a very peculiar property. For example, in the next chapter we will be discovering that you need to spin an electron around twice to return it to its starting position! Crucially, though, these peculiarities do not necessarily signify that the particle is not physically rotating.

As was explained at the start of this chapter, when billions of particles work together to form macroscopic phenomena, there is an "averaging out" of quantum mechanical behaviour, and all humans ever see is the classical form of spin. Hence, quantum spin gets turned into classical spin by this averaging process. As in all examples of quantum mechanical behaviour, the classical behaviour arises from the quantum behaviour. But at the base level, they both arise from the same root cause: quantum spin becomes classical spin.

An accurate explanation of spin is provided by Robert Oerter in his book *The Theory of Almost Everything*: "What is this thing called spin? The electron's spin, as the name implies, has to do with rotation. Take a beam of electrons that are all spinning in the same direction and fire it at, say, a brick. If you could keep this up for long enough, and if there were no other forces acting on the brick, the electrons would transfer their rotation to the brick and it would begin to rotate."

Thank you so much Mr. Oerter! It is reassuring to find a popular science author who is not content to repeat the usual "non-rotation" script.

A similar argument is presented by Luboš Motl in a blog posting entitled "The electron is spinning, after all" (<http://tinyurl.com/electronisspinning>).

And so that concludes our introduction to quantum mechanics and quantum spin. In the next chapter we will discover how one of the greatest mathematical physicists of all time used this knowledge of quantum mechanics and spin to obtain extraordinary insights into the structure of matter and the atom.

3

THE AMAZING MR. DIRAC

Paul Dirac was born in Bristol, England in 1902. His father was a harsh disciplinarian who imposed a strict work ethic on the young boy. As his mother later said: "His father's motto has always been to work, work, work, and if the boy had showed any other tendencies, then they would have been stifled. But that was not necessary. The boy was not interested in anything else." As a result of this sheltered upbringing, Dirac grew up quiet and withdrawn, and rather emotionally stunted. "This balancing on the dizzying path between genius and madness is awful", Einstein later said of Dirac. However, Dirac's talent, hard work and phenomenal mathematical ability eventually resulted in Stephen Hawking describing him as "probably the greatest British theoretical physicist since Newton."

Dirac's technical ability at mathematics was apparent from an early age. In 1919 as a young student, Dirac was profoundly affected by a breakthrough in the field of physics. As Graham Farmelo recounts in his biography of Dirac: "No event in Dirac's working life ever affected him as deeply as the moment when relativity 'burst upon the world, with a tremendous impact' as he remembered nearly sixty years later."

The predictions of special relativity agreed with Newtonian physics for speeds which were much lower than the speed of light, but special relativity modified Newton's laws for speeds close to the speed of light. Purely as a hobby while he was studying as an undergraduate in college in Bristol, Dirac practised upgrading Newtonian theories to incorporate special relativity. According to Dirac: "There was a sort of general problem one could take, whenever one saw a bit of physics expressed in a non-relativistic form, to transcribe it to make it fit in with special relativity. It was rather like a game, which I indulged in at every opportunity."

When he won a scholarship to Cambridge University, Dirac applied his mathematical virtuosity to quantum mechanics, operating at a far higher mathematical level than his fellow physicists who often came from an engineering background, and therefore viewed the atom as a mechanical object. Dirac's approach proved fruitful, showing that a purely mathematical approach was more suited to capturing quantum mechanical behaviour.

The Dirac equation

The challenge for physicists in the 1920s was to combine quantum mechanics with the special theory of relativity.

Erwin Schrödinger had derived a famous equation which described the quantum mechanical behaviour of a particle, but the equation was not relativistic, which meant it did not describe the behaviour accurately as the particle's speed approached the speed of light. Paul Dirac was determined to find a relativistic equation which accurately described the quantum mechanical behaviour of an electron.

In Chapter Eleven of his biography of Dirac, Graham Farmelo describes the motivation and thought processes of Dirac in detail which provides a fascinating insight into Dirac's approach as he successfully derived one of the most important equations in physics, now simply known as the *Dirac equation*.

We will now derive the Dirac equation. What follows might appear to be rather complex. However, there is a considerable reward for us if we take our time and work through this. We will uncover the truth as to why the electron has spin. We will discover why the behaviour of matter particles (such as electrons) makes a solid object feel hard to the touch (and why, conversely, you cannot feel a ray of light). And we will discover how this leads to an understanding of all of chemistry: why the elements have their different characteristics, and how they combine to produce everyday materials. We will even discover why there is matter and antimatter.

And we will also be obtaining an insight into how one of the greatest minds in physics derived one of the most important results in the history of physics.

Dirac took as his starting point the most important equation in special relativity, which is the *energy-momentum relation*:

$$E^2 = (pc)^2 + (mc^2)^2$$

where E is the total energy of a particle, m is its mass, p is its momentum, and c is the speed of light (this equation was derived and considered in detail in my third book). This equation reveals the relationship between energy, mass, and momentum, and it applies to absolutely everything in the universe, from a rolling billiard ball to the energy and momentum of light itself.

You will see that if a particle is stationary, i.e., if its momentum, p , is set to zero, then the equation reduces to Einstein's famous equation $E=mc^2$. However, the energy-momentum relation is more general than Einstein's equation as it can be shown to apply even to massless objects, such as photons.

You will see that the energy-momentum relation can also be written as:

$$E = c\sqrt{p^2 + (mc)^2}$$

Dirac considered this equation and did not like the fact that the p and mc terms were squared. In his biography of Dirac, Graham Farmelo explained Dirac's motivation: "Believing that the relativistic equation would be fundamentally simple, he thought it most likely that the equation would feature the electron's energy and momentum just as themselves, not in complicated expressions such as the square root of energy or momentum squared."

So Dirac considered the content of the square root and tried to express it purely in terms of p and mc , without those terms being squared. What he then had to do was work out the relative amounts of each term.

So Dirac tried to represent the energy-momentum relation as two bracketed terms multiplied together: [2]

$$p^2 + (mc)^2 = (ap + bmc)(ap + bmc)$$

where a and b are some numbers which have to be calculated. They represent the amounts of p and mc which are required.

If we multiply-out the two bracketed terms, we find we get something which looks very close to the energy-momentum relation, but is not quite exactly right. The result includes a term which does not appear to fit (I call this the "unwanted part" in the following diagram):

$$(ap + bmc)(ap + bmc) =$$

$$ap(ap + bmc) + bmc(ap + bmc) =$$

This part closely resembles the energy-momentum relation

$$\boxed{a^2 p^2 + b^2 (mc)^2} + \boxed{(ab + ba) pmc}$$

The "unwanted part"

Considering the first part of the result, we can see that if we set $a=1$ and $b=1$ then the a and b terms effectively disappear (multiplying by 1 is the equivalent of not multiplying at all) and we are left with precisely the old energy-momentum relation. So it would appear that those two values for a and b would represent a solution to Dirac's relativistic equation for the electron. However, the problem is that the "unwanted part" does not vanish with those values of a and b .

So Dirac was stuck with a problem. He needed to find values for a and b such that $a^2=1$ and $b^2=1$. However you will see from the "unwanted part" that he also needed $(a \times b + b \times a)$ to equal zero to remove the entire "unwanted part". Unfortunately, it was clear that no simple numbers satisfied these requirements. In fact, bizarrely, the requirement for $(a \times b + b \times a)$ to equal zero appeared to indicate that a and b had to be mathematical objects for which a different order of multiplication produced a different result (so that $a \times b$ might produce a positive number, while $b \times a$ produced an equal negative number — the sum of those two numbers then being zero).

So where have we heard of this type of noncommutative multiplication before, multiplication in which the ordering matters?

The story is that Dirac was staring into the fireplace at Cambridge when he was struck by a stroke of genius. He realised that a and b were not simple numbers at all. Instead, he realised that matrices exhibited precisely this type of noncommutative multiplication which was required (as we discussed in the previous chapter).

Here is an example of two matrices which would meet Dirac's requirement: [\[3\]](#)

$$a = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \quad b = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$$

Remember, the first requirement is that the square of either of the matrices must be equal to one. So let's pick one of the matrices — say, matrix a — and square it (multiply it by itself):

$$\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \times \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

You will see the result is a matrix which has ones in the top-left to bottom-right diagonal, and zeroes everywhere else. This is called the *identity matrix* and it is the matrix equivalent of "1" (because, if you multiply a matrix with the identity matrix then the original matrix is unchanged — just as if you were multiplying with 1). So the first of Dirac's requirements is satisfied (you might want to check that the square of matrix b is also the identity matrix).

The second of Dirac's requirements is that $(a \times b + b \times a)$ must equal zero. Let us test that this second requirement is satisfied:

$$a \times b = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \times \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$$

$$b \times a = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \times \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}$$

So therefore:

$$(a \times b) + (b \times a) = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} + \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$$

(Matrix addition is performed simply by adding the numbers which have the same positions in the two matrices).

You will see that the result of $(a \times b + b \times a)$ is the zero matrix (a matrix with zeroes in all its positions). So the second of Dirac's requirements is also satisfied by these two matrices.

So have we solved the problem? Have we found the relativistic equation of the electron?

Well, no, there is a problem.

According to relativity, space and time are placed on an equal footing and are combined to create *spacetime*. Spacetime is therefore four-dimensional (three dimensions of space, and one of time). But the analysis so far has only considered two dimensions: one dimension of space (a single value for momentum) and the time dimension. Remember, Dirac was trying to create a relativistic theory. So to be fully consistent with relativity, we have to consider the additional two space directions.

In the analysis so far, we had to find two matrices a and b such that either matrix squared equalled one, and also satisfied the requirement that $(a \times b + b \times a)$ must equal zero. Now we are moving to consider the two additional dimensions, we need to find a total of **four** matrices — a , b , c , and d — which satisfy the following requirements:

- a^2 must be equal to one, but b^2 (along with c^2 and d^2) must be equal to minus one.[\[4\]](#)
- If you take **any** two of the four matrices (let's call the two selected matrices x and y), then $(x \times y + y \times x)$ must

equal zero.

(You will see that these requirements are virtually identical to the earlier situation in which we only considered two dimensions and two matrices).

However, it is simply not possible to find four 2×2 matrices which satisfy these requirements. Dirac found he could only satisfy these requirements by using larger 4×4 matrices. These important matrices are called the *gamma matrices*:

The Gamma Matrices

$$a = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix} \quad b = \begin{bmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{bmatrix}$$

$$c = \begin{bmatrix} 0 & 0 & 0 & -i \\ 0 & 0 & i & 0 \\ 0 & i & 0 & 0 \\ -i & 0 & 0 & 0 \end{bmatrix} \quad d = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \\ -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}$$

This might be a good time to take your pen and paper out and check that these gamma matrices are correct and satisfy Dirac's requirements. Remember, a^2 (matrix a multiplied by itself) must be equal to one (the identity matrix). However, b^2 (along with c^2 and d^2) must be equal to minus one (the negative of the identity matrix).

Also, check that if you select **any** two of these gamma matrices (let's call the two selected matrices x and y), then $(x \times y + y \times x)$ must equal zero.

(Remember that i is the square root of -1 . So if during the calculation you find you get a term which is i multiplied by i then the result is -1).

So, at last, these gamma matrices satisfy Dirac's requirements. And this is so important because — as we shall see — it is these gamma matrices which form the basis of the Dirac equation, and hence they describe the remarkable behaviour of electrons.

The equation in the Abbey

Once he had found his gamma matrices, Dirac then had to apply the final step in the creation of his relativistic equation of the electron: he had to "quantize" the equation, to make the equation agree with quantum mechanics. Fortunately, we already know how to do this as we studied it in the last chapter: it is simply to use the standard eigenvalue/eigenvector form which — as stated earlier — is used to describe all quantum mechanical measurements.

A concise form of the Dirac equation is shown in the following diagram. You should recognise the standard form of the eigenvalue/eigenvector equation as described in the previous chapter. On the left hand side of the equation is an operator and a eigenvector (the state vector, Ψ , considered in the previous chapter), and on the right hand side of

the equation is an eigenvalue multiplying the same eigenvector:

The diagram shows the Dirac equation $i\gamma\partial\psi = m\psi$. Labels with lines pointing to the equation are: "Operator" pointing to $i\gamma\partial$ (which is enclosed in a dashed box), "Eigenvector (state vector)" pointing to ψ , "Gamma matrices" pointing to γ , and "Eigenvalue" pointing to m .

You will see that the set of the all-important gamma matrices (denoted by the Greek letter "gamma", γ) is included in the operator.

Paul Dirac died in 1984, and a commemorative plaque was installed on the floor of Westminster Abbey in London. You can see that the Dirac equation (which we have just derived) is inscribed on the plaque just below Dirac's name:

So, well done, we have derived the Dirac equation, one of the most important equations in physics. According to

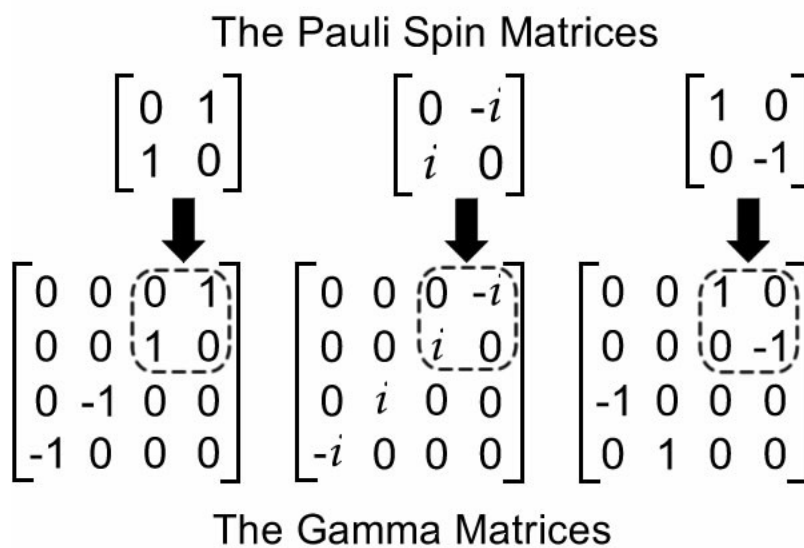

Nobel Prize winning physicist Frank Wilczek: "Of all the equations of physics, perhaps the most magical is the Dirac equation. It is the most freely invented, the least conditioned by experiment, the one with the strangest and most startling consequences. It became the fulcrum on which fundamental physics pivoted."

The only question left now is ... what does it all mean?

The absolute wonder

So now we have derived the Dirac equation, the relativistic equation for the electron, we have to determine what are the implications of the equation for the behaviour of the electron. We will find that the many implications are really quite remarkable, and explain the properties of the matter of which the world is made.

Firstly, if we examine three of the gamma matrices, we find that the 2x2 matrices in the top right segment of the gamma matrices precisely match the Pauli spin matrices (describing the spin of the electron) which we considered in the previous chapter:

It appears that the gamma matrices seem to be describing the spin of the electron. Indeed, according to Dirac: "The gamma matrices are new dynamical variables which it is necessary to introduce in order to satisfy the conditions of the problem. They may be regarded as describing some internal motions of the electron, which for most purposes may be taken as the spin of the electron postulated in previous theories."

So this is really something quite remarkable. Dirac derived the need for electron spin **purely mathematically!** It is as if mathematics alone is predicting that the electron must be spinning (this derivation is in contrast to how we derived the Pauli spin matrices merely by **observing** electron spin and trying to model it mathematically).

This was truly an amazing achievement by Dirac. The physicist John Van Vleck compared Dirac's explanation of electron spin to "a magician's extraction of rabbits from a silk hat." According to Leon Rosenfeld, "the equation was immediately seen as **the** solution. It was regarded really as an absolute wonder."

This was perhaps the first time that mathematics on its own was used to predict the behaviour of Nature. It revealed the extraordinary power of mathematics as a tool for theoretical physics.

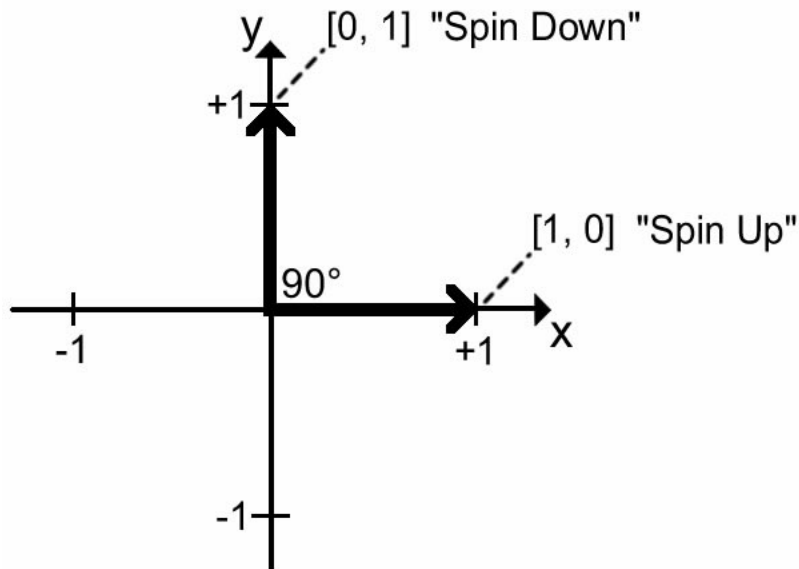

The spinning spinor

So we have now seen that the Dirac equation can be used to give us the Pauli spin matrices which describe the spin of an electron. And we have also seen that the Pauli spin matrices show that we will only measure an electron as being in one of two possible states: either "spin up" or "spin down".

Now let us consider what happens when an electron is rotated. We will find that the answer is quite astonishing.

In order to explain this behaviour, remember that in the previous chapter it was explained how the "spin up" and

"spin down" states of the electron can be expressed as vectors. The "spin up" state can be described by the vector $[1, 0]$ and the "spin down" state can be described by the vector $[0, 1]$. Let us draw those two vectors on a graph:

In the previous graph, you can see that the "spin up" state is denoted by a thick horizontal arrow from the graph centre to the coordinate $[1, 0]$ ($x=1, y=0$), thus forming the "spin up" vector. You can also see that the "spin down" state is denoted by a thick vertical arrow from the graph centre to the coordinate $[0, 1]$ ($x=0, y=1$), thus forming the "spin down" vector.

Note that the two vectors are at 90° to each other (for this reason, the two states are said to be *orthogonal*).

But here is the crucial point: in order to convert a "spin up" electron into a "spin down" electron we have to physically rotate the electron in real space by 180° (turning something pointing up into something pointing down). Amazingly, this suggests that if we physically rotate an electron by 180° , its quantum state (described mathematically by vectors) only gets rotated by 90° .

This reveals that the quantum state of an electron gets rotated by only half the amount that the electron is physically rotated. It is as if the physical electron is connected to its quantum state by a 2:1 gearing system. Bizarrely, this reveals that to return the quantum state to its original position (requiring a full spin of the quantum state by 360°), we have to physically rotate the electron by two full spins: 720° .

This is an amazing and crucial result: **an electron must be physically rotated twice, 720° , in order to rotate the quantum state by 360° , thus bringing the electron back to its original quantum state.**

This is really quite an extraordinary claim. Nothing in our everyday experience behaves like this: you don't have to rotate any ordinary object twice in order to bring it back to its original position — just one full turn is always enough! However, in the strange world of fundamental particles, we have to forget about our everyday experience and have an open mind about new modes of behaviour.

Now let us see what happens when we physically rotate our electron by 360° . Intuitively, we would expect a "spin up" electron to return to its initial "spin up" state when it is rotated by one full turn in physical space. However, we have just shown that a quantum state is rotated by only half the amount of the rotation of the physical electron. This means that the quantum state of the "spin up" electron is only rotated by 180° :

In the previous diagram, you will see that the $[1, 0]$ "spin up" electron vector (pointing to the right) has been rotated around the centre of the graph by 180° so it ends up pointing to the left. This represents the rotation of the physical electron by one full turn: 360° . But we can see that the coordinates of the resultant vector (pointing to the left) are $[-1, 0]$. We can see that these are not the coordinates of the "spin up" electron. In fact, they are the coordinates of the "spin up" electron **multiplied by -1** (because $[1, 0]$ multiplied by -1 gives $[-1, 0]$). Most obviously, the vector is multiplied by -1 because it is the same length as the initial vector but **points in precisely the opposite direction**. It is the negative of the initial vector.

So, remarkably, this reveals that when we rotate an electron by a full 360° we do not end up with the same quantum state we started with. Instead we get the original quantum state multiplied by -1 . **We will see in the next section that this is a hugely important result.**

This is an example of a mathematical object called a *spinor* (pronounced "spin-or" not "spine-or"). A spinor is an object which you have to rotate twice in order to return it to its original state. Needless to say, there is nothing in our everyday experience which behaves like this — we are obviously used to objects returning to their original state when we turn them by one full rotation. However, if you rotate a spinor by one full revolution, 360° , it is equivalent to multiplying the spinor by -1 . If you then rotate it a further 360° you return the object to its original state (because -1 multiplied by -1 would give $+1$). So to return a spinor to its original state you have to rotate it by two full spins: 720° .

A particle (such as an electron) which you have to rotate twice to return to its original state is called a *spin- $\frac{1}{2}$* particle (you might say a full rotation only gets you halfway!).

Rather wonderfully, this is best illustrated by a practical example. It so happens that the rotation of the elbow and shoulder in the human arm is a perfect model of a spinor (there are some undoubted evolutionary advantages to this spinor design, allowing the hand to rotate fully without the arm getting tangled). I have recorded a video showing me using my arm to rotate a glass of water which represents an electron.

I can recommend you watch the video at <http://tinyurl.com/particlerotation>.

Here are some still images from the video:

0°

180°

360°

540°

720°

Though it might sound almost unbelievable that spin- $\frac{1}{2}$ particles have to be rotated by 720° to return to their original state, it has been directly experimentally proved. A stream of neutrons, whose spin was all oriented in the same direction, was split into two beams. One stream was rotated about an axis along its direction of motion, and then the two beams were recombined. When the rotation angle was 360° , the two beams cancelled-out. Amazingly, though, when the particles were rotated twice, through 720° , the two beams combined to produce a stronger signal. This shows the peculiar rotational behaviour of spin- $\frac{1}{2}$ particles is a genuine measurable effect.

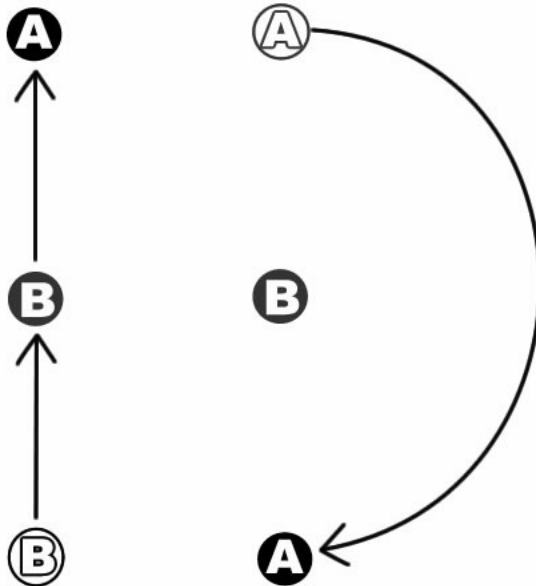

The Pauli exclusion principle

All spin- $\frac{1}{2}$ particles are called *fermions*. Fermions are the particles which form atoms, and hence form all the matter in the universe. But why should spin- $\frac{1}{2}$ particles be the matter particles? Well, we will now discover that the reason that fermions behave like matter particles is directly linked to their peculiar rotation characteristics.

The secret lies in what happens when we exchange two particles. Imagine we have two fermions of the same type: particle A and particle B (see the following diagram). These might be electrons, for example. We want to exchange (swap) the two particles. The most obvious way we could do this would be by moving particle A to the position of particle B while, at the same time, moving particle B to the position of particle A:

However, this is not the only way we could exchange the particles. It is possible to exchange the particles using a different method while still producing exactly the same result. As shown in the following diagram, we could translate both particles vertically, and then **rotate the whole system around the centre of particle B**. This would produce exactly the same end result, with particle B now above particle A:

But what happens to the quantum state (the wavefunction) of the system when the system is translated and rotated like this? Well, firstly, the translation has no interesting effect. So that means we have done something extremely clever here: we have converted the process of particle exchange into a process of simple rotation of particles: we have shown that the mathematics of particle exchange and particle rotation is essentially the same. And we know precisely how fermions behave when they are rotated as we worked it out in the previous section. We have seen that fermions behave quite peculiarly when they are rotated. So we will have to examine the impact of the rotation on the quantum state of the system.

It can be seen that particle A was rotated by 180° , and particle B was also rotated by 180° (around its centre). The total rotation as far as the quantum state of the system is concerned is the sum of the rotations of the two particles, which is therefore 360° (for more details of this approach to particle exchange and rotation, see the footnote [6]).

This is a crucial result. Because, as saw in the previous section, a 360° rotation of a spin- $\frac{1}{2}$ particle results in the quantum state being multiplied by -1 . It is said that the wavefunction in that case is *antisymmetric* (because it does not join up with itself when it is rotated: it is multiplied by -1). We can now see that particle exchange is also antisymmetric: if you exchange two fermions, the quantum state is multiplied by -1 .

(If you continue and exchange the particles back again, the quantum state is multiplied by -1 again, thus restoring

the original quantum state because -1 multiplied by -1 gives $+1$).

Now let us consider the situation when two fermions which are in the same state are exchanged. Firstly, we will have to consider what does it mean for two particles to be in the same state.

As described in Chapter One, all particles of a particular type are identical: every electron is the same as every other electron. But does this mean that all electrons are indistinguishable from each other? No, of course not. There are obviously many separate electrons in the universe, and we (and Nature) can distinguish each electron from every other electron because they are in different positions, or they might be moving at different velocities. So even though every electron is **identical**, electrons are not **indistinguishable**.

There are only a few ways in which particles can be distinguished (e.g., their position, their momentum) and these distinguishing features are called *degrees of freedom* (considered in my third book).

For electrons orbiting the same atomic nucleus, there are only a very few ways in which those electrons can be distinguished from each other (they have very few degrees of freedom). As a result, the possibility arises that two electrons might be in exactly the same state. If those two electrons are exchanged, there clearly cannot be any overall change to the quantum state of the system because the electrons are **completely indistinguishable**. Nature has fundamentally no way of distinguishing them. If the electrons are exchanged, nothing can possibly change.

However, as we have just seen, if any two fermions are exchanged then the quantum state of the system must be multiplied by -1 . These two results — one saying nothing can possibly change, one saying the quantum state must change — are clearly contradictory. In fact, the only number which does not change when it is multiplied by -1 is the number zero. It would appear that the system can only be described by a wavefunction with the value of zero. We can come to only one conclusion: this contradictory state cannot exist.

We have derived the *Pauli exclusion principle*: **two identical fermions cannot occupy the same quantum state**.

As Jim Baggott says in his book *Higgs*: "The principle derives from the mathematical form of the wavefunction for any composite state consisting of two or more electrons. If the composite state were assumed to be created with two electrons which have precisely the same physical characteristics, then the wavefunction has zero amplitude — such a state could not exist."

Atoms are mainly empty space, so why can't I push my finger through a wooden desk? Isn't there enough empty space for two atoms to pass through each other? Well, it is the Pauli exclusion principle which brings solidity to matter. I cannot push my finger through a wooden desk because any penetration of my finger would result in the electrons in the atoms in my finger being in the same state (same position) as the electrons in the atoms in the wood. The exclusion principle states that is simply not possible. Hence, the wood appears impenetrable to your finger.

So the Pauli exclusion principle results in fermions taking the role of the matter particles, the particles which compose all of the objects in the material world. Cars, trees, water, gases, human beings, are all composed of fermions: protons, neutrons, and electrons.

The root of all chemistry

So, we have now seen that no two fermions can occupy the same state. This is definitely going to have an impact on electrons in a atom orbiting the atomic nucleus.

If you remember back to the discussion in Chapter One, electrons can orbit the nucleus in only certain quantized orbits (or *shells*), the shells being nested around each other like Russian *matryoshka* dolls. The shell in which an electron resides is determined by the energy of that electron. It would appear that any two electrons in the same shell would be in the same state (possessing the same energy). Therefore, according to the Pauli exclusion principle, this would appear to prohibit each shell from containing more than one electron.

However, there are a few other ways in which the state of orbiting electrons can be distinguished. This is because the spherical shells are not necessarily completely identical. Essentially, they can wobble in an elliptical manner (think of a soap bubble wobbling as it rises in the air). These deformations of the shells provide us with a few more ways to distinguish the states of electrons which possess the same energy (i.e., the electrons have a few additional degrees of freedom).

In fact, an electron orbiting the nucleus can be defined by three quantum numbers: n (the shell number, determined by the energy of the electron), l (the shape of the shell), and m (the direction in which the shell is pointing). There are strict rules as to what values these numbers can take. For a given shell number, n , the rules are:

1. l can take any integer value from 0 to $(n-1)$.
2. m can take any integer value from $-l$ to l .

You will see that these two simple rules can be used to construct the following table (which considers the first three shells in which n is 1, 2, or 3). What we are interested in is how many unique combinations of the three numbers there can be, because that tells us how many electrons (each being in a unique state) there can possibly be in each shell. You can clearly see from the table just how many unique combinations there can be for any value of n :

n	l	m	Number of combinations for a particular value of n
1	0	0	1
2	0	0	4
2	1	-1	
2	1	1	
3	0	0	9
3	1	-1	
3	1	0	
3	1	1	
3	2	-2	
3	2	-1	
3	2	0	
3	2	1	
3	2	2	

This table suggests that there is only one unique combination of the three quantum numbers in the first shell, there are four combinations in the second shell, and nine unique combinations in the third shell. In other words, the number of combinations is given by n^2 .

This number should also represent the number of electrons it is possible for a shell to hold (because each of those electrons would be in a unique state). In other words, the lowest energy shell should be capable of holding just one electron, the second shell should be capable of holding four electrons, and the third shell should be capable of holding nine electrons.

However, this is not quite right as there is one additional degree of freedom possessed by each electron, and that is the value of electron spin. Remember, each electron also has the freedom to be either "spin up" or "spin down". These two options means that the number of electrons it is possible for each shell to hold must be multiplied by two. The formula therefore becomes $2n^2$.

This doubling means we should now expect the first shell to be capable of holding two electrons, the second shell should be capable of holding eight electrons, and the third shell should be capable of holding eighteen electrons. And so on.

This, finally, is correct. The number of electrons each shell can hold is 2, 8, 18, 32, 50, ...

Let us see what this means in practice by considering the structure of some chemical elements.

Hydrogen is the lightest element, having an atomic number of 1. This means that an atom of hydrogen has just one proton — and one orbiting electron. However, oxygen has an atomic number of eight, which means it has eight orbiting electrons. All of these eight electrons cannot fit into the lowest energy shell because we know only a maximum of two electrons can fit into that shell. Therefore, two electrons go into the lowest shell, and the remaining six electrons have to go into the next higher shell:

The important factor is now the number of electrons in the outer shell of these atoms. These are called the *valence* electrons. We can see that the hydrogen atom has one valence electron, while the oxygen atom has six valence electrons. This raises the possibility of two hydrogen atoms sharing their valence electrons with one valence electron of the oxygen atom:

In the diagram above we can see that each of the two hydrogen atoms is sharing its valence electron with one of the valence electrons of the oxygen atom. In this way, each hydrogen atom effectively gains one more electron in its outer shell (thus filling its outer shell, which can only contain two electrons), and the oxygen atom effectively gains two electrons in its outer shell (thus filling its outer shell, which can contain eight electrons).

This forms a molecule of water: H₂O (two atoms of hydrogen, one atom of oxygen).

This method of sharing valence electrons is called *covalent bonding* and is the structural method which forms molecular compounds such as carbon dioxide, methane, glucose, or even buckminsterfullerene:

Buckminsterfullerene's "bucky ball" structure is an example of an *allotrope* of carbon, just one example of how sixty carbon atoms can join together to form a molecule (which resembles a microscopic football). Other allotropes of carbon (different structural arrangements) are diamond and graphite, and also *graphene* — hexagons of carbon atoms which join together to form a layer which is just a single atom thick (an illustration of graphene is shown on the front cover of this book). Graphene is acclaimed as the new wonder material, 200 times stronger than steel, yet transparent and flexible.

However, some atoms have full outer shells of electrons. These are the so-called *noble gases*: helium, neon, argon, krypton, xenon, and radon. Because they have full outer shells, atoms of these gases do not combine with other atoms to form molecules. This makes them chemically inert.

We can see that the Pauli exclusion principle — and the numbering of electrons in the shells of atoms — is therefore responsible for the whole of chemistry. As Jim Baggott says in his book *The Quantum Story*: "By preventing the electrons from collapsing or condensing into the lowest-energy orbit, the exclusion principle allows complex multi-electron atoms to exist in the pattern described by the periodic table. It enables the existence of a marvellous variety of elements, the multitude of possible chemical combinations, and hence all material substance, living and non-living. This was a fantastic achievement."

We have covered a great deal of ground in this chapter, and some of the material was challenging, but I hope you can now see that it was worth it. We have derived the Dirac equation, shown how it predicts the spin of electrons, shown how the antisymmetric nature of that spin leads to the Pauli exclusion principle, and finally shown how the Pauli exclusion principle leads to the solidity of matter and prevents all the electrons in an atom collapsing to the lowest energy shell — thus giving atoms their structure. It is that structure which leads to the whole of chemistry. The Dirac equation undoubtedly deserves a book all to itself.

And we have not even considered the most extraordinary prediction of the Dirac equation ...

4

ANTIMATTER

The date is 30th June 1908.

Sergei Semenov had just finished his breakfast and was sitting outside his house, enjoying the cool air before the summer sun rose in the sky to bring the extreme summer heat. Occasionally, hunters and fishermen would pass by, but usually his only neighbours in this remote region of Siberia were the bears and deer who roamed the endless pine forest.

As Sergei peered up into the cloudless sky that morning, suddenly he saw the sky split in two, divided by a towering wall of flame. The heat was so intense that Sergei felt as though his shirt was on fire. However, before he could rip his shirt off, a shockwave hit Sergei, blowing him off his feet and sending him sprawling several metres away.

Sergei's wife ran out of the house, in a state of panic. When she saw her husband virtually unconscious, she dragged him back into their house. But there was no safety to be found there. The earth shook, and rocks started falling from the sky like fiery cannon balls. Sergei and his wife cowered on the floor of their home, waiting for what was surely the end of the world.

Thirteen years passed. World War One, and the 1917 Russian Revolution, all passed without impacting on remote Siberia in any way. Then, in 1921, a mineralogist Leonid Kulik based in St. Petersburg heard the rumours of the catastrophic event, apparently centred on the Tunguska river valley, in one of the most remote regions of Siberia. Kulik believed the event was caused by a meteorite impact, and managed to persuade the Soviet Academy of Sciences to pay for a mission to recover iron from the meteorite which could be used by Soviet industry.

Kulik's team faced an arduous journey to the site of the explosion, carrying heavy equipment largely by hand as they fought through uncharted forest and swamp. When Kulik arrived at the site he was amazed to find scorched trees flattened like matchsticks over an area about the size of Greater London, but he found no impact crater (which would be expected for a meteorite of that size).

Here is one of Kulik's original photographs:

Kulik drained many of the swamps in the area, but found no evidence that any of them were impact craters. He plotted the position of every tree, but no evidence of meteorite fragments were found. Kulik continued to investigate Tunguska for a further 20 years without finding evidence of a meteorite impact. When the Nazis invaded Russia in 1941, Kulik volunteered to fight for the Red Army. He was captured by the Germans, and died a year later.

Asteroid 2794 *Kulik* was named in honour of Leonid Kulik.

Meteorite impact remains the most likely explanation for the explosion. However, Prof. Frank Close of Oxford University has another explanation. In his book *Antimatter* he considered the theory that a block of antimatter might have been the cause of the explosion. Antimatter is perhaps best known as the power source behind a *Star Trek* warp

drive, but it is most certainly a real substance possessing incredible power. Antimatter is the precise opposite of everyday matter which, for example, makes cars and trees. Everyday matter is made of fermions (*fermionic* matter), the particles we have already considered. Antimatter is made of *antifermions*.

When antimatter comes into contact with matter, they annihilate each other in a blinding flash of energy (gamma rays, high-energy light). Antimatter releases more explosive energy than anything else in existence. An antimatter bomb would be 1,000 times more efficient (in terms of fuel) than the fission bombs dropped on Hiroshima and Nagasaki. An antimatter power source would be 100 times more efficient than nuclear fusion.

Undoubtedly, antimatter is being taken seriously by the military as the ultimate weapon of mass destruction. In 2004, Kenneth Edwards, the director of the Munitions Directorate at Eglin Air Force Base in Florida, gave a keynote speech at the NASA Institute for Advanced Concepts. His speech stressed that even small granules of antimatter — almost invisible — could possess devastating destructive potential. Just 50 millionths of a gram of antimatter would generate a blast equal to the explosion at the Federal Building in Oklahoma City in 1995, which killed 168 people.

The theory that a lump of "antirock", one metre across, was the cause of the Tunguska blast is based on the fact that no solid evidence of a meteorite or its crater has ever been found. Whatever caused the Tunguska blast disappeared into thin air — just like an antimatter/matter annihilation. The antirock theory might just be one of many highly speculative suggestions about the source of the Tunguska explosion, suggestions which include the idea that a missing 1972 atomic bomb might have dropped through a wormhole and travelled backward in time to 1908. However, at the very least, the antimatter theory draws our attention to the undoubted vast power and potential of the mysterious substance known as antimatter.

Angels and demons

Antimatter also plays a central role in Dan Brown's bestselling book (and movie starring Tom Hanks) *Angels and Demons*. Though the plot of *Angels and Demons* is fairly preposterous, the science related to antimatter is accurate. Indeed, CERN (the largest particle physics laboratory in the world) has even created its own *Angels and Demons* website:

<http://angelsanddemons.web.cern.ch>

You will notice the Dirac equation is featured at the top of the following page on the CERN webpage. This is a clue as to the nature of antimatter:

<http://angelsanddemons.web.cern.ch/antimatter>

Warning: spoilers ahead. The plot of *Angels and Demons* considers a rogue scientist who secretly uses the LHC (Large Hadron Collider, based in CERN) to create a quarter of a gram of antimatter. The antimatter was suspended in a vacuum by a magnetic field to stop it annihilating and exploding by touching the sides of the canister (this is all good science: CERN has trapped antimatter for 57 days using a similar method — a world record).

In the book, the antimatter is used to form a bomb which threatens the Vatican City. The quarter gram of antimatter is equated to an explosive power of five kilotons of TNT (about a quarter of the power of the Hiroshima nuclear explosion).

The main character in the book, Robert Langdon (played in the movie by Tom Hanks), then has to pursue many clues in a frantic chase to discover the antimatter before it destroys the Vatican. In this respect, the task of Robert Langdon is similar to the task of a physicist: solve a series of puzzles and follow a series of clues to get to the bottom of things.

As an example, some of the clues which Langdon has to unravel take the form of *ambigrams*, which are symmetric words which read the same when they are turned upside down. An example of an ambigram version of the word "Antimatter" is: [7]

Antimatter

Yes, turn the book upside down and you will see that the word is still the same upside down. How remarkable. So when we do physics we have to think like Robert Langdon. We have to look for clues, and solve mysteries.

As an example, let us consider one of Paul Dirac's gamma matrices. We might stare at it for a while, and wonder about its significance. We might even turn our book upside down in desperation. In which case we would notice something highly significant ...

... the gamma matrix is an ambigram!

Just like one of Robert Langdon's symmetric words, if you rotate this book 180°, turning this gamma matrix upside down, then you find the gamma matrix looks the same. All the ones and zeroes appear in the same position. We have discovered a vital clue. This property of the gamma matrices surely has some deep underlying significance.

We know that one half of a gamma matrix gives us one Pauli spin matrix, and we know that that Pauli spin matrix describes an electron which is either "spin up" or "spin down". But what does the other half of the gamma matrix represent?

When the Dirac equation was derived in 1928, it was quickly realised that the "other half" of the gamma matrices had to represent negative energy states of the electron. If we consider the energy-momentum equation again (which Dirac used to derive his equation) we see it is a formula for the square of the energy, E^2 . That meant that the actual value of E could be a positive value **or a negative value**, because the square of a negative value also gives a positive result. However, no negative energy had ever been observed. A stationary object has zero energy of motion, and once it starts moving its energy only increases. To talk of negative energy seemed absurd.

Many physicists criticised the Dirac equation on the basis of its prediction of negative energy states. In response, Dirac felt obliged to defend his theory, and presented a possible solution which made use of the Pauli exclusion principle. Dirac suggested that all of the negative energy states had already been filled by a vast "sea" of electrons. This is not unreasonable, as electrons would naturally seek the lowest energy state, and a negative energy state is, of course, lower than any positive energy state. The Pauli exclusion principle then states that no two electrons can be in precisely the same state, so with all the negative states occupied there would be no more room for other electrons to enter negative states. The remaining electrons would effectively be forbidden from having negative energy.

Dirac went even further. He suggested that any unoccupied "hole" in the Dirac sea of negative energy states would effectively represent a positive charge (because it would require a negatively-charged electron to fill the hole). Hence, Dirac suggested that these "holes" might be positively-charged protons. It was only when it was realised that a proton is approximately 2,000 times heavier than an electron that Dirac shelved that idea.

By 1931, most physicists had lost interest in the "Dirac sea" proposal, and even Dirac appeared to have lost confidence in his "hole" theory as well. Instead, Dirac now predicted something much more solid: "A hole, if there was one, would be a new kind of particle, unknown to experimental physics, having the same mass and opposite charge to an electron. We may call such a particle an anti-electron."

Paul Dirac had just predicted the existence of antimatter.

The discovery of antimatter

Before the days of particle accelerators, experimental particle physicists used a *cloud chamber* for discovering new particles. A cloud chamber is a sealed glass container containing water vapour. Any charged particle which passes through the cloud chamber leaves a thin trail of condensed water droplets in its wake, like vapour trails behind a jet aircraft. By measuring the curvature of the trail under the influence of a magnet, it is possible to tell if the particle is positively or negatively charged (the particles curve in different directions). The paths of lighter particles are curved by a greater amount.

The Earth is constantly bombarded by *cosmic rays*, which are high-energy particles from outer space. These are actually an excellent source of particles for experimental purposes, with some of these particles possessing far greater energies than can be produced by our largest particle accelerators. Cosmic rays can be detected by cloud chambers, leaving wispy ghost-like trails as they pass through.

In 1932, a research student at Caltech called Carl Anderson was using a cloud chamber when he noted something unusual. Electrons are light particles, and leave thin wispy trails through a cloud chamber. Anderson saw several particles leaving these wispy trails, but they curved in opposite directions. This appeared to indicate that some of the electrons had positive charge. This is precisely what would be expected of the mirror-image antimatter version of the electron: the *positron*.

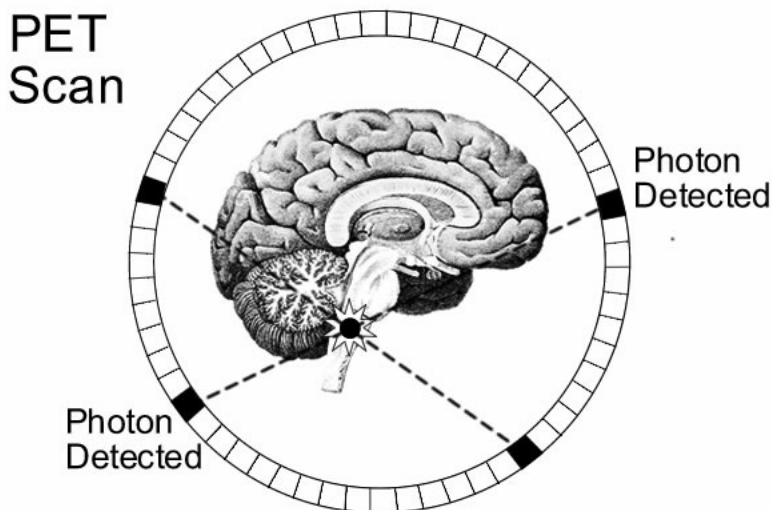

Antimatter had been detected. Dirac's theory had been confirmed. Carl Anderson received the Nobel Prize in 1936 for his discovery.

Dirac's equation applies to all fermions, not just electrons. So a proton also has an antiparticle, called the *antiproton*. And the antiparticle of the neutron is the *antineutron*. In fact, we now know that every particle has an antiparticle.

Antimatter can be produced naturally by radioactive sources. Even a banana — which contains potassium-40 — produces one positron about once every 75 minutes. Antimatter can also be produced in particle accelerators, though the amounts are extremely small: the total produced by CERN is only about 15 nanograms. If all the antimatter produced by humans was annihilated at the same time, the energy produced would not be enough to make a cup of tea.

Because it is produced in such small quantities, antimatter is the most expensive substance in existence. Gold is worth 56 dollars per gram. Platinum is worth 60 dollars per gram. Rhino horn is worth 110 dollars per gram. Heroin is worth 130 dollars per gram. All of these substances are expensive, but antimatter is slightly more costly, at 6.25 trillion dollars per gram.

Antimatter has found a use in medical science. In Positron Emission Tomography (PET) scanning, the patient is injected with a radioactive positron source. When the positrons are emitted, they are immediately annihilated by the surrounding matter (in the tissue). This annihilation produces gamma rays (high-energy light). The gamma rays are actually composed of two photons, travelling in precisely opposite directions (due to conservation of momentum). If the patient is placed inside a circular detector, a line can be drawn between the two detected photons. This allows very accurate three-dimensional models of the tissues of the body to be constructed on a computer.

Backward in time

Richard Feynman is regarded as one of the greatest physicists of the 20th century. He is also regarded as one of the most flamboyant, with a love of playing the bongo drums, and a gift for explaining complex ideas in an imaginative and entertaining manner. Feynman worked on the Manhattan Project, developing the atomic bomb, but it was for his work on developing a quantum explanation of the electromagnetic force that he obtained his Nobel Prize in 1965 (we will be considering this in detail in Chapter Six).

As part of Feynman's solution, he developed a series of simple diagrams to represent interactions between particles. These are called *Feynman diagrams*. As an example, all electromagnetic phenomena can be reduced to the simple interaction shown in the following Feynman diagram:

The diagram represents a single *vertex* from a Feynman diagram. In the diagram, you will see that there is a time axis flowing from left to right. The vertical axis represents space. So this particular Feynman diagram represents an electron coming in from the left side of the diagram, and emitting a photon (denoted by the wavy line), with the result that the path of the electron is altered. This is due to conservation of momentum: imagine you are ice skating, and you throw a heavy object to one side, your path would be modified to the opposite direction.

Back to the diagram, the theory of relativity tells us that we can treat time as just another dimension — just like the three dimensions of space. So, rather wonderfully, this gives us the freedom to rotate a Feynman diagram to any orientation (effectively exchanging time and space) and the interactions which result will still be valid.

As an example, the following diagram shows the previous Feynman diagram rotated 90° anticlockwise:

This diagram now reveals something remarkable. Let us analyze it.

We still see the bottom electron entering the diagram from the left, and it is moving in the forward time direction. But the top electron now appears to be moving in the reverse time direction! Surely that cannot be correct, can it?

Well, let us imagine the top electron is actually an anti-electron: a positron. In that case, we can re-interpret the diagram as showing an electron and a positron coming in from the left, and annihilating each other releasing energy (the photon). So the diagram makes sense if we interpret the top electron as a positron.

But the top electron is clearly moving in the backward time direction. Remarkably, what this reveals is that we can interpret a positron (an anti-electron) as an electron moving in the backward time direction!

It is quite an amazing result, but it is now generally accepted: a positron is an electron which is moving backward in time. (This ties in nicely with the theme of my third book, which explored the idea of negative energy as motion in the backward time direction).

The origin of quantum field theory

Let us see what other remarkable things we can discover from this Feynman diagram. Let us continue to rotate our Feynman diagram, this time by a further 180°:

Again, this is quite remarkable. We now see a photon coming in from the left, and the photon producing a pair of particles: an electron and a positron (the top electron which is travelling backward in time). The photon is not a fermion, it is not a matter particle, so we can interpret this diagram as the production of a pair of matter particles from — essentially — pure energy. It is clear from this that the number of matter particles in the universe is not fixed.

What is even more remarkable is that — according to the uncertainty principle of quantum mechanics — it is possible for a small amount of energy to appear essentially "out of nothing" (as long as it is only present for a short time). You might think of this as a short-term bank loan: you can borrow money from nothing, as long as you pay it back after a short time. This means that energy (and, therefore, matter particles) can appear essentially "out of nothing".

This, then, changes the way we have to look at particles — and empty space. Instead of considering particles as simply wandering around in empty space, we now see that particles are being constantly produced and annihilated in space. Space is clearly not empty, but is a seething mass of particles appearing and disappearing. Instead of "empty" space, we now consider space as being the *vacuum*. The vacuum is far from empty.

In fact, if the number of particles is not fixed, and particles can easily appear and disappear, then this underlying vacuum or field of space should be considered as being "more fundamental" than the particles themselves. It is the properties of the vacuum that should be considered, as it is the constant presence of the vacuum which truly controls the particles. Essentially, this represents a move away from a particle-based theory toward a field-based theory.

As Roger Penrose says in his book *The Road to Reality*: "The key property of an antiparticle is that the particle and antiparticle can come together and annihilate one another, their combined mass being converted into energy, in accordance with Einstein's $E=mc^2$. Conversely, if sufficient energy is introduced into a system then there arises the strong possibility that this energy might serve to create some particle together with its antiparticle. Thus, our relativistic theory certainly cannot just be a theory of single particles, nor of any fixed number of particles whatever. Indeed, according to a common viewpoint, the primary entities in such a theory are taken to be the quantum fields, the particles themselves arising merely as 'field excitations'."

This reveals a move away from a quantum theory of particles to *quantum field theory*. Later in this book we will examine how quantum field theory provides us with an explanation of the fundamental forces between particles.

This brings us to the end of the first part of this book. We have considered the structure of the atom, specifically "the forces which hold the atom apart". We have seen how energy quantization prevents electrons from spiralling into the nucleus. We have also seen how the Pauli exclusion principle prevents all the electrons from occupying the ground state — the lowest energy level — thus giving the electron shells of atoms their characteristic form.

We will now move onto the second part of the book, "the forces which pull the atom together". And we will start by considering two of the most important principles in physics.

5

SYMMETRY AND CONSERVATION

In this chapter we will be considering some of the most valuable tools in the particle physicist's toolkit: the laws of conservation, such as the law of conservation of energy. We will also be uncovering a remarkable and surprising link between conservation and symmetry, a link which has proven to be remarkably fruitful in the attempt to make sense of the behaviour of elementary particles.

As Paul Davies says in his introduction to Richard Feynman's book *The Character of Physical Law*: "A great unifying theme among particle physicists has been the role of symmetry and conservation law in bringing order to the subatomic zoo."

What is a law?

In human terms, we might have laws restricting where we can park our cars, or maybe laws prohibiting us from stealing from supermarkets. These laws have been developed for the good of all society, and most people abide by those laws, maybe because of a sense of moral duty, or maybe because of a fear of punishment for any transgression. However, if we so wished, we could choose to break any of these laws.

In this respect, the laws of Nature are different from human laws. Try breaking the law of conservation of energy! You will have great difficulty (hint: it's not possible).

And the laws of Nature do not just constrain the behaviour of humans — they constrain the behaviour of everything in existence. The behaviour of all atoms, all particles, must abide by these fundamentally unbreakable laws of Nature. As Vincent Icke describes in his book *The Force of Symmetry*: "The essential uncertainty of quantum behaviour might create the uneasy suspicion that anything goes in this world. But since the universe has a very definite structure, it seems very unlikely that everything is allowed. As it happens, there are many things that are forbidden, and it is the forbidding rules that give structure to the world."

You may well be aware of conservation laws such as the law of conservation of energy, or the law of conservation of momentum. A conservation law says that some measurable property of a system is maintained at a constant value over a period of time. For example, consider two objects colliding with each other. If you calculate the total momentum of both objects before the collision, you will find the total value is the same after the collision. This is an example of the law of conservation of momentum.

The law of conservation of energy is very similar. If you calculate the total energy before the collision, you will find that total value is unchanged after the collision. Another way of stating this principle is to say that energy cannot be either created or destroyed.

However, you might very well discover that the total kinetic energy of the objects (the energy associated with the movement of the objects) is not maintained after a collision. This is because energy can take different forms. There is energy associated with heat, and with sound, and with radiation. If the objects produce a tremendous crash when they collide, then some of the kinetic energy has been converted into sound, and probably into heat as well. The total kinetic energy might well be reduced, but if you could calculate the total of all forms of energy after the collision then you would, indeed, find that the total amount of energy had been conserved.

Brian Cox explained this conservation principle in his BBC TV Series *Wonders of Life*: "Over the years, the nature of energy has proved notoriously difficult to pin down, not least because it has the seemingly magical property that it never runs out — it only ever changes from one form to another. The key thing is, energy is conserved: it is not created or destroyed. The fact that energy is neither created nor destroyed has a profound implication. It means energy is eternal. The energy that's here now has always been here, and the story of the evolution of the universe is just the story of the transformation of energy from one form to another. Every single joule of energy in the universe today was present at the Big Bang 13.7 billion years ago."

Several conservation laws have been discovered, most notably the law of conservation of energy, conservation of momentum, conservation of angular momentum, and conservation of electric charge. The first three of these conservation laws demand that a particular quantity (for example, the amount of energy) in a system remains constant over time. However, the fourth of these laws — the conservation of electric charge — is an example of a different type of conservation law in that it simply involves the "counting" of objects. Some elementary particles — for example, electrons — have negative electric charge. Some different elementary particles — for example,

positrons — have positive electric charge. The charge conservation law requires a bit of counting: add up the number of particles with positive charge, subtract the number with negative charge, and you will find the total number does not change with time.

(The "counting" conservation laws are perhaps the most intuitive of the conservation laws. Place a number of balls in a bag. Come back three days later and you will still find the same number of balls in the bag. We take these things for granted, but that is a conservation law in action! Richard Feynman simply referred to a law of "conservation of objects", though we might consider it being fundamentally due to a law of conservation of mass and energy.)

Why are the conservation laws so extremely valuable to particle physicists? Well, if you know that some total property of a system of particles is going to be conserved, you can use this information to infer which type of particles can possibly be produced, for example, during a collision. If you find your sums do not add up — for example, if you have a surplus of energy left over after the collision — you might infer that an additional particle had been produced to account for the surplus energy.

But bear in mind that any additional particle would have to satisfy **all** the conservation laws. In other words, it would have to comply with the law of conservation of energy, and conservation of momentum, and of spin, and of charge. So all these conservation laws impose considerable constraints on particle production.

Let us examine this more closely by considering an example of particle decay. Particle decay occurs when a particle spontaneously (and randomly) transforms into other particles. As an example, the process of beta radioactive decay involves the decay of a neutron — in the nucleus of an atom — into a proton. An electron is also emitted in the process, and it is this electron which constitutes the beta radiation emitted by the nucleus.

However, when physicists applied the law of conservation of energy to this decay process, they found something was missing. The energy of the resultant proton and electron did not add up to the energy of the initial neutron. So where did the excess energy go?

In 1930, Wolfgang Pauli proposed that the excess energy went into creating an additional emitted particle. This would ensure that the energy of the particle going into the interaction matched the energy of the particles coming out of the interaction. This gives you an idea of how the conservation laws are a vital tool which can be used to predict the existence of new particles.

But what else did the conservation laws say about this new particle? Well, let us consider the law of conservation of electric charge. The neutron going into the interaction did not have any electric charge (hence its name). Coming out of the interaction, the proton had a positive charge, but this was balanced by the electron coming out of the interaction which had a negative electric charge. So the law of conservation of electric charge was already correctly balanced: no charge going in, no net charge coming out. This meant that the hypothetical new particle could have no electric charge or that would cause an imbalance. For this reason, in 1934 Enrico Fermi gave the new particle the name *neutrino* (a "small neutral thing" — in Italian).

The neutrino was eventually discovered in 1956, but its existence and properties had been predicted twenty years earlier thanks to the conservation laws.

Particle accelerators

In a particle accelerator, electrically-charged particles are accelerated by electric forces (the modern descendent of Ernest Rutherford's cathode ray tube). A magnetic field is then used to curve the path of those particles, and this can result in particles travelling around a large loop, accelerating to a speed close to the speed of light. The particles are then made to collide with a variety of targets. By examining the results, we can learn about the structure of matter.

The Large Hadron Collider (LHC) is the largest particle accelerator ever made. In fact, it is the largest machine ever made. The LHC is a 27-km circumference loop which straddles the French-Swiss border. It is buried 175 metres deep (not for any scientific reason — only because it was simply cheaper than buying land in Geneva).

The purpose of the LHC is to accelerate beams of protons to nearly the speed of light, and then to collide two beams and examine the results.

Nothing can move faster than the speed of light, so the speed of light forms the upper speed limit for accelerated particles. However, the energy of a particle increases sharply as it approaches (but does not exceed) the speed of light. An accelerated proton in the LHC can move at 99.9999991% of the speed of light, at which point its energy is 7 TeV ("eV" represents "electronvolt" — a small unit of energy which is the standard measure of energy in particle accelerators, with 1 TeV being equal to a trillion electronvolts). An energy of 1 TeV represents the energy of a single flying mosquito. So at the LHC, the energy of 7 flying mosquitos is packed into a single proton (about a million million times smaller than a mosquito). This represents the current world record for particle accelerator

energy.

The two beams of protons travel around the LHC in opposite directions before colliding head-on, giving a total collision energy of 14 TeV (7 TeV per beam).

The 27-kilometre circumference of the LHC might sound a long way, but a proton accelerated to nearly the speed of light will make over 11,000 circuits of the loop each second. At this speed, the entire beam of protons has the same energy as a French TGV train travelling at top speed. In fact, the protons are travelling so fast that in their 10-hour lifetime in the accelerator they travel 10 billion kilometres: equivalent to the distance to Neptune — and back. In ten hours!

So what is the purpose of these extraordinary particle accelerators? Why must the collision energies be so large?

There is, perhaps, a general misconception as to the purpose of these machines. It is not helped by the use of the term "atom smasher" to describe them. The impression is often that these machines need high collision energies to "break" particles into "smaller and smaller pieces". However, as was described in Chapter One, elementary particles are believed to be infinitely small points, with no internal structure — no constituent parts. It is simply not possible to break them down into smaller units.

No, the reasoning behind the construction of these giant accelerators is based on the principle of the conservation laws we have been considering in this chapter. In order to see why this is the case, we need to introduce the concept of particle *mass*.

Mass is a **property** of particles. In the same way that a particle might have a certain amount of electric charge, a particle might have a certain amount of mass. A particle's mass determines its resistance to being accelerated, and it also determines its gravitational attraction.

A particle which has mass is called a *massive* particle. We use this term "massive" in everyday language, but we are often rather careless in using the word to describe the size of objects, for example: "The cruise liner is massive". However, physicists use the term "massive" in the very strict sense of describing an object "which possesses mass" (there is also the related word "massless" for describing particles which do not possess mass).

As an example, a neutron star can be about the size of a city, but it is much more massive (i.e., it possesses far more mass). A teaspoon of neutron star material would weigh a billion tons. So "massive" is not a measure of size. With this in mind, remember that all elementary particles should be considered as being infinitely small points with no size. So an elementary particle can be "massive", but have no size! Just think of mass as simply a number — a property — which we assign to a particle.

So a massive particle has a certain amount of mass. And, because of Einstein's famous formula for mass-energy equivalence, $E=mc^2$, we can therefore think of a particle as being composed of a certain amount of energy. With this in mind, the purpose of modern particle accelerators is not to split particles, the aim is to concentrate enough energy into a small volume of space so that a massive particle might be spontaneously created. The more massive the particle, the more energy is required to create it.

As an example, an electron is a massive particle which has a mass of 9×10^{-31} kg. This is such an awkward, extremely small value that the mass is more usually given in terms of its energy equivalent: 0.5 MeV (where "MeV" represents a million electronvolts — remember the electronvolt is a unit of energy which was introduced earlier). So in order to produce an electron from a collision, particles would have to be accelerated to tremendous speeds, thus giving them sufficient kinetic energy. The aim is that the act of compressing enough energy into a small volume of space would allow a massive particle to be spontaneously created from the collision.

So particle accelerators are not "atom smashers" at all — they are particle creators. And the effectiveness of this approach was clearly demonstrated when the Higgs boson was recently created and detected by the LHC with a mass of 126 GeV (1 GeV being equal to a billion electronvolts).

(At the time of writing — December 2015 — the latest news from the LHC is that another particle has possibly been found at 750 GeV, though we will have to wait until summer 2016 for confirmation).

In a BBC documentary entitled *Dancing in the Dark*, Professor David Charlton who works at the LHC explained how new massive particles might be created in the LHC: "When the protons collide, most of the particles which are produced tend to be low-mass particles, such as the familiar protons and neutrons. But sometimes, very rarely, you produce these much more massive particles, and that is what we are looking for. So we might produce Higgs particles, or maybe we might produce even more massive particles which are ones we don't know about — they would be beyond the Standard Model. These are the particles we are really looking for."

David Charlton goes on to explain how these new particles might be detected: "The idea is we are looking for imbalances of momentum of the event that signifies that there are unobserved particles emitted with high-energy, carried out of the detector. What we are seeing is an absence of something, an **imbalance** of something. It is some particles which we can't observe but we can infer that they are there by looking at the rest of the event."

I want to emphasise Prof. Charlton's use of the word "imbalance". We will return to this concept of balance and

imbalance later in this book as I believe it is the key to obtaining new insights about the behaviour of Nature. The concept of balance is essential to understanding the universe. Basically, the universe always has to be in balance, and it resists that balance being upset.

But you will recognise how the techniques described by Prof. Charlton for detecting new particles — detecting imbalances in the energy in and out of the interaction — is exactly the same technique described earlier in this chapter which was used to predict the existence of the neutrino, before it was discovered in 1956. And at the core of this approach lie the crucial laws of conservation: energy and momentum, which must be conserved throughout the interaction.

Symmetry

So now we have considered the conservation laws, and seen how they provide a valuable tool for the particle physicist. However, the conservation laws go hand-in-hand with another vitally important principle.

The other great tool has been the discovery of the importance of symmetry. It might come as a surprise to learn that conservation and symmetry appear to be bound together in a very fundamental way. The connection between symmetry and the conservation laws is one of the most profound connections in physics.

We all recognise symmetry when we see it. For example, a human face has left/right *mirror symmetry*. A snowflake has rotational symmetry:

While we all recognise symmetry when we see it, we will need a more formal definition of symmetry for our purposes. And that definition is that if you apply a transformation to an object (for example, rotating the snowflake by sixty degrees) and the transformed object remains identical to the original object then that represents a symmetry. This definition makes it clear that the snowflake possesses rotational symmetry.

Symmetry plays a remarkable role in physics, at a very fundamental level. In this book, we will be exploring how symmetry provides not only the conservation laws, but also the properties of particles, and the forces between those particles. Nobel Prize-winning physicist Phil Anderson has even stated: "It is only slightly overstating the case to say that physics is the study of symmetry."

In order to explain the importance of symmetry, and the connection with conservation, let us introduce the construct known as the *Lagrangian*. The Lagrangian is a hugely important concept in physics, seemingly revealing something profound about the behaviour of Nature. If we are considering classical mechanics (i.e., the study of the motion of large objects — not including quantum mechanics) then we can define the Lagrangian as being equal to the difference between the kinetic energy and the potential energy of an object. In itself, this is not very interesting. However, it becomes interesting when we consider how the value of the Lagrangian changes when an object moves.

We can calculate the Lagrangian of a moving system throughout its motion to get a series of values. If we then sum all those values we get what is known as the *action*. If we consider the action of our moving system over a period of time, we will find that the value of that action will always be the lowest possible value. This very important principle is called the *principle of least action*.

As an example, consider the following image of the trajectory of a ball:

We can calculate the Lagrangian of the motion of the ball (remember: the Lagrangian is the difference between the kinetic energy and the potential energy) at each point, and then we can sum all of those points to calculate the action. The principle of least action tells us that the action will be the smallest possible value for the path taken by the ball. In this case, the smooth path taken by the ball results in the smallest action.

We already know Newton's laws of motion which tell us how an object moves, so why do we need this Lagrangian approach? Well, firstly it can be shown that we can derive Newton's laws of motion from the Lagrangian, so both approaches are equivalent. But the Lagrangian approach seems to be revealing a deeper truth about Nature. Rather than just stating an arbitrary law (e.g., Newton's second law of motion states that the acceleration of an object is proportional to the applied force), the principle of least action seems to reveal a general principle, almost a "desire" by Nature to minimise a certain quantity. As Jerry Marion says in his book *Classical Dynamics of Particles and Systems*: "In the Newtonian formulation, a certain force on a body is considered to produce a definite motion; that is, a definite **effect** is always associated with a certain **cause**. According to the principle of least action, however, the motion of a body may be considered to result from the attempt of Nature to achieve a certain **purpose**, namely, to minimize the time integral of the difference between the kinetic and potential energies."

So this underlying purpose appears to provide a rationale as to why objects move the way they do. This generality — this deep truth — means the Lagrangian approach can also be applied to fields, and general relativity, and even to quantum mechanics. As Dwight Neuenschwander says in his book *Emmy Noether's Wonderful Theorem*, the generalizability of the principle of least action to the widest scope of physics, even far beyond mechanics, gives the principle "a depth and versatility not shared by the other mechanical principles."

In order to get useful results from the Lagrangian approach we need to introduce the *Euler-Lagrange equation*:

$$\frac{d}{dt} \left(\frac{\partial L}{\partial \dot{x}} \right) = \frac{\partial L}{\partial x}$$

The equation may look rather daunting but I will attempt to explain it as simply as possible.

The Euler-Lagrange equation is important because it represents the condition when the action is at a minimum value (remember the principle of least action). So the Euler-Lagrange equation can be used to predict the behaviour of Nature (as an example, the Euler-Lagrange equation can be used to derive Newton's laws of motion).

So let us analyze this important equation piece-by-piece.

Firstly, on the right-hand side of the equals sign we find an expression which represents the rate at which the Lagrangian changes when one of the variables describing the motion of the system changes (for example, x might represent the coordinate of a thrown ball as it flies through the air):

The rate of change of the Lagrangian, L , with respect to some variable, x .

$$\frac{d}{dt} \left(\frac{\partial L}{\partial \dot{x}} \right) = \frac{\partial L}{\partial x}$$

We can make this part of the equation a lot simpler if we only consider situations in which the Lagrangian has a symmetry. In a symmetrical situation, as was explained earlier, some value remains unchanged when we apply a transformation. So the rate of change of the Lagrangian in the case of a symmetrical situation would be zero (the Lagrangian does not change when the coordinates change). And so, for symmetrical situations, we can set the right-hand side of the Euler-Lagrange equation to zero. This leaves us with a simpler form of the equation:

$$\frac{d}{dt} \left(\frac{\partial L}{\partial \dot{x}} \right) = 0$$

Now considering the left-hand side of the equals sign, the d/dt part means the differential of an expression "with respect to time". This means the "rate of change" of an expression, or — more simply — the speed at which some expression is getting larger or smaller:

The rate of change with respect to time, t

$$\frac{d}{dt} \left(\frac{\partial L}{\partial \dot{x}} \right) = 0$$

Because in this new equation we have set this value equal to zero (on the right-hand side of the equation), this means that the rate of change of the expression in the brackets is zero. Or, put more simply, the expression in the brackets is not changing with time, which means the expression in the brackets is **conserved**.

So, to sum up, this analysis of the Euler-Lagrange equation has shown us that if there is a symmetry in the Lagrangian (i.e., if the value of the Lagrangian is not changed when one of its coordinates changes) **then there will be a conserved quantity**.

As an example, the laws of Nature do not change when we move an object in space. Basically, it does not matter where in space you perform your experiment — you will always get the same result. This is called *space translation invariance* and it was considered in my earlier books. Space translation invariance actually represents a symmetry: remember, a symmetry occurs when we apply a transformation and nothing changes.

As we have seen, the Euler-Lagrange equation indicates that if the Lagrangian does not change with respect to one of the variables of the system then we should be able to find some quantity which is conserved over time. In the

particular example of symmetry in space, the conserved quantity (in the brackets) according to the Euler-Lagrange equation is momentum. [8]

So the Euler-Lagrange equation predicts the law of conservation of momentum **because there is a symmetry in space.**

But this is a very mathematical approach. Can we achieve a more intuitive understanding of this principle? Yes, we can. In his book about the Standard Model of particle physics called *The Theory of Almost Everything*, Robert Oerter presents the example of a skateboarder in a half pipe. The following diagram shows the half pipe oriented in such a way that the skateboarder rolls up and down the pipe, travelling from left to right:

Considering the direction the skateboarder is travelling, there is no symmetry in the half pipe: the pipe drops down, then rises up the other side. Similarly, the skateboarder's momentum is not constant: he is fastest at the bottom of the half pipe, but slows to a stop at the top.

Now let us consider a different orientation of the half pipe. Let us rotate the half pipe. In the following case, the skateboarder again travels from left to right inside the half pipe, but this time the half pipe has symmetry from left to right: the height does not alter:

In this case, the momentum of the skateboarder is a constant: he travels at the same constant velocity along the base of the half pipe. In other words, the momentum of the skateboarder is conserved.

So when there is a symmetry in space, momentum is conserved.

The Euler-Lagrange equation can also be used to show that where there is a symmetry in time, energy is conserved. So in our universe — which has both space translation invariance and time translation invariance — we find we have a law of conservation of momentum, and a law of conservation of energy.

However, the full connection between symmetry and conservation was revealed in 1915 by the German mathematician Emmy Noether.

Noether's theorem

Amalie "Emmy" Noether was born in Bavaria, Germany, in 1882. Her father, Max, was a mathematician in the University of Erlangen, and Emmy decided to follow in her father's footsteps by studying mathematics at the university. However, life was not easy for a Jewish female in academia at that time. Indeed, the faculty senate at the university declared that admitting women would "overthrow all academic order". Noether had to work hard throughout her career to overcome prejudice and establish her reputation as a brilliant mathematician.

After earning her Ph.D., Noether published several impressive papers before applying for an academic appointment in the renowned mathematics department at the University of Göttingen. The great mathematician, David Hilbert, who worked at Göttingen, fought for Noether at a faculty meeting: "I do not see that the sex of the candidate is an argument against her admission as an associate professor. After all, we are a university, not a bathhouse."

Hilbert managed to skirt the rules by employing Noether as a guest lecturer. It was shortly after arriving at Göttingen that Noether published the theorem which bears her name.

Noether showed that the previous results from the Euler-Lagrange equation were merely special cases of a more general result. As we saw earlier, the Euler-Lagrange equation indicates that if the Lagrangian is symmetrical with respect to one of its spatial coordinates, then there will be a conserved quantity. Emmy Noether generalised this result by revealing that **if there is any symmetry in the Lagrangian at all, then there is always a conserved quantity**. This result is called *Noether's theorem*.

It is this result of Emmy Noether's which has proven to be of tremendous value for particle physics. If a symmetry is discovered, there will be an associated conserved quantity. The conserved quantity could be something other than momentum or energy. And Noether's theorem works the other way round as well: if a conserved quantity is discovered, there will be an associated symmetry.

So let us end this chapter with a limerick written by David Morin of Harvard University:

*As Noether most keenly observed
(And for which much acclaim is deserved),
We can easily see
That for each symmetry,
A quantity must be conserved.*

6

GAUGE THEORY

At this point, as we continue our quest for "the forces which hold the atom together", we start to consider the force which holds electrons in their orbit around the atomic nucleus. This is the electromagnetic (or, more simply, the electric) force. In the 18th century it was discovered that positive electric charge attracts negative electric charge, while charges of the same sign repel each other. So, at this point, it would be quite possible to simply state that negatively-charged electrons are held in orbit around the positively-charged nucleus due to the electromagnetic force. And then consider the matter settled, and move on to the next chapter.

However, we can do better than that. Developments in quantum field theory in the second half of the 20th century have provided us with great insights into the fundamental nature of the electromagnetic force. It has been discovered that there is a principle called *gauge theory* which emerges from symmetry and appears to lie at the heart of the behaviour of forces. In this chapter we will examine gauge theory, discovering how it generates forces, and how it predicts the existence of additional fundamental particles.

The electromagnetic force

So electrons are held in their orbit by the electromagnetic force. Electrons have negative electric charge, and are therefore attracted to the protons which have positive electric charge. But why does this attraction exist? Our task in this chapter is to try to get to the fundamentals of this force, analysing how it can reach out over space to attract two objects together.

Crucially, in our attempt to get to the bottom of the electromagnetic force, we have been given a big clue: electric charge is always conserved. This was first discovered by Benjamin Franklin in 1747. If you have a closed system (no charge is allowed to enter or leave the system), then the total amount of charge (positive charge minus negative charge) in the system will not vary with time.

So what can we infer from this conservation of charge? Well, Noether's theorem tells us that whenever we have a conserved quantity, there will always be an associated symmetry. Now we start to see the value of Noether's theorem: we have to find the symmetry inherent in electric charge.

Well, fairly obviously, there is a symmetry between positive charge and negative charge: they are just the two flip sides of the same thing. It appears we have the freedom to instantaneously change every positive charge to a negative charge — and vice versa — without changing the overall situation. This freedom to apply a sudden reversal of a property across the entire universe is called a *global symmetry*.

However, in the mid-1950s, physicists Chen-Ning Yang and Robert Mills realised there was a problem with this universe-wide transformation. They realised that the theory of special relativity prohibited any such global instantaneous transformation across space: no signal can propagate faster than the speed of light. Yang and Mills realised that the change would have to be spread across the universe at the speed of light via a **field**.

Let's imagine we have an electron and we somehow manage to invert its electric charge by making it positive (this is called a *local symmetry* transformation). Essentially, we have taken one corner of the universe and given it a tweak: we have upset the balance of the universe. Remember, the universe only continues to function normally if **every** charge is swapped at the same time. In his book *Deep Down Things*, Bruce Schumm calls this upsetting "a delicate and precise balance" (this theme of balance is becoming a recurring theme). It is as if we have turned-over just one corner of a huge rubber sheet. There will be a ripple of change spreading out across the sheet until the whole sheet turns over. It is just the same for the universe. Our tweak generates a field of change which has to spread out across the whole universe.

Hence, we have discovered that the presence of a local symmetry must result in a field. This necessary connection between symmetry and fields forms the basis of gauge theory which lies at the heart of modern particle physics.^[9] As the idea was developed by Yang and Mills, gauge theories are often called *Yang-Mills theories*.

For the case of electric charge symmetry, the gauge field is the electromagnetic field which spreads through space. It is the electromagnetic field which keeps track of charge, responding to any disturbance, and effectively maintaining the balance of the universe. We will now see how this electromagnetic field is itself formed of

fundamental particles.

Bosons

Earlier in the book, we considered the fermions, which are particles with antisymmetric wavefunctions (if you rotate a fermion by 360° , we saw that its wavefunction is multiplied by -1). The elementary fermions were therefore called spin- $\frac{1}{2}$ particles. The antisymmetric nature of the fermion wavefunction meant that fermions resisted being together in the same state.

There is another group of particles called *bosons*. In many ways, bosons are the opposite of fermions. If you rotate a boson by 360° , its wavefunction is unchanged (in line with our intuition of how physical rotation should behave). A photon is an example of a boson which has to be rotated once to return to its original state. For this reason, a photon is an example of a *spin-1* particle.

This symmetric behaviour of the bosons means that — contrary to the behaviour of fermions — they like being in the same state. The wavefunction of bosons in the same state does not cancel out (as in the case of fermions), instead it accumulates and becomes larger. This means there is more chance of finding bosons in the same state. Bosons like to congregate together, which explains why many photons like to congregate together to form a ray of light, spreading through space.

All particles can be categorised as either fermions or bosons. It is therefore the most important categorisation of particles.

As was explained in Chapter Three, it is the refusal of fermions to occupy the same state which results in them taking the role of the matter particles, the particles which compose all of the substance in the material world. Cars, trees, water, gases, human beings, are all composed of fermions. The bosons, however, have no resistance to being in the same state, which results in them being intangible and insubstantial. This fact makes it all surprising that — in the *Star Wars* universe — the Jedi Knights decided to construct their swords from light. Lightsabers would be fundamentally incapable of damaging a fermion-based opponent. The moral of this tale is that you should never construct your swords from bosons.

It was James Clerk Maxwell who showed that light was an electromagnetic wave, a disturbance of the electromagnetic field. And it was Einstein who showed that we should think of light as a stream of photons. Hence, we can think of the photon as the boson which forms the electromagnetic field. This makes a lot of sense, as we have just discussed how bosons like to congregate together in vast numbers, which makes them the ideal particle for forming an extended field stretching across space.

So what have we discovered so far in this chapter? Well, in the first section we studied gauge theory, and it was revealed how a local symmetry introduces the necessity for a gauge field which spreads through space. It was stated that, for electric charge symmetry, the resultant gauge field is the electromagnetic field. Now, in this section, it has been explained how the electromagnetic field is itself composed of particles: photons.

In fact, every gauge field is composed of bosons, and these are called *gauge bosons*.

The photon is perfectly suited to the task of being a gauge boson: it is massless and long-range, as suited to the task of keeping track of electric charge across the universe as it is to bringing us light from the distant stars at — well — the speed of light (fairly obviously!).

But there is another interpretation of the role of gauge bosons ...

Particles of force

We considered the Feynman diagram of an electron emitting a photon in the chapter on antimatter. We can now consider the diagram of the emitted photon deflecting the path of a second electron:

So what does this interaction appear to represent? Well, clearly we could imagine this interaction as representing the electric repulsion between two electrons, two particles with the same electric charge repelling each other. This deflection of electrically-charged particles is the result of the electromagnetic field, which extends through space to affect the paths of electrically-charged particles. This makes a lot of sense, as we have just discussed how the photon is the boson which constitutes the electromagnetic field.

But, from the Feynman diagram, we can also see that we can think of the photon as transferring force. We have two matter particles (the fermions: the electrons), and we have an intangible boson (the photon) transmitting a force across space between the two electrons. Hence, we can think of gauge bosons as the force particles, responsible for transmitting forces between two material objects made of fermions.

To sum up, at the start of this chapter we saw how gauge theory connected the symmetry of electric charge with the necessity for the electromagnetic field. In the next section we saw that the particle which constitutes a field is a boson, and for the electromagnetic field the boson is the photon. In this section, we have seen that we can think of these bosons as being the particles which transmit forces. Hence, the photon is the boson which transmits the electromagnetic force.

But, most importantly, we have discovered a connection between gauge symmetry and forces. In particular, we have seen how gauge symmetry of electric charge results in the electromagnetic force. This is a hugely important result as it is now believed that all of the four fundamental forces arise from gauge symmetry. Gauge theory lies at the heart of the Standard Model of particle physics.

Digging deeper

It is interesting to note that we have not considered the truly fundamental principle underlying the symmetry of electric charge.

As has been discussed earlier in the book, quantum mechanics predicts that every particle also has a wavelike nature: a wavefunction. And every wave — even the waves on the sea — has an associated *phase*. If two waves meet and they are "in phase" then they will interfere constructively and become larger. Conversely, if they are "out of phase" they will interfere destructively and the result will be smaller.

Quantum mechanics tells us that if we have a group of particles — and their wavefunctions — then we can increase or decrease the phase of all the wavefunctions by a constant amount without changing the overall situation. This is because all that matters is the **difference of the phases** of the wavefunctions, **not the absolute values** of the wavefunctions. The difference between phases is important because it can create interference patterns (as in the famous double-slit experiment).

So this is the true source of the symmetry which leads to the electromagnetic field. We have the freedom to increase or decrease the phase of the wavefunctions of particles without changing the overall situation. However, this transformation has to be applied globally in order not to disturb the overall balance of the universe. In order to

ensure the global balance is not disturbed, this requires the electromagnetic field. Hence, this is the true source of the gauge field.

If the **sign** of the phase (not just the amount of the phase) of a wavefunction is completely inverted (positive to negative, or vice versa, as if it is reflected in a mirror) then this has the effect of changing the sign of the charge of the particle. So, as was discussed earlier, this is how we have the freedom to completely invert the sign of the charges of a group of particles without changing the overall situation. [\[10\]](#)

And it is this "gauge symmetry" — this freedom to rotate the phase of a particle's wavefunction — which leads to the law of conservation of electric charge (remember: Emily Noether said that each symmetry implies a conserved quantity). [\[11\]](#)

We have now reached the conclusion of an important part of this book. In our discussion of "the forces which hold the atom apart" and "the forces which pull the atom together", we have now considered all the forces involved in forming the overall shape of the atom, i.e., the electron shells.

In this chapter, the fundamentals of the electromagnetic force have been described, the force responsible for holding electrons in orbit. We have seen how gauge theory emerges from the conservation of electric charge, and the associated symmetry. It is gauge theory which predicts the existence of the photon, the particle which actually transmits the electromagnetic force.

Hence we have completely examined the forces governing the outer shell of the atom. It is now time to look inside the atom, and examine the nucleus.

The strong force

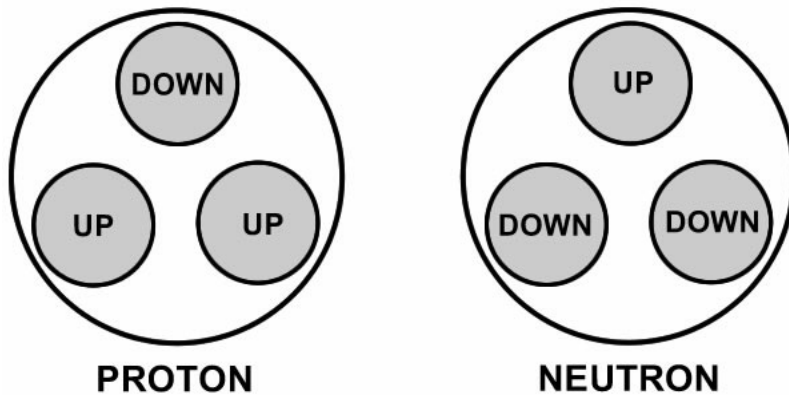

In this discussion of electromagnetic attraction and repulsion, a thought might have occurred to you: as protons have positive charge, how can they be tied together so closely in the nucleus without strongly repelling each other? It turns out that a different, stronger force is required to hold the protons together in the nucleus, and this is the *strong nuclear force*.

However, it turns out that the strong nuclear force does not represent a truly fundamental interaction. The true force is even stronger, and operates on a smaller scale, operating **inside** protons and neutrons. The strong nuclear force is then only a residual force, leaking-out of the protons and neutrons, but still strong enough to hold the protons and neutrons together to form atomic nuclei. So to understand the truly fundamental interaction, we have to go inside the protons and neutrons, to uncover the fundamental force known as the *strong force*.

In our discussion so far, we have only dealt with truly elementary particles, particles which are not composed of any smaller particles. However, it has been discovered that both protons and neutrons are each composed of three smaller particles called *quarks*. Quarks are believed to be truly fundamental particles, i.e., they are not composed of anything smaller.

Protons and neutrons are composed of two different types of quarks called *up* quarks and *down* quarks (there are four other types of quarks with hugely greater masses which can only be formed in high-energy particle accelerators, but they all rapidly decay to up and down quarks).

A proton is composed of two up quarks and one down quark. A neutron is composed of one up quark and two down quarks:

But how can this combination of quarks result in the proton having a +1 electric charge, while the neutron has neutral electric charge? For this to be the case for the proton, it appears that twice the charge of the up quark plus the charge of the down quark must equal a +1 electric charge. While for the neutron, it appears that the charge of the up quark plus twice the charge of the down quark must equal zero electric charge. So you might want to remember your high school mathematics and try solving the necessary simultaneous equations to find the answer:

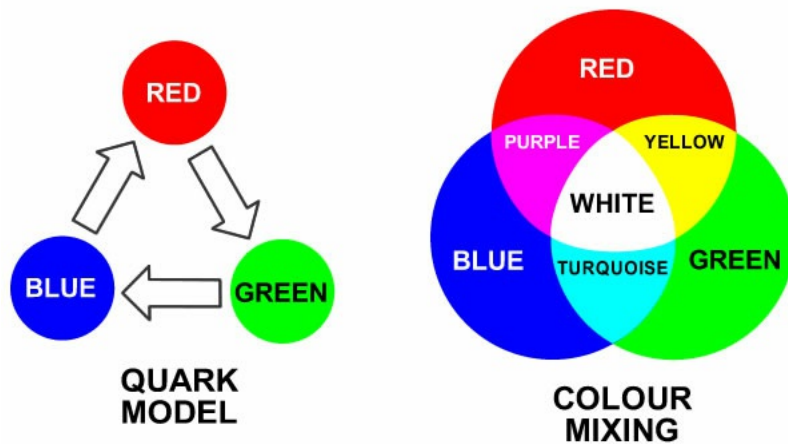

$$\begin{aligned} 2U + D &= 1 \\ U + 2D &= 0 \end{aligned}$$

where U is the electric charge of the up quark, and D is the electric charge of the down quark.

If you do your sums correctly, you will find that — surprisingly — the quarks must have fractional electric charge. The up quark must have a positive two thirds electric charge, while the down quark must have a negative one third electric charge.

However, electric charge is not the charge which holds the quarks together. "Charge" is a generic term which describes how a particle reacts to a particular field (e.g., the electromagnetic field). Only particles with certain charge will react to the field, for example, only particles with electric charge will react to the electromagnetic field. Quarks have a form of charge called *colour charge*. A quark can have either red, green, or blue colour charge, named after the primary colours of light (there is no actual colour involved in any of this — it is just a naming convention).

Just as particles with positive and negative electric charge get attracted together, so quarks with different colour charge get attracted together. But the rule underlying this attraction is quite unusual: quarks are attracted together so that the resultant composite particle has no overall colour. How can this be? Well, consider the mixing of light. A computer (or television) screen is composed of a grid of red, green, and blue dots or stripes, and when all three colours are illuminated, the result is white light (i.e., no colour). This is called additive colour mixing. So quarks are attracted together to form composite particles which are white overall, which can be achieved by attaching a red, green, and blue quark together:

Hence, this explains how three quarks can be grouped together to form protons and neutrons. This principle — that composite particles made of quarks are always colourless — does not just apply to protons and neutrons. For example, we can consider the antiparticle version of a quark (*antiquark*) as having negative colour charge. Hence it is possible for a quark to bind with its antiquark equivalent, for example, a red up quark and a red antidown quark, with the result being colour-neutral. These two-quark particles are called *mesons*. In theory, it is even possible for more than three quarks to form composite particles — as long as the overall result is colourless. In 2015, a *pentaquark* — composed of five quarks — was discovered at the LHC. Again, the pentaquark was an arrangement of quarks which had no overall colour.

One interesting aspect of the behaviour of the strong force is that the quarks become more strongly attracted the further apart they are separated, but at small distances (e.g., inside the proton) there is no longer an attraction, instead the quarks are very loosely bound. This behaviour is called *asymptotic freedom*. As Robert Oerter explains in his book *The Theory of Almost Everything*: "As we go to longer distances, the strength of the color force increases. Conversely, at shorter distances, the strength of the color force decreases. It's like putting two fingers inside a rubber band to stretch it. The farther apart you pull your fingers, the larger the force. But if you move your fingers together, the rubber band goes slack."

We will be returning to consider asymptotic freedom in the next chapter.

Like the electromagnetic force, the strong force emerges as a result of another gauge theory. There is a gauge theory because there is a conserved quantity (colour charge is conserved throughout all interactions), and there is therefore an associated symmetry. Robert Oerter describes this colour symmetry in his book: "If we could reach inside every proton and neutron in the universe and instantaneously replace every red quark with a green quark, every green quark with a blue quark, and every blue quark with a red quark, there would be no way to tell that we had done so. The universe would continue on exactly as before the change."

Note the similarity of this description to the symmetry of charges in the electric force. This is just what you would expect in every gauge theory: if you swap particles in a symmetrical way, you effectively change nothing.

And it is clear we can think of this symmetry transformation as a form of rotation of a quark "colour wheel". When we rotate the colour wheel, red goes to green, green goes to blue, and blue goes to red. This quark colour wheel is shown in the following diagram:

The technical name for this symmetry is $SU(3)$, because there are three different quark colours, three different positions on the colour wheel. [\[12\]](#)

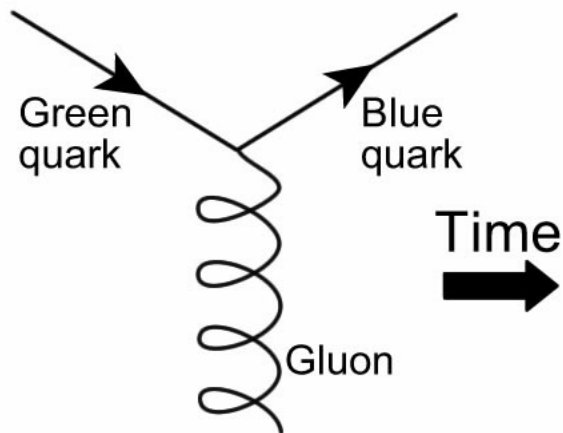

Compare this form of abstract mathematical rotation of particle types on a "symmetry colour wheel" with the actual physical rotation of the snowflake we considered earlier:

In both cases you can see that it is possible to rotate the object (snowflake, or quark colours) by a certain angle while leaving the situation unchanged. This shows how the principle of symmetry lies at the heart of particle physics.

But what is responsible for this rotation? Well, the strong force is another example of gauge theory, and if we have a gauge theory, we need to have gauge bosons. For the electromagnetic force, the gauge boson was the photon. In the case of the more complicated strong force, there is a group of gauge bosons called *gluons*.

The following vertex of a Feynman diagram shows a gluon modifying the path of a quark in much the same way as we have seen a photon modifying the path of an electron:

(Note that the symbol for the gluon on a Feynman diagram is different from the symbol for a photon. Yes, they are both gauge bosons, but you can see that the gluon is denoted by a curly line, whereas the photon was denoted by a wavy line.)

We know that the gluon is the gauge boson for the strong force, so the gluon forms the gauge field which is responsible for keeping track of any changes in local symmetry (any rotation of the local colour wheel) and transmitting those changes across space. We can see in the previous diagram how this is achieved: the gluon has the ability to change the type of a quark. In the diagram, the gluon changes a green quark into a blue quark. So in this way, any local changes of a quark type (any local rotation of the colour wheel) can be effectively transmitted by gluons, changing other quark types accordingly (just like the turning over of a corner of a rubber sheet, described earlier in this chapter).

How many gluons are required? In other words, how many gauge bosons are needed by the strong force? Well, the rule for gauge theories is that you have to count each possible position on the symmetry colour wheel, which in the case of the strong force means we have three different quark colours on the colour wheel. If we call this number n then the number of gauge bosons which are required is given by n^2-1 . So, the strong force requires eight gauge bosons, eight different types of gluon.

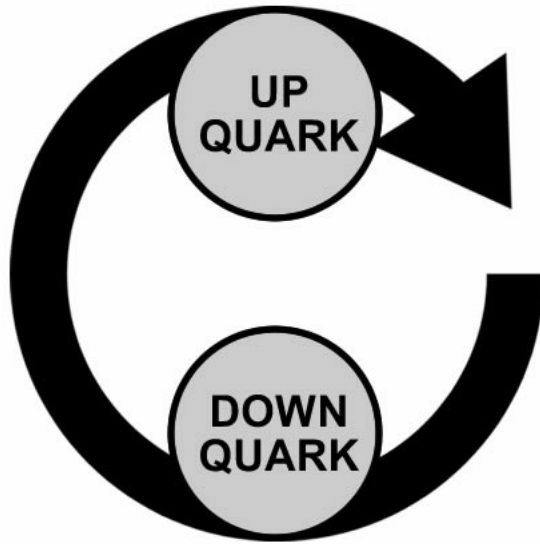

The theory we considered earlier which describes the electromagnetic force in terms of the interactions between electrons and photons is called *quantum electrodynamics*, or QED. The theory we have just considered which describes the strong force in terms of the interactions between quarks and gluons is called *quantum chromodynamics*, or QCD (where "chromo" means "colour").

The weak force

There are four fundamental forces. So far, we have considered the electromagnetic force, and the strong force. Gravity will be considered in the later chapters of this book. Which means we can now move on to consider the *weak force*.

The weak force is another example of a gauge theory. And if we have a gauge theory, then that means there must be another symmetry. The weak force is based on the symmetry between a down quark and an up quark: a down quark can be changed (rotated on the wheel) into an up quark, and vice versa. There is also a similar symmetry between an electron and a neutrino. When we find two particles connected by a symmetry in this way, they are called a *doublet*.

So the symmetry of the weak force is actually rather simpler than that of the strong force. There are three positions on the "colour wheel" of the strong force, but we see that there are only two positions of symmetry rotation on the symmetry wheel of the weak force:

Technically, this is called an SU(2) symmetry (because there are only two positions on the symmetry wheel). How many gauge bosons are required by the weak force? Well, remember the rule: if n is the number of positions on the symmetry wheel (in this case, $n=2$) then the number of gauge bosons is given by n^2-1 . So, the weak force requires three gauge bosons, and these are called the W^+ , W^- , and Z bosons. The W^+ has a positive electric charge, the W^- has a negative electric charge, and the Z is neutral (we will soon see why these bosons must have charge). The following vertex of a Feynman diagram of the weak force shows a down quark changing to an up quark (remember: these two particles form a symmetrical doublet according to the weak force), with the emission of a W^- boson:

Note the similarity of this diagram representing a weak force interaction with the earlier diagram showing an electron deflected by a photon (according to the electromagnetic force), and also the earlier diagram of a quark deflected by a gluon (according to the strong force). The form of all three diagrams is basically identical, showing that all three gauge theories work on the same principle. Let us briefly consider those earlier diagrams. According to the electromagnetic force, when the photon "hits" the electron, the photon rotates the symmetry wheel of the electron (actually, the wavefunction of the electron gets rotated — as explained earlier in this chapter). In the diagram of the strong force, when the gluon "hits" the quark, the gluon rotates the symmetry colour wheel of the quark, changing the colour type of the quark. And in the diagram of the weak force, when the W boson "hits" the quark, the boson rotates the symmetry wheel of the quark, changing

the down quark into an up quark.

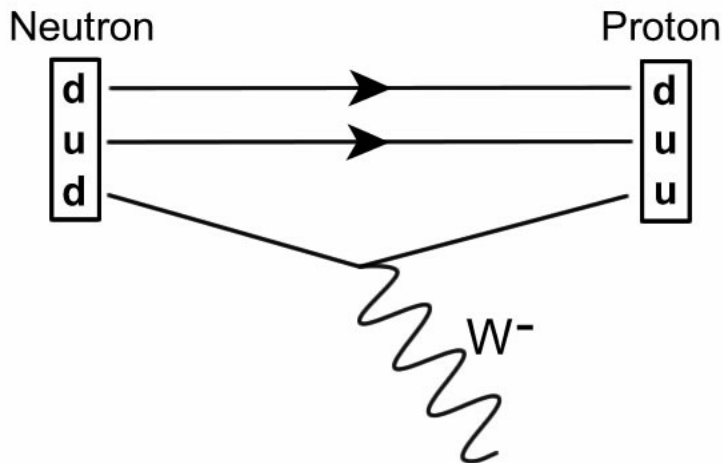

So, for each of the three fundamental forces, we see a gauge boson causing a rotation of a particle's symmetry wheel, usually causing that particle to change into a different particle (the next position on the symmetry wheel). [13]

In all three of the Feynman diagrams, we see a fermion (matter particle: electron or quark) being deflected by a boson. Clearly this, then, is the origin of forces. But we can also see from this discussion that the true root cause of forces is gauge symmetry.

Now let us return to consider the weak force again. The previous diagram showed a down quark changing into an up quark (via the weak force). At this point you might realise we have a problem regarding conservation of electric charge. This is because — if you remember earlier — the down quark has a negative one third electric charge, while the up quark has a positive two thirds electric charge. This means that the difference in electric charge of the quark coming out of the interaction and the quark going into the interaction is one positive unit of electric charge. Essentially, the overall electric charge has increased by one unit — which breaks the law of conservation of electric charge. The only way in which balance can be restored is if the emitted W^- boson possesses one negative unit of electric charge. This explains why the W^- boson has to be negatively-charged (which is why it has a minus sign). Once again, note the importance of the concept of "balance" in this interaction.

Let us now consider the implication of this conversion of a down quark into an up quark via the weak force. Earlier in this chapter, it was described how the neutron is composed of two down quarks and one up quark. Therefore, if one of those down quarks is converted to an up quark, then that neutron is converted into a proton (remember, a proton is composed of two up quarks and one down quark). This conversion of a neutron into a proton is what happens during radioactive beta decay.

The following diagram shows beta decay as a result of the weak force:

See if you can identify the position of the earlier Feynman diagram for the weak force in this diagram of beta decay. Hence, we can see that forces also provide the mechanism of particle decay.

The emitted W^- boson rapidly decays into an electron and antineutrino (as explained in the earlier discussion in Chapter Five of how the neutrino was predicted), and it is the emitted electron which forms the beta radiation.

The Standard Model

With the successful application of gauge theory to particle physics in the 1960s and the 1970s, the field of particle physics was considered to be so mature and well-established that an accurate orthodox model could be constructed. This became known as the Standard Model of particle physics (more usually referred to as simply the *Standard Model*). The Standard Model was developed by many physicists, and has been described by Sheldon Glashow — one of the key architects of the Standard Model — as "a tapestry woven by many hands".

The Standard Model contains a listing of all known elementary particles, together with a deep understanding of their interactions. Experiments have tested the predictions of the Standard Model to great accuracy. The Standard

Model is truly an accurate model of the subatomic world.

Because the Standard Model accurately describes the building blocks of our world, it can be used to derive and explain almost all other scientific theories. For example, it is possible to use the Standard Model to derive the laws of electricity and magnetism, thermodynamics, optics, and nuclear energy. It can explain how a star produces energy, and it can explain the functioning of an ant.

So is the Standard Model truly the long-awaited "theory of everything"? Well, not quite. The biggest omission is that the Standard Model says nothing at all about the dominant force in the universe: gravity. It also leaves some other unresolved puzzles, most notably it provides no clue as to the nature of dark matter which supposedly constitutes over 80% of the matter in the universe.

The Standard Model is usually presented as a listing of seventeen elementary particles. We have considered almost all of these particles already in this book:

Let us examine the diagram. Firstly, let us consider the twelve fermions in the diagram (the matter particles: the quarks, electrons, and neutrinos on the left of the diagram). We have considered the quarks in this chapter. Electrons have been considered throughout this book (the diagram reveals that there are actually three different types of electron, two of which have vastly greater masses). Neutrinos were considered in Chapter Five (again, the diagram reveals that there are three types of neutrino).

On the right hand side of the diagram we find the five bosons, of which four are gauge bosons. In this chapter we have considered the photon's role in the electromagnetic force. We have also considered the role of gluons in transmitting the strong force (as was explained earlier, there are actually eight gluons in total, but these do not all feature on the diagram), and we have considered the role of the W and Z gauge bosons in transmitting the weak force.

So the only particle we have not yet considered is the Higgs boson ...

The unification of forces

On the previous diagram of the particles of the Standard Model, you will see that the Higgs boson stands out on its own. This is because the Higgs boson is not a gauge boson like the other bosons on the diagram — because the Higgs boson does not arise from gauge theory.

Instead, the Higgs boson is the particle associated with the *Higgs field*, and the Higgs field is responsible for giving mass to the elementary particles. Particles which interact more strongly with the Higgs field gain more mass.

We can think of the mass of an object as the object's resistance to being accelerated by a force (or, equivalently, the amount by which the object feels the strength of gravity). In this respect, it is possible to describe the effect of the Higgs field as being similar to the effect of a sea of molasses, slowing the particle down. The Higgs field acts to resist any acceleration of the particle, so the particle gains mass (mass being defined as resistance to acceleration).

What makes the Higgs field interesting from the point of view of the Standard Model is that particle types do not interact with the Higgs field in a symmetrical manner. We can therefore think of the Higgs field as "breaking the symmetry" of particles which would otherwise be identical — in effect, producing the different particles of the Standard Model. As an example, you can see on the previous diagram of the Standard Model that there are three

different types of electron: the electron, the muon, and the tau. The only thing which separates these particles is their mass (the tau is heavier than the muon, and the muon is heavier than the electron). If the Higgs field had not given these particles different masses then they would be identical in every way.

Of particular interest is the way the Higgs field appears to have broken the symmetry of four of the gauge bosons: the photon (of the electromagnetic force), and the three gauge bosons of the weak force. It is believed that these four gauge bosons were originally the gauge bosons of a single force, called the *electroweak force*. However, the Higgs field had an asymmetric effect: the end result was to give mass to the weak force bosons, while the photon emerged as massless particle. As a result, the weak force — with its massive bosons — remained short-ranged and confined to the atomic nucleus, while the massless photons were long-ranged and free to roam the universe. This gave an impression of two separate forces: the long-ranged electromagnetic force, and the short-ranged weak force.

It is believed that this separation of the electroweak force into two separate forces happened in the first moments after the Big Bang, when the universe cooled from extremely high temperature. Perhaps this suggests that forces become unified at high energies?

Indeed, one of the most intriguing outcomes of high-energy particle accelerator experiments is an indication that the effect of the strong force becomes weaker at higher energies, while the strength of the electromagnetic force increases. This seems to suggest that the strengths of the three forces would be the same at extremely high energies. These energies would be a thousand million times greater than can be reached by current particle accelerators, but these conditions would have existed in the first fractions of a second after the Big Bang. Maybe all four fundamental forces — including gravity — were actually one unified force at the time of the Big Bang. After just a fraction of a second after the Big Bang, the universe cooled and the four separate forces would have become "frozen out" to become distinct forces.

QUANTUM GRAVITY

Up to this chapter, this book has reflected orthodox physics. The book has been based on the Standard Model of particle physics, which has been experimentally tested to tremendous accuracy time and again. I would imagine all professional physicists would agree with the majority of the book so far.

However, as readers of my previous books will know, my books tend to follow a pattern. The majority of the material presented represents orthodox physics, but I do like to include some original ideas and hypotheses towards the end of the books. This book is no exception. If you wish, you could certainly stop reading this book at this point and feel satisfied that you have read a useful primer on particle physics. But if you are feeling adventurous, and fancy something a bit different (and rather challenging), please press onward. Just bear in mind that much of the material presented in the remaining chapters (especially the material representing my own ideas) should be considered speculative.

However, be reassured that I have confidence in everything which follows.

The Standard Model is undoubtedly a marvellous achievement, but it is not complete: it says nothing about gravity. And that is a fairly monumental omission as gravity is the dominant force which essentially rules the universe.

Einstein's wonderful theory of general relativity is most certainly not the final theory of gravity. General relativity predicts a universe completely spanned by a *gravitational field*. The gravitational field determines how objects move when they are in free-fall, so it effectively defines the force of gravity. However, the gravitational field is a *classical* field — just like Maxwell's electromagnetic field — in that it has no reference to quantum mechanics whatsoever. Einstein's gravitational field is a smooth, continuous surface in all places — not quantized into particles. However, we know that all particles (and fields) have to comply with the principles of quantum mechanics, so there is a need to develop a quantum version of general relativity, with a gravitational field quantized into particles (which, optimistically, have already been given a name: *gravitons*). This would be the final and correct theory of quantum gravity.

Quantum gravity is an active research field in fundamental physics, but definite progress has been painfully slow (non-existent?). The development of a successful theory of quantum gravity is the holy grail of modern fundamental physics.

The biggest challenge for research into quantum gravity is that the two relevant theories — general relativity and quantum mechanics — operate on two completely different scales. General relativity (gravity) is the theory which dominates at large scales, holding stars and galaxies together. Whereas quantum mechanics is the theory which dominates the atomic world. Gravity becomes an irrelevancy for particle interactions — it is simply too weak a force for particles with such small masses. But if we are trying to develop a theory of quantum gravity, that will entail generating equations which describe quantum mechanical behaviour and general relativity **in the same equation**. However, there is simply no way of checking such an equation, or basing such an equation on observations, if we cannot observe anything in the universe for which quantum mechanics **and** general relativity are **both** relevant. The scales of the two phenomena are simply too wide apart: either we observe galaxies and large-scale objects (gravity only — no quantum effects) or we observe particles (quantum mechanics only). It seems there is nothing in-between scales for us to base our equation on.

However, there is just one thing suitable: a black hole.

Black holes are such extreme objects that they can only be completely understood by a theory that must combine both quantum mechanics and general relativity. The event horizon of a black hole is particularly interesting in this respect. Clearly, general relativity is vital to understand the event horizon as general relativity predicts extreme curvature of space at the position of the event horizon (the *Schwarzschild radius*). However, the importance of quantum effects also cannot be ignored at the event horizon. Most notably, Hawking radiation (considered in my second book) is predicted to be generated at the event horizon purely by quantum mechanical effects, and Hawking radiation is vitally important as it is supposed to be the mechanism which eventually results in the evaporation of the black hole.

So in order to fully understand the behaviour of black holes, we will have to develop an equation which describes

both general relativity **and** quantum mechanics. Black holes really are quite unique objects.

However, even if we are unable to study a black hole closely, our existing knowledge of general relativity and quantum mechanics can provide us with clues about the behaviour of quantum gravity. Starting with quantum mechanics, we know that the uncertainty principle places fundamental limitations of our ability to make accurate measurements of the width of an object. Specifically, if an object has a mass, m , then we can only accurately measure the width of that object if its width is no smaller than the object's *Compton wavelength*:

$$l_C = \frac{h}{mc}$$

where h is the Planck constant, and c is the speed of light. If we try to measure any smaller distance than this then quantum effects — and quantum uncertainty — become dominant.

Remember we are trying to develop a theory of quantum gravity. We have just considered quantum mechanics, so now let us consider general relativity.

General relativity imposes a similar limit on our ability to measure small objects. We know that if we compress a mass to a distance smaller than its Schwarzschild radius then it forms a black hole. So the Schwarzschild radius represents the distance at which general relativity becomes crucial for understanding the behaviour of objects:

$$r_S = \frac{Gm}{c^2}$$

where G is the *gravitational constant*.

Remember, we are interested in developing a theory of quantum gravity, so we want to find objects for which both quantum mechanics and general relativity are essential. We therefore need an object with a width equal to its Compton wavelength **and** its Schwarzschild radius. So let us set the formula for Compton wavelength equal to the

$$\frac{h}{mc} = \frac{Gm}{c^2}$$

formula for Schwarzschild radius:

Solving for m , we get:

$$m_P = \sqrt{\frac{hc}{G}}$$

This is called the *Planck mass*. Note that the formula for the Planck mass includes the two fundamental constants of general relativity (G and c), and the fundamental constant of quantum mechanics, h .

Now we will take this formula for the Planck mass and substitute it back into the formula for either the Compton wavelength or the Schwarzschild radius (it doesn't matter which one we choose — we have set them both equal in this case). Let's select the Schwarzschild radius:

$$r = \frac{Gm}{c^2} = \frac{G}{c^2} \times \sqrt{\frac{hc}{G}}$$

Square both sides of the equation to get rid of the square root:

$$r^2 = \frac{G^2}{c^4} \times \frac{hc}{G} = \frac{hG}{c^3}$$

Now take the square root of both sides of the equation (to get us back to a formula for distance — not the square of the distance):

$$l_P = \sqrt{\frac{hG}{c^3}}$$

This distance is called the *Planck length*. Again, note that this formula for the Planck length just includes the two fundamental constants of general relativity (G and c), and the fundamental constant of quantum mechanics, h . This is encouraging: it indicates the length is significant for both general relativity and quantum mechanics — just what we were looking for. The Planck length is considered to be the most important distance in quantum gravity research. The suggestion is that the laws of physics at distances smaller than the Planck length could only be described by a joint theory of quantum gravity.

Unfortunately, if you put actual values into the formula you can calculate that the value of the Planck length is an incredibly small distance: 1.6×10^{-35} metres, which is about 10^{-20} times the size of a proton. The fact that this is such a small length is often quoted as the reason why observations of quantum gravity would be so difficult to obtain (particle accelerators would require astronomical energies to probe such small distances).

Rather disappointingly, this represents pretty much the state-of-the-art of what we know for sure about quantum gravity (this, Hawking radiation, and the spin value of the graviton). I told you progress has been slow.

The previous calculation shows that if we want to study the behaviour of quantum gravity, we need to obtain a sample of matter equal to the Planck mass (surprisingly large: about 21 micrograms) and then compress it to its Schwarzschild radius (which, in the case of the Planck mass, is equivalent to the Planck length). Of course, by doing this we are effectively creating a black hole (any mass compressed to its Schwarzschild radius forms a black hole). So what we really need from a theory of quantum gravity is a theory which can describe behaviour at distances smaller than the Schwarzschild radius of a black hole (to be precise, a Planck mass black hole).

At this point, a novel hypothesis which I presented in my earlier books emerges as a potential theory of quantum gravity as it clearly fulfils this requirement. The modified gravity hypothesis (MGH) was first presented in my second book. The whole basis of the MGH is that it predicts novel behaviour inside the Schwarzschild radius. We also saw earlier that any theory of quantum gravity would have to be a theory which can describe the behaviour of black holes — and the MGH fulfils that requirement perfectly.

This is encouraging, but it is only half the battle. To get a full theory of quantum gravity we would need to obtain a quantum version of the MGH, which is what we will consider later in this chapter. But first, please allow me to briefly recap the modified gravity hypothesis.

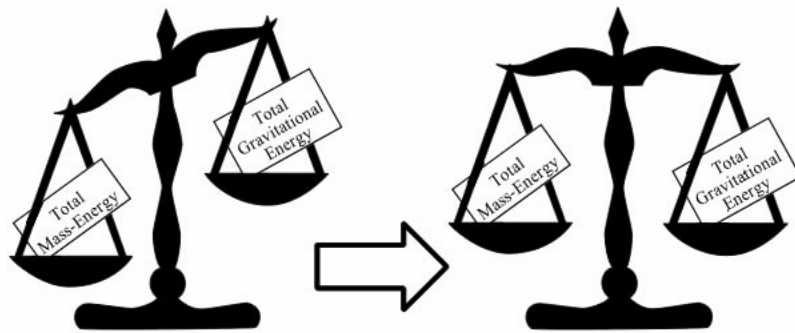

The modified gravity hypothesis (MGH)

Gravity still remains something of a mystery. We still do not know what happens at the predicted *singularity* at the heart of black holes, or why the expansion of the universe appears to be accelerating. If you read my second book, you will know that it proposed a simple and ingenious modification to the theory of general relativity which solved these — and many more — problems. We sorely need some new insights into how gravity operates at the quantum level, thus providing some pointers to a possible theory of quantum gravity. We will now consider if the modified gravity hypothesis (MGH) proposed in my second book might provide pointers in this direction.

To start, here is a brief reminder of the motivation behind the MGH, and a list of the quite remarkable predictions provided by such a simple idea. I will try to keep this brief, so for the details see my second book.

Firstly, the motivation behind the MGH is that the universe has zero total energy. This statement seems to have become almost accepted as orthodox physics. It is possible for the universe to have zero total energy if gravitational energy is considered to be negative. Richard Feynman considered the relevant equation in one of his 1960s lectures: "If now we compare the total gravitational energy to the total rest energy of the universe, lo and behold, we get the amazing result that the total energy of the universe is zero. Why this should be so is one of the great mysteries — and therefore one of the most important questions in physics. After all, what would be the use of studying physics if the mysteries were not the most important things to investigate?"

If we take the implications of Feynman's equation seriously, we find a universe predicted to expand to a certain equilibrium distance, at which point the gravitational energy of the universe will be in perfect balance with the energy contained in the mass of the universe:

So, once again, we find the importance of the concept of balance in the universe. We have seen throughout this book how balance plays a vital role in constraining and determining the laws of Nature. In our earlier discussion of the conservation laws, we found Professor David Charlton working at the LHC explaining how new particles can be detected from the requirement that the energy going into a particle interaction must be perfectly balanced with the energy coming out. Also, in the previous chapter, it was explained how gauge theory arises from any local disturbance in the balance of the universe, a field being required to correct what Bruce Schumm called "a delicate and precise balance". And in the MGH we again find a universe fighting to restore a balance of energies. As I explained in my second book, it is as though the motivation as to why forces exist at all is because they reconfigure the structure of the universe in order to correct imbalances.

The equilibrium distance, as predicted by the MGH, turns out to be a well-known distance: the Schwarzschild radius. The Schwarzschild radius is best known as the radius of the event horizon of a black hole (if you compress a mass to a size smaller than its Schwarzschild radius, it forms a black hole). But every mass has an associated Schwarzschild radius — not just black holes. What makes the MGH so ingenious is the fact that for almost every object in the universe its Schwarzschild radius is an almost undetectably small distance (the Schwarzschild radius of a human being is about a trillionth of the size of an atom). So, crucially, this results in the MGH predicting an attractive force of gravity which is in agreement with all the well-tested measurements of general relativity.

However, among the remarkable predictions of this simple hypothesis are the following:

- A universe which is spatially flat — without inflation (as a universe which expands to its Schwarzschild radius will be naturally spatially flat).
- A universe with an accelerating expansion — without fine-tuned dark energy.
- A simple solution to the black hole information loss paradox, and a simple explanation as to why the entropy of

a black hole is proportional to the area of its event horizon.

It is a very elegant solution to some of the most pressing problems in cosmology. However, as explained earlier, we now want to move on a try to find the implications for quantum gravity.

The asymptotic freedom of gravity

As was explained earlier in this chapter, inside the incredibly small Planck length, it is predicted that the effects of general relativity and quantum mechanics become equally dominant. We really have no idea what reality is like at these scales, though there have been some educated guesses. The most famous guess was by John Wheeler in 1955. Wheeler realised that — at distances smaller than the Planck length — quantum mechanics would play a major role in shaping the spacetime of general relativity. The Heisenberg uncertainty principle would result in random twisting turbulence in the structure of space itself. Wheeler gave this the name *quantum foam* or *spacetime foam*. Unfortunately, in the absence of a theory of quantum gravity, we have no way of testing Wheeler's idea.

The major roadblock in the development of a theory of quantum gravity has been the tendency of infinities to enter candidate theories. The problem in creating a quantum theory of gravity stems from the fact that there is energy contained in the gravitational field connecting the masses. That field energy increases the effective mass of the objects (via $E=mc^2$). But if we increase the mass of the objects, then that increases the strength of the gravitational field, etc. etc. You can imagine how the strength of gravity in this model appears to rapidly shoot off to infinity. And if we have infinities in a physical theory, it shows the theory is flawed. So any potential theory of quantum gravity we might construct would have to possess some mechanism for avoiding these infinities.

The MGH suggests that gravity is not a universally attractive force in all circumstances, but in fact acts to move objects to a certain equilibrium distance (the Schwarzschild radius). Outside the equilibrium distance, gravity acts as a purely attractive force, but inside the equilibrium distance gravity is no longer attractive and no longer acts to bind objects closely together.

Now, put your thinking caps on and try and remember where we have encountered a similar phenomenon earlier in this book.

If you remember back to our discussion of the strong force in the previous chapter, it was explained how quarks become more strongly attracted the further apart they are separated, but at small distances (e.g., inside the proton) there is no longer an attraction, instead the quarks are very loosely bound. This was the phenomenon of asymptotic freedom. A comparison was made to a rubber band being stretched between fingers. **It is clear that asymptotic freedom is a very similar phenomenon to the behaviour of gravity at short distances as predicted by the MGH.** This reveals a possibly intriguing connection between the behaviour of the strong force (QCD) and the behaviour of gravity.

I can quote the Wikipedia article on the development of the theory of asymptotic freedom: "The discovery was instrumental in rehabilitating quantum field theory. Prior to 1973, many theorists suspected that field theory was fundamentally inconsistent because the interactions become infinitely strong at short distances." This sounds uncannily similar to the current puzzling situation regarding the force of gravity, which is predicted to rise to a huge force at small distances, and an infinitely strong singularity in the heart of black holes. The MGH predicts that gravity will no longer be attractive inside the Schwarzschild radius, and I find this similarity to asymptotic freedom intriguing and suggestive. The MGH appears to predict that gravity becomes asymptotically free inside the Schwarzschild radius.

Just as the theory of asymptotic freedom rescued the strong force, maybe the MGH can get the current theory of gravity out of a (very black) hole?

This would maybe suggest that the behaviour of gravitons (the gauge bosons of gravity) has to be similar to the behaviour of gluons (the gauge bosons of the strong force). This is perhaps not such a surprise. The reason given for asymptotic freedom in the strong force is that the gluons can interact with other gluons in complicated ways — giving surprising results. It is known that gravitons must also interact with themselves: gravitons form the gravitational field, the gravitational field contains energy, and energy has a gravitational pull. So "gravity gravitates".

In his book *The Trouble With Physics*, Lee Smolin explains this problem with self-interaction: "Gravitational waves interact with each other. They interact with anything that has energy, and they themselves carry energy. This problem does not occur with electromagnetic waves, because though photons interact with electric and magnetic charges, they are not themselves charged, so they go right through each other."

Just as self-interacting gluons generate asymptotic freedom, perhaps self-interacting gravitons also exhibit

asymptotic freedom?

So the MGH not only explains the universe on the largest scale, but it also points to a new direction for research on the very smallest scale of quantum gravity.

The modified gravity hypothesis (MGH) makes a wide range of predictions which agree with observation.

It explains why gravity is always seen as an attractive force (in agreement with general relativity), but predicts repulsive gravity for the universe as a whole — powering an accelerating expansion. It predicts a spatially-flat universe without inflation. It provides a simple solution to the black hole information loss paradox, and explains the value of black hole entropy. Finally, an asymptotically-free version of gravity arises naturally from the hypothesis, suggesting a new direction for quantum gravity research. It even makes predictions about the behaviour of gravitons.

The MGH is clearly extremely wide-ranging, making predictions below the Planck length, and also at cosmological scales. Hence, the hypothesis starts to resemble a candidate *theory of everything* (or, perhaps more accurately, a *theory of quite a lot*). However, whereas it might require an entire book to describe other theories of everything — such as string theory or loop quantum gravity — the MGH could be described by just a single sentence: "If the universe has zero total energy, then that implies gravity acts to move the masses in a system to the Schwarzschild radius of that system".

We hear a lot about how "string theory predicts gravity". Well, according to the MGH, a zero-energy universe alone predicts Newtonian gravity (for the equations, see my second book). It's all wonderfully simple. [\[14\]](#)

Nobel Prize winner Sheldon Glashow makes another point about string theory: "Superstring theory does not follow as a logical consequence of some appealing set of hypotheses about Nature". However, the MGH most certainly derives from a single logical principle. Indeed, it was built-up from that principle.

While string theory makes few (if any?) firm predictions, the MGH clearly predicts a spatially flat universe. It also predicts a naturally-occurring accelerating expansion of the universe — which is known to be a problem for string theory. The hypothesis also provides a simple solution to the black hole information loss paradox.

I am not suggesting that string theory is wrong. But what I am suggesting is that the modified gravity hypothesis is more predictive, more testable, and is based on a stronger logical foundation.

The MGH requires no external setting of arbitrary parameters, no landscapes of possible solutions, no multiverses, no hidden dimensions. And unlike other theories — such as string theory, supersymmetry, and loop quantum gravity — the modified gravity hypothesis does not require us to search deeper to discover new structures and particles. Instead, the hypothesis suggests we just need to try harder to make sense of what we already know.

THE GREAT UNIVERSE MANIA

To end this book, here is a very peculiar tale.

In the 1930s, a strange fever afflicted the physics department of Cambridge University. But this was no biological virus. This was a strange virus of the mind, a contagious idea so apparently compelling but — at the same time — so cruelly destructive that the reputations of many of the most renowned physicists were permanently damaged.

An article in the journal *Nature* disparagingly called the Cambridge fever "the great universe mania". In this chapter we will examine the cause of this mania, seeing why it caused so much uproar in physics, and trying to understand why so many careers and reputations were damaged. We shall see that among those swept up by the enthusiasm — and destructiveness — of the movement was none other than the great Paul Dirac. It was to be Dirac who made some of the wildest pronouncements during the period of the great universe mania.

Although Dirac received heavy criticism at the time, we shall see that it is possible that Dirac was simply a hundred years ahead of his time.

The numbers of Arthur Eddington

In 1929, the American astronomer Edwin Hubble discovered that the furthest galaxies appeared to be retreating at a faster rate. This appeared to indicate that the universe was expanding, which, in turn, appeared to imply that the universe originated from a small region of space. This was the *Big Bang* theory of the universe, which ushered in a scientific revolution of our image of the universe. Hubble's discovery kickstarted the area of physics research known as *cosmology*, which considers the structure of the entire universe at the largest scales.

The discovery of the Big Bang generated huge ripples of excitement throughout the scientific community. In Cambridge, some of the most notable physicists started to investigate this fledgling field of cosmology. Arthur Eddington was a professor who was one of the first physicists at Cambridge to understand the principles of general relativity. Eddington had created a sensation by showing that light rays bent around the Sun (seen in a photo taken during a solar eclipse), thus proving Einstein's theory of general relativity to be correct. Eddington also became a cosmologist, applying the principles of general relativity to create models of the structure of the universe as a whole.

When Eddington became aware of Hubble's discovery of an expanding universe, he immediately suspected that the *cosmological constant* in Einstein's general relativity equations was the source of the expansion. He then sought to find a mechanism by which the value of the constant might be set to a value which would lead to the observed expansion. But Eddington was also something of a maverick, with an unorthodox style of doing physics. And so the mechanism which Eddington suggested was unlike anything seen before.

Essentially, Eddington realised that we have to use measurement apparatus made of particles (e.g., protons, electrons) in order to measure anything at all. So the size of particles inevitably becomes an intrinsic part of the measurement. According to Eddington, "any apparatus used to measure the world is itself part of the world". So if we want to measure the size of the universe, then the size of particles will inevitably be involved in the measurement result in some way. Eddington took this to mean that there would inevitably always be some fixed relationship between the size of the universe and the size of a particular particle. Hence, although the observed value for the size of the universe might appear to be set to an arbitrary value, it might be possible to find an analytical relationship between the size of the universe and the size of a particle.

If this all sounds a bit crazy, bear with me. It gets crazier.

As an example of the type of peculiar calculation performed by Eddington, we find that the value of the ratio of the strength of the electromagnetic force to the gravitational force is approximately 10^{40} . So what did this value mean? Eddington had no idea. So he decided to see where else this number appeared in physics.

At this point, Eddington entered dangerous territory. He started to use *numerology*. Numerology — as far as physics is concerned — is a largely discredited "science" which essentially involves "working backwards from the answer". The idea is to take some numerical constant and then try to mathematically construct that constant from other known constants, such as pi, or the charge of an electron. If you happen to get lucky — hey — it would appear you have managed to discover some deep secret about Nature. You would have effectively discovered a numerical

answer without knowing the underlying theory.

However, this method of "working backwards from the answer" is clearly not as satisfactory as initially constructing a well-founded hypothesis which unambiguously predicts the value of the constant, which is the way good physics is supposed to be done. As John Barrow says in his book *The Constants of Nature*, such a hypothesis would "supply a large and consistent theoretical edifice from which the prediction would follow."

Another problem is that it is possible to play around with numerology without having any expertise in physics, any ability to construct well-founded hypotheses. As a result, numerology has got a bad press as the domain of untalented amateurs who try to promote their dubious (and usually flawed) hypotheses with relentless zeal. Arthur Eddington was also a highly-successful populariser of science, and John Barrow had this to say about Eddington's range of books: "The most interesting thing about Eddington's attempts to explain the constants of Nature by algebraic and numerical gymnastics is their enduring effects on the readers of his popular science books. He liked to tell his general readers about his new 'calculations' of the constants of Nature and the overwhelming impression he conveyed was that it might be possible to unlock some of the most deeply hidden secrets of the universe by a little bit of inspired guesswork and numerology. If you noticed that some equations had solutions that lay close to the numbers like 137 and 1840 then you were in business as a rival to Einstein. I believe that Eddington's work, and his widespread popularisation of it in books that sold in huge quantities and continued to be read for more than 60 years after they were first published, inspired a generation of amateurs who dreamed of finding the numerical explanation for the constants of Nature. Every week I receive letters that contain calculations of a sort that owe much to Eddington's style and approach to Nature. They are characterised by very detailed numerical calculations, a confinement of interest to a small subset of the constants of Nature, and no desire to predict anything new."

If we return to consider Eddington's interest in the huge number 10^{40} (the ratio of the strength of the electromagnetic force to the gravitational force), Eddington realised that this was approximately equal to the square root of the total number of protons in the observable universe, which is believed to be approximately 10^{80} . This became known as the *Eddington number*. However, Eddington was not satisfied by the apparent imprecision in its value. So during a transatlantic boat crossing, Eddington calculated the number to great precision (by hand), eventually proclaiming: "I believe that there are 15,747,724,136,275,002,577,605,653,961,181,555,468,044,717,914,527,116,709,366,231,425,076,185,631,031,296 protons in the universe, and the same number of electrons."

Unfortunately, as John Barrow explains in his book, one of the problems with numerology is that "after a while it starts to become addictive". Eddington certainly seems to have been caught by the bug, and it was this contagion which spread around Cambridge University. Eddington started applying his dubious methods to an ever-wider range of constants, often receiving scorn from fellow physicists.

One of Eddington's complicated mathematical formulae supposedly resulted in the value 136, the inverse of the *fine structure constant* (which describes the strength of the electromagnetic force). However, when later measurements placed the value nearer the inverse of 137, Eddington changed his reasoning to suggest that a value of one should be added to his calculation. At this point, some of his critics suggested he should be called "Arthur Adding-one".

After one of Eddington's lectures, two physicists were overheard talking. One said "Do all physicists go off on crazy tangents when they get old?" To which the other physicist replied "Don't worry, you have nothing to worry about. A genius like Eddington may perhaps go nuts, but people like you just get dumber and dumber."

However, I can't help feeling that — as far as physicists are concerned — the main crime committed by numerology is that it has never been successful: it has never been used to correctly predict the value of a constant. Not once. I can't help feeling that if it had ever had any success — however small — then the method would have been rapidly re-evaluated as a perfectly reasonable approach to doing physics. A rather similar re-evaluation seems to have recently happened to multiverse theories which used to be regarded as unscientific but are now being sold as the solution to the current slow progress in physics. If numerology had enjoyed any success then I suspect we would all now be numerologists instead of string theorists. Even a small success can attract a huge amount of attention and research effort.

With this in mind, it might be said that there is nothing particularly unreasonable about an intelligent approach to numerology. As the renowned physicist James Jeans said: "Few, if any, of Eddington's colleagues accepted his views in their entirety; indeed, few if any claimed to understand them. But his general train of thought does not seem unreasonable in itself, and it seems likely that some such vast synthesis may in time explain the nature of the world we live in, even though the time may not be yet."

The return of the amazing Mr. Dirac

In 1937, Paul Dirac was the Lucasian Professor of Mathematics at Cambridge University, one of the most prestigious academic posts in the world. When Dirac made an announcement, the world listened. So it must have come as a great surprise when he announced his decision to change his research area from quantum mechanics to cosmology. As Graham Farmelo says in his biography of Dirac, this involved "refocusing his imagination from scales of a billionth of a centimetre to thousands of light years."

Dirac's first contribution to the topic was written while he was on his honeymoon. It was a 650-word letter to the journal *Nature*. The letter showed that Dirac was not immune to the numerology fervour, as it became clear that Dirac had been largely influenced by the work of Eddington. When Niels Bohr read the letter, he said "Look what happens to people when they get married."

Like Eddington, the letter considered the number 10^{40} , the ratio of the strength of the electromagnetic force to the gravitational force. But Dirac compared this number to the ratio of the radius of the universe to the radius of a proton. The results were very similar, certainly similar enough to convince Dirac that there was a connection. It is certainly unusual to find such a huge number in science, and even more surprising to find approximately the same number arising from two different calculations. As John Barrow said: "There must exist some undiscovered mathematical formula linking the quantities involved. They must be consequences rather than coincidences."

This is called the Dirac *large numbers hypothesis*.

However, it was realised that there was a fundamental problem with Dirac's idea: the universe is expanding. If the universe is expanding, then that suggests that the universe will be larger in the future, and that it was smaller in the past. But Dirac was only using the current radius of the universe in his formula. How could the formula (radius of the universe to the radius of a proton) continue to give the vital 10^{40} number if the radius of the universe was varying?

Dirac provided a fairly astonishing answer. He realised the 10^{40} number could not be maintained in an expanding universe: it was bound to increase. So he suggested that the other magic number — the ratio of the strength of the electromagnetic force to the gravitational force — was also increasing at the same rate. Dirac suggested this increasing ratio would be possible if the strength of the gravitational force was steadily decreasing.

This is surely a sign that Dirac's hypothesis was in deep trouble, with an attempt by Dirac to patch over the problem. If the gravitational force is decreasing, then that suggests the force was much greater in the past. However, it was realised that this increased gravity would have resulted in increased energy output from the Sun, and the Earth would have been much hotter in the past. In 1948, the American physicist Edward Teller showed that in the pre-Cambrian era, 200-300 million years ago, Dirac's workaround would have resulted in the oceans boiling, and life on Earth could not have survived.

So Dirac's hypothesis was falsified, proved to be untrue. Dirac appears to have rapidly lost interest in his idea. But is it now possible to revisit the large numbers hypothesis and show that Dirac was correct in believing that there was a deep underlying connection between the two ratios?

The Dirac connection

The problem with Dirac's approach was that he used the current radius of the universe in order to produce the magical 10^{40} value. In an expanding universe, this value was bound to vary accordingly, thus breaking Dirac's suggested connection.

However, at this point the modified gravity hypothesis (MGH) can step in and provide a solution to Dirac's problem. If you remember, the MGH suggests that the universe has a certain equilibrium radius, and the universe will expand until it reaches that radius. The universe may currently be smaller than the equilibrium radius, or it may currently be larger, but — crucially — **the value of the equilibrium radius does not alter with time**. It is the equilibrium radius which reveals deep truths about the universe — not the current value of the radius, which is an arbitrary value. If we consider the equilibrium radius of the universe then all of a sudden Dirac's hypothesis makes a lot more sense.

If Dirac had used the equilibrium radius instead of the current radius then he would have got the same numerical result. If you remember, the MGH predicts an equilibrium radius for the universe equal to:

$$R_U = \frac{2GM_U}{c^2}$$

where M_U is the mass of the universe.

The ratio of this radius of the universe to, say, the radius of an atom is then approximately:

$$\frac{GM_U}{c^2} \times \frac{1}{R_{ATOM}} \approx 10^{40}$$

So we get the same magical 10^{40} value, but, crucially, all the values in this expression are constant values which do not depend on the current radius of the universe. **So this value does not alter with time.** And if the value does not alter then there is no longer any need for Dirac's horrible workarounds such as a varying force of gravity, which effectively falsified his hypothesis.

It is important to note that this is no longer numerology as practised by Eddington and Dirac. This is a prediction of a well-founded (though admittedly highly-speculative) hypothesis, constructed from first principles, a hypothesis which makes predictions and agrees with known measurements. Dirac's large numbers hypothesis was based on his conviction that these numerical coincidences were revealing some deep — but unknown — truth about the universe. It is possible that the modified gravity hypothesis is the truth he was seeking.

The universe as an atom

However, of course, this is only half the story. So far, we have calculated the value for the ratio of the size of the universe to the size of an atom, and found the value equal to 10^{40} . Crucially, we have also just shown that this value does not necessarily have to alter with time. For the next step, if you remember, Dirac considered this 10^{40} value and found it was the same as the ratio of the strength of the electromagnetic force to the gravitational force.

Is this a just a crazy coincidence? Or could the radiuses of the universe and an atom be related to the strengths of the electromagnetic and gravitational forces in some way?

Firstly, considering the atom. What forces control the size of the atom? Well, the strong force is short range, confined to the nucleus, and so does not play a role. And gravity is too weak at these scales. So it is the electromagnetic force which controls the overall shape of the atom, holding electrons in orbit around the nucleus.

Secondly, considering the universe, the electromagnetic force tends to cancel in atoms, positive charge equalling negative charge, so large objects become electrically neutral. Hence, the electromagnetic force does not play a role in shaping the universe. It is gravity which is the dominant force in the overall size of the universe, even though it is by far the weakest of the four forces. Gravity dominates because all mass has the same gravitational charge (there is no such thing as negative mass). Hence, for very large objects, the force of gravity steadily accumulates until it becomes the dominant force.

So the strength of the electromagnetic force controls the size of the atom, and the strength of gravity determines the size of the universe.

Remember we are now dealing with objects which are in an equilibrium state, meaning the forces holding them together are precisely equal to the forces pulling them apart. This results in an equilibrium radius for the object, and it is this equilibrium distance which interests us. The MGH suggests the universe has an equilibrium radius in much the same way that an atom has an equilibrium radius.

Gravity dominates the universe and determines its size in much the same way as the electromagnetic force determines the overall size of atoms. It is as though the universe is a scaled-up atom!

So, as wild and crazy and randomly unconnected as it may have appeared at first sight, it appears that there might

well be an underlying logic to the Dirac large numbers hypothesis.

At these two extremes of scale — the atom and the universe — we find similar situations. We find objects in stable, equilibrium situations dominated by a single particular force. This results in simplicity at the two extremes of scale.

Neil Turok considered this simplicity in his 2015 talk at the Perimeter Institute called *The Amazing Simplicity of Everything* (<http://tinyurl.com/turoklecture>): "The astonishing thing about recent discoveries in physics is that they tell us the universe is surprisingly simple and regular, on the tiniest scale and on the hugest scale. It's only complicated in the middle. To first approximation, the universe is absolutely uniform in all directions. The whole universe is as simple as the simplest atom. If you think about a hydrogen atom, how many numbers do you need to describe an atom? An atom is a pretty simple thing: you have a nucleus, you have an electron going around it, you have the force of electrical attraction between the nucleus and the electron. Well, it turns out to describe the universe you need just one number. That number describes the universe — fewer numbers than you need to describe a single atom. So the universe turns out to be the simplest thing we know."

The celestial spheres

When we look up at the night sky, we see a number of different celestial objects. Perhaps we see the Moon, maybe we see planets, we almost certainly see stars. In other words, we see **spheres**. And this spherical model applies over the largest range of scales: the largest star has a volume 100 trillion times larger than the Earth, but they are both spheres.

And this consistency over scales still applies if we look down to the smallest scale, where we find atoms, more spheres. Even quarks in a proton are distributed in a spherically symmetric way (for this reason, Bruce Schumm called a proton a "subnuclear atom"). A sphere is an object in perfect balance: the forces which pull the sphere together are balanced by the forces which push the sphere apart. Nature likes balance. Nature tries to correct imbalance.

However, our best current theory of gravity predicts two of the most important objects of all are in a state of raging imbalance. Those two objects are black holes, and the entire universe itself. General relativity predicts that black holes are so totally imbalanced that they are crushed down to an infinitely-small singularity at their centre. As far as the entire universe is concerned, general relativity predicts another out-of-control imbalance — this time in the opposite direction: an ever-increasing expansion of the universe until it is infinitely large.

The modified gravity hypothesis restores balance. It eliminates the infinities.

It predicts spheres.

The modified gravity hypothesis predicts black holes which have their mass smeared around their Schwarzschild

radius (in practice, the mass would be concentrated in the accretion disk which surrounds every black hole). For the entire universe, the hypothesis predicts an equilibrium radius, with the universe expanding to that equilibrium like a soap bubble.

The modified gravity hypothesis reveals a universe which seeks perfect balance, from the scale of atoms and protons, up to the scale of black holes, galaxies, and the universe itself.

A universe in perfect balance.

NOTES

- [1] For details, see Section 3.4 of Leonard Susskind and Art Friedman's book *Quantum Mechanics*.
- [2] As this is now the square of two identical terms, the square root of this expression is just one of these two terms. So if we take just one of these terms we will be able to eliminate the square root from the energy-momentum relation.
- [3] Do you recognise these two matrices? They are actually two of the Pauli spin matrices we considered in the previous chapter. This is a big clue as to what is coming later.
- [4] Why should the sign be positive for a, but negative for b, c, and d? This is because distances in space and time do not work in quite the same way. The further you travel in space, the shorter the distance you travel in time. Hence, a space-travelling astronaut will age more slowly than his counterpart left on Earth.
- [5] Yes, I am aware that the gears in the arrangement shown in the diagram will actually rotate in opposite directions. Please just ignore that — it is not important.
- [6] For more details of this approach, see Chapter Twelve of *Quantum Field Theory and the Standard Model* by Matthew D. Schwartz.
- [7] Custom ambigram designed specially for this book by FlipScript Corporation.
- [8] This is because the formula for kinetic energy (used in the formula for the Lagrangian) is $\frac{1}{2}mv^2$, so the partial differential of the Lagrangian with respect to velocity (the partial differential being the conserved quantity) is mv , which is the formula for momentum.
- [9] "Gauge" means a standard of measurement. Gauge theory is based on the principle that it is possible to choose a different standard at each point in space.
- [10] This is called *CP-symmetry*, where the "CP" stands for "charge parity". It is known that there are some violations of this symmetry.
- [11] Technically, this type of symmetry, being able to rotate the wavefunction of a particle, is give the term U(1) symmetry. The term "U(1)" means "rotation in one complex dimension". For more information, see the book *Deep Down Things* by Bruce Schumm.
- [12] The term "SU(3)" means "rotation in three complex dimensions". For more information, see the book *Deep Down Things* by Bruce Schumm.
- [13] Positioning different particle types on a symmetrical rotating wheel is described mathematically by *group theory*. It is possible to transform any element in the group into any other element of the group merely by rotating the wheel. For particle physics, the type of continuous groups which interest us are called *Lie groups* (pronounced "Lee").
- [14] As a purely speculative thought, it is interesting that the principle that the universe has zero total energy when "viewed from outside" is reminiscent of the colour-neutrality of quark composites produced by the strong force (e.g., protons have zero colour when "viewed from outside"). We can consider mass/energy to be the charge of the force of gravity. Hence, it appears that forces create composite objects which are charge-neutral when viewed from outside: gravity creates objects which are energy-neutral, the strong force creates objects which are colour-neutral, and the electric force creates objects which are electrically-neutral (such as atoms). Is this significant?

APPENDIX

PREFACE

Why are there only three dimensions? It is surprising just how little research there has been on why there are three dimensions of space. In fact, I believe this is only the second book dedicated to the precise question which has ever been written (the first book was written by Ptolemy, two thousand years ago).

You might imagine that the question of why there are three dimensions of space would be one of the most outstanding and pressing questions facing physics today. But it is rarely mentioned in that respect. Whenever a list is compiled of the most important questions facing physics, the usual suspects always appear: unifying gravity and quantum mechanics, dark energy and dark matter, the so-called hierarchy problem in particle physics. But you will rarely see the question arising of why there are only three dimensions. Is the question considered too difficult, and is therefore best ignored?

Admittedly, as we shall see later, string theorists might argue that there is plenty of research in string theory to provide an answer to why we only observe three dimensions — though string theory actually predicts there are ten dimensions of space! So string theory is not so much a drive to answer the question of why there are only three dimensions — it is more a drive to answer the question of why we do not observe the troublesome seven dimensions which are predicted by string theory but do not fit the bill.

This book also contains a description of the very exciting recent discovery of gravitational waves.

I have really enjoyed writing this book, probably my most enjoyable book so far. I have found it to be a fascinating topic, with lots of interesting side-issues emerging. I hope you enjoy reading it as much as I enjoyed writing it.

I think the conclusion in the final chapter is particularly convincing.

Once again, thank you for your support.

THE MAGIC NUMBER

In 1990, the American hip-hop trio De La Soul had one of their biggest international hit singles. The track was called *The Magic Number*, and it reached No. 7 in the UK pop chart. The song emerged at a time when rap music was dominated by violent and misogynistic themes. In contrast, De La Soul sang about love and peace and harmony, themes which were more commonly associated with the 1960s hippie community.

In the lyrics of the song, De La Soul appear quite convinced that the "magic number" is the number three. As an inquisitive physicist, I was intrigued by this apparent certainty as we clearly live in a universe which has three dimensions. An object can move in three independent directions: left/right, forward/back, and up/down. Perhaps surprisingly, we simply do not know why it is the case that there are three dimensions. Why is three genuinely a magic number in this respect?

So I was intrigued by the De La Soul track and decided to investigate the lyrics more closely. Had this talented but otherwise seemingly unremarkable trio stumbled upon a secret which had so far eluded the best minds of the scientific community?

Perhaps it was a long shot. And, after reading the lyrics, I must admit I was disappointed.

At the core of De La Soul's thesis seemed to lie the idea that three was a "magic number" purely on the basis that there were three musicians in their group. Furthermore, they appeared to regard their repeated assertion that "Three is the magic number" as some sort of substitute for a testable scientific hypothesis.

So what is so special about the number three? This opening chapter will just consider the number three. Is there anything obviously remarkable about this number? Is it inherently special?

The prime number

After my initial disappointment, I returned to consider the De La Soul track and decided that perhaps there might be some truth in what they said. I came to this conclusion because, basically, it's a great track. You don't mind that their argument is unconvincing because the lyrics work in the overall context of the song. What is more, the song was a big hit, which seems to suggest that a lot of people agreed with De La Soul: the number three certainly seemed

like a plausible contender to be a magic number.

So why did the number three work in the context of the song? That question is equivalent to asking why treating the number 17, or 54, or 378.25 as the magic number simply would not work as the lyric.

"378.25, and that's the magic number." I don't think so.

Of course, an obvious answer is that the word "three" only has one syllable, whereas the phrase "three hundred and seventy eight point two five" has eleven syllables, so it simply would not fit into the rhyming structure of the line. But the word "six" has only one syllable, as does "one", "two", "three", "four", "five", "eight", "nine", "ten", or "twelve". With all these possible alternatives, why pick three as the magic number? Let us consider the properties of the number.

Firstly, three is a *natural number*, which are the numbers used for counting. For example, we might say "There are six apples on the table". The natural numbers are the non-negative integers. According to the German mathematician Leopold Kronecker: "God made the first ten numbers; the rest is the work of man." With this quote, Kronecker emphasized that the whole mighty edifice of mathematics is fundamentally based on simple numbers.

Animal bones dating back to 30,000 BC have been found with scratch marks which seem to indicate some form of early counting behaviour. This probably indicates a hunter recording his kills, or of early farmers counting livestock. It is known that shepherds frequently used pebbles to count their sheep (the word "calculate" derives from the Latin *calculus* which means "pebble"). Our natural acquaintance and use of the non-negative natural numbers for counting purposes — a direct connection with the physical world — might provide one explanation for our apparent affinity with certain natural numbers. For example, De La Soul would have been unlikely to sing "Minus five, that's the magic number".

Secondly, three is a *prime number*. It is the smallest odd prime number. A prime number cannot be divided precisely by any other number (apart from the number one). Other prime numbers include 2, 5, and 7. So clearly there are plenty of prime numbers distributed among the smaller numbers. However, the prime numbers become rarer as they get larger (because there is more likelihood of there being a smaller divisor number).

The ancient Greek mathematician Euclid proved that any natural number can be created by multiplying prime numbers together. This is called the *fundamental theorem of arithmetic*. For example, $20 = 5 \times 2 \times 2$. This reveals how the prime numbers might be considered the primordial elements from which all the numbers are constructed. Indeed, the words "prime" and "primordial" share the same root from the Greek word *primus* (meaning "first"), as does the word "primitive". This makes the prime numbers appear as if they are the fundamental building blocks of mathematics. The close link between mathematics and physics is well established. So, for this reason, we should perhaps not be surprised to find a prime number of spatial dimensions: we are dealing with one of the fundamental physical constants — the building blocks of Nature.

The fundamental nature of the primes was considered by Enrique Gracián in his book *Prime Numbers*: "In the same way that atoms combine to form molecules, prime numbers combine to form composite numbers."

Is there any reason why we might find the prime numbers intuitively more appealing? In 2014, the *Guardian* newspaper ran a poll to discover the "World's Favourite Number". After 44,000 people had voted, it was announced that the number seven was the most popular number, with the number three in second place. Both seven and three are prime numbers. Almost half the submissions were for the numbers between one and ten.

The least popular numbers were the numbers which were divisible by ten, i.e., numbers which finished with the digit zero. Perhaps those composite numbers were unpopular because they seemed rather clinical, calculated, and sterile. In contrast, the popularity of the prime numbers is possibly because they seem more fundamental, more "earthy". Indeed, in one of the quotes on the *World's Favourite Number* website (<http://tinyurl.com/numberwebsite>), one of the respondents said she deliberately chose the number seven because it was prime.

According to the mathematician Alex Bellos, who arranged the poll: "The point here is that we are always sensitive to arithmetical patterns, and this influences our behaviour — even if we are not conscious of it, and irrespective of our ability at maths."

So maybe that is the reason why De La Soul chose three to be their magic number.

The number of sufficient magnitude

Let us continue this examination of the role of the number three in our culture by examining how we express the number in our natural languages.

In his book *Receiving Aristotle in an Age of Crisis*, the professor of philosophy David Roochnik explores what he calls the "exceptional nature" of the number three: "In ordinary language, both Greek and English at least testify to the exceptional nature of the three. If my eyes hurt, and you ask me 'Which one hurts?' I will answer 'Both of them'

rather than 'All of them'. The word 'all' is first used when I have at least three items to count."

Roochnik is suggesting that three is the first number to be of sufficient magnitude to be considered as representing a significant number of objects. We find similar differences in terminology when we consider the difference between the *cardinal* numbers and the *ordinal* numbers. A cardinal number is the form of a number which is used for counting, such as one, two, three, etc. The ordinal version of the number refers to a position in a ranking system, such as first, second, third, etc. We can see that the cardinal and ordinal versions of the numbers one and two are very different: "one/first", "two/second". However, the cardinal and ordinal versions of numbers greater than two are similar: "three/third", "four/fourth", "five/fifth", etc. We find this similarity of cardinal and ordinal for numbers three (or greater than three) in other languages: French, German, and Italian. So, again, it appears that once we consider the numbers three and greater, we reach a milestone in that we are now considered to have a large multiplicity of numbers. The number three is the first number which represents a significant amount, and in language we treat it differently from the numbers one and two.

The number three certainly seems to play an important role in our culture. When a group photo is being taken, the photographer will often say "I will count to three and then take the photo", which seems to reinforce the idea that three is the first number of sufficient magnitude (counting to one or two would not provide enough time for everyone to get ready).

In baseball, three is the number of strikes before the batter is out, based on the notion that three should be a sufficiently large number of attempts for any batter. Similarly, the "Three strikes and you're out" principle has also entered the American legal system. Currently, twenty four states impose harsher sentences for a third offence. As an example, California requires a criminal who has committed three serious or violent felonies to go to prison for a minimum of 25 years (and could be as much as a life sentence). The principle behind these Three Strikes laws is that three chances are deemed to be a sufficiently large number of chances to give to any criminal. Again, we find the principle of three being a number considered to be of sufficient magnitude.

In association football (soccer) a player who scores three goals is said to have scored a *hat trick*, one of the most cherished achievements. The scoring of a hat trick is celebrated much more than the scoring of two goals or four goals, and the scorer traditionally takes the match ball home as a prize. Again, the hat trick celebration reinforces the idea of three being the first number of sufficient magnitude, and the achievement of three successes being regarded as exceptional.

This book is structured rather like a detective whodunnit. We will be considering the evidence, examining various theories, rejecting some theories while retaining some theories which show promise. And — even at this early stage — I think we have found a shred of evidence here. In many aspects of life, the number three is the smallest number which is considered suitable for performing many tasks.

In the final chapter of this book it will be proposed that one and two dimensions of space would not be sufficient to perform a particular requirement of Nature — and this will emerge as a potential solution to the question of why there are three dimensions of space.

Occam's razor

William of Ockham (or "Occam") was an 14th century English monk who was one of the major figures of medieval philosophy.

Surprisingly, one aspect of William of Ockham's work has remained influential even into the modern era. His modern fame and influence is based entirely on one phrase he wrote in Latin: *Entia non sunt multiplicanda praeter necessitatem*, which means "Entities should not be multiplied beyond necessity". This phrase is commonly known as *Occam's razor*.

So why is this particularly relevant to our attempt to discover why there are only three spatial dimensions? Well, it is relevant for the simple reason that three is certainly quite a small number. Out of all the infinity of possible numbers — some of which are inconceivably huge — why do we end up with just three dimensions? We might certainly imagine that Nature has applied Occam's razor: "Entities should not be multiplied beyond necessity."

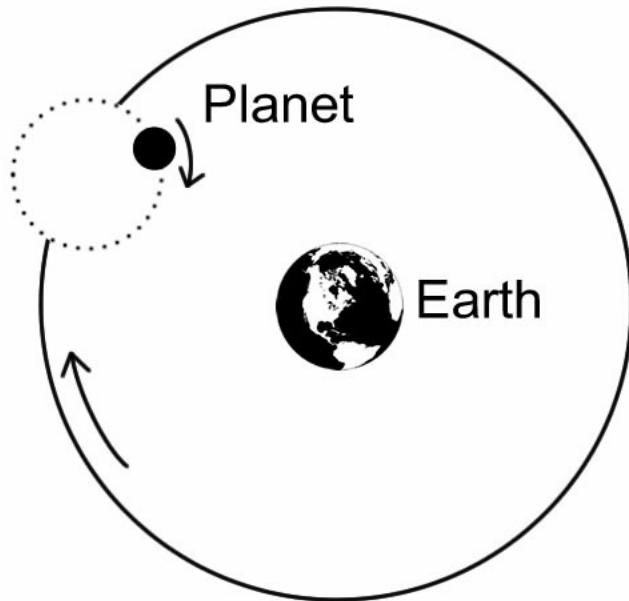

Essentially, Occam's razor is a statement in favour of simplicity. Another translation of the phrase (which is perhaps more relevant to our discussion) is: "Among competing hypotheses, the one with the fewest assumptions should be selected." Phrased in this way, Occam's razor becomes a form of guidance for physicists. It is not strictly scientific, it is not even always correct, but as a general rule it has been repeatedly shown to have value when judging the value of various hypotheses about Nature. Put simply, the simplest theory (which predicts the same results) is almost always correct. [\[1\]](#)

In many ways, physics could be seen as a drive towards simplicity. We seek the simplest explanations for the phenomena we observe. Simpler explanations reveal deeper underlying truth. And physics is (hopefully) a search for truth.

In his book *The Fabric of Reality*, David Deutsch describes how theories which are more fundamental can be both simpler and fewer in number. Deutsch says his motivation in physics is nothing less than the goal of "understanding everything". This might seem like an impossibly ambitious goal, but, as Deutsch explains, this does not mean he wants to "know everything" — Deutsch has no interest in memorizing all the facts of the world's encyclopaedias. Instead, he wants to **understand** all the reasons why the physical world works the way it does. Understanding a comparatively simple theory (for example, general relativity) can explain a multitude of facts (the precise motion and position of the stars and planets, for example). And, while it is certainly not possible to know all the facts about the world, it might be possible to know a few simple theories which explain those facts. As Deutsch says: "Confronted with this vast and rapidly growing menu of the collected theories of the human race, one may be forgiven for doubting that an individual could so much as taste every dish in a lifetime, let alone, as might once have been possible, appreciate all known recipes. Yet explanation is a strange sort of food — a larger portion is not necessarily harder to swallow. A theory may be superseded by a new theory which explains more, and is more accurate, but it is also easier to understand, in which case the old theory becomes redundant, and we gain more understanding while needing to learn less than before."

Deutsch then presents probably the classic example of this drive toward simpler theories: the move to a

heliocentric (Sun-centred) model of the Solar System. The ancient model developed by Ptolemy placed the Earth at the centre of the Solar System, and this *geocentric* model dominated for fifteen centuries. Because it was known that the motion of the planets was irregular (with the planets sometimes appearing to change direction) it was necessary to introduce the idea of *epicycles*, a smaller orbit contained within the planet's usual orbit around the Earth. Here we see a planet orbiting on its additional smaller epicycle:

The epicycle allowed the planet to sometimes move backwards when viewed from Earth. This geocentric model of the universe was dominant until the 16th century when the Polish astronomer Nicolaus Copernicus realised that the model could be greatly simplified by placing the Sun at the centre of the Solar System and having the planets (including the Earth) orbit the Sun.

Copernicus's model was simpler than the Ptolemaic model, and it not only explained the retrograde motions of the planets but it also explained why the Earth experienced the seasons as it orbited the Sun once a year. So a simpler model can explain more.

The adoption of the Copernican model was a classic example of the value of Occam's razor in practice. Its obvious simplicity when compared to the Ptolemaic model meant it was to be preferred as an explanation.

Theories can have another quality which is similar to "simplicity" and that is "beauty". Beauty is perhaps more associated with mathematical theorems, and Bertrand Russell once described mathematical beauty in the following words: "Mathematics, rightly viewed, possesses not only truth, but supreme beauty — a beauty cold and austere, like that of sculpture, without appeal to any part of our weaker nature, without the gorgeous trappings of painting or music, yet sublimely pure, and capable of a stern perfection such as only the greatest art can show. The true spirit of delight, the exaltation, the sense of being more than Man, which is the touchstone of the highest excellence, is to be found in mathematics as surely as poetry."

The great physicist (and mathematician) Paul Dirac certainly believed in the importance of beauty in physics, as he wrote in 1939: "The research worker, in his effort to express the fundamental laws of Nature in mathematical form, should strive mainly for mathematical beauty. It often happens that the requirements of simplicity and beauty are the same, but where they clash the latter must take precedence."

Nobel Prize-winning physicist Frank Wilczek has recently written a book called *A Beautiful Question* in which he wonders why the world is apparently so beautiful.^[2] Is there any reason why that should be the case? Wilczek even compares the world to a work of art, and his lavishly-illustrated book compares human artworks with beautiful structures from physics.

I was fortunate to meet Frank Wilczek recently. I congratulated him on his excellent book, and I asked him whether "beauty" was rather a subjective concept. In reply, he felt that there were clear objective standards of beauty, which had remained consistent down the ages: everyone seems to agree on "great art". He had gained a very strong appreciation for renaissance art in particular. He felt that the discovery of perspective by renaissance artists

was an example of objectivity in art: "By understanding how the same scene can appear different, depending on the viewpoint from which it is perceived, we learn to separate the accidents of viewpoint from the properties of the thing itself. By treating subjectivity objectively, we master it."

Here is a photo of me with Frank Wilczek:

According to Frank Wilczek, Nature's "artistic style" has two obsessions:

- Symmetry — a love of harmony, balance, and proportion.
- Economy — satisfaction in producing an abundance of effects from very limited means.

The importance of symmetry — and especially balance — in fundamental physics was explored in my previous book. The importance of economy — "producing an abundance of effects from very limited means" — reflects the influence of Occam's Razor.

Beauty, however, still seems to me to be rather a subjective notion to evaluate possible theories: what you might find to be a beautiful theory, I might find ugly. However, that is not the case for simplicity, because, surprisingly, it is possible to obtain a quantitative measure of the simplicity of a theory.

A measure of simplicity can be found because simplicity is the opposite of *complexity*, and there is a large body of science which deals with complexity.

How can we measure complexity (how complicated something is)? Well, consider a pattern, say, a square of black and white dots, or maybe a binary sequence or zeroes and ones. How complex would you say the pattern is? How would you measure the complexity of the pattern? Or, imagine you have two patterns, two squares of black and white dots. Which pattern would you say is the most complex? How could you decide between the two patterns?

Well, it turns out that we can measure the complexity of the patterns quite objectively. There is a measure called *Kolmogorov complexity*, which sounds quite complex in itself but is actually quite a simple and clever idea. The Kolmogorov complexity of a pattern can be found on the basis that a computer program could be used to calculate the pattern, and print out the black and white dots. As an example, if a pattern of zeroes and ones is a repeating pattern then the computer program to print the numbers would be quite short: just a few lines, with the code probably featuring a loop. For example, the repeating pattern:

```
xyxyxyxyxyxyxyxyxyxyxyxyxyxyxyxy
```

which has 32 characters could be represented by the code "xy 16 times", which only has 11 characters. This shows it is possible to compress the pattern to a smaller length, while still retaining the same amount of information.

Alternatively, if the pattern of zeroes and ones is truly a complex pattern, then the computer program needed to print the pattern could be very long. In the extreme case — for the most complicated patterns — the computer

program would be as long as the pattern. In that case, it would not be possible to make the computer program any shorter than the original pattern. The minimum length of the computer program needed to print the pattern is called the Kolmogorov complexity of the pattern. We can see that the Kolmogorov complexity describes the *compressibility* of the pattern: if the pattern can be produced by a computer program which is shorter than the actual pattern, then we can say that the pattern can be compressed to a shorter length (it can be represented by a computer program with a shorter length).

So we see we can obtain an objective measure of the complexity — or, inversely, the simplicity — of any pattern. And that is very useful for our purposes because a physics theory is, after all, nothing more than a pattern of letters when it is written down. So we can objectively measure the simplicity of any theory. This idea is expressed by the mathematician Gregory Chaitin: "This idea of program-size complexity is also connected with the philosophy of the scientific method. You've heard of Occam's razor, of the idea that the simplest theory is best? Well, what's a theory? It's a computer program for predicting observations. And the idea that the simplest theory is best translates into saying that a **concise** computer program is the best theory. What if there is no concise theory, what if the most concise program or the best theory for reproducing a given set of experimental data is **the same size** as the data? Then the theory is no good, it's cooked up, and the data is incomprehensible, it's random. In that case the theory isn't doing a useful job. A theory is good to the extent that it compresses the data into a much smaller set of theoretical assumptions. The greater the compression, the better!"

So whereas it is impossible to objectively measure the **beauty** of a physics theory (your idea of beautiful might be my idea of ugly), it is possible to objectively measure the **simplicity** of a theory.

The natural number

There are a many important constants (special numbers) in mathematics, some of which are quite famous. Perhaps the most famous of the mathematical constants is pi (π) which is the ratio of a circle's circumference to its diameter, and has the approximate value 3.14159. Other important mathematical constants include Euler's number (e) which has the approximate value 2.718, and the golden ratio which has the approximate value 1.618. For a full list of these constants, refer to the Wikipedia page on "Mathematical constants". [\[3\]](#)

If you consider the list of mathematical constants on the Wikipedia page, you might discover something surprising: almost all of the constants have a value quite close to one. The largest constant listed is the Feigenbaum constant which has an approximate value of 4.669. So none of the listed constants have large values of the order of 10,000, or several million. This is a known fact about the mathematical constants: they tend to be close to one. This is a very useful fact as far as physicists are concerned.

These mathematical constants can often be produced by an infinite series of calculations, each calculation producing a more accurate result. For example, in 250 BC the Greek mathematician Archimedes realised that pi could be approximated by fitting a regular polygon inside a circle, and then adding up the lengths of all the sides of the polygon. The more sides the polygon has, the closer to pi the approximation becomes:

So why are the values of these mathematical constants close to one? Well, if you consider the form of these infinite series used to calculate the mathematical constants, you will find that the first term in many of these series is the number one. For example, one infinite series which can be used to calculate pi is:

$$\frac{\pi}{4} = 1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \frac{1}{9} \dots$$

and an infinite series to calculate Euler's number, e , is:

$$e = 1 + \frac{1}{1!} + \frac{1}{2!} + \frac{1}{3!} + \frac{1}{4!} \dots$$

and an infinite series to calculate the golden ratio, ϕ , is:

$$\phi = 1 + \frac{1}{1 + \frac{1}{1 + \frac{1}{1 + \dots}}}$$

You will see that the first term in all of these infinite series is the number one (with the following terms becoming progressively smaller). So we can see how the mathematical constants are frequently derived from the number one, and so tend to have low values. This was described by Einstein in a letter to an old student friend, Ilse Rosenthal-Schneider (you will note how he refers to the calculation of Euler's number, e , using the infinite series we considered earlier): "I see from your letter that you did not grasp my hint about the universal constants of physics. I will therefore try to make the matter clearer. Basic numbers are those which, in the logical development of mathematics, appear by a certain necessity as unique individual formations. For example:

$$e = 1 + \frac{1}{1!} + \frac{1}{2!} + \frac{1}{3!} + \frac{1}{4!} \dots$$

Einstein continues: "It is the same with π , which is closely connected with e . In contrast to such basic numbers are the remaining numbers which are not derived from 1 by means of a perspicuous construction. It would seem to lie in the nature of things that such basic numbers do not differ from the number 1 in respect of the order of magnitude, at least as long as consideration is confined to 'simple' or, as the case may be, 'natural' formations."

There are constants in physics as well, for example, the speed of light, or the gravitational constant. It is clear that these values can quite possibly have extremely huge (or small) numerical values depending on the units selected to express the constant. For example, the speed of light is the extremely large value of 3×10^8 m/sec. However, if we choose a different unit — for example, using kilometres as the unit of length instead of metres — then we get a smaller number: 3×10^5 km/sec (note the change of unit). So by choosing different units, we change the numerical value of the physical constant.

However, there are some constants in physics which are just plain numbers, i.e., they have no associated units.

One of the most famous is the *fine structure constant*, which is related to the strength of the electric charge and has the numerical value of $1/137$ (note: in this case there are no units involved — it is just a number). So these values always stay the same — irrespective of units (because they have no units). Even a civilisation of aliens in a different galaxy would calculate exactly the same numerical value for these constants. That makes them particularly interesting for a physicist as they seem to reflect very deep truths about Nature.

Because mathematical constants tend to be close to one, there is justification to expect the physical constants (which — at the lowest level — are surely derived from the mathematical constants in some way, via some mechanism) to also be close to one. (Remember: this is only true for physical constants which are not expressed in any particular units).

So we are entitled to expect any physical constants (which are not expressed in units) to be close to the number one. This principle is called *naturalness* (and the physical constants are then said to be *natural*).

This insight into the importance of naturalness is generally ascribed to Einstein, and it was described in his only publication on the subject in the German journal *Annalen Der Physik* in 1911: "The unit-free numerical factors, whose magnitude is only given by a more or less detailed mathematical theory, are usually of the order of unity. We cannot require this rigorously for why shouldn't a numerical factor like $(12\pi)^3$ appear in a mathematical-physical deduction? But without doubt such cases are rarities."

This extremely fortuitous principle has proven to be a useful tool for physicists. As John Barrow explains in his book *The Constants of Nature*: "In every formula we use to describe the physical world, a numerical factor appears ... which is almost always fairly close in value to 1 and they can be neglected, or approximated by 1, if one is just interested in getting a fairly good estimate of the result."

Conversely, if we encounter any physical constants which are very far from the value of one, then we should suspect that we are not at the fundamental level, and we are missing some deeper mechanism. Our formula is not describing a fundamental process. There is some additional fundamental behaviour which needs explaining because it is not being captured by our formula. We need to dig deeper.

And, of course, this entire book is based on one particular constant which requires no units, and that is the number of dimensions of space. The number three, used merely for counting in this way, is just a number. It is not three metres, or three seconds, or three kilograms. It has no units. It is just three. It is just a number. And, on the basis of Einstein's insight, this is precisely what we should expect to find. Three is a **natural** result for the number of dimensions. It is natural because it is a number close to one. The closer to one, the better, the more in line with our expectations.

So, by arguments purely based on naturalness, we should not expect there to be 10,000 dimensions of space. We should not expect there to be 100 dimensions of space. It might be argued that we should not even expect to find ten dimensions of space.

However, even without knowing the precise underlying mechanism which generates the dimensions, we would expect there to be (approximately) three dimensions. Certainly, we would expect a number close to one. Our task is then to discover the fundamental mechanism which naturally produces that result.

The Standard Model of particle physics is our best model of the physical world and has been tested to remarkable accuracy. However, there remains approximately 20 unit-free constants in the Standard Model which appear to have arbitrary values which have to be set on the basis of experimental ("empirical") measurement. Einstein believed that the presence of these arbitrary constants reveals our theory is not truly fundamental: "In a reasonable theory, there are no unit-free numbers whose values are only empirically determinable. Of course, I cannot prove this. But I cannot imagine a unified and reasonable theory which explicitly contains a number under which the whim of the Creator might just as well have chosen differently, whereby a qualitatively different lawfulness of the world would have resulted."

So, how can these arbitrary constants be eliminated, thus creating a theory which is more fundamental? This is possible if we strive to create more natural theories. If all arbitrary constants in a theory have a value which is close to one, then those arbitrary constants effectively disappear (because multiplying by one is equivalent to not multiplying at all: the original term remains unchanged). So a natural theory is a simpler theory: it would have fewer arbitrary constants. We can therefore think of naturalness as arising from Occam's razor: the simplest theories are more natural. [\[4\]](#)

Occam's razor and the principle of naturalness are therefore closely related, and it appears that both act to drive down the number of spatial dimensions to a low value. Working in the opposite direction, we find the principle that three is the first "number of sufficient magnitude" to perform a certain task — which acts to drive up the number of spatial dimensions (as shown in the following diagram).

On that basis, our quest to discover why there are three dimensions becomes a quest to discover why one and two dimensions of space would not be sufficient to perform a particular requirement of Nature. We will be returning to this theme in the final chapter of the book.

So is three really a magic number, as De La Soul suggested? Well, it's starting to look like, yes, De La Soul might have been onto something after all.

2

DIMENSIONS

When we say there are three dimensions of space, what exactly do we mean? What is a dimension? This question will be answered for the specific case of the spatial dimensions, but then a more general concept of a "dimension" will be introduced.

Put simply, the three spatial dimensions refer to the usual concepts of depth, width, and height. We can specify a position in three-dimensional space using three coordinates:

In the previous diagram, you will see that the dashed arrow points to a point in space which is a distance x along the horizontal axis, and is a distance y along the vertical axis, and a distance z along the axis which is coming out of the page. We can therefore define the position of the point by a list of its coordinates: (x, y, z) .

It is possible to consider spaces which do not have three dimensions. For example, position on a flat plane (such as graph paper) could be described by just two coordinates: x and y . Hence, a flat plane would represent a two-dimensional space. Position on a line could be represented by just a single coordinate: the length along the line. Hence, a line represents a one-dimensional space. We can see that the number of coordinates required to define a point determines the number of dimensions.

No matter what the number of dimensions, it is important to be able to measure the distance between two points. A formula which can be used to calculate distances is called a *metric*. Let us first consider space with just two dimensions, described by two coordinates: x and y . In that case, the following diagram shows that travelling from point A to point B necessitates travelling a distance x horizontally, and a distance y vertically:

This forms a right-angled triangle, so from Pythagoras's theorem we could calculate this distance as the square root of x^2 plus y^2 . So this gives us our metric on a flat two-dimensional plane:

$$d = \sqrt{x^2 + y^2}$$

As shown in the earlier diagram of three-dimensional axes, it is easy to extend this metric to three-dimensional space just by adding the extra z coordinate:

$$d = \sqrt{x^2 + y^2 + z^2}$$

Even though we cannot visualize spaces with more than three spatial dimensions, it is very easy to describe them mathematically: we simply add extra coordinates to our list which describes a point. For example, a point in a four-dimensional space might be described by (w, x, y, z) . Once, again, the number of coordinates determines the number of spatial dimensions.

The metric for that four-dimensional space is also easily generated by adding another coordinate:

$$d = \sqrt{w^2 + x^2 + y^2 + z^2}$$

OK, so that is a basic description of the concepts involved when we describe spatial dimensions. But we have not yet considered the crucial question ...

What is a dimension?

We all have an instinctive understanding of space which allows us to move freely, avoiding obstacles, and performing everyday tasks such as driving a car. Unfortunately, this very intimate connection we have with space — acquired over millions of years of evolution — makes it very difficult for us to stand back and be objective about the nature of space. We all live inside space — we cannot observe it from outside. So we find it very difficult to be objective when answering the question "What is a spatial dimension?"

However, one of the most important skills of being a good physicist is to be able to ignore our human

preconceptions and intuitions, and to have an open analytical mind, able to consider the data in an objective manner. And when we apply that objectivity to the subject of space and dimensions, we realise that the spatial coordinates of an object, (x, y, z) , just represent properties of that object, just as the colour of an object is another example of the property of an object. Each coordinate represents a dimension of space; each coordinate represents a way in which an object's properties can be modified. We may interpret variation of those spatial coordinates as "an object moving around in space", but that interpretation gains us nothing more than just considering the variation in the positional property of an object. If an object moves, its positional property varies. Likewise, if an object changes colour, its colour property varies.

I particularly like the following quote from the German philosopher Hans Reichenbach which makes it clear how all an object's properties can be treated as dimensions, with no distinction between space and colour: "Let us assume that the three dimensions of space are visualized in the customary fashion, and let us substitute a colour for the fourth dimension. Every physical object is liable to changes in colour as well as position. An object might, for example, be capable of going through all shades from red through violet to blue. A physical interaction between any two bodies is possible only if they are close to each other in space as well as in colour. Bodies of different colours would penetrate each other without interference. If we lock a number of flies into a red glass globe, they may yet escape: they may change their colour to blue and then be able to penetrate the red globe."

So, if we can treat a dimension as a range of property values, then we can also treat a range of property values as a dimension. For example, let us continue this theme of treating colour as a property which can be expressed as a dimension. It is the case that any colour can be generated by mixing together various amounts of red, green, and blue primary colours (this is how a computer monitor can generate any colour: each point on the screen is composed of microscopic red, green, and blue dots). So we can represent any single colour — yellow or purple, for example — as particular combinations of red, green, and blue. Hence, any colour can be represented as a point in a three-dimensional space, with the three axes of that space representing the three primary colours. As Frank Wilczek says in his book *A Beautiful Question*: "We can specify any perceived colour by saying how much red, how much green, and how much blue it takes to match it. This is completely analogous to how we can specify a place in space by saying how far it is in the north-south, east-west, and vertical directions. Ordinary space is a three-dimensional continuum, and so is the space of perceived colours."

Continuing this theme of treating property values as a dimension, Lisa Randall gives several examples in her book *Warped Passages*: "When you peg someone down as one-dimensional, you actually have something rather specific in mind: you mean the person has only a single interest." Lisa Randall presented the example of Sam, who sits at home all day watching sports on TV. The number of hours Sam watches TV could be represented as a point in a one-dimensional space.

Let us consider a similar example. Let us consider a book with a certain number of pages. Again, the book can be represented as a point in a one-dimensional space:

Let us now consider a second book-related property: the colour of a book's cover. This can be represented as a point in a continuous spectrum of all possible colours. The following diagram shows a book with a green cover represented by a point in a different one-dimensional space:

There is clearly a unifying theme behind these two one-dimensional properties: they can both refer to a single book. So let us combine these two properties, forming a two-dimensional space:

From the previous diagram, it can be seen how a book can now be completely described by a single point in a two-dimensional space (instead of previously being described by two separate points in two different one-dimensional spaces). From that single point in the previous diagram, you can see that we can determine that the book has fifty pages, and has a green cover.

So it is possible to unify two different descriptions by creating a higher-dimensional space, and we shall see later in this book how this method of unification has become very popular in physics.

Considering the book example, this is all well and good: the unification of page count and cover colour was based on a single underlying entity (a book), and so the unification made good logical sense. However, it is very easy to apply this technique to any two different descriptions — even if they have nothing in common! Mathematically, we can combine any two descriptions into a single higher-dimensional space, and the result will be valid. But, in physics, the big question is whether it is legitimate to perform the unification in this way. Does the unification represent a true underlying connection? Does there exist an object which logically combines the two descriptions? Or are we artificially "glueing" the two descriptions together, with no actual basis in reality?

As an example, we might count the number of wings on an animal (for example, a bird has two wings, but a bumblebee has four wings), and we might count the number of tentacles on an animal (for example, an octopus has eight tentacles, but a jellyfish can have more than a hundred), and represent these two descriptions (wings and tentacles) as two points in two different one-dimensional spaces. However, we could then "glue" those two descriptions together to form a single point in a two-dimensional space. That single point would tell us the number of wings on a particular animal, **and** the number of tentacles on that animal — we have unified two apparently completely different descriptions!

That might appear to be a great achievement, however, this is a totally artificial approach as the combined two-dimensional object — a "flying octopus" — does not exist in Nature.

As we shall see later, this unification approach in physics using higher dimensions has become very popular. As we have just seen, it is an easy way of achieving an impressive result — almost too easy. Basically, we can unify any two properties using higher dimensions. But we have to ask ourselves, while the resultant unification might be valid mathematically, does it have physical relevance?

Or are we just making flying octopuses?

Spacetime

One example of this type of unification is the "glueing" together of three-dimensional space and one-dimensional time in order to produce a higher-dimensional four-dimensional *spacetime*. It was actually Einstein's former mathematics tutor at the Zurich Polytechnic — Hermann Minkowski — who realised that it made sense to combine space and time to form spacetime. Minkowski realised that his former pupil's theory of special relativity indicated that time and space were not independent entities, but in fact motion through space could affect motion through time (famously, the astronaut who flies away from Earth at a speed close to the speed of light will find — when he returns to Earth — that he has aged less than someone who remained on Earth).

As Hermann Minkowski said: "Henceforth space by itself, and time by itself, are doomed to fade away into mere shadows, and only a kind of union of the two will preserve an independent reality."

The "glueing" together of the space and time dimensions to form a four-dimensional spacetime is valid because there exists a physical entity which must be described by **both** a point in space **and** a point in time. That physical entity is the *event*. We are used to dealing with events in everyday life: a public meeting might be advertised at occurring at a certain venue at a certain time. The meeting is therefore described by an event incorporating space and time. But even at the level of fundamental particle physics we have to deal with events: the decay of a particle can only be described by both the position of the particle and the time at which the particle decay occurred. So the concept of the event has genuine physical significance. Hence, we are most certainly not creating a "flying octopus" — a unification with no physical significance — when we glue together space and time.

Absolute space

Let us now consider a concept which was introduced by Isaac Newton in the *Principia* which has implications for our quest to determine why there are three dimensions of space (or, equivalently, four dimensions of spacetime). As described in my first book, Newton was a firm believer in *absolute space*, the idea that space took the form of a permanent grid-like background inside which objects could move:

Essentially, absolute space represents a three-dimensional "box". Even if all the matter in the entire physical universe was removed, Newton believed absolute space would still exist as an entity in its own right. This certainly has consequences for our quest into the origin of three dimensions: is there a pre-existing three-dimensional "box"?

However, Newton's idea of absolute space has been categorically refuted. Instead, it is now accepted that individual observers — moving at constant velocity — can define their own *inertial frame of reference*, essentially defining their own set of coordinate axes. And the principle of relativity tells us that the laws of physics are the same for all observers — regardless of their velocity. Hence, every observer's frame of reference is equally valid: there can be no single definition of absolute space which can apply to all observers. An equivalent argument is that absolute space could be used to determine if an observer was absolutely stationary, but relativity tells us that there is no experiment which can distinguish between being stationary and moving at constant velocity.

Instead of absolute space, Newton's great rival Gottfried Leibniz proposed that space must be relative, with spatial positions emerging from the relationships between the objects within the universe:

In the model of relative space, space emerges from the properties of the objects **within** the universe. I believe this is an important clue in our quest to discover why there are three dimensions of space: we should expect three-dimensional space to **emerge** from the properties of the objects (fundamental particles) which compose the universe, rather than expecting the dimensions to already exist as some absolute background three-dimensional axes.

We will be returning to this theme in the final chapter.

3

THE GEOMETRY OF THREE DIMENSIONS

In this chapter, we will be considering the geometry of three-dimensional space. Is there anything particularly special about three-dimensional geometry? Does it possess any particular properties which are not shared by geometries in other numbers of dimensions?

Let us start by considering *polygons*. A polygon is simply a shape composed of a connected sequence of straight lines forming a loop. A rectangle is an example of a polygon with four sides. The simplest polygon which can exist is the triangle with three sides (again: the magic number). Bearing this in mind, perhaps the number three is the smallest allowable number which can represent the existence of a physical body? A "number of sufficient magnitude"? The triangle is also the most stable physical shape which is widely used in construction and design, perhaps most notably in the *geodesic dome*. The geodesic dome is the most stable structure which can be produced from the least amount of materials.

Does Nature take advantage of the strength of this triangle-based design principle? We will find out later.

Of particular interest are the *regular polygons*. These are polygons which have all sides equal, and all angles equal. A square is the regular polygon with four sides, and the equilateral triangle is the regular polygon with three sides.

The following diagram shows the regular polygons with three, four, five, and six sides (including the regular pentagon and the regular hexagon).

Interestingly, there are only three possible ways to tile a plane using regular polygons. The following diagram shows how this can only be achieved by using equilateral triangles, squares, and regular hexagons. Any other type of regular polygon (for example, a regular pentagon or regular octagon) cannot tile the plane.

So there is that magic number again: the number three.

The Platonic solids

Let us now move from two dimensions into three dimensions. A three-dimensional object which is built from connected polygons is called a *polyhedron* (plural: *polyhedra*). As an example of a polyhedron, a cube can be constructed from six squares, one square on each face. A polyhedron which is constructed purely from regular polygons is called a *regular polyhedron*. Only five regular polyhedra exist in three-dimensional space. These are the tetrahedron, the cube, the octahedron, the dodecahedron, and the icosahedron. These five regular polyhedra are shown in the following diagram:

Tetrahedron
(4 faces)

Cube
(6 faces)

Octahedron
(8 faces)

Dodecahedron
(12 faces)

Icosahedron
(20 faces)

These five regular polyhedra — the only regular polyhedra which exist — have been known since antiquity. They are more commonly known as the *Platonic solids*, named after the ancient Greek philosopher Plato. Plato considered these objects to be perfect forms, inhabiting a special realm of mathematical perfection. In contrast, all physical objects on Earth — such as balls and rough cubes — could only ever be approximations of these perfect mathematical forms.

Interestingly, Platonic solids appear in the natural world. As an example, the shape of *radiolaria* — single-celled marine life — can take the form of a regular icosahedron:

So, in radiolaria, we find an example of Nature taking advantage of the strength of a triangle-based design, just like the geodesic dome we considered earlier. In his book *A Beautiful Question*, Frank Wilczek considers the design of the herpes virus, which is another Platonic solid. He suggests that this is an example of the simplicity of Occam's razor: "This is a case of simplicity giving the appearance of sophistication, or more precisely of simple rules giving rise to apparently complex structures that on reflection become ideally simple. The point is that the DNA of viruses, which must instruct them in all facets of their existence, is very limited in size. To economise on the length of the construction manual, it helps to make your product from simple, identical parts, identically assembled. Because the part generates the whole, the virus does not need to know about dodecahedra, or icosahedra — but only about triangles, and a rule or two for latching them together."

Because all the faces of a Platonic solid are exactly the same, they are often used to make dice. As each face is identical, there is an equal chance of each face being selected. Hence, the dice are perfectly fair. You have surely seen a cube used to make dice, but the other four Platonic solids are also used to make dice for role-playing games:

As there are only five Platonic solids, there can only ever be these five fair dice.

In the 16th century, the German astronomer Johannes Kepler created a model of the Solar System in which the orbits of each of the then-known five planets related to one of the five Platonic solids. In Kepler's model, the Platonic solids were placed inside each other, and the outer edges of the solids was supposed to provide the correct orbital distance of the related planet. Again, this is based on Plato's idea of the Platonic solids representing some ideal form. The following diagram shows Kepler's model:

Kepler abandoned this idea as it was not accurate enough, but he did later calculate the formula for the correct motion of the planets, which was based on elliptical orbits.

The Platonic solids in higher dimensions

So far, we have considered geometry in two and three dimensions. However, as discussed in the previous chapter, we can consider the geometry of any number of dimensions. Of particular interest to us is the construction of Platonic solids in spaces with more than three dimensions. It is impossible to visualise such structures, but their construction follows the same rules as the construction of the Platonic solids in three dimensions: every side has to be a regular polygon, and every angle has to be the same.

What is particularly interesting is the number of Platonic solids which can exist in spaces with different numbers of dimensions. We have seen that only five Platonic solids exist in three-dimensional space. Perhaps it might be imagined that spaces with higher numbers of dimensions would permit greater numbers of Platonic solids to exist, but this is not the case.

We have just considered the three-dimensional case, with only five regular polyhedra — the Platonic solids — being possible in three dimensions.

As we move to consider greater than three dimensions, the polyhedra are now given the name *polytopes*. In four dimensions, it turns out that there are six regular polytopes. This is perhaps not very surprising: we have added another dimension, and discovered one extra regular polytope.

However, as soon as we go beyond four dimensions, the sequence changes completely. In five dimensions, there are only three possible regular polytopes. In six dimensions, there are — again — only three possible regular polytopes. In fact, for every number of dimensions greater than four, there are only three possible regular polytopes.

The mathematical physicist John Baez has considered the possible implications of this remarkable fact on his website: "You might think things would keep getting more complicated in higher dimensions. But it doesn't! Four

dimensional space is the peak of complexity as far as regular polytopes go. From then on, it gets pretty boring. This is one of many examples of how four dimensional geometry and topology are more complicated, in certain ways, than geometry and topology in higher dimensions. And the spacetime we live in just happens to be four-dimensional. Hmm." [5]

In that last sentence you can see that John Baez clearly considers it possible that this result has some significance as to why there are four spacetime dimensions. I also think this is a significant result, but only in a general sense. As John Baez says, it shows that the geometry of three and four dimensions has particularly interesting properties which are not shared by the higher dimensions. Cambridge University physicist John Barrow has published a comprehensive review paper entitled *Dimensionality* (a link is in the footnote[6]). In *Dimensionality*, Barrow examined the mathematical properties exhibited by the lower numbers of dimensions, "examining whether or not 3 and (3+1) dimensions lead to special results in pure mathematics. Remarkably, it does appear that low dimensional groups and manifolds do have anomalous properties."

We will be returning to consider the special geometrical properties of three-dimensional space in the final chapter, where we will be uncovering what I believe to be the truly important unique property possessed by three-dimensional space, and the reason why space must have three dimensions.

The stability of orbits

It is surprising that the three-dimensional geometry of space plays a central role in many equations in physics, in ways that are not immediately obvious. As an example, we can consider Newton's formula for the attractive gravitational force, F , between two masses, m_1 and m_2 :

$$F = \frac{Gm_1m_2}{r^2}$$

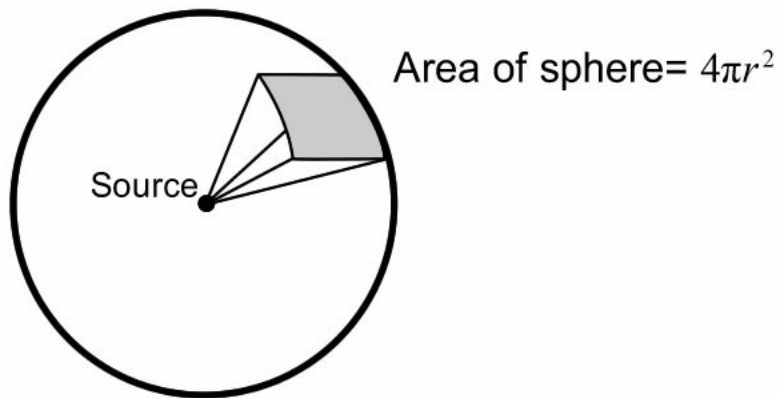

where G is the gravitational constant.

You will see that the distance between the two masses, r , is on the bottom line of the fraction. This means there is an inverse relationship between the strength of the gravitational pull between the two objects, and the distance between the two objects: if the objects are closer (the distance is smaller) then the force of attraction is larger, and if the objects are further away (the distance is larger) then the attraction is smaller. But what is particularly interesting is that in the equation, the distance r is squared.

In her book *Warped Passages*, Lisa Randall describes this effect: "It is known as an *inverse square law*, which means that the strength of gravity decreases with distance proportionally to the distance squared. For example, if you double the distance between two objects, the strength of their gravitational attraction goes down by a factor of four."

Why is the distance squared? In the case of inverse square laws we can see a very clear logic determining why these formulas have that form, and it is due to the three-dimensionality of space.

We can imagine a mass as being a "source" of a gravitational field, and a second mass will be attracted to that first mass of the basis of the strength of that field in the immediate locality of the second mass. We can also imagine a spherical region of space, with the source mass at the centre of that spherical region:

The gravitational attraction from the source mass is clearly going to be distributed evenly around the spherical region. As we move further away from the source mass, we can see that the spherical region will grow larger (the sphere will be larger). Hence, the influence of the source mass will become more and more diluted the further the distance from the source mass. So this is the true reason why gravity becomes increasingly weaker with distance.

The formula for the area of a sphere is $4\pi r^2$, where r is the radius of the sphere. So the sphere area — and hence the rate at which gravity weakens — is proportional to the square of the distance from the source mass (the square of the radius of the sphere). So now we see the true origin of the inverse square law of the force of gravity: it is caused by the dilution of the effect of the source as it radiates into three-dimensional space. And because of the purely geometrical nature of this effect, the inverse square law also applies to many other phenomena such as the weakening of an electric field, or light, or sound.

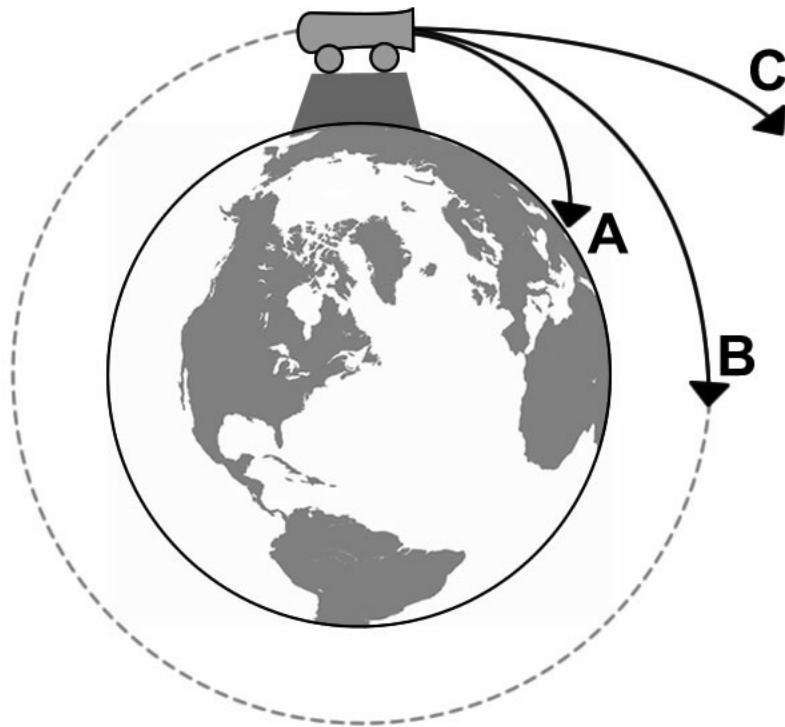

As Lisa Randall says in *Warped Dimensions*: "The way in which the gravitational force law depends on distance, which is encoded in Newton's inverse square law, is intimately connected to the number of spatial dimensions. This is because the number of dimensions determines how quickly gravity diffuses as it spreads out into space."

But what if there are more than three dimensions of space? For example, what if there were four dimensions of space? In that case, gravity would no longer be described by an inverse square law, instead it would be described by an inverse cube law. This would result in the force of gravity varying with distance at a greater rate: in four dimensions, gravity would become very much stronger if objects moved closer together, and would become very much weaker if objects moved further apart. This effect would become even more pronounced if there were more than four spatial dimensions. [7]

We will now consider the important consequences of this fact for the stability of the planetary orbits (such as the orbit of the Earth around the Sun).

It was Isaac Newton who first realised that objects could be placed into stable gravitational orbits. Newton came to this conclusion by considering an ingenious thought experiment which is now known as *Newton's cannonball*.

Newton imagined an enormous cannon on top of a very high mountain. The cannon is aimed in a direction which is perfectly parallel to the Earth's surface (see the following diagram). Newton realised that if the cannon fired a cannonball at a low speed then it would reach the surface of the Earth after having travelled just a few miles, following trajectory A in the following diagram. Newton also realised that if the cannonball was fired at a tremendously high speed then it would travel straight into space along trajectory C. Newton's great insight was that there had to be an intermediate speed between those two velocities which would result in the cannonball following trajectory B in the following diagram:

You can see from the diagram that if the cannonball follows trajectory B it will travel on a course which will take it completely around the Earth back to its starting point. Hence, that cannonball could be placed into a perpetual stable orbit around the Earth.

The speed at which the cannonball (or any object) must be fired to remain in that orbital path is called the *orbital velocity*.

Let us now consider the forces involved when an object is in orbit. Let us consider a satellite — for example, the International Space Station — in orbit around the Earth. I suspect it is generally believed that satellites such as the International Space Station stay in orbit in space because gravity is virtually non-existent in space, so satellites are weightless. This is most certainly not the case. The International Space Station is in orbit only 250 miles above the surface of the Earth. I live in the west of Britain, which is not a large country, but I am frequently nearer the International Space Station than I am to London. At that low height, the force of gravity is only slightly weaker than it is on the Earth's surface (the strength is actually 88% of the strength of gravity on the surface of the Earth). If you dropped an object from that height, it would most certainly fall toward the Earth at great speed.

No, the reason the International Space Station (and all other satellites) stay in orbit is because they are travelling so fast — as anyone who has seen the International Space Station shooting across the night sky will agree.^[8] The International Space Station is travelling at 17,100 mph. As you know, if you have a heavy bucket attached to a rope, and you swing the bucket around yourself, it will feel as if the bucket is pulling on the rope. This apparent outward force is called *centrifugal force*.^[9] It is this force which holds the satellite in orbit above the surface of the Earth. The formula for the value of the centrifugal force, F , is:

$$F = \frac{mv^2}{r}$$

where m is the mass of the orbiting object, v is the velocity of the object, and r is the orbital radius.

Now let us consider the stability of an orbit. What would happen if the International Space Station slowed

slightly, maybe after being hit by a rock? This would result in a considerable reduction of centrifugal force which, as we see from the formula, is proportional to the square of the velocity of the satellite. Gravity remains as strong as ever, so would this reduction in centrifugal force result in the satellite rapidly plummeting to the Earth, in an ever-accelerating descent? In other words, is the orbit unstable?

Well, the quick answer is no. And this is because of the law of conservation of angular momentum. The formula for angular momentum, L , is given by:

$$L = mvr$$

so:

$$v = \frac{L}{mr}$$

This formula shows that as the radius of the orbit gets smaller, the velocity increases (given that angular momentum is conserved: the value of the L term stays constant). This is the same principle as an ice skater spinning on the spot, who brings their arms in closer together in order to spin faster.

The smaller radius brings greater speed, and it is this greater speed which saves the International Space Station from plummeting to its doom.

Let us substitute this value of v into the earlier formula for centrifugal force to get:

$$F = \frac{m}{r} \left(\frac{L}{mr} \right)^2 = \frac{L^2}{mr^3}$$

This shows that the value of the centrifugal force varies as the inverse **cube** of the distance, r . But we know that gravity only varies as the inverse **square** of the distance. So as the satellite moves closer to the Earth, gravity

increases — but the centrifugal force increases quicker. Hence, at a certain distance, the value of the centrifugal force will increase so that it balances gravity again. The International Space Station will be saved!

This analysis has shown that orbits are stable: a slight variation in velocity will not result in a satellite plummeting downwards.

However, as explained earlier, the strength of gravity is strongly dependent on the number of spatial dimensions. So this result suggesting the stability of orbits is only applicable in three dimensions. As explained earlier, if there are more than three dimensions then gravity becomes very much stronger as objects move closer together. This effect would overwhelm the increase in centrifugal force, so nothing could prevent gravity from pulling the satellite to its doom.

In other words, orbits are only stable in three dimensions.

Anthropic theories

The stability of orbits might just be regarded as a fortuitous consequence of three-dimensional space. However, the stability of orbits also has a surprising interpretation: it appears to mean that life can only develop in three-dimensional space. As John Barrow said in *Dimensionality*: "If hundreds of millions of years in stable orbit around the Sun are necessary for planetary life to develop then such life might only develop in a three-dimensional world."

This restriction is also the case for fewer than three dimensions. Max Tegmark, a physicist at MIT, has suggested that intelligent life could not exist in only two dimensions of space because "two nerves cannot cross."^[10] This theme was continued in John Barrow's book *The Constants of the Universe* in which he considered the difficulties of life in two dimensions. For example, a two-dimensional creature would be split into two pieces by its digestive system:

If you are not convinced that the evolution of intelligent life requires the existence of planets in stable orbits, perhaps you might be convinced by the fact that the three-dimensional restriction also applies to the orbits of electrons around the atomic nucleus. Atoms simply could not exist if there were more or less than three dimensions of space. How could life develop in a universe with no atoms? With no chemistry? As John Barrow says: "If we assume the structure of the laws of physics to be independent of the dimension, stable atoms, chemistry, and life can only exist in fewer than four spatial dimensions."

Because of life's apparent requirement for three-dimensional space, in 1955, the English cosmologist Gerald Whitrow was the first to propose a radical idea.^[11] Whitrow considered the stability of orbits and realised that the evolution of life would have been impossible if the universe had not permitted stable orbits. For this reason, Whitrow proposed that the universe **had** to have three dimensions, for the simple reason that life could not have evolved in any other type of universe, and so we simply would not exist in order to observe the universe. Whitrow's

idea has come to be known as the *anthropic principle*.

It is the case that several other crucial fundamental constants — most notably the *cosmological constant* — appear to be set to life-friendly values. According to the basic form of the anthropic principle, we should not be at all surprised that that is the case. After all, it could be no other way.

In its most basic sense, the anthropic principle merely states the obvious: the universe clearly has to be amenable to life (with the fundamental constants set to life-friendly values) or else we simply would not exist, and so would not be observing the universe. It is virtually impossible to disagree with this form of the anthropic principle, which should be regarded as a tautology.

However, there is a complicating factor. As it appears to be the case that the fundamental constants could conceivably possess values which are not life-friendly, then the emergence of a life-friendly universe appears to be an extremely fortuitous coincidence. And physicists instinctively don't like coincidences. Coincidences appear to indicate some deeper — or external — unknown mechanism.

In an attempt to explain-away the coincidences, some physicists have proposed a particularly controversial version of the anthropic principle. It has been suggested that there are many separate universes — forming a *multiverse* — with the fundamental constants being set to different values in each individual universe. Hence, we should not be surprised to observe life-friendly conditions in our universe.

This version of the anthropic principle eliminates the coincidences: we just happen to inhabit one of many different universes, a universe which must have life-friendly conditions. But there is clearly a price to be paid in terms of the proposed (and unobserved) multiverse of many (possibly an infinity) different unobserved universes. For this reason, you might imagine that this strong form of the anthropic principle would be generally unpopular, generating little interest.

However, for many physicists, and in many particular areas of fundamental research, quite the opposite has happened. Not only has the strong anthropic principle been welcomed, but it is seen as being capable of providing an explanation for many intractable problems: "Why are there three dimensions of space? Because there are an infinity of universes with different numbers of dimensions of space, and humans could have only evolved in one of those universes which had three dimensions."

On that basis, the anthropic principle solves everything! We might as well retire from physics and spend the rest of our lives down the beach. There are no more problems to be solved.

However, I hope you realise that this forms a very unsatisfactory form of "explanation". Indeed, it does not really resemble an explanation at all, not in the true sense of conventional analytical physics. In his book *The Trouble with Physics*, Lee Smolin regrets the adoption of the anthropic principle by some physicists: "because it has been understood for some time that it is a very poor basis for doing science." Joseph Conlon includes a memorable criticism in his book *Why String Theory?:* "While the anthropic principle is not vacuous, it can be seductive. It offers the dangers of the open cookie jar at Fat Camp — the soft route of easy temptation. It also encourages a solipsistic attitude to science. For example, I could ask why the Cuban missile crisis did not end in mutual assured destruction, with a nuclear conflagration that destroyed the world. If I felt sufficiently brazen, I could respond that the answer is the anthropic principle. If a nuclear war had occurred in 1962, my parents are unlikely to have met a decade later, and I would never have been born in 1981. However, many would feel that the fact that I am right now contemplating the marvel of my own existence is not a satisfactory explanation for why Kennedy and Khrushchev managed to avoid taking their respective nations to war."

For this book, I conducted a survey of existing theories as to why there are three dimensions of space. And, unfortunately, I have to say that the anthropic approach dominates these theories. As well as the previously-discussed stability of orbits, other examples of these anthropic theories include:

- In space with four or more spatial dimensions, all stars either collapse into black holes, or disperse. And no stars means no people. [\[12\]](#)
- Only a three-dimensional universe would expand at a rate which would allow the formation of large-scale structures such as galaxies. [\[13\]](#)
- Waves only travel without distortion or reverberation in three-dimensional space. As John Barrow says in *Dimensionality*: "Three-dimensional worlds appear to possess a unique combination of properties which enable information-processing and signal transmission to occur via electromagnetic wave phenomena ... This situation has led many to suppose that life could only exist in an odd-dimensional world because living organisms require high-fidelity information transmission at a neurological or mechanical level." In other words, no information processing means no people.

I get the impression that anthropic theories such as these are invoked when a problem seems so difficult — so impossibly insurmountable — that it is hard to conceive of any conventional analytical solution. Anthropic theories could then be thought of as "theories of last resort". However, I would suggest it is best never to resort to such theories.

Instead, if we really want to solve the problem of why there are three dimensions of space, we are going to need the highest-quality science. Let us start with our best theory of the geometry of space ...

4

GENERAL RELATIVITY

In November 1907, Albert Einstein was sitting in a chair in the patent office in Bern where he worked as an assistant examiner. According to Einstein: "All of a sudden, a thought occurred to me. If a person falls freely, he will not feel his own weight." This was the thought which started Einstein on the eight-year road to formulating his great theory of general relativity. Later, he was to call this the happiest thought of his life.

In this book, we are considering clues as to why there are three dimensions of space. As general relativity remains our best theory of space and time — a hundred years after it was discovered — in this chapter we will consider general relativity in some depth.

The idea of a free-falling person not feeling their own weight may not seem to be a particularly surprising or inspiring thought. Indeed, it is a concept which seems so familiar to us that we would take it for granted, and think no more of it. However, as Nobel Prize-winning chemist Albert Szent-Györgyi said: "Scientific discovery consists of seeing what everyone else has seen, but thinking what no one else has thought."

Perhaps we can understand Einstein's insight by considering the modern-day equivalent of his falling man thought experiment, which would be a *reduced-gravity aircraft* flight. A reduced gravity flight gives its occupants (sometimes prospective astronauts, but more often simple thrillseekers willing to pay the \$5000 price) a brief experience of genuine weightlessness (approximate duration of 25 seconds). The flight involves a steep climb and then a rapid descent.

The force of gravity at the bottom of the hump is roughly twice as large as normally experienced. The plane then starts to climb and the sequence starts over again. There are typically 40-60 manoeuvres in a flight. This results in approximately two thirds of the passengers feeling nauseous. Hence, these aircraft have been nicknamed the "vomit comets".

The following NASA photograph shows Stephen Hawking's zero-g flight in 2007.

What the vomit comet (and Einstein's thought experiment) reveals is that it is possible to eliminate the force of gravity purely by placing objects in an accelerated environment. This appears to reveal a fundamental equivalence between gravity and acceleration. This so-called *equivalence principle* means that a passenger in a spaceship in a weightless environment in deep space will feel the force of gravity if the spaceship is accelerated (the passenger will be pushed into their chair).

NASA are considering building a spaceship which generates its own artificial gravity by continuously rotating, rotation being a form of acceleration. However, the equivalence principle tells us that this is no "artificial" gravity — no, **gravity and acceleration are precisely the same thing**. There is nothing "artificial" about this artificial gravity — it genuinely is the force of gravity.

Einstein stated this equivalence principle in 1907: "We assume the complete physical equivalence of a gravitational field and a corresponding acceleration of the reference system."

The curvature of space

The equivalence principle means that if we consider a spaceship in deep space in a weightless environment, and if we then consider that spaceship being accelerated, then the effect on the objects inside that spaceship will be precisely equivalent to the force of gravity. So let us imagine that there is a small window in the side of the spaceship through which light from a nearby star is entering the spaceship. According to the point-of-view of a passenger in the spaceship, the beam of light entering through the window appears to curve to the floor as the spaceship accelerates (as the light crosses the spaceship, it moves closer to the floor as the spaceship accelerates upward).

The following image shows this curved beam of light inside the spaceship:

We know from the equivalence principle that this accelerated spaceship is effectively experiencing the force of gravity. So the light appears to be dropping to the floor under the influence of gravity. This is quite a revelation: the path of light is affected by the force of gravity. Indeed, it was the observed deflection of starlight around the Sun during a solar eclipse which provided the first confirmation of the accuracy of general relativity.

But we know that light always tends to travel in a straight line through space (in fact, as we shall shortly see, light is actually travelling the shortest distance between two points — which usually happens to be a straight line). So if light truly is continuing to travel in a straight line through space under the influence of gravity, then this implies that **space itself must be curved**.

This is the main message of general relativity: **the effect of gravity is caused by the curvature of space** (actually, the curvature of spacetime). We will see later in this chapter precisely how this curvature of space causes the forces we associate with gravity.

In the later years of his life, Einstein explained his thought processes to his youngest son Eduard. Describing his insight that gravity was the curving of spacetime, he said: "When a blind beetle crawls over the surface of a curved branch, it doesn't notice that the track it has covered is indeed curved. I was lucky enough to notice what the beetle didn't notice."

Tensors

Once Einstein realised that gravity was caused by the curvature of space, he was faced with the task of expressing that curvature mathematically (so it could be included in the eventual final equation). Einstein's mathematical skills were good, but he was not a professional mathematician, and he realised he needed help. So, in 1912, Einstein called on his old friend Marcel Grossman.

Grossman had taken the class notes when Einstein had missed the mathematics lectures at the Zurich Polytechnic. According to Walter Isaacson in his biography of Einstein, Einstein had scored 4.25 out of 6 in his geometry class at the polytechnic, while Grossman had scored a perfect 6.

Grossman was very excited when Einstein asked for his help to describe the curvature of space in a mathematical form. Grossman consulted the literature, and discovered that Einstein required *non-Euclidean geometry* to describe the curvature. Euclidean geometry is the conventional geometry taught in schools based on lines, squares, circles, etc. drawn on a flat plane. However, non-Euclidean geometry extends this geometry to consider shapes drawn on curved surfaces. The resultant geometry can appear very counter-intuitive. For example, the interior angles of a triangle can sum to more or less than 180° when drawn on a curved surface, and parallel lines can eventually meet.

In the previous diagram, we might imagine the sphere as representing the Earth. We can then imagine two explorers at different positions on the Equator, and they both decide to walk in a straight line in a precisely northerly direction (along the lines shown in the diagram). The paths they take will gradually become closer together until they eventually meet at the North Pole. We might interpret this apparent attraction between the explorers as being due to the force of gravity, but really they are just following straight lines along curved space. It is the curvature of space which introduces gravity.

As we move off the two-dimensional plane and consider the possibility of non-Euclidean geometry in higher dimensions, the important factor for describing those spaces mathematically is how we measure the distance between two points. As we shall see, this is because — in curved space — the shortest distance between two points can be different from the distance in flat space.

As was described in Chapter Two, the mathematical formula for the shortest distance between two points is called the *metric*. Firstly, let us see recap how this metric is defined on a two-dimensional flat surface.

In the following diagram, imagine we want to travel from point A to point B via the shortest possible route (the shortest possible route between two points in geometry is called a *geodesic*). The shortest distance between the two points is shown by the dotted line. You will see that travelling from point A to point B necessitates travelling a distance x horizontally, and a distance y vertically:

This forms a right-angled triangle, so from Pythagoras's theorem we could calculate this distance as the square root of x^2 plus y^2 . So this gives us our metric on a flat two-dimensional plane:

$$d = \sqrt{x^2 + y^2}$$

However, this metric is not necessarily the same for curved surfaces. In order to see why that can be the case, consider an aircraft flying from Seattle to Zurich (see the following diagram). Clearly, the airline will want the

aircraft to take the shortest possible route (to save fuel). It so happens that Seattle and Zurich both lie at the same latitude (47° North), which implies that Zurich is precisely east of Seattle. We might therefore expect the aircraft to fly in a precisely easterly direction (which we might consider to be the horizontal x direction). On flat space, this would be correct: in the following diagram we would expect the aircraft to follow one of the many circular lines of latitude which are drawn in light grey around the globe:

However, because the surface of the Earth is curved, you will see on the diagram that the route the aircraft takes is not the easterly route along one of the lines of latitude. Instead, the aircraft takes a more northerly route, as far north as Greenland (the route is shown by the curved black line on the diagram). [\[14\]](#)

So, whereas on a flat surface, the shortest distance between Seattle and Zurich would simply have been the distance in the easterly (x) direction, the situation is more complicated for curved surfaces. On a curved surface, the shortest route might be very different.

Grossman realised that Einstein would need to use *tensors* to describe curvature in his eventual equation for general relativity. A tensor is similar to a *vector*, and vectors were introduced in my previous book. A vector is a column matrix — a matrix (a rectangular array of numbers) which has just one column:

$$\begin{bmatrix} x \\ y \\ z \end{bmatrix}$$

In my previous book, we saw how vectors can be used for representing points in space. For example, the vector shown above could be used to represent the point with the coordinates (x, y, z) .

A tensor is the more general case of the vector. For our purposes, we can consider a tensor as being a two-dimensional array of numbers. For example, a flat surface is represented by the following *metric tensor*:

$$\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

A metric tensor allows us to compute the distance between two points in any space.

So why is this the metric tensor which describes a flat surface? Well, let us imagine you are an aircraft pilot, and you want to know how far you will actually travel (and therefore how much fuel you will use) if you travel a certain distance in the easterly (x) direction, and a certain distance in the northerly (y) direction. On a flat surface, the formula which calculates the distance you will actually travel — the metric — is given by:

The metric tensor

$$d^2 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x^2 \\ y^2 \end{bmatrix}$$

This formula is in the form of a matrix multiplication (a tensor multiplying a column matrix), so let us perform the matrix multiplication and see what we get (the technique of matrix multiplication was described in my previous book).

When we multiply the matrices, we get:

$$d^2 = x^2 + y^2$$

which means:

$$d = \sqrt{x^2 + y^2}$$

which, as we saw previously is the metric for a flat two-dimensional plane (which we calculated previously from Pythagoras's theorem).

So we have, indeed, discovered the metric tensor for a flat surface, and it is:

$$\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

But space has three dimensions. What if we want to calculate the distance travelled (and the fuel used) by the aircraft as it not only moves along the surface, but also flies up into the air? In that case, we have to consider a third (z) dimension, and our metric tensor becomes a 3×3 matrix:

$$d^2 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x^2 \\ y^2 \\ z^2 \end{bmatrix}$$

You will see the metric tensor for three-dimensional flat space has a similar form to the two-dimensional case (a *diagonal matrix*: all the elements which are not on the main diagonal are set to zero).

But Einstein knew that special relativity implied that the universe is not built on just the three dimensions of space — it is built on the four dimensions of spacetime. So Einstein knew that the metric tensor describing the curvature of four-dimensional spacetime would have to be a 4×4 matrix.

But, before we consider the necessary matrix, we have to ask the question: how do we actually measure distance in spacetime? Well, the distance travelled by an observer in spacetime can be measured simply as the elapsed time measured on a clock carried by that observer (this is called *proper time*).

This has an interesting consequence: even for an observer who is stationary in space, the clock will continue to show the passing of time, meaning that the observer is actually travelling in spacetime. As explained in my third book, even a stationary observer is actually moving at the speed of light in spacetime. This means that, if the clock of a stationary observer shows that a time t has passed, the observer will actually have travelled a distance ct in spacetime (where c is the speed of light).

There is an additional factor we have to consider. According to special relativity, an observer who travels at high speed (for example, close to the speed of light) will experience less time passing than an observer who remains stationary. This is the principle of *time dilation*. For example, consider an astronaut who flies off from Earth reaching nearly the speed of light. When that astronaut returns to Earth, he will have aged less than an observer who has remained on Earth. Special relativity has therefore revealed that the greater the distance you travel through space, the less distance you will travel through time — and vice versa. As far as the metric tensor is concerned, this means the element of the tensor which multiplies the time component must be the opposite sign (positive or negative) to the sign of the element which multiplies the space component.

To see this, the following diagram shows the metric tensor needed to describe flat (uncurved) spacetime. You will see that the single element in the tensor which multiplies the time component is positive (+1), whereas the three elements which multiply the space components are negative (-1): [\[15\]](#)

The metric tensor

$$d^2 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix} \begin{bmatrix} (ct)^2 \\ x^2 \\ y^2 \\ z^2 \end{bmatrix}$$

When we perform the matrix multiplication, we get:

$$d = \sqrt{(ct)^2 - x^2 - y^2 - z^2}$$

which is the correct formula for distance in a flat (uncurved) spacetime. For a curved spacetime, the metric tensor would be different and so the formula for spacetime distance would also be different. [16]

What is more, **all** observers — no matter how they are moving — will agree on the same measured spacetime distance, d . Einstein realised this property was essential: relativity tells us that all frames of reference should be considered equally valid. No observer can claim that his frame of reference (and any single set of coordinate axes) are preferred over any other observer's frame of reference (in Chapter Two it was explained how there can be no absolute time and space in the universe, no single reference for time and space). By using this tensor formulation, the equation would apply to all observers — no matter how they were moving. As we have just seen, it is possible for tensors to produce invariant values on which all observers can agree. Therefore, no single observer — and no single set of coordinate axes — is special or preferred in any way.

Einstein called this invariant property of tensors *general covariance*. Much of the eight years Einstein spent developing general relativity was spent ensuring his equation had this property of general covariance.

Tidal forces

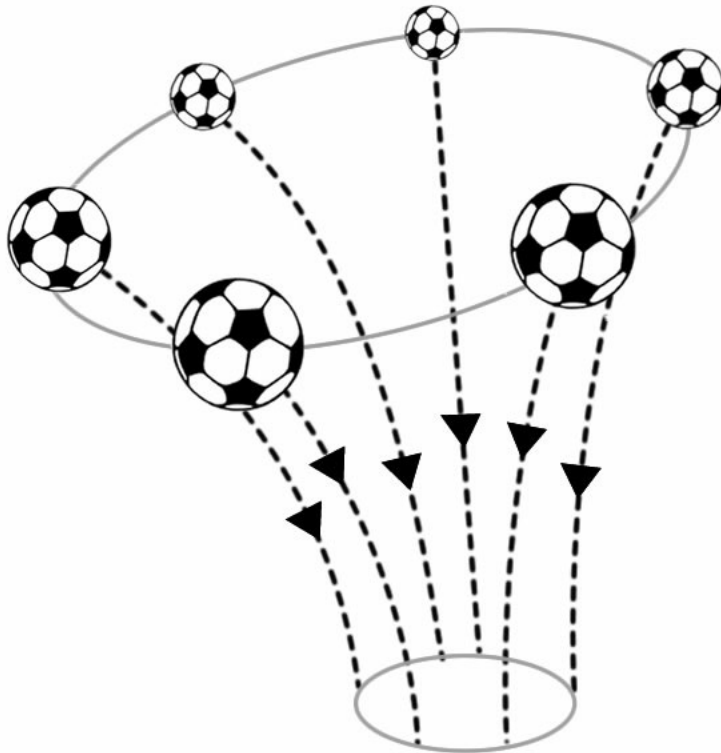

As we saw earlier in our discussion of the equivalence principle and the "vomit comet", it is possible to virtually eliminate the effect of gravity if an object is in free-fall. However, it is actually quite difficult (effectively impossible) to completely eliminate the effect of gravity. That is because space possesses curvature, and that curvature means objects never fall in precisely the same direction — even in a vomit comet. In other words, the geodesic lines of objects never point in exactly the same direction. It is very difficult to choose a region in which space is completely flat (uncurved). But by choosing a very small region — for example, the interior of a vomit comet — space will be approximately flat. To see why, consider a very small region on the surface of a sphere. A small region will be approximately flat (for example, we feel the Earth is flat when we inhabit just a small region of its surface), but there will still be a small degree of curvature present in that small region which can never be completely eliminated.

This ever-present curvature of space can never be completely eliminated in an accelerated frame. The

gravitational effects of this curvature are, therefore, the true effects of gravity, and it is these effects we want to consider. These effects are called *tidal forces*.

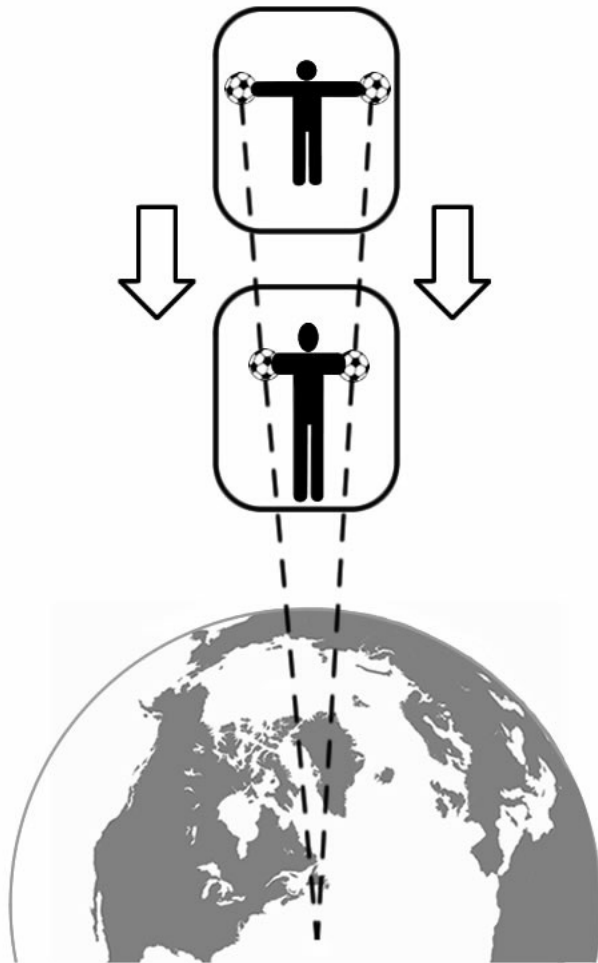

These tidal forces emerge when objects fall along lines (geodesics) which point in **different** directions — not the same direction. Hence the saying "gravity is caused by the **curvature** of spacetime".

In the following explanation of tidal forces, we will be considering the movement of a number of footballs (soccer balls) as they each follow their geodesic lines through space. The resultant deformation in the arrangement of the footballs will reveal the action of gravity on structures.

To see the effect of these tidal forces (due to curvature), we need to consider a larger region of space. So consider an observer inside an extremely large elevator, floating freely in space a few hundred miles above the surface of the Earth. Not only will the observer be floating in a weightless situation, but any objects with him in the elevator will also be floating. Imagine there are two footballs in the elevator with the observer. These are floating by the side of the observer, with the balls separated by a certain distance. As was explained earlier, by considering the motion of these footballs in free-fall, we can learn about the behaviour of gravity.

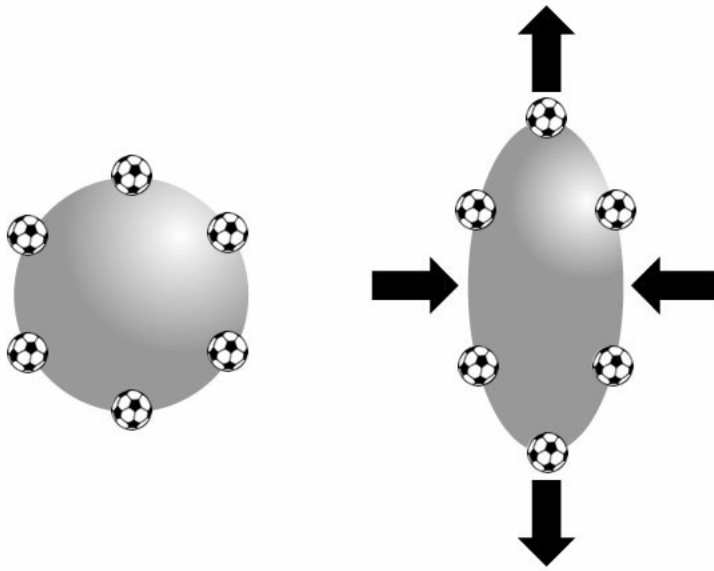

As the elevator continues on its free-fall journey toward the Earth's surface, both the observer and the footballs will be attracted toward the precise centre of the Earth. The footballs follow their geodesics towards the centre of the Earth. This will inevitably result in the paths of the balls slowly converging (see the following diagram — the geodesics of the footballs are denoted by dashed lines). From the point of view of the observer, he will see the balls floating on either side of him, and then he will see those balls slowly drifting together as they follow the converging geodesics:

As well as the balls slowly drifting together, there is also a stretching of the observer in the vertical direction (also shown on the diagram). This is due to the difference in the strength of gravity in the vertical direction. This stretching effect is called *spaghettification* and is the effect which will kill you if you are unlucky enough to fall into a black hole. Remember: in free-fall (falling into a black hole, for example) you do not feel the effect of gravity — you only feel the tidal forces, and it is those tidal forces which will rip you to shreds.

In order to discover the effects of these tidal forces on three-dimensional objects, let us replace our observer in the elevator with a very large rubber weather balloon. The footballs are now glued around the edge of the balloon, so that the movement of the footballs (in free-fall along their geodesics) controls the shape of the balloon.

As in the previous example with the observer, the effect of the tidal forces is to squeeze the balloon horizontally, while stretching it vertically. The balloon therefore forms an elliptical shape:

Crucially, even though the balloon forms this elliptical shape, **the volume of the balloon does not change**. Even though the balloon is squeezed around the middle, it is stretched at its ends, and the end result is a volume which is unchanged. Another crucial point is that there is nothing — no mass — inside the balloon (apart from air). So in this situation in which the balloon is empty, the volume of the balloon does not change due to the tidal forces.

Now let us put some mass in the balloon. In fact, we will put a lot of mass in the balloon. Imagine a balloon considerably larger than the Earth, and let us put the Earth inside the balloon. Again, some footballs are glued around the edge of the balloon so that — as the footballs fall along their geodesics — we can observe the effect on the shape of the balloon.

As you can see from the previous diagram, the footballs all fall along their geodesics (straight lines directed to the centre of the Earth). So, in this case, there **is** a volume reduction in the size of the weather balloon.

Einstein realised he would have to capture this volume-reducing effect of gravity (due to the presence of mass) in his equation for general relativity. The tensor which can be used to describe volume reduction of an element of space is called the *Ricci tensor* (pronounced "Reechy") which we will denote by $R_{\mu\nu}$.

The rate of volume reduction (described by the Ricci tensor) is then proportional to the mass inside that volume. The distribution of mass (and therefore also the distribution of energy via the conversion equation $E=mc^2$) is described by the *energy-momentum tensor*, $T_{\mu\nu}$. This gives us the following equation:

$$R_{\mu\nu} = k T_{\mu\nu}$$

where k is some proportionality factor. It turns out that k must be equal to $8\pi G$ (in order to agree with Newtonian gravity). So the equation then becomes:

$$R_{\mu\nu} = 8\pi G T_{\mu\nu}$$

This equation was Einstein's initial proposal for the general relativity equation. Essentially, what it is telling us is something quite simple: it is telling us that the curvature of space (spacetime) is proportional to the mass (and energy) contained within that volume of space.

However, Einstein realised there was a problem with this initial proposal for a general relativity equation. The problem was due to the law of conservation of energy. Let us first consider the right hand side of the equation, which deals with the distribution of mass and energy. The law of conservation of energy states that the amount of energy in a closed volume of space must remain constant over time. The right hand side of the equation satisfies this law because if we consider the derivative of the energy-momentum tensor (the derivative is the rate of change of a value over time) then we find that it is equal to zero: the amount of energy in the volume does not change over time, i.e., energy is conserved. We can express this as:

$$\nabla T_{\mu\nu} = 0$$

where the ∇ symbol represents the derivative. [\[17\]](#)

However, the derivative of the Ricci tensor is not zero, so Einstein's equation could not be correct (the derivative of the right hand side of the equation was zero, but the derivative of the left hand side of the equation was not equal to zero). Instead, the derivative of the Ricci tensor, is:

$$\nabla R_{\mu\nu} = \frac{1}{2} R \nabla g_{\mu\nu}$$

where R on the right hand side is called the *Ricci scalar* (it is derived from the Ricci tensor, and it is just a number which is not zero if the surface is not flat), and $g_{\mu\nu}$ is the metric tensor which we considered in the previous section.

Einstein realised he could take the right hand side of the equation over to the left hand side, changing its sign in the process, and taking the derivative outside the bracket (as it was a factor which was common to both terms):

$$\nabla(R_{\mu\nu} - \frac{1}{2} R g_{\mu\nu}) = 0$$

We see we are now taking the derivative of the expression inside the bracket, and the result of that derivative is zero. We saw earlier that the derivative of the energy-momentum tensor is also equal to zero. So Einstein realised that these two terms (on which the derivative was being applied) were equivalent. This meant:

$$R_{\mu\nu} - \frac{1}{2} R g_{\mu\nu} = T_{\mu\nu}$$

We also need to include the previous $8\pi G$ proportionality factor:

$$R_{\mu\nu} - \frac{1}{2} R g_{\mu\nu} = 8\pi G T_{\mu\nu}$$

And that's it! That is Einstein's equation for general relativity, the derivation of which is generally considered to be the greatest scientific achievement in the history of humanity. It is called simply the *Einstein equation* (yes, that's correct, $E=mc^2$ is **not** the "Einstein equation").

So, although the equation looks rather daunting and mathematical, we can see from our earlier analysis that it is actually telling us something which is really quite simple. In a simplified form, it is telling us that an amount of mass (on the right hand side of the equation) will result in curvature of spacetime (the left hand side of the equation) around that mass. And that, basically, is the essence of gravity.

In his biography of Einstein, Walter Isaacson put Einstein's achievement into perspective: "Einstein had shown that the fabric of spacetime became not merely a container for objects and events. Instead, it had its own dynamics that were determined by, and in turn helped to determine, the motion of the objects within it. The curving and rippling fabric of spacetime explained gravity, its equivalence to acceleration, and, Einstein asserted, the general relativity of all forms of motion. In the opinion of Paul Dirac, the Nobel laureate pioneer of quantum mechanics, it was 'probably the greatest scientific discovery ever made'. Another of the great giants of twentieth century physics, Max Born, called it 'the greatest feat of human thinking about nature, the most amazing combination of philosophical penetration, physical intuition and mathematical skill.'"

On the largest of scales (which is where general relativity's modification of Newton's law becomes measurable), general relativity correctly predicted *gravitational lensing* (light bent around stars and galaxies), black holes, and the expanding universe.

The final confirmation of general relativity made global headlines recently. General relativity states that gravitational effects are not transmitted instantaneously (after all, nothing travels faster than light). Instead, gravity is transmitted across the universe in the form of *gravitational waves*. As an example, if the Sun disappeared instantaneously, the Earth would continue to orbit the position of the Sun for seven minutes until the bad news reached us in the form of gravitational waves.

Gravitational waves are predicted to carry energy, just like any other form of wave (you may have felt the force of waves in a rough sea). Unfortunately, gravitational waves are also predicted to be extremely weak and very difficult to detect. As an example of the weakness of gravitational waves, the largest source of gravitational waves in the Solar System is due to the orbit of Jupiter around the Sun, but the amount of energy emitted by Jupiter in the form of gravitational waves is only about that of a 40-watt light bulb.

However, despite their weakness, several teams of researchers have spent decades searching for gravitational waves using highly inventive experiments and sensitive detectors. The most sensitive is the Advanced LIGO project (Laser Interferometer Gravitational Wave Observatory) which consists of two observatories based in Livingston in Louisiana and Hanford in Washington State. The experimental equipment at the two sites consists of two four-kilometre long tubes oriented at ninety degrees. Laser beams are shone down both tubes, reflected at the ends 280 times (giving a combined distance of over 1,000 kilometres), before being combined back at the base station. As a gravitational wave passes, it is predicted to slightly shorten the length of one of the tubes while slightly lengthening the other (because the tubes are at ninety degrees). The difference in the path length of the laser beams would then result in an interference pattern when the two laser beams are recombined at the base station.

The following picture shows the LIGO observatory in Hanford. You can see the two tubes oriented at ninety degrees:

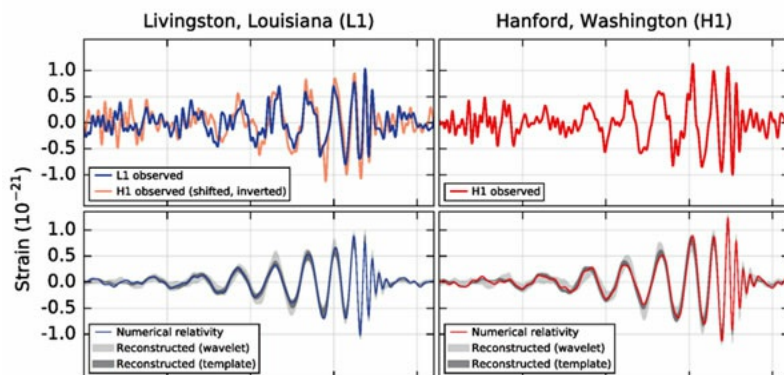

The search bore fruit at 9:50 a.m. on the 14th September 2015 when the two Advanced LIGO observatories independently detected a brief burst of gravitational waves from the collision and merger of two black holes. As the gravitational wave passed through the Earth, it changed the length of the four-kilometre LIGO tube by just ten thousandth of the width of a proton, equivalent to detecting a change in the distance to the nearest star by the width of a hair.

At its peak, the energy of the gravitational waves produced by this cataclysmic event was 50 times greater than the combined power of all the light radiated by all the stars in the observable universe. Effectively, the mass of three Suns was converted into raw energy.

If the energies involved were so huge, then why was the signal detected on Earth so weak? To put it simply, the black hole merger happened in a galaxy far, far away and a long time ago. The merger actually happened 1.3 billion years ago (in a galaxy 1.3 billion light years away, logically). At that time, the only life on Earth was composed of simple single cells floating in the oceans. The gravitational wave started its journey across space to be intercepted — 1.3 billion years later — by multi-cellular human beings which had fortunately evolved over that period.

The following graphs show the "chirp" signal received from the black hole merger which lasted just 0.2 seconds — approximately the same time as the blink of an eye. The first column shows the signal received in Livingston, the second column shows the signal received in Hanford just seven milliseconds later (the time it takes for light to travel across the USA).

The lower graphs show how the signal was predicted to appear (including the so-called black hole "ringdown" after the merger), showing how well general relativity correctly predicted the nature of the event.

The following diagram shows how the merger of the two black holes related to the detected "chirp". Remember,

this whole process took just 200 milliseconds to complete. The black holes were orbiting each other at a distance at which they were only 350 km apart. Over the 200 millisecond period, the orbital velocity of the black holes increased from 30% of the speed of light to 60% of the speed of light.

This represented the first direct detection of gravitational waves, and is regarded as one of the most important discoveries in the history of science.

5

INTO THE FIFTH DIMENSION

When you have made the greatest scientific discovery of all time, the question then becomes: "How do I follow that?" That was surely the challenge facing Einstein after he discovered general relativity in 1915. However, his course of action probably appeared quite clear. Just as is the case today, there were a few fairly clear problems in fundamental physics which cried out for solutions. And, just as is the case today, these questions tended to revolve around the problem of unification.

As described in my first book, if we find we have two theories which explain two apparently different behaviours of Nature, we might find it possible to replace both those theories with a single theory which still manages to explain both of those behaviours. When this happens, the process is called *unification*. The resultant unified theory will be simpler than either of the two previous theories.

As was described in Chapter Two of this book, one way of combining two apparently different behaviours is to introduce extra dimensions (remember the "flying octopus"?). In this chapter we will be examining the first attempt at unification using extra dimensions.

Today, one of the greatest quests in physics is to find a unification between general relativity and quantum mechanics. These are the two dominant theories of the physical world, and the unification of these theories stands out quite clearly as a problem in urgent need of a solution.

In Einstein's time, there was also a very clear need for a unification, a unification between the theory of electromagnetism and Einstein's own theory of general relativity. In order to understand why this was such an important quest, we need to imagine travelling back in time to the early decades of the 20th century, and putting ourselves into the mindset of the physicists of that period.

In the 19th century, the greatest advance in physics since the time of Newton was achieved. This was the development of the theory of *classical* (i.e., non-quantum) *electromagnetism*. In 1820, French physicist Andre-Marie Ampère had shown that wires carrying electric current generated a magnetic field, and those wires were either attracted or repelled by the magnetic force between them, depending on the direction of the electric current. In 1831, Michael Faraday discovered the inverse of this result by demonstrating that a magnet moving through a coil of wire produces an electric current in that wire. So there was clearly a symmetry between electricity and magnetism. It was then left to the great Scottish physicist James Clerk Maxwell who, in 1862, formalised this unification between electricity and magnetism in mathematical form. Maxwell published four equations, now simply known as *Maxwell's equations*.

Of particular interest to Einstein had been the form of Maxwell's equations in a vacuum (empty space containing no electric charges or current). Maxwell had shown that his equations made the symmetry between electricity and magnetism clear:

- A changing magnetic field creates an electric field.
- A changing electric field creates a magnetic field.

Hence, the magnetic field can generate an electric field, and the electric field can generate a magnetic field. The result is a self-sustaining wave of alternating electric and magnetic fields called an *electromagnetic wave*. This wave was capable of traversing the vacuum, and the equations implied that the wave would travel at precisely the speed of light. From this, Maxwell deduced that light was a form of electromagnetic wave. What is more, the equations seemed to indicate that the speed of light would be independent of the speed of the observer. Einstein took this result as the basis for his theory of special relativity, with his landmark 1905 paper being called "On the **electrodynamics** of moving bodies". Hence, with special relativity Einstein was unifying Maxwell's new electromagnetic theory with the existing theories of mechanics at speeds close to the speed of light. This was a clear first sign of the need to unify the new results from electromagnetism with existing theory, a situation which only became more pronounced with the discovery of general relativity ten years later.

What is more, we have to realise that in 1915 the secrets of the atom (specifically, the forces contained within the nucleus of the atom) had not yet been revealed. So the electromagnetic and gravitational forces were the only two

forces known. The clear challenge was to unify electromagnetism with general relativity.

Einstein was particularly drawn to the idea of finding a geometrical explanation of the electromagnetic force. If gravity was simply the result of curvature of spacetime, might it be possible that the electromagnetic force also had a similar explanation? Einstein might even have suspected that the solution would be rather simple and intuitive (remember his simple idea of a free-falling person not experiencing the force of gravity?). Einstein explained his goal in his Nobel Prize acceptance speech: "The mind striving after unification cannot be satisfied that two fields should exist which, by their nature, are quite independent. We seek a mathematically unified field theory in which the gravitational field and the electromagnetic field are interpreted only as different components or manifestations of the same uniform field."

Unfortunately, Einstein's efforts were to end in failure. However, the effort to produce a unified theory introduced some new ideas which resonate to this day. One of those ideas has emerged as the dominant theme in fundamental theoretical physics over the last thirty years: the introduction of extra spatial dimensions. We will now consider the revolutionary theory which has formed the template for these higher-dimensional theories.

In other words, we will now consider the theory which formed the template for string theory.

Kaluza-Klein theory

In 1919, Einstein received a letter from an obscure German mathematician named Theodor Kaluza. In today's world, the letter would probably have been dismissed as the ramblings of a "crackpot" — the central idea was so bizarre and apparently nonsensical. However, Einstein had a more open mind, and he gave serious consideration to the contents of the letter.

According to Brian Greene in his book *The Elegant Universe*: "Kaluza's suggestion has revolutionized our formulation of physical law. We are still feeling the aftershocks of his astonishingly prescient insight."

In the letter, Kaluza described an approach for unifying the gravitational force and the electromagnetic force. In order to achieve this, Kaluza had considered how gravity would behave if there were five spacetime dimensions instead of four dimensions. Yes, it sounds like a crazy idea — the universe surely only has four spacetime dimensions? However, the additional dimension seemed to introduce behaviour which was identical to the behaviour of electromagnetism. Could this really be the solution to unification? Does the universe really have five spacetime dimensions?

In order to achieve this apparent miracle, Kaluza did nothing particularly remarkable: he simply considered what would happen if another spatial dimension was added to Einstein's equation for general relativity. As we have seen in the last chapter, the metric tensor used in general relativity is a 4×4 matrix. With the addition of an extra space dimension, Kaluza, therefore, had to increase the size of the metric tensor to a 5×5 matrix (which could now be used for calculating distances in five dimensions):

You will see in the previous diagram that the old 4×4 matrix of Einstein's general relativity is retained (in the top left). However, the larger size of the new metric has introduced two new vectors containing four elements (a metric tensor is actually symmetrical, so these two new vectors are actually identical). [18]

Crucially, Kaluza discovered that this new vector represented the laws of electromagnetism. So it appeared that by expanding general relativity to four space dimensions, electromagnetism was automatically incorporated. Hence, the gravitational and electromagnetic forces would be unified if there were four spatial dimensions (five dimensions in total, when the time dimension is also included).

So where does this connection with electromagnetism come from? Well, let us consider what we have done. We have extended Einstein's metric tensor by adding an extra space dimension. We know that Einstein's metric tensor for general relativity described a universe with one dimension of time and three dimensions of space. We have added an additional dimension of space, and produced a vector with four elements. We would therefore expect just one of the elements in this new vector to be a time component (as was the case in the old metric tensor). And this is the case. The new vector has one time component, and three space components:

The structure (and behaviour) of this vector is well-known in electromagnetic theory and is called the *electromagnetic vector potential* (alternatively called the *electromagnetic four-potential*). The single time

component is a single number and this is called the *electric potential*. The three remaining components form a vector which is called the *magnetic vector potential*.

So clearly this vector combines both electric and magnetic behaviour in a single vector. In other words, it describes a combined **electromagnetism**. So we appear to have obtained a description of electromagnetism purely by extending general relativity to five dimensions.

And that, basically, is the principle behind Theodor Kaluza's unification of electromagnetism and gravity.

Can we get a deeper understanding of this connection between electromagnetism and gravity? Well, the connection appears to rely on the vector which was produced: the electromagnetic vector potential. That vector included the electric potential, and the magnetic vector potential. I hope you can see a common theme here: it is this property called **potential**, which keeps appearing.

It would appear that in order to obtain a deeper understanding of the connection between gravity and electromagnetism we will have to explore this property called "potential". In particular, we have to examine why it appears to suggest the existence of an extra dimension of space.

Potential

As a first step toward unification of electromagnetism and gravity, we might ask what they have in common. Well, both forces are transmitted via fields. It was Michael Faraday in 1849 who first suggested that the magnetic and electric fields were independent entities which spread through space. The movement of an object was then determined by the local magnitude and direction of the field at any point in space. Einstein applied similar reasoning in general relativity. Gravitational effects could not be transmitted instantaneously (as suggested by Newton). Instead, objects responded to the local strength of the gravitational field, and gravitational effects were transmitted through the field at the speed of light (gravitational waves).

So what determines the strength and direction of the field (electromagnetic or gravitational) at any particular point in space? To answer that question we need to consider energy.

If we move an object against the natural direction of a field (for example, pushing two electrically-charged particles together, pushing two north poles of two magnets together, or lifting an object against the force of gravity) then we increase the *potential energy* of the object. If you then release the object (for example, dropping a rock you have lifted off the floor), the force will act to move the object back to its initial position. The potential energy of the object will then decrease. Because of the law of conservation of energy, energy can never be created or destroyed: it can only be converted into a different form of energy. Hence, the kinetic energy of the object will increase accordingly: the motion of the object will accelerate.

We can think of potential energy as being an energy difference between the current position of the object and the position the object would attain if it was released. The greater the difference, the greater the potential energy. For example, the gravitational potential energy of an object is proportional to the height the object is lifted off the ground. So potential energy is clearly an energy associated with the position of an object. And if an object is in a force field (gravitational or electric) then the potential energy of the object is related to the position of the object in that field.

We can therefore consider the field independently and say that a particular point in the field represents a certain amount of potential energy. We have to consider the potential energy which would be possessed by an object with a mass of just one unit (or electric charge of just one unit) at that particular position in the field. We can then say that a particular point in the field has a certain *potential*.

But we want to discover what determines the strength and direction of the force experienced by the object. We will now show that objects will tend to move from points in the field which have high potential to points which have low potential.

To illustrate this, we shall consider a very useful analogy between the flow of electricity and the flow of water under the influence of gravity. Let us consider the potential energy of water in a hydroelectric plant. Water from a reservoir or river flows down a tube to a lower height, until it hits a turbine at the bottom of the tube. The force exerted by the water is sufficient to turn the turbine and generate electricity.

As any civil engineer will know, the force (pressure) exerted by the water on the turbine is proportional to the height difference between the top surface of the water in the lake and the height of the turbine. This is called *hydraulic head*. Hydraulic head is equivalent to the potential energy of the water. And, as we have just discussed, there is a direct connection between potential energy and the potential of the underlying field (in this case, the gravitational field). We can see that water will flow from points with high gravitational potential to points with low potential.

In this respect, there is a perfect analogy with electricity. This is because another name for electrical potential difference is *voltage*. Electricity flows from high potential to low potential, from high voltage to low voltage. So, in our quest to unify electromagnetism with gravity, here we have another similarity between the electromagnetic force and the gravitational force: both forces tend to move objects from high potential to low potential.

In our discussion of the hydroelectric plant, we can see that the only important factor which determines the strength of the force is the potential **difference** (the difference in the height of the water). This seems to indicate that it is the **relative** change in potential which is important — not the **absolute** value of the potential.

As an example, it has been mentioned that another name for a difference in electrical potential is **voltage**. So let us consider a typical 1.5 volt battery:

When you buy a battery you are, of course, buying a battery with two terminals: a positive terminal and a negative terminal (shown in the previous diagram). The 1.5 volts refers to the potential difference between the two terminals.

So let me ask you a question: what is the voltage of the positive terminal? You might say, "positive 1.5 volts". Are you sure? Well, if you're sure then I will just remove the negative terminal altogether and sell you a battery with only the positive terminal. After all, the 1.5 volts of electricity provided from the positive terminal should be enough to power your device:

I hope you will be very happy with your new battery. I will even sell it to you for half price.

Of course, this is a nonsense. Your new battery with its "1.5 volt terminal" is now incapable of powering anything. A battery with one terminal is useless — it no longer has a voltage. Remember, a voltage is a potential difference. When you buy your battery, you are buying a potential **difference**, and a difference requires two terminals.

If the only important factor is the potential difference then that implies that the absolute value of the potential does not matter. To return to our water analogy, it implies that the absolute height of our hydroelectric power station is irrelevant: the only important factor is the difference in the height of the water, not the absolute value of the height of the water. Hence, we could locate our hydroelectric power station at ground level, or at the top of a mountain, or at any height in between: the potential difference of the power station would be unchanged, and hence the output of the power station would be unchanged.

As that is the case, then imagine you are provided with the value of the output from a particular power station on the mountain. It is clear that there is no clue in the output value as to the absolute height of the station which provided the power. In fact, if the only information available to us is the power output of the station, then this freedom of motion of the station in the vertical direction would be effectively hidden from us. In other words, there is a freedom of motion of the absolute value of the potential: the absolute value of the potential is hidden from us.

Similarly, because the electromagnetic force is also dependent on potential **difference** (voltage) there is also a freedom of the **absolute** electromagnetic potential which is fundamentally hidden from our eyes: it is unobservable.

As was discussed in Chapter Two, it is possible to express the variation of any property value as movement in a dimension. On that basis, it is possible to describe the freedom of variation of absolute electromagnetic potential as movement in a dimension. And, as variation in the absolute value of potential is fundamentally hidden from our eyes, this has to be movement in a **hidden dimension**.

So now we can see the connection between potential and motion in a fourth dimension of space, which was revealed by Kaluza's theory. If you remember back to the discussion earlier in the chapter, Kaluza made the radical suggestion that this motion of absolute electromagnetic potential in a hidden dimension actually represented motion in a real dimension of space! Kaluza showed that it was possible to extend general relativity to five spacetime dimensions, in which case the extra dimension of space behaved like electromagnetic potential. We can now see that this additional fourth dimension of space would be hidden from our eyes.

But what form might this dimension take? How can there be an extra dimension of space which we are fundamentally unable to observe?

The circular dimension

Remember that even though Kaluza's theory was intriguing, there was still absolutely no evidence of a fourth spatial dimension. Theodor Kaluza was a firm believer in the power of theory (he taught himself to swim by reading a manual and jumping into the sea), but in this case theory did not appear to match reality.

However, in 1926 Felix Klein came up with a proposal which not only described the shape of the additional spatial dimension, but also explained why it was hidden from our eyes.

What Klein managed to do was identify the true nature of the connection between the gravitational force and the electromagnetic force indicated in Kaluza's theory. They are both an example of a *gauge theory*. Those of you who read my previous book will already be aware of gauge theory. It is currently believed that all four fundamental forces (gravity, electromagnetic, and the weak and strong nuclear forces) are examples of gauge theory.

Gauge theories arise from symmetry in Nature. A symmetry occurs when you transform an object in some way, but the transformation leaves the original object unchanged. For example, a snowflake has rotational symmetry: if you rotate a snowflake by sixty degrees then the transformed snowflake remains identical to the original snowflake, and that represents a symmetry. The gravitational force is the force which describes the behaviour of space and time, and we find symmetries in both space and time: if we move an experiment to a different location in the universe, we find we get the same result. This is called *space translation invariance* (it is the freedom we have to locate our power station anywhere in the vertical direction). And if we perform an experiment at a different time, we also find we get the same result (this is called *time translation invariance*). [19]

But what symmetry does the electromagnetic force represent? Well, once again the answer was described in my previous book. We will now discover that the symmetry represented by the electromagnetic force is the rotational symmetry of a circle.[20] To understand why this is the case, we need to consider quantum mechanics.

Quantum mechanics tells us that an electrically-charged particle (such as an electron) is described by a *wavefunction*. A wavefunction — as the name implies — has a shape like a wave. And, like any wave, the wavefunction has an associated *phase*. The phase of a wave determines where the peaks and troughs of the wave lie.

As you can see in the following image, we can imagine a wave being created by a point on a revolving wheel (the revolving wheel is shown on the left in the following image):

The phase of the wave is then defined as the angle of the wheel when time (on the horizontal axis) equals zero, as shown in the previous diagram.

You will see that the last two waves, waves C and D, have phases of 90° and 270° respectively. Hence, there is a 180° difference in their phases. If these two waves were to combine then they would cancel each other out (destructive interference) because the peaks and troughs of one wave would be precisely the opposite of the other wave.

Quantum mechanics tells us that if we have a group of particles — and their wavefunctions — then we can increase or decrease the phase of all the wavefunctions by a constant angle without changing the overall situation. This is because all that matters is the difference of the phases of the wavefunctions, not the absolute values of the wavefunctions. The difference between phases is important because it can create interference patterns (as in the double-slit experiment in which two particles create an interference pattern). So the absolute value of the phase is effectively unobservable — the only thing we can observe is the difference between the phases. [21]

So all we can measure is a difference — the absolute value is unobservable. This is therefore very similar to the earlier discussion of electromagnetic potential (voltage). In our discussion of electromagnetic potential, we saw that it was only the difference of the potential that mattered — the absolute value of the potential was irrelevant (in fact, it was unobservable). We have therefore now made a remarkable connection between electromagnetic potential (voltage) and the phase of the wavefunction of a charged particle: only differences matter — absolute values are unobservable.

This connection is not a coincidence. Instead, this reveals the very deep connection between the phase of the wavefunction of a charged particle (such as an electron) and the absolute value of the electromagnetic potential of the underlying field. As Bruce Schumm says in his book *Deep Down Things*: "The quantum-mechanical requirement

of local phase invariance, miraculously, just matches the freedom of choice one has in specifying the electromagnetic potential function for those fields."

Now remember that we considered the unobservable motion of the electromagnetic potential as being motion in a hidden dimension, the hidden fifth dimension in Kaluza's theory. So Felix Klein now made the connection between the varying phase of the wavefunction (motion around a circle) and the motion in Kaluza's hidden fifth dimension. Hence, Klein came to a remarkable conclusion: the fifth dimension must be in the form of a circle. According to Klein, electromagnetism — as experienced in our four dimensions of spacetime — came from motion around this hidden circular fifth dimension.

But can we really make the leap from rotational gauge symmetry of the electromagnetic force to the suggestion that this represents an additional dimension of space? The physicist Juan Maldacena appears dubious: "In physics, we do not know whether this circle is real. We do not know if indeed there is an extra dimension. All we know is that the symmetry is similar to the symmetry we would have if there was an extra dimension. In physics we like to make as few assumptions as possible. An extra dimension is not a necessary assumption, only the symmetry is." [22]

Remember back to the discussion in Chapter Two of how unification can be achieved by "glueing" together two different dimensions into a higher-dimensional space. Well, Maldacena's quote is suggesting that this is a classic example of that approach. The two dimensions being "glued" together is four-dimensional spacetime and the one-dimensional symmetry of the electromagnetic force. Yes, as Maldacena suggests, there is a common element: they both exhibit symmetries. However, does the combined higher-dimensional space represent an actual physical entity, or are we merely creating another "flying octopus"?

Microscopic dimensions

Nothing in our discussion so far has explained why we are unable to detect this supposed circular fifth dimension. We can clearly detect motion in the three dimensions of space, and we can also detect motion in time, which is the fourth dimension (we can detect motion in time simply by using a clock). So how can this circular fifth dimension be hidden? Where is it?

To explain the missing dimension, Klein came up with a bold and — as it turns out — extremely influential idea. Remember, this was 1926, and Klein decided to incorporate some of the ideas from the newly-discovered quantum mechanics. In particular, he used the result discovered by Louis de Broglie which stated that a particle also acts like a wave (this was the complementary result to Einstein's discovery of the photon: Einstein showed that a wave could act like a particle, de Broglie showed that a particle could act like a wave). If you read my previous book you will know that Niels Bohr used this result of de Broglie to suggest that only a whole number of electron wavelengths could fit in an orbit around the nucleus of an atom:

Klein did a very similar thing to Bohr, but instead of suggesting that only a whole number of wavelengths could fit around the nucleus of an atom, Klein suggested that only a whole number of particle wavelengths could wrap around the circular fifth dimension. So how long would those wavelengths be? Well, Klein used de Broglie's formula for the wavelength of a particle:

$$\lambda = \frac{h}{p}$$

where λ is the particle wavelength, p is the momentum of the particle, and h is Planck's constant. Because h is such a small value (6.63×10^{-34} joule seconds) the formula predicts an extremely small value for particle wavelength (which explains why we never normally see particles — or matter — acting like a wave). In fact, because of the small value of h , de Broglie's formula predicts a wavelength for the fifth dimension which is an extraordinarily small distance — close to the Planck length, which is the smallest distance we can meaningfully measure (the Planck length is a thousandth of a millionth of a billionth of a billionth of a metre).

So this provided an explanation of why the circular fifth dimension was hidden from our eyes: it was wrapped in incredibly small circles, a smaller distance than any current instrument can probe.

This implies that each point in our four-dimensional spacetime is actually represented by a circle, or loop, in the microscopic fifth dimension. Another way of looking at it is that a one-dimensional line is actually a cylinder (a series of loops). The following diagram shows a section of an apparently one-dimensional line being magnified to reveal it is actually a microscopic cylinder (being formed of a series of loops):

So, if we were sufficiently small, then as well as travelling up and down the line (in one dimension), we could also travel in a circular direction around the cylinder (adding another dimension).

This process — by which higher-dimensions are looped and are too small for us to detect — is called *compactification*.

These two combined theories of Theodor Kaluza and Felix Klein — suggesting that electromagnetism is a result of a microscopic circular fifth dimension of space — is called *Kaluza-Klein theory*.

And, if you are a regular reader of popular science books, you might now be suspecting that this idea of Kaluza-Klein — microscopic loops in higher dimensions — sounds strikingly similar to string theory. In that case, you would be absolutely correct: Kaluza-Klein theory is now recognised as an important precursor to string theory.

6

STRING THEORY

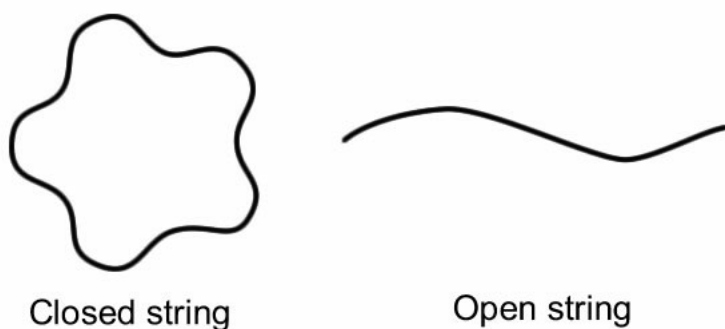

The last thirty years of fundamental physics research has been highly unusual in its nature. It has been dominated by a single theory — *string theory* — which was conceived in the early 1970s. The theory is particularly relevant to this book as it predicts a universe with a large number of hidden compactified dimensions.

In our study of string theory, let us first return to consider an implication of Kaluza-Klein theory. We have seen that the fifth dimension is proposed to be circular and microscopic. We have also seen how the addition of a fifth dimension has the effect of introducing the electromagnetic field in four-dimensional spacetime. But we know that the electromagnetic field is composed of billions of photons (the particles of electromagnetic radiation — such as light). So let us now imagine that the fifth dimension is completely empty of all matter. If that is the case, then it appears that a photon (a field particle) has been produced purely by a loop of fifth-dimensional space. In other words, a particle has been produced purely by a loop in space: a particle purely from geometry!

String theory generalises this result. String theory says that a particle is not produced by an empty loop of a higher-dimensional space, but there is actually a physical object which loops around in that higher dimension. Fairly obviously, this is called a *string*, and it gives the name to string theory. The string is not "made" of anything else — it is fundamental.

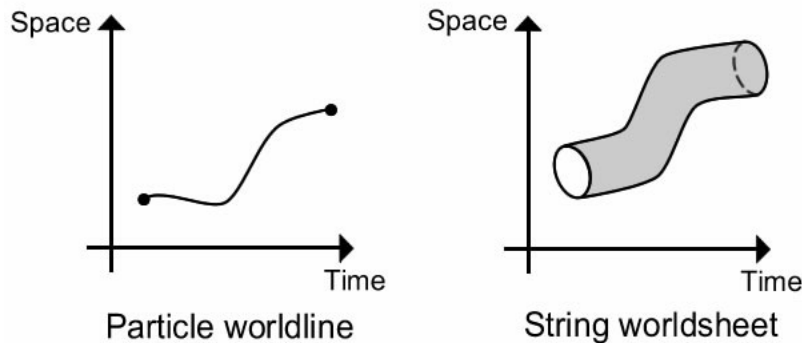

By introducing a physical object, this introduces the possibility of new structures and modes of behaviour — we are no longer restricted to considering just a simple closed loop. As an example of this, some string theories allow the possibility of *open strings* as well as *closed strings*:

In string theory, therefore, particles are considered as being strings in higher dimensions. Because these higher dimensions are so small, the strings actually appear like microscopic particles. So, according to string theory, elementary particles such as electrons and quarks are not pointlike particles at all but are actually microscopic strings. These strings are so small that they even appear like pointlike particles under the highest magnification currently available: we would need accelerator energies a million billion times more powerful than our current particle accelerators to be able to observe these strings.

There are some theoretical advantages from considering particles as being strings. In order to understand why, we

need to consider how particles exist in spacetime. As a particle naturally moves forward in time (time passes), it is clearly able to move in space as well over that period. The following diagram shows both space and time plotted in a diagram — a *spacetime diagram*. Note that only one dimension of space is shown along the vertical axis (it is not possible to plot more than one dimension of space in these diagrams as the other axis represents the time dimension). In the diagram on the left you can see how a particle plots a curved line in a spacetime diagram as it moves in space (on the vertical axis) as time progresses (along the horizontal axis). This traces the position of the particle at each moment in time. For a particle, this line is called a *worldline*:

Strings, however, are clearly not infinitely small point-particles. We have seen how strings can be looped structures, so as these loops move through time they actually plot a two-dimensional *worldsheet* (as shown on the right in the previous diagram).

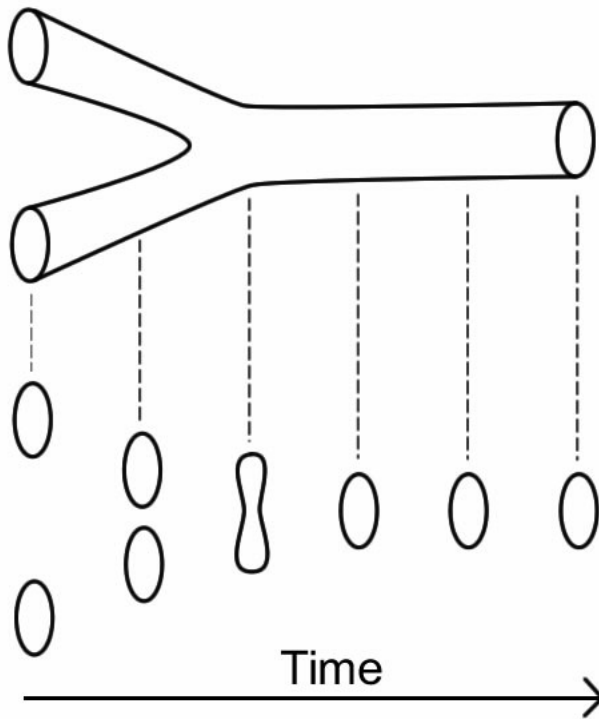

So, bearing in mind that a particle plots a worldline whereas a string plots a worldsheet, let us now examine the spacetime diagram for particle interactions. In the following diagram, the diagram on the left shows two particles colliding to produce a third particle (for example, this might be an electron and a positron annihilating to produce a photon):

You will see there is a clearly-defined *interaction point* where the two particles meet. Having such a clearly-defined infinitely small interaction point for the two particles introduces problems: unavoidable infinities enter the equations describing this interaction, and infinities must be avoided in any accurate model of the natural world (it is the apparently zero distance between the particles at the interaction point which leads to the infinities).

However, the diagram on the right in the previous diagram shows the same interaction but this time the particles are represented by string loops. So instead of the particles plotting a one-dimensional worldline on the spacetime diagram, the strings now plot two-dimensional worldsheets. As you can see on the diagram, this now avoids there being any clearly-defined interaction point — the strings have the effect of spreading the interaction. The zero-distance problem — and hence the undesirable infinities in the equations — can be avoided.

By taking slices through the worldsheet at different instances of time we can see how the worldsheet represents two string loops (two particles) interacting to produce a third particle. In the following diagram, you can see the interactions of the string loops underneath the worldsheet. You can see that two string loops (coming in from the left) representing two different particles interact to produce a single string loop (a single particle). Notice how smooth the interaction has become:

The music of strings

One of the most surprising features of string theory is that the strings are modelled very much as if they were everyday strings — in fact, just like a guitar string. Yes, string theory really is a theory of physical strings! And, just like a guitar string, a string in string theory can oscillate at a certain frequency. If we imagine a guitar string fixed at both ends, we can see that only particular frequencies are possible:

Considering the diagram above, you can see that it is possible for the two ends of the guitar string to loop back round and connect to each other, thus forming a closed loop with a discrete (integer) number of wavelengths allowed:

(This might remind you of the whole number of electron wavelengths fitting in orbit around the Bohr model of an atom).

Just as with a guitar string, we can think of these different *modes* of vibration as representing different musical "notes". So what do these different vibrational modes represent? Well, intuitively, we can think of the shorter wavelengths as representing more energetic motion, so the higher the wavelength, the greater the energy of the string. You might also be reminded of Planck's result which linked the energy of a photon to the frequency of the electromagnetic radiation carried by that photon in which, again, higher frequencies (shorter wavelengths) mean more energy. And, through $E=mc^2$, if a string has more energy then that means it must have more mass. So the pattern of vibrations of a string determines the mass of that string and, therefore, the mass of the elementary particle which the string represents.

This is a major departure from the usual way in which we think about the mass of particles. We usually think of particles as being fundamentally different, made of different "stuff", so to speak. However, if string theory is correct, then all particles are made of exactly the same thing: a string, and the only thing which differentiates the particles is

the particular mode of vibration of that string. The mass of the particle is determined by the vibration of the string.

Let us now consider the lowest mode of string vibration, with the lowest possible frequency and therefore the lowest possible mass:

If the value $n=1$ is entered into the formula for string mass, then the formula gives a value of zero, which means the associated string would have no mass. This appears to indicate the presence of an unknown massless particle, and this was initially considered to be a failed prediction of string theory. However, in 1974, Joel Scherk and John Schwarz suggested that this massless particle might well be the *graviton*, the particle which is proposed to carry the force of gravity (the graviton would have to be massless to transmit the force of gravity across the entire universe via gravitational waves).

We have already seen that string theory can predict the photon, the particle which transmits the electromagnetic force. String theory now appeared to predict gravity, another of the fundamental forces. At a stroke, string theory changed from a theory with limited interest to potentially being able to unify the four fundamental forces. From this point on, string theory emerged as the leading contender to be a potential "theory of everything".

The best-kept secret in mathematics

I hope you have enjoyed this gentle introduction to string theory. Unfortunately, nothing so far in this chapter on string theory has been directly relevant to this book and its central theme of the number of spatial dimensions, which is what we will consider in this section.

In this discussion of the basic principles of string theory I hope the theory has appeared reasonable, with nothing remotely astonishing or bizarre. This has been quite a deliberate approach on my part, because things are about to get seriously weird!

We are about to derive the number of spacetime dimensions predicted by string theory.

If someone was to tell you that the sum of all the numbers was minus one twelfth I suspect you might imagine the person was mildly crazy. Well, this is actually an established mathematical fact: the sum of all the numbers is minus one twelfth (or, in decimals, -0.083). Let me be more precise about what, specifically, is being stated here. We are actually referring to the sum total of all the natural numbers. We discussed the natural numbers in Chapter One: they are the numbers used for counting: 1, 2, 3, etc. So what is actually being stated here is that the infinite sum of $1+2+3+4 \dots$ comes to minus one twelfth.

Let's write that out:

$$1 + 2 + 3 + 4 + 5 + \dots \infty = -\frac{1}{12}$$

We can express this infinite sum in mathematical notation by the following mathematical expression, which is taken directly from Joseph Polchinski's popular and authoritative textbook on string theory which is called, simply, *String Theory*:

$$\sum_{n=1}^{\infty} n \rightarrow -\frac{1}{12}$$

On the left hand side of the expression, you will see the Greek letter sigma (Σ) which represents a sum. You will see that in this case it represents a sum of the variable n as n takes all the values from 1 to infinity (so this is just a mathematical way of representing the infinite series $1+2+3+4 \dots$). The right hand side of the expression shows that this series will indeed eventually take the value minus one twelfth.

You might not believe this is true: how can an infinite sum of positive numbers ever result in a finite negative value? I'll admit, this is a difficult result to understand, but I can only repeat that this is a generally-accepted important result in mathematics and physics, and is absolutely central to string theory. It is central to string theory because this result is used by string theory to predict the number of spatial dimensions.

We will now derive this result. I have to say that this derivation can also be found in an excellent video on YouTube in which two physicists from the University of Nottingham explain it in a very entertaining manner. I can highly recommend you watch the video:

<http://tinyurl.com/sumofallnumbers>

The video went viral and currently has four million views on YouTube, which I am sure is a record for a video about string theory. Well done to those physicists.

There is also a *New York Times* article which considers the result: <http://tinyurl.com/timesinfinity>

In that *New York Times* article, Edward Frenkel, a mathematics professor from Berkeley, says: "This calculation is one of the best-kept secrets in mathematics. No one on the outside knows about it."

I would suggest that four million YouTube viewers might now disagree with the professor.

OK, so now let us proceed with this amazing derivation (as I said, the YouTube video of the Nottingham physicists is perhaps a clearer version of this). Let us start by writing out that infinite sum of natural numbers, and let us call the result of the infinite sum S :

$$S=1+2+3+4+5+6+\dots$$

Remember, we want to calculate the value of S .

Now let us consider a second infinite sum. Let us define the sequence $S1$ as:

$$S1=1-1+1-1+1-1+1\dots$$

Note that the signs alternate from minus to plus on each number. What is the total value of $S1$? Well, you will see that if we stop the sequence after a $+1$ then the sequence $S1$ will have the value $+1$. Alternatively, if we stop the sequence after a -1 then the sequence $S1$ will have the value 0 . So what possible single numeric value can we give the sequence if the sequence extends to infinity? The only value which makes any sense is an average of $+1$ and 0 , which means the value of the infinite sum $S1$ must be 0.5 .

Now let us consider a third infinite sum, $S2$:

$$S2=1-2+3-4+5-6+7\dots$$

Let us now calculate the value of the sum $S2$ multiplied by two. We can do this by adding $S2$ with itself, but we will shift this second version of $S2$ by one place to the right:

$$\begin{array}{r}
 S2=1-2+3-4+5-6+7\dots \\
 S2= \quad 1-2+3-4+5-6\dots \quad + \\
 \hline
 \quad 1-1+1-1+1-1+1\dots \\
 \hline
 \end{array}$$

If you consider the sums of each number vertically you can see that the result of this addition is the infinite sum of $1-1+1-1+1-1+1-1$ which is just the sequence $S1$. And we already know that $S1$ has the value 0.5. Therefore:

$$2 \times S2 = 0.5$$

which means that $S2$ has the value 0.25.

Now let us consider what we get when we subtract the sequence $S2$ from sequence S (in the following subtraction, remember that subtracting a negative number turns it into a positive number):

$$\begin{array}{r}
 S = 1+2+3+4+5+6\dots \\
 S2=1-2+3-4+5-6\dots \quad - \\
 \hline
 \quad 4+0+8+0+12\dots \\
 \hline
 \end{array}$$

so we get the infinite sum $4+8+12+16\dots$ which is the series S multiplied by four. Therefore:

$$S - S2 = 4S$$

We already know that $S2$ has the value 0.25, so this means:

$$S - 0.25 = 4S$$

Subtracting S from both sides gives:

$$-0.25 = 3S$$

so therefore:

$$S = -\frac{1}{12}$$

and that's it! The sum of the infinite sequence S , which is $1+2+3+4\dots$ is minus one twelfth!

You might find this hard to believe, but I can assure you that this is an established and accepted result in mathematics, and it was rigorously proved by the great mathematician Leonhard Euler in 1749. The result is also used in physics in a formula which is completely unconnected with string theory and gives completely accurate experimentally-verified predictions about the behaviour of Nature.[\[23\]](#) So this is a correct result!

The recently-released film *The Man Who Knew Infinity* tells the story of the Indian mathematician Srinivasa Ramanujan. Ramanujan was born in 1887. He came from a background of extreme poverty and had no formal

training in mathematics, but he had a tremendous natural talent and instinct for the subject, with a particular talent for constructing infinite series. Ramanujan sent some of his original work to the mathematician G.H. Hardy at Cambridge University. Hardy was amazed at Ramanujan's skill and original methods. Hardy invited Ramanujan to study at Cambridge, and Ramanujan eventually became a Fellow of the Royal Society.

Ramanujan's story is relevant to this chapter because he also derived the result that the infinite sum of the natural numbers is equal to minus one twelfth. Ramanujan's method was very similar to the method described earlier and shown on YouTube. After calculating this amazing result, Ramanujan wrote to Hardy: "Dear Sir, I am very much gratified on perusing your letter of the 8th February 1913. I was expecting a reply from you similar to the one which a mathematics professor at London wrote. I told him that the sum of an infinite number of terms of the series $1+2+3+4\dots = -1/12$ under my theory. If I tell you this you will at once point out to me the lunatic asylum as my goal."

Ramanujan's derivation is shown below in his own handwriting:

Another way of finding the constant is as follows - 41
 Let us take the series $1+2+3+4+5+\dots$. Let C be its constant. Then $C = 1+2+3+4+\dots$
 $\therefore 4C = 4+8+12+\dots$
 $\therefore -3C = 1-2+3-4+\dots = \frac{1}{(1+1)^2} = \frac{1}{4}$
 $\therefore C = -\frac{1}{12}$

I would suggest that this is one of the most remarkable results in the whole of science.

So what has this got to do with string theory? Well, we have already seen that there are an effectively infinite number of modes of oscillation for a string ($n=1, n=2$, etc.). So the total number of modes in which a string can oscillate will be an infinite sum of all these modes:

$$\sum_{n=1}^{\infty} n$$

So the infinite sum of all the natural numbers appears in the equation giving us the number of modes in which a string can oscillate. We now see that our earlier apparently crazy piece of infinite arithmetic has relevance to string theory. What is more, our crazy piece of arithmetic has tamed the infinities! As was explained earlier, the mass of a string (and, therefore, its energy) depends on all the modes of vibration. If the sum of all the modes of vibration had been an infinite number, then the energy of a string would be infinite and string theory could not possibly be a correct theory of reality (we do not see infinities in the physical world). However, our apparently crazy arithmetic has produced a finite result, so string theory can be a *finite* theory. This is a vital feature of any theory.

For the next part, we need to consider the number of directions in which a string can oscillate. This is described by Joseph Conlon in his book *Why String Theory?*: "A string can be plucked, and can oscillate, in every direction transverse to its length. A string living in two spatial dimensions has one direction it can oscillate in; a string in three spatial dimensions has two directions it can oscillate in; a string in twenty-five spatial dimensions has twenty-four directions it can oscillate in."

On that basis, a string in three dimensions of space (four dimensions of spacetime) can oscillate in two perpendicular directions — transverse to its length — and this is shown in the following diagram:

This reasoning implies that, in D dimensions of spacetime, a string is able to oscillate in $(D-2)$ directions. To calculate the total energy of a string, we have to consider the infinite sum of all the modes in which a string can vibrate, and multiply that sum by the number of directions in which the string can vibrate. Hence, the sum of all energies of the string is given by:

$$(D - 2) \sum_{n=1}^{\infty} n$$

Using this result, we are now in a position to calculate the number of dimensions, D , predicted by string theory. Without going into details, the actual equation we need to solve to find D is: [\[24\]](#)

$$\frac{1}{2}(D - 2) \sum_{n=1}^{\infty} n = -1$$

We have just shown that the infinite sum in this equation is equal to minus one twelfth. So let us replace the sigma term in the equation with the value minus one twelfth, which results in:

$$\frac{1}{2}(D - 2) \times -\frac{1}{12} = -1$$

Multiplying both sides of the equation by -24 gives:

$$D - 2 = 24$$

which means $D=26$. Therefore, string theory predicts 26 dimensions of spacetime! In other words, string theory predicts one dimension of time, and 25 dimensions of space.

I think the immediate response of most people on discovering a theory predicts 25 dimensions of space would be a feeling of disappointment shortly followed by a rejection of the theory for being incorrect. As Lee Smolin says in his book *The Trouble with Physics*: "The world does not appear to have twenty-five dimensions of space. Why it is that the theory was not just abandoned then and there is one of the great mysteries of science." However, the theory was most certainly not abandoned. With string theory, I think the phrase "putting a positive spin on things" takes on a whole new meaning. A direct quote from one of my string theory textbooks provides an example of how this apparently negative outcome is frequently presented as a positive feature: "Since the dimension of spacetime is uniquely selected by the requirement of consistency, we can say that string theory predicts the dimension of spacetime!" [25]

Well, I suppose that predicting a finite integer number of spacetime dimensions must be considered some kind of an achievement. It is just a shame that it is the wrong finite integer number of spacetime dimensions.

The hidden dimensions of string theory

So far we have seen that string theory is able to predict the existence of the photon and the graviton, in other words string theory can predict the particles which transmit the forces. If you read my previous book, you will know that these intangible particles are called *bosons*. For this reason, the version of string theory we have considered so far is called *bosonic string theory*.

Bosonic string theory was the original version of the theory developed in the early 1970s and might be considered to be the core of string theory. However, if you read my previous book you will know that all particles are divided into one of two groups: they are either bosons, or they are *fermions*. Whereas bosons are the intangible particles (which form a light beam, for example), fermions are the particles which make matter. So fermions are the particles which form a chair, a car, a human, for example. And the trouble with bosonic string theory is that it cannot be used to produce fermions. Hence, bosonic string theory on its own cannot be a realistic theory.

A solution to this problem emerged in the 1970s in the form of *supersymmetry*. Supersymmetry predicts a symmetry in which bosons can be exchanged for fermions. So incorporating supersymmetry into string theory produced a complete theory which could now predict the existence of fermions.

String theory which incorporates supersymmetry is called *superstring theory*. One attractive side-effect of superstring theory is that the predicted number of spacetime dimensions was reduced to ten. It is clearly still not correct, but it might be regarded as a step in the right direction.

Supersymmetry also predicts the existence of a huge range of additional undiscovered particles called *superpartners*. By incorporating supersymmetry, superstring theory has made itself something of a hostage-to-fortune to the discovery of these additional particles. If the superpartner particles are not discovered, then it would deal a fatal blow to superstring theory. So far, the Large Hadron Collider at CERN has not discovered any supersymmetric particles. This is bad news for supersymmetry and, therefore, bad news for superstring theory.

By the late 90s, string theory was not in the best of shape having splintered into five variations. However, in 1998, Ed Witten (the effective leader of the superstring theory field) announced that it might be possible to unify these five theories into a single theory (which he called *M-theory*). Unfortunately, this unification was achieved by the usual method of introducing an additional dimension of space. String theorists greeted the M-theory proposal with great excitement — despite the newly-predicted eleven dimensions of spacetime being even more inaccurate than the previous ten-dimensional prediction.

Whichever variation of string theory you consider, one feature is clear: the theory will predict considerably more than four spacetime dimensions. The problem then arises: where are these extra dimensions, and why do we not see them? The proposed solution is based on the Kaluza-Klein idea that the extra dimensions are compactified — too small to detect. A particular structure — called the *Calabi-Yau space* — has been suggested as a way in which six spatial dimensions might be compactified (much like the single spatial dimension is compactified into a circle in Kaluza-Klein theory). The following diagram shows a projection (in two-dimensions, obviously) of the six-dimensional Calabi-Yau space:

Unfortunately, it appears there are many tens of thousands of different Calabi-Yau spaces, and string theory does not indicate which is the correct one. What is more, each different Calabi-Yau space — each different folding of the extra dimensions — would result in different laws of physics, and a different set of elementary particles. If string theory is unable to select one particular Calabi-Yau space then it would appear that string theory is unable to predict a unique set of laws of Nature.

It has even been suggested that there might be a vast "landscape" of possible universes with different Calabi-Yau foldings in each universe. This represents another form of the anthropic argument in which virtually any outcome is possible. As a result, string theory has been criticised as being untestable and potentially unscientific.

For these reasons, it appears that string theory research is moving away from an attempt to find a fundamental theory of quantum gravity. Instead, the field appears to be splintering, with some researchers more interested in string theory purely because of the new mathematical techniques that have been developed.

7

WHY THREE DIMENSIONS?

OK, this is the last chapter, so let's have a bit of fun.

If you have read my previous books, you will know I like to include some of my own original ideas in the later stages of my books, and this book is no exception. So far, we have considered several of the main hypotheses as to why there are three spatial dimensions, and in this chapter I will present my own idea. So bear in mind that the material presented in this chapter should be considered speculative (however, all the material in this book — with the exception of the chapter on general relativity — should be considered speculative as absolutely no one knows the real reason why there are three dimensions of space).

The solution which will be presented here is particularly appealing because it includes principles from almost every area of fundamental physics: relativity, quantum mechanics, particle physics, and thermodynamics. It will also include several of the "fundamental principles" which have been considered in my previous books.

I had several guidelines in mind when I developed this theory:

- The theory would have nothing to do with anthropic reasoning. Therefore, it could include no reliance on unseen parallel universes. Instead, a unique solution would have to emerge from clear logical reasoning. As Joseph Conlon says about anthropic theories in his book *Why String Theory?*: "The argument lacks the redeeming precision of cut-and-dried mathematical argument." We will be searching precisely for a cut-and-dried argument, and we will even be ending up with a simple equation which gives us the answer we seek: the number three.
- The theory would clearly and unambiguously have to predict three spatial dimensions. Not ten dimensions — three dimensions. This is in line with the naturalness argument (considered in Chapter One) which suggests a number of dimensions close to the value of one, and it is also in agreement with every observation which has ever involved counting the number of spatial dimensions.
- As explained at the end of Chapter Two, we should not expect to find three-dimensional space as a pre-existing absolute background. Instead, we should expect three-dimensional space to **emerge** from the properties of the fundamental particles which compose the universe. This principle was described by Einstein in the *New York Times* in 1919: "Till now it was believed that time and space existed by themselves, even if there was nothing — no Sun, no Earth, no stars — while now we know that time and space are not the vessel for the universe, but could not exist at all if there were no contents, namely no Sun, no Earth, and other celestial bodies." Einstein repeated this insight that time and space emerged from the behaviour of matter in the *New York Times* in 1921: "Up to this time the conceptions of time of time and space have been such that if everything in the universe were taken away, if there were nothing left, there would still be left to man time and space." Einstein had realised that if there is no matter, there is no space. To find our solution, we need to consider the behaviour of matter.
- The theory would have to be simple. We are dealing with the most fundamental of physical entities: the number of dimensions of space. It is a firm belief of all my books that, as we approach the fundamental level, our theories should get simpler — not more complicated.

The proposed solution presented in this chapter will be composed of five simple parts:

1. A bit of relativity.
2. A bit of thermodynamics.
3. A bit of particle physics.
4. A bit of quantum mechanics.
5. Why three dimensions?

OK, let's get started ...

Part 1: A bit of relativity

As explained earlier in this book, Hermann Minkowski realised that special relativity suggested that time and space should be combined into a higher-dimensional combined spacetime. And it is this spacetime model which provides us with a simpler way of looking at special relativity. This simplification is described by Brian Greene in his excellent book *The Fabric of the Cosmos*: "The combined speed of any object's motion through space and its motion through time is always precisely equal to the speed of light." In other words, it can be considered that all objects travel through spacetime at the speed of light. As mentioned in Chapter Four earlier in this book, even an object which is stationary, i.e., is not moving in space, is clearly still moving through time (a watch, for example, clearly shows the passage of time). For the complete details of why this speed through spacetime is necessarily the speed of light, see my third book.

This principle allows us to understand special relativity in a simpler form. As Brian Cox and Jeff Forshaw explain in their book *Why Does $E = mc^2$* : "This newfound way of thinking about how things move through spacetime can help us get a different handle on why moving clocks run slow. In this spacetime way of thinking, a moving clock uses up some of its fixed quota of spacetime speed because of its motion through space and that leaves less for its motion through time."

This interpretation of special relativity provides us with a simpler way of understanding the time-travelling astronaut. An astronaut who flies away from the Earth at nearly the speed of light before returning to the Earth will have travelled a greater distance through space than his friend who stayed on Earth. However, because the astronaut will have travelled a greater distance through space, he will have travelled a smaller distance through time (as everything travels at the same speed in spacetime). In other words, he will have aged less.

So special relativity provides us with the first principle we need on our quest to understand why there are three dimensions of space: everything travels through spacetime at the speed of light.

Part 2: A bit of thermodynamics

The nature of time still remains something of a mystery to us. This is because — certainly down to the atomic level — all physical processes appear to be reversible with time.^[26] For an example from Newtonian mechanics, consider a movie of a moving ball colliding with a stationary ball. The first ball would stop and the second ball would move off at speed. If the movie was played backwards, the events would still make sense according to the laws of physics. This time, though, the second ball would come in reverse, strike the stationary first ball, and the first ball would then move off in reverse. Everything would happen perfectly in reverse, and it would look as though it was happening in the forward time direction.

So if the laws of physics are time-symmetrical, why do so many processes exhibit a so-called *arrow of time* in the forward time direction? For example, we might see an egg breaking (in the forward time direction), but we never see a broken egg reforming itself — so clearly that is not a process which is time-symmetrical. The answer as to why there is an arrow of time comes from the increase in *entropy*, which can be regarded as the amount of disorder in a system. It is known that the amount of entropy in a system will always tend to increase with time, in other words a system will become more disordered over time. Hence, we see cars rusting (their molecules becoming more disordered), but we do not see rusting cars becoming new again. This principle that the entropy of a closed system increases with time is called the *second law of thermodynamics*.

But entropy is a statistical property which can only be measured from a group of particles. It therefore makes no sense to talk about the entropy of a single particle — a single elementary particle has no internal parts, so it can never get disordered, or fall to bits over time. In a similar fashion, it makes no sense to talk about the temperature or pressure of a single particle (temperature and pressure are also statistical properties of a group of particles). As Joseph Conlon says in his book *Why String Theory?*: "The concept of temperature requires many particles."

So — if this is the case — then how does a single elementary particle experience time? If it is not subject to increasing entropy then it is not subject to the usual arrow of time. However, we know that elementary particles do experience time because of experimental observations. For example, when protons from space hit the upper atmosphere of the Earth, they produce *muons*, which are a heavier form of electron. Because the muons are heavy, that means they rapidly decay to lighter particles: the average lifetime of a muon is 2.2 microseconds. In that very

short period of time, even muons travelling at close to the speed of light will only travel 660 metres before they decay. This means very few muons should actually reach the surface of the Earth. However, in practice, many more muons reach the Earth's surface. This is because of time dilation predicted by special relativity: the particles are travelling at close to the speed of light, so time passes slower for the muons. Hence the muons "age slower" and it takes them longer to decay.

It is also well known from particle accelerator experiments that elementary particles take longer to decay when they are moving close to the speed of light. This was described by Luboš Motl in a blog posting entitled *The world as seen by the LHC protons*: "All the processes occurring 'inside' the moving particle are slowed down due to time dilation. That's true for the 'ageing process' of the particle, too." [\[27\]](#)

But if an elementary particle has no internal structure, it can have no internal clock. And if it has no internal parts then it has no entropy and is therefore not subject to the usual entropy-based arrow of time. So how do elementary particles experience time? How do elementary particles "age"? This is a very fundamental question.

We will shortly be returning to this question as we shall see it possibly holds the key as to why there are three dimensions of space.

Bear with me ... we are getting there!

Part 3: A bit of particle physics

The world of particle physics can seem a very confusing place. However, if you read my previous book you will know that all particles can be placed in one of two simple categories: a particle is either a *fermion* or it is a *boson*.

Fermions resist being in the same state as other fermions. It is this tendency which causes fermions to be the particles which form atoms. Electrons are fermions, and they orbit the atomic nucleus (composed of quarks, which are also fermions) in clearly-defined shells. The clearly-defined electron shells prevent two electrons from being in identical states.

Because fermions resist being in the same state, an object composed of fermions will resist our touch, feeling solid. Hence, fermions are the particles which form matter: trees, cars, gases, tables, and humans.

The other category of particles are the bosons. A photon (a particle of light) is an example of a boson. In contrast to the behaviour of fermions, bosons like to be in the same state. Hence, billions of photons will congregate to produce a beam of light. Because photons do not mind being in the same state, bosons feel intangible: a light beam does not resist our touch. Hence, bosons are not suitable particles for forming matter.

This distinction between fermions and bosons is vital for our quest to determine why there are three dimensions of space. This is because of our human bias when considering questions about space (considered in Chapter Two). We are made of fermions. The objects we manipulate are made of fermions. The objects we have to avoid when we navigate space are made of fermions (we generally don't have to avoid a beam of light). Atoms are made of fermions, and galaxies are made of fermions. In fact, it could be said that we define space in terms of fermionic matter.

This is important for our quest to understand why there are three dimensions of space. To see why, let us ask the hypothetical question: how many dimensions would we experience if we were made of light? Special relativity tells us that an object ages slower as its speed approaches the speed of light. An object made of fermions has mass, and can never reach the speed of light. However, light is composed of massless bosons and is therefore able to travel at ... well ... the speed of light. Light, therefore, does not experience time. Harry McLaughlin, one of the top contributors on the *Quora* website, describes the experience of light quite beautifully: "Imagine watching a sunset. A photon is emitted from an atom in the solar photosphere and journeys across space until it reaches your eye and is absorbed by a molecule in your retina. From your point-of-view, this photon had a lifespan of about eight minutes. However, for the photon, its own emission and absorption is a single event. There are no defined notions such as 'happening', 'process', or 'experience'. For a photon, time is non-existent and meaningless."

With this in mind, let us return to our hypothetical question: how many dimensions would we experience if we were made of light? From the previous discussion it is clear that if we were made of light we would not even be asking the question "Why does the universe have four spacetime dimensions?" because we would not experience four spacetime dimensions. Just like light, we would not experience the time dimension. In other words, we would have lost a dimension!

And I think this is a vital point: the number of dimensions of the universe depends on your viewpoint. Is your universe defined by bosons or fermions? This makes it very clear that — to repeat a point made in Chapter Two — the dimensions emerge from the behaviour of matter in the universe. The spatial dimensions do not form a pre-existing system of axes. Newton's idea of absolute space has been refuted. There is no absolute "box" of spatial axes

"outside the universe" which would remain if all the matter in the universe was removed. Instead, the dimensions come from the behaviour of that matter: the dimensions emerge from the behaviour of particles.

So, if we truly want to understand why there are three spatial dimensions, we need to consider the behaviour of particles. Specifically, we need to consider the behaviour of fermions, because that is how we define our space.

Part 4: A bit of quantum mechanics

In the first two decades of the 20th century, physics was rocked by the two major developments of quantum mechanics and relativity. However, the incompatibility of these two developments posed (and still does pose) a major challenge for physicists.

If you read my previous book, you will know that in 1928 the British physicist Paul Dirac made a major breakthrough by successfully combining quantum mechanics with special relativity for the first time. In his famous Dirac equation, he managed to accurately describe the quantum mechanical behaviour of an electron which incorporated the rules of special relativity. He achieved this by using a *matrix*. A matrix is a rectangular array of numbers which can be used to transform one set of coordinates into another set of coordinates (for example, a rotation of an object can be described by a matrix). So, in his equation, Dirac used a matrix to transform spatial coordinates into time coordinates — according to the rules of special relativity. This resulted in a description of how the electron behaved in combined spacetime. [28]

So, what did the Dirac equation reveal about the electron? Amazingly, it revealed the electron had to spin. It was already known that an electron possessed the property of spin, but for the Dirac equation to predict the necessity for spin was an extraordinary achievement.

How are we to interpret this necessity for electron spin? Well, perhaps we should not be too surprised. Paul Dirac introduced the rules of special relativity into quantum mechanics, and we know from our earlier discussion that special relativity has a simple interpretation: everything travels at the speed of light in spacetime. If we consider a stationary electron, how can it possibly continue to move through spacetime at the speed of light? The simple answer is: it has to spin. Remember in our earlier discussion of entropy, the question was asked how can an elementary particle move through time? An elementary particle has no internal parts, so increasing entropy cannot explain the arrow of time for a single particle. Instead, perhaps we can consider the necessity for a particle to spin as representing the only way a stationary elementary particle can continue to travel through spacetime. How does a stationary elementary particle travel through time? The only way it can: it spins. [29]

But if particle spin represents a particle's speed through spacetime, at what speed should we expect it to spin? You might be able to guess: we would expect it to spin at the speed of light — the same speed that everything travels through spacetime. This was suggested by Paul Dirac in his Nobel Prize-winning lecture in 1933: "It is found that an electron, which seems to us to be moving very slowly, must actually have a very high frequency oscillatory motion of small amplitude superposed on the regular motion which appears to us. As a result of this oscillatory motion, **the velocity of the electron at any time equals the velocity of light**. This is a prediction which cannot be directly verified by experiment, since the frequency of the oscillatory motion is so high and its amplitude is so small."

However, even though it is impossible to experimentally measure the electron spinning at the speed of light, it is possible to perform a simple calculation to show that this is likely to be the case (the calculation is included in the Appendix).

But, really, the details of this are irrelevant. The only two things we need to know are that our reality is defined in terms of fermions, and that a fermion must spin. Those two facts alone are enough to determine that space must have three dimensions — as we shall now see ...

Part 5: Why three dimensions?

Congratulations — we have made it! This is the last step on our quest to discover why space has three dimensions.

On the basis of what we have just discovered, the solution is very simple. Because of our human bias, our space is defined in terms of fermions. A fermion with mass, travelling slower than the speed of light in the x direction, needs to spin. Spin requires a plane in two dimensions, so an additional two dimensions — y and z , shown in the following diagram — perpendicular to the direction of motion are required:

So three dimensions arise from the fermion's need to satisfy the rules of special relativity. And, as we define our reality in terms of fermions, our space therefore must have three dimensions, three degrees of freedom.

Referring back to Chapter One, the idea of three being a "number of sufficient magnitude" was introduced. We can now see how that principle is applicable: one or two dimensions of space would not be enough as the fermion would not be able to spin. Three dimensions is the smallest number of dimensions which allows spin perpendicular to motion, thus allowing the fermion to satisfy special relativity.

But, you might protest, this still does not specifically identify three dimensions of space. OK, one or two dimensions would not be enough, but surely this would still be possible in four dimensions of space, or five or six or any other large number of dimensions? Well, rather wonderfully, it turns out that three-dimensional space has a unique characteristic in this regard (as described in the discussion of three-dimensional geometry in Chapter Two, it is often the case that spaces with low number of dimensions can possess unique characteristics which are not shared by higher-dimensional space). John Barrow explains this unique characteristic in *Dimensionality*: "There is one simple geometrical property unique to three dimensions that plays an important role in physics: universes with three spatial dimensions possess a unique correspondence between rotational and translational degrees of freedom. Both are defined by only three components."

This is going to require some explanation.

Imagine a two-dimensional plane: a flat desert. And on that flat desert there is a car. The car is free to drive anywhere on the desert, so the car can move anywhere across that two-dimensional space. In other words, the car has two translational degrees of freedom. But how free is the car to rotate? The car rotates around the vertical axis when it turns left and right — when the driver turns the steering wheel. So the car has only one rotational degree of freedom (hence, the car has only one steering wheel — a steering wheel being required for each rotational degree of freedom).

To sum up, in two-dimensional space there are two degrees of translational freedom, but only one degree of rotational freedom. So, in two dimensions, the number of translational degrees of freedom is not equal to the number of rotational degrees of freedom.

Now let us consider the situation in three-dimensional space.

Unlike a car — which is restricted to movement in two dimensions — an aeroplane is free to move in a straight line in any direction in three-dimensional space: forward/back, up/down, left/right. So an aeroplane has three translational degrees of freedom. But how free is the aeroplane to rotate? It turns out that there are also three

rotational degrees of rotation available to the aeroplane, and these are called *roll*, *pitch*, and *yaw*:

So an aeroplane has three rotational degrees of freedom. For this reason, an aeroplane effectively needs three steering wheels — one for each rotational degree of freedom — and these are incorporated into a joystick:

Just to make it clear, a car or boat is able to move in two dimensions, but only needs one steering wheel (it is only able to rotate around one axis). An aeroplane can move in three dimensions and needs three steering wheels (it is able to rotate around three axes). As John Barrow said, in three dimensions — and three dimensions only — the number of rotational degrees of freedom is equal to the number of translational degrees of freedom.

There is a formula which gives the number of "steering wheels" (number of rotational degrees of freedom) in n dimensions of space, and that formula is:

$$\frac{1}{2}n(n-1)$$

Try calculating the result of this formula for various values of n , such as $n=1$ or $n=2$.

- For $n=1$ (one-dimensional space — a line) you will find the formula gives the value 0. This is because you cannot rotate in one-dimensional space, you can only move forwards and backwards along the line, so no "steering wheels" are required. So, in the case of one-dimensional space, the number of steering wheels, 0, is clearly not equal to 1, the number of dimensions.
- For $n=2$ (two-dimensional space — a plane) you will find the formula gives the value 1. This is the case of the car or the boat which can travel in two dimensions but are only able to rotate about a single axis — so only have one steering wheel. So, once again, the number of steering wheels is clearly not equal to the

dimensionality of the space.

- For $n=4$ you will find the formula gives the value 6, which is clearly not equal to 4.

However, for $n=3$ you will find the formula gives the value 3. So three steering wheels are required to navigate three-dimensional space. And, crucially, it can be shown that this is only true for $n=3$. No other number of dimensions will satisfy this formula.

Effectively, we are solving the magic equation:

$$n = \frac{1}{2} n(n - 1)$$

You might like to use a bit of high-school algebra to calculate the value of n from that equation yourself. You will find that putting $n=3$ satisfies the equation, which is clearly the correct answer for the number of spatial dimensions. [\[30\]](#) This makes it clear what an important role is played by spin (rotation) in defining the number of spatial dimensions.

So that is my proposal for why there are three dimensions of space.

To recap, we define our space in terms of fermions, which are the matter particles such as electrons. A fermion has to comply with the rules of special relativity (is said to be *Lorentz invariant*) and hence requires a plane of rotation in order to spin. But only in three-dimensional space is a single plane of rotation uniquely specified which is perpendicular to the particle's direction of motion.

And that is why I believe three is the magic number.

Thank you.

APPENDIX

This appendix presents a simple calculation to show that a particle spins at the speed of light (a similar calculation was performed in the early days of quantum mechanics).

In my previous book, it was stated that elementary particles are considered as being infinitely-small pointlike particles. But if the radius of a particle is truly zero, then how can we measure the speed at which a point on the surface of the particle spins? Well, quantum mechanics introduces an element of uncertainty into all measurements due to the Heisenberg uncertainty principle. Because of wave/particle duality, every particle can be thought of as having a wavelength as well. In the following calculation, the radius of the particle will be given by this wavelength, the *Compton wavelength*, which is equal to:

$$r = \frac{h}{mc}$$

where m is the mass of the particle, c is the speed of light, and h is Planck's constant. We will be modelling a particle by a spinning disk which has an angular momentum, L , equal to:

$$L = \frac{mvr}{2}$$

where v is the velocity with which the particle is spinning.

Replacing the value of r in this equation with the value of the Compton wavelength gives:

$$L = \frac{mv}{2} \left(\frac{h}{mc} \right)$$

Replacing the value of angular momentum with the spin angular momentum, $h/2$, gives:

$$\frac{h}{2} = \frac{mv}{2} \left(\frac{h}{mc} \right)$$

You will see that the h , and the m , and the 2 all cancel, leaving us with $v=c$. In other words, the particle spins at the speed of light.

NOTES

[1] I have often wondered why Occam's razor is called a "razor". Surely it does not have anything to do with shaving? Well, in the true spirit of Occam's razor, the simplest solution (and our first guess) is correct: it does indeed have something to do with shaving. Occam's razor is said to "shave" away unnecessary assumptions, cutting away the complexity.

[2] Frank Wilczek was the joint-discover of asymptotic freedom in the strong force.

[3] http://en.wikipedia.org/wiki/Mathematical_constant

[4] I believe this apparent connection between naturalness and simplicity is the reason for the current popularity of naturalness as a guiding principle in developing new theories — even though it might not always be applicable to all areas, such as particle physics. See Sabine Hossenfelder for a discussion: <http://tinyurl.com/sabinenaturalness>

[5] John Baez, *Platonic Solids in All Dimensions*, <http://tinyurl.com/johnbaez>

[6] J.D. Barrow, *Dimensionality*, <http://tinyurl.com/barrowdimensionality>

[7] So here we find a reason for the mysterious naturalness of the physical constants (discussed in Chapter One). The value of the numerical constants in our formulas is heavily-dependent on the dimensionality of space (see Chapter Ten of John Barrow's book *The Constants of Nature*). So because the number of dimensions of space is natural (three is a small dimensionless constant) this ensures that the other constants are also natural: the physical constants are natural because space is natural.

[8] It is quite easy to see the International Space Station at night: it is the third brightest object in the sky and it is amazing to see it passing overhead at great speed. There is a website which tells you when you can see the station: <http://iss.astroviewer.net/observation.php>

[9] The tendency of the bucket is to fly off in a straight line. So the only force actually acting on the bucket is the tension in the rope (this inward force is called the *centripetal force*). So the apparent outward centrifugal force you feel is considered to be a *fictitious force*.

[13] M. Gasperini, *The cosmological constant and the dimensionality of space-time*, Physics Letters B, Volume 224, June 1989, pp. 49-52.

[14] This flight pattern — which goes so far North — is called a *great circle*. Unfortunately, the *Titanic* hit an iceberg because it was following a northerly great circle route (the fastest route to New York) which took it into an ice field.

[15] This sign convention (+---) is sometimes called the *West Coast metric*. This is to distinguish it from the (-+++ sign convention which is sometimes called the *East Coast metric*. Some would say either convention is equally valid, but the West Coast metric clearly makes more sense to me as it applies to objects with a *timelike* world line, i.e., objects which cannot move faster than light (which is the case for all objects). In contrast, the East Coast metric applies to events with *spacelike* separation.

[16] Actually, this formula — which measures spacetime distance as the time measured by a travelling clock — means that objects move so as to **maximise** their distance through spacetime, not **minimise** their distance. This is because objects moving along a geodesic will show the maximum time on their clock (whereas as astronaut who deviates from the geodesic — by travelling to Jupiter and back, for example — will show less time passing, less spacetime distance, on his clock when he returns). But the end result is the same: objects tend to travel along geodesics.

[17] More precisely, this represents the *divergence*, which is a measure of how quickly a property "spreads out" from a point in space.

[18] You will also notice a g_{55} element in the bottom right corner. This represents an undiscovered particle called a *dilaton* and is a known problem with Kaluza's theory. Theodor Kaluza ignored it, and so shall we.

[19] These are examples of *global symmetries* because the same symmetry transformation is applied at every point in the universe. Gauge theory arises from *local symmetry* in which different transformations can be applied at each point in the universe.

[20] Technically, this is called *U(1) symmetry*, which means "rotation in one complex dimension". For more

information, see the book *Deep Down Things* by Bruce Schumm.

[21] Why is the phase of a wavefunction unobservable? Because quantum mechanics can only tell us the probability of an event occurring, for example, the probability that a particle will be at a certain position. If you read my fourth book you will know that the German physicist Max Born showed that the value of the **square** of the wavefunction represented the probability that the electron is found at a particular location. But when we square the wavefunction, we lose all the phase information (the phase being represented by a complex number). So the phase information is fundamentally unobservable — we can only measure the probabilities.

[22] Juan Maldacena, *The symmetry and simplicity of the laws of physics and the Higgs boson*, <http://arxiv.org/abs/1410.6753>

[23] It is used in the calculation of the *Casimir effect*. If two plates are placed just a few nanometres apart in a vacuum, there will be a small attractive force between the plates due to the vacuum energy of the electromagnetic field. The $-1/12$ value explains why summing over all the possible vacuum energy states does not result in an infinite value. The minus sign explains why the Casimir force is attractive.

[24] The expression on the left-hand side actually represents the sum of the lowest energies of each oscillator mode (the so-called *zero-point energies*). The $\frac{1}{2}$ term comes from the standard result for the lowest energy of a quantized harmonic oscillator (a vibrating string is a harmonic oscillator). The -1 term on the right-hand side represents the fact that the ground state energy is not zero, but has a small negative value called the *Casimir energy* (the value is the negative of the $n=1$ lowest-energy state).

[25] Chapter 12 of *A First Course in String Theory* by Barton Zwiebach.

[26] At the level of individual particles, the interactions of the weak force do not appear to be completely symmetric with respect to time. However, according to *CPT symmetry*, if the charge of a particle (C) and the parity of a particle (P) and time (T) are all reversed then all physical interactions are indeed reversible — even interactions due to the weak force.

[27] <http://tinyurl.com/lhcprotons>

[28] The resulting description of the electron is said to be *Lorentz invariant*, meaning that the description of the electron does not depend on how the observer is moving, i.e., the description conforms to the rules of special relativity.

[29] In accordance with the energy-momentum relation in special relativity, translational momentum in the space dimension transforms into angular momentum — spin — in the time dimension (if you are protesting that the intrinsic spin of a particle does not represent actual rotation, please refer to my previous book in which it is argued that it does, indeed, represent actual physical rotation).

[30] $n=0$ is the other — not very interesting — solution.

EPILOGUE

PREFACE

I am pleased to say that the subject of this book is the hottest topic in fundamental physics research today. Physics blogs and forums are buzzing with discussions about "fine-tuning" and the related subject of "naturalness".

These questions have taken increased priority after experiments at the Large Hadron Collider did not reveal any of the "Beyond the Standard Model" (BSM) physics which many particle physicists hoped would appear. With little new data to analyse, many particle physicists fear for their jobs. Does this represent the beginning of the end of fundamental physics research?

The LHC discovered the Higgs boson, but the mass of the Higgs boson has emerged as something of a puzzle in its own right. As we shall see later in this book, we have no idea why the Higgs mass is so small. Is the value "natural", or is it "fine-tuned"? Is the universe itself fine-tuned for life?

As you can see, these are seriously big questions. Though I have also included several side-stories to keep you entertained.

Once again, thank you for your support.

at all those infinite stars,
it made me realize how insignificant
they really are."*

- PETER COOK, BRITISH COMEDIAN

1

THE ANTHROPIC PRINCIPLE

In 1973, Brandon Carter, an Australian-born theoretical physicist, had just written a scientific research paper containing an idea which he knew was potentially explosive. Carter, who was studying at Cambridge University at the time, was unsure about the wisdom of publishing such a controversial paper. However, a young Stephen Hawking was intrigued by Carter's work and encouraged him to present his idea to the world.

By one of those strange twists of fate which sometimes occur, 1973 also happened to mark the 500th anniversary of the birth of Nicolaus Copernicus, the great Polish mathematician and astronomer. It was Copernicus who first proposed the theory that the Earth was not the centre of the universe, but, in fact, the Earth orbited the Sun. Previously it had been believed that the Earth held a very special position in the universe. But according to the Copernican principle, the Earth was nothing more than just another mediocre planet, and humanity was nothing more than some unremarkable chemical compound smeared over the face of the planet.

But now, for the first time in 500 years, the science of Brandon Carter was about to challenge Copernicus.

To mark the anniversary of the birth of Copernicus, a conference was being held in the Polish town of Krakow where Copernicus had studied. The timing was perfect for Carter. If Carter wanted to create a big stir in the audience, he certainly managed it. He picked just the right occasion to maximise the impact of his paper.

Carter's important and influential paper is available here:

<http://tinyurl.com/carterpaper>

Carter agreed with Copernicus that our position in the universe was not special or central in every way. However, Carter realised that this did not mean that our position could not be special in **any** way. Indeed, in some ways it was clear that our position **was** privileged. As an example, the Earth orbits the Sun at a comfortable distance so that its surface is not boiling hot like Venus, or freezing like Neptune. As another example, the strength of the Earth's gravity has the perfect value to retain a thick atmosphere, while not being too strong to crush any complex lifeforms which might emerge. It does seem fairly inarguable that our position — as far as the emergence of life is concerned — **does** appear to be privileged to some extent. Take a trip to Venus if you don't believe me.

But Carter went even further.

Carter had realised that not only was the Earth uncannily suited for life, but also that the laws of physics and the values of the fundamental constants seemed to have forms and values which appeared particularly suited for the emergence of life. If some of the values were only slightly different then it appears that the emergence of life in the universe might well have been impossible. It was almost as if the universe was "fine-tuned" for life.

As the great physicist John Wheeler said: "It is not only that man is adapted to the universe, the universe is adapted to man. Imagine a universe in which one or another of the fundamental dimensionless constants of physics is altered by a few percent one way or another. Man could never come into being in such a universe."

The six numbers of Martin Rees

It turns out that there is quite an extraordinary number of these "life-friendly" coincidences. Martin Rees has written a book called *Just Six Numbers* in which he considers just six of these remarkable numbers. According to Martin Rees: "The nature of our universe is remarkably sensitive to these numbers. If you can imagine setting up a universe by adjusting six dials, then the tuning must be precise in order to yield a universe that could harbour life."

Here are the six numbers of Martin Rees:

1. The value of N , which is the ratio of the strength of the electromagnetic force to the gravitational force. N has the value approximately equal to 10^{40} , which is 10,000,000,000,000,000,000,000,000,000,000.

Put simply, this means that the force of gravity is extraordinarily weaker than the electric force. However, unlike the electric force — which can be either attractive or repulsive — gravity is always attractive. So, even though gravity is extremely weak, the attractive force accumulates and becomes dominant for large masses. In

fact, gravity becomes so strong that any planet larger than Jupiter would become crushed by gravity — so the Earth is very lucky that gravity is not stronger. Not only would the Earth be crushed, but all life on Earth would be crushed as well.

Similarly, as gravity becomes stronger for larger masses, this means that stars must necessarily be huge in order to overcome the tremendous outward pressure generated by the fusion reactors in their core. It was the American physicist, Robert Dicke, who first realised that stars are so big because gravity is so weak. If gravity was stronger then stars would be very much smaller, and their lifetimes would then be too short to allow the evolution of complex life.

The strength of gravity will be considered in detail in the final chapter of this book.

2. The value of ϵ , the Greek letter *epsilon*, which represents the amount of energy released by the nuclear fusion reaction inside stars. The main fusion reaction combines hydrogen atoms to form helium atoms. The nucleus of a hydrogen atom is formed of a single proton, whereas the nucleus of a helium atom is formed out of two protons and two neutrons. But the nucleus of a helium atom weighs only 99.3% as much as the two protons and the two neutrons out of which it is made. The remaining 0.7% is released as energy during the fusion reaction, the energy coming from the loss of that small amount of mass according to $E=mc^2$. Hence, the value of epsilon is 0.7%, or 0.007.

Martin Rees then considers the case if the value of epsilon was 0.006 instead of 0.007. This would be the case if the strong nuclear force holding the protons and neutrons together was slightly weaker. As a result of this weakening of the force, protons could not be bound together during fusion and we would be left with a universe composed entirely of hydrogen. There would be no chemistry in such a universe — and no life.

Rees then considers the alternative situation in which epsilon was 0.008 instead of 0.007. This would represent a strengthening of the strong nuclear force. In that case, all the hydrogen would have disappeared from the universe shortly after the Big Bang, quickly fused into helium. There would then have been no fuel for stars, no water, and no life.

So, according to Martin Rees: "If epsilon were 0.006 or 0.008, we could not exist."

3. The value of Ω , the Greek letter *omega*, which represents the ratio between the total amount of mass and energy in the universe, and the *critical density* of the universe (the formula for the critical density was derived in my second book). The value of omega determines the eventual fate of the universe. If the total mass and energy contained within the universe is too small (less than the critical density), then the force of gravity will be too small to pull the universe back together again, and the universe will expand forever (this situation is called an *open* universe). Conversely, if the total mass and energy contained within the universe is larger than the critical density, the universe will eventually get pulled back together again by gravity (this situation is called a *closed* universe).

Observations of the universe indicate that the value of omega is close to one (indicating a *flat* universe, rather than open or closed). This appears to represent another case of fine-tuning of the value of omega: if the value of omega was much less than one, the universe would have expanded too fast to allow galaxies and stars to condense, and there would be no chance of life. Conversely, if the value of omega was much greater than one, the universe would have collapsed into a "Big Crunch" too quickly for stars to form. According to Martin Rees: "It looks surprising that our universe was initiated with a very finely-tuned impetus, almost exactly enough to balance the decelerating tendency of gravity. It's like sitting at the bottom of a well and throwing a stone up so that it comes to a halt exactly at the top — the required precision is astonishing."

There are, however, a couple of caveats to this apparent fine-tuning coincidence. Firstly, the popular inflation hypothesis predicts a flat universe — without the need for fine-tuning (though it has been suggested that inflation itself requires additional fine-tuning^[1]).

Secondly, this entire discussion is based on the behaviour of gravity at the largest of scales: will gravity pull the universe back together, or will gravity be too weak to prevent continual expansion? If our knowledge of gravity at the scale of the entire universe is wrong then it will have to be replaced by a theory of *modified gravity*. In that case, the fine-tuning requirement might be avoided. This possibility will be considered later in this book.

4. The value of Λ , the Greek letter *lambda*, which represents the *cosmological constant*.

We now know that the expansion of the universe is accelerating. This is due to a phenomenon which has been called *dark energy*. Dark energy is often suspected to be the vacuum energy present in empty space. However, our best estimate of the value of the vacuum energy is wildly inaccurate, and it appears that the

actual value must be fine-tuned to an incredibly small value.

We will see later how Leonard Susskind has described the apparent fine-tuning of the cosmological constant as a "cataclysm" for physics. The cosmological constant will be considered in detail in Chapter Four of this book.

5. The value of Q , the size of the initial "ripples" in the structure of the universe which seed the growth of all cosmic structures.

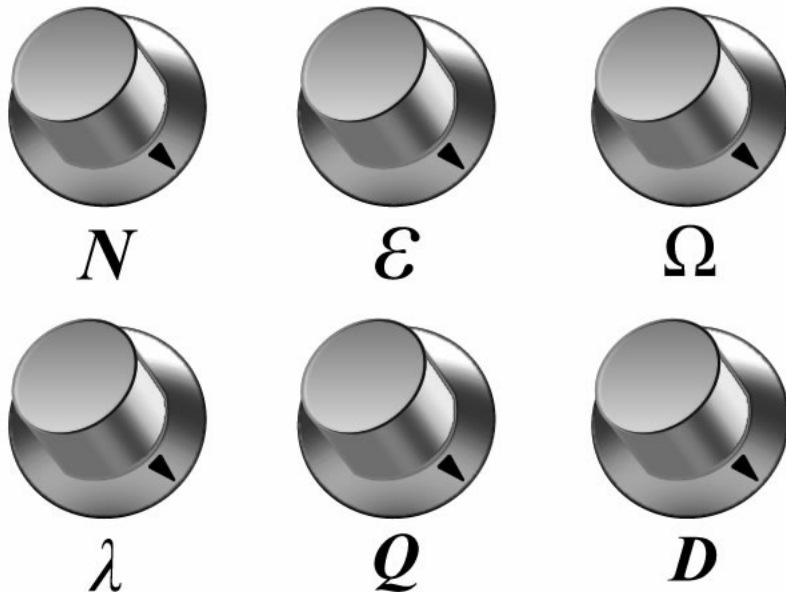

Martin Rees explains the importance of these initial irregularities being sufficiently large: "If the universe had started off completely smooth and uniform, it would have remained so throughout its expansion. It would be cold and dull: no galaxies, therefore no stars, no periodic table, no complexity, certainly no people." However, if the ripples had been too large then massive chunks of matter would have congealed into vast black holes. There seems to be some conflicting opinion over the problems introduced by a large Q , though there seems to be agreement over the necessity that Q should not be too small.

6. The value of D , the number of spatial dimensions of the universe — which is obviously set to three dimensions.

The number of spatial dimensions was the subject of my previous book. As I explained there, life could not exist if D was equal to two or four. However, in my book I came to the conclusion that this number was unlikely to be a fine-tuned coincidence. Any integer value close to one is likely to have a "natural" explanation (we shall be considering *naturalness* again later in this book). There is likely to be a simple mechanism which generates the number of dimensions, such as the simple mechanism which was proposed in my previous book.

With his listing of six arbitrary numbers, Martin Rees presented an analogy of six dials which have to be turned to particular values. As Martin Rees said: "The nature of our universe is remarkably sensitive to these numbers. If you imagine setting up a universe by adjusting six dials, then the tuning must be precise in order to yield a universe that could harbour life."

Here are Martin Rees's six numbers represented as dials:

There are more than just six arbitrary numbers, however. The Standard Model of particle physics requires the setting of the value of 25 fundamental constants — which would require a lot of dials! [2]

So Brandon Carter's 1973 paper really did cause a stir, the implications of which are still being felt to this day. But what made Carter's paper so controversial was that he also proposed an explanation for the fine-tuning coincidences.

To understand Carter's explanation, we will need to spend a day at the races ...

How to predict the winner of every horse race

Derren Brown is one of the most impressive performers currently on British television. His main act is that he is a mentalist, which means he appears to read people's minds. His mind reading act is so impressive that you become convinced he must have special powers. Brown can also get people to perform crazy feats through mind control. For example, he once convinced a group of old age pensioners to commit an art robbery — purely by mind control (the gallery was made aware of the impending theft).

What makes Brown's act so appealing is that he obviously has a good grasp of the science behind his technique, and he mixes scientific and mathematical techniques in with his magic. Sometimes it is difficult to tell where the science ends and the magic begins.

On British television in February 2008, Brown presented what is often regarded as his masterpiece. It was, quite simply, a way of predicting the winner of every horse race.

The show was called *The System*. Here is a description of the system in Brown's own words as he stands in the crowds of Sandown Park Racecourse at the start of the programme: "I have developed a guaranteed system for winning at the horses. This system allows me to predict — 24 hours in advance — which horse will win in big, high-profile races. Now, to prove this, six weeks ago I took a woman — a random member of the public — and I told her which horse was going to win in a certain race. It did win. She was intrigued. I then did it again, and again, and again. She started to bet larger and larger amounts of money. Now today, that woman has scraped together every last penny that she can find, and she is risking it all on one final race."

Ok, to clarify: this was a woman who was genuinely selected as a random member of the public. This was a single mother, a charming lady called Khadisha, who was working two jobs and who Derren Brown thought could most benefit from the winning money. Brown sent her a series of anonymous tips via email for several weeks. Because of Brown's apparent infallibility at picking winners, Khadisha was persuaded to bet large amounts of her own money on high-profile races. On the first race, Khadisha won £28. The second race went to a photo finish and there were a few tense minutes before it was announced that Khadisha's horse had won again. This time Khadisha won £360.

The fifth race proved particularly exciting with the predicted winner lying a long way back in third place going into the final jump fence. However, at the final fence the two leading horses both fell, so Khadisha's horse was then able to stroll through to an easy victory. Khadisha won just under a thousand pounds. Her only regret was that she had not betted more money so that she could have retired on the winnings.

So Derren Brown persuaded Khadisha to raise £4,000 (including £1,000 borrowed from her father) to bet on the sixth and final race. In the final race, the predicted horse won again (after a bit of classic showmanship from Brown) and Khadisha took home £13,000.

The entire video of *The System* is available on YouTube at the following link:

<http://tinyurl.com/derrenbrownssystem>

If all else fails, the following link to the video should always work:

<http://tinyurl.com/derrenbrownbackup>

At this point, it might be a good idea to put down this book and go and watch the video, and try to work out how

such a remarkable feat could have been achieved. I guess the solution would be called an example of lateral thinking — it is quite ingenious. I can tell you that I managed to work out the secret before Brown explained how he did it at the end of the video. See if you can do the same.

At about the nine-minute mark of the video, Brown announces that he is going to perform another seemingly impossible feat: "Part of what makes the System seem so impossible is that it defies our understanding of probability. I'm going to show you something now which is impossible in exactly the same way. I am going to toss a coin, fairly, ten times in a row and have it come up heads every time."

As Brown said, this was to be filmed under controlled conditions with multiple cameras running continuously which would not cut away, and it was a genuine coin with heads on one side and tails on the other. But then Brown said something more: "I want you to watch this (the coin tossing) and try and work out how it can be possible. Because the key to understanding this is the key to understanding the System."

Indeed, it was after Brown had performed this second seemingly-impossible feat that I worked-out the basic secret of how Brown was going to achieve his feat of predicting the winners of the horse races. Because, while there could be an element of skill in predicting the results of the horse races (by possessing expert knowledge of the horses, the jockeys, and the conditions), there could be no such skill which would help you throw a coin and get ten heads in a row.

There was only one possibility, and that is we were not being told the whole story.

The selection effect

Warning: spoilers ahead.

At about the 29-minute mark of the video, Derren Brown explains how the System works.

He starts by considering a similar example, an example of a person who takes a homeopathic remedy (homeopathic medicine is generally regarded as being unscientific) but finds it to be an effective cure: "You might have a viral infection, you might take the homeopathic remedy, you might then feel better and decide, therefore, that it must be an effective cure. The point is, it works for you — what more proof could you need? The trouble is that when these things are tested properly over thousands of people they are shown to have no effect whatsoever. The trap that people fall into is that they do not realise how limiting their own perspective can be. Khadisha believes in the system — she is convinced by it — because she is only looking at it from her own perspective. Now it is time to force a change in perspective, and to look at the bigger picture."

So why is all this relevant to the theme of this book, trying to decide whether or not the universe is "fine-tuned" for our existence? Well, it is precisely because we can only ever consider the problem from our own perspective — and that can be deceptive. We might interpret our existence as being the result of an impossibly improbable sequence of events, just as it was deceiving Khadisha picking her impossibly improbable sequence of winning horses (Derren Brown calculated that the probability of picking the sequence of winning horses correctly was one in 1.48 billion).

As Derren Brown said: "To work out the System, you need to understand that we can only know what comes from our own limited experience. And our experience can often be very far from the truth."

To explain the secret of the System, Derren Brown then returns to consider his feat of predicting ten correct coin tosses in a row: "To predict a run of ten heads in a row, and then make it happen, is hugely unlikely: the chance of it happening is about one in a thousand. However, if you flip a coin thousands of times, and record the results, then somewhere along that line of heads and tails then a line of ten heads is actually very likely to appear."

So that is how Derren Brown did his coin trick. What we saw — Brown tossing ten heads consecutively — represented only the final minute of what he called "an excruciatingly long day". Brown and his team filmed for over nine hours, with Brown tossing the coin continuously until he threw a consecutive sequence of ten heads. As Brown says: "the impossible became the inevitable".

So only the last minute of Brown's long day was selected for broadcast. But from our very limited viewpoint, it appeared that Brown had simply thrown ten heads in a row. What appeared to be an incredible coincidence was actually an inevitability.

Then Derren Brown explains how the horse racing trick was done. It was based on a similar principle to the coin

tossing trick in that we only got to see a very small part of the bigger picture. Initially, 8,000 people were contacted by email — not just Khadisha. Each of those 8,000 people received different tips as to which horse would win the first race. After the race, apologies were sent to all the people whose horse did not win and their bets were refunded. Khadisha happened to be in the group of people who had a winning horse in the first race.

The remaining people were then given different tips on a second race. Again, apologies (and refunds) were sent to the losers, and only the winners (including Khadisha) progressed to the next race.

By the time of the sixth race, there were only six people left, and they were each assigned a different horse in the final race. Of course, one of them **had** to win — the impossible became inevitable. It just happened to be Khadisha who received winning tips for all six races, and it was only Khadisha's story which was broadcast.

So what we have here is a large group of initial data (a large group of people) and only a small sample was taken from that group (a single person). But there was clear bias in the selection process as only the person who won all six races was ever going to be chosen as the representative sample.

Let us now consider another example of selection bias.

Let us imagine we want to determine the percentage of the population who have access to a telephone. The way we might decide to determine this is to conduct a poll: to pick a small sample of the population, see how many of them have a telephone, and then extrapolate that result to determine the percentage of the general population who have telephones. However, the way we decide to select our sample is via a phone poll: we ring up 1,000 people at random. I am sure you can anticipate the problem here. Out of that 1,000 people, we find that 100% of them have telephones. We then extrapolate that result to decide that everyone in the general population has a telephone. But, of course, there was clear bias in the way we selected our sample: only people who had a telephone in the first place could have been contacted via our phone poll. So of course it appeared that everyone had a phone.

When there is bias in the selection of a sample from a larger population, the misleading result is called a *selection effect*. It has been suggested that the apparent life-friendly coincidences in our universes could be a result of selection effects — in which case the apparent fine-tuning of the universe would be nothing more than an illusion. Let us now consider this suggestion.

The weak anthropic principle

In our previous discussion of selection effects, we have seen that any form of selection bias in a sample of data can lead to misleading conclusions being made. In particular, it can appear that uncanny coincidences have occurred, when, in fact, no such coincidences exist. With this in mind, when we consider the nature of the universe — to discuss whether or not it is fine-tuned — we can see that our existence as a form of intelligent life acts as a form of selection bias.

This is fairly obvious, after all, if conditions in our particular part of the universe were not amenable to the emergence of life then we would not be here to observe the life-friendliness of the universe — we simply would not exist. So, just like the previous example of the phone poll, if we ask the opinions of a privileged few people (people with telephones, or intelligent life living in comfortable regions of the universe) then you are going to get a false impression. On the basis of the responses, the universe is going to seem like a privileged environment, uncannily friendly and comfortable for life (with plenty of telephones as well).

So life is only ever going to be found in regions of the universe which are amenable to life. And any intelligent lifeform is then going to interpret the universe as being life-friendly. As Derren Brown pointed out, we can only ever consider the problem from our own perspective — and that can be deceptive. This tendency of intelligent life to interpret the universe as life-friendly is a selection effect and is fairly obvious. It should therefore be regarded as a tautology or truism.

In his book about the anthropic principle called *The Goldilocks Enigma* (also known as *Cosmic Jackpot*), Paul Davies makes this point: "Nobody can be at all surprised by this simple tautology. It merely says that observers will find themselves located only where life can exist. It could hardly be otherwise."

This fairly obvious principle is called the *anthropic principle*. The anthropic principle was presented for the first time (and given its name) in Brandon Carter's seminal 1973 paper, which was linked earlier but I will repeat here:

<http://tinyurl.com/carterpaper>

Specifically, this simple version of the anthropic principle which explains life-friendly coincidences as selection effects is called the *weak anthropic principle*.

As an example of the weak anthropic principle, we might look at the surface of Venus through a telescope and see

frightening conditions: towering volcanoes over a lava surface, with surface temperatures over 700 degrees Celsius as heat is trapped by its 95% carbon dioxide atmosphere (it is actually the worst-case scenario for the greenhouse effect). On the plus side, it does rain occasionally — but the rain is composed of sulphuric acid.

Now, when we observe the surface of Venus, our naive reaction might be to think: "What an awful place! Isn't it lucky we don't live there? It is surely an uncannily fortunate coincidence that we live on comfortable Earth and not horrific Venus."

But, of course, the weak anthropic principle explains this apparent lucky coincidence as a mere selection effect: intelligent life is only ever going to be found in life-friendly environments. It is no coincidence we are based on Earth and not Venus: human beings could never have evolved on the surface of Venus.

The weak anthropic principle states that if conditions vary with location throughout the universe, then life will only emerge in locations in which those conditions are amenable for life. That selection effect might then result in intelligent life naively interpreting the universe as being uncannily life-friendly, i.e., "fine-tuned".

So the weak anthropic principle is really fairly obvious, and could be regarded as common sense. Unfortunately, like any fairly-obvious common sense idea, the weak anthropic principle does not provide us with any particularly powerful insights about life or the universe. The weak anthropic principle should be regarded as a truism, and the Google definition of "truism" is: "a statement that is obviously true and says nothing new or interesting" — which is a perfect description of the weak anthropic principle. It is called "weak" for a very good reason. All the weak anthropic principle really does is act as a warning that we should be careful not to be fooled by some fairly obvious selection effects.

In particular, while the weak anthropic can explain some very simple naive fine-tuning problems (e.g., "Why is the surface of the Earth just the right temperature for life?") it cannot solve the fine-tuning problems we are really interested in. To be precise, the weak anthropic principle cannot be used to explain why the laws of physics and the values of the fundamental physical constants are apparently life-friendly. If we want to use the anthropic principle to explain these deeper coincidences, then we are going to have to take a deep breath and consider a much more controversial and contentious principle.

We are going to have to consider the strong anthropic principle.

The strong anthropic principle

In the previous discussion of the weak anthropic principle we have considered properties which are important to life (such as temperature, abundance of chemical elements) which vary with location throughout the universe. In that case, our interpretation of conditions as being life-friendly can be explained as a simple selection effect. So, if conditions vary with time or space, the weak anthropic principle can explain the apparent life-friendliness of our environment.

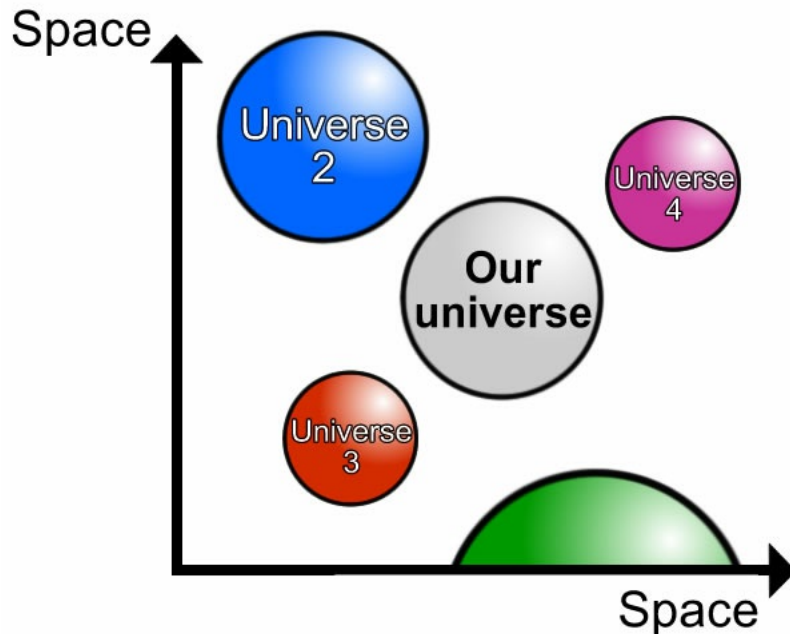

However, in this book we are interested in whether or not the laws of physics and the values of the physical constants are fine-tuned for life, and it appears that the laws of physics and the values of the physical constants have not changed with time and do not change with location. If we observe deepest space with our most powerful telescopes, the same laws of physics seem to apply in deepest space as in our local laboratory. Also, the value of the fundamental constants are not believed to have altered over time.

So the weak anthropic principle cannot explain the apparent fine-tuning of the universe. But there is a more powerful version of the anthropic principle which attempts to do just that.

The *strong anthropic principle* (again, described for the first time in Brandon Carter's 1973 paper) considers the situation in which the laws of physics and the value of the constants **do** vary with location. In that case, once again, the life-friendliness of the universe can be explained merely as a series of selection effects. But how can the laws of physics possibly change with location? This is only possible if we take a highly-speculative leap into the unknown.

It is only possible for the laws of physics to change with location if we imagine there to be other "bubble universes" located outside our own observable universe. The laws of physics, and the value of the fundamental constants, might then be set to different values in each universe.

The following diagram shows our universe surrounded by various other bubble universes. The total collection of all these bubble universes is called the *multiverse*. So, as we vary our location throughout this multiverse, we find the laws of physics varying:

This is called the *multiverse hypothesis*.

If the multiverse really exists then the strong anthropic principle can be used to explain anthropic coincidences as mere selection effects.

What is more, if there really is a multiverse then, as Brandon Carter suggested for the first time in his 1973 paper, we can use it to provide an explanation as to why the laws of physics take the form they do. The laws of physics would take the form we observe simply because we happen to inhabit the particular universe in which the laws of physics and the fundamental constants are set to those particular values. If we happened to inhabit a different universe, we would observe the laws of physics and the values of the constants set to different random values.

The strong anthropic principle is finding a new-found popularity at the moment due to its apparently unlimited explanatory potential: it can explain anything — the form of the laws of physics can be explained as random selection effects. This idea was first proposed in Section Five of Brandon Carter's paper which I linked earlier (he refers to the multiverse as a "world-ensemble"): "It is of course philosophically possible — as a last resort, when no stronger physical argument is available — to promote a **prediction** based on the strong anthropic principle to the status of an **explanation** by thinking in terms of a 'world-ensemble'."

This idea first presented by Brandon Carter in 1973 has become highly influential over the last ten years. As progress in fundamental physics has stalled, the strong anthropic principle appears to present an easy and attractive means of "explaining everything". I considered anthropic reasoning in detail in my fourth book when I repeated the common criticism that a theory which predicts everything predicts nothing. I returned to this theme in my previous book when I suggested that we should consider anthropic theories to be "theories of last resort" — just as Brandon Carter suggested in his previous quote.

What is more, the whole multiverse hypothesis is frequently criticised as being unscientific as it cannot be tested or disproved.

At the end of his paper, Brandon Carter presented his own concerns about the use of the strong anthropic principle to determine the values of the physical constants: "The acceptability of predictions of this kind as explanations depends on one's attitude to the world-ensemble concept. The idea that there may exist many universes, of which only one can be known to us, may at first sight seem philosophically undesirable. I would personally be happier with explanations of the values of the fundamental coupling constants etc. based on a deeper mathematical structure."

Paul Davies agrees with this viewpoint in his book *The Goldilocks Enigma*, stressing that the promotion of the strong anthropic principle undermines the efforts of physicists who are attempting to develop conventional analytical methods for understanding the universe: "For those theoretical physicists hard at work trying to formulate a unique final theory, the multiverse comes across as a cheap way out. Transforming cosmology into a messy environmental science looks a shabby let-down when set alongside the inspiring magnificence of a unique final

theory that would explain everything. Randomness plus observer selection strikes many physicists as an ugly and impoverished explanation compared with an overarching mathematical theory."

I hope in this discussion I have managed to convey the impression that the anthropic principle is really not a very useful tool for explaining anything: the weak anthropic principle is too weak, and the strong anthropic principle is too speculative and too unscientific. What is more, as we have discussed, anthropic reasoning based on the strong anthropic principle threatens to undermine the whole process of doing good physics.

In short, the anthropic principle is bad news all round.

But the anthropic principle has certainly had a wide influence. In my experience, there is a tendency in the educated wider public (and many physicists) to dismiss **all** life-friendly coincidences as merely selection effects, influenced by the weak or strong anthropic principle. Certainly my friends I have talked to about this subject seemed to think like that — they seemed to be under the impression that the fine-tuning problem had already been explained as a simple selection effect, perhaps unknowingly invoking the anthropic principle. However, as this discussion has shown, it is unjustified to dismiss these coincidences as selection effects. If we try to explain the apparent fine-tuning of the laws of physics and the fundamental constants as mere selection effects then we have to introduce highly-speculative and controversial ideas, such as the multiverse hypothesis.

Instead, the message which I will be presenting in this book is that we need to follow a different, more scientific approach to explaining the life-friendly coincidences in the universe. Basically, instead of jumping to embrace simple solutions, we need to acknowledge that these problems are difficult — and rise to the challenge.

2

BAYES' THEOREM

Essentially, the question of whether or not the universe is fine-tuned comes down to a question of probability. If it is the case that the universe is fine-tuned, then that is equivalent to saying that the fundamental constants have surprising, improbable values. In that case, if the values are improbable, then we would not normally expect to encounter them by pure chance — something strange is happening. Conversely, if the universe is **not** fine-tuned, then that is equivalent to discovering that the fundamental constants having highly-probable, highly-likely values.

So, the fine-tuning question is really a question about probability, and in this chapter we will be considering the science of mathematical probability. We will be seeing if the universe really is — as has been suggested — "Unlikely. Very unlikely. Deeply, shockingly unlikely." [3]

As human knowledge advances relentlessly, it is very comforting to imagine that we will eventually know everything — though that might prove to be an impossible goal. There might always be some pockets of ignorance. The casinos of Las Vegas rely on that ignorance for their income. For example, we are completely ignorant of the outcome when we roll a pair of dice. Will we roll a seven, or ten, or five? We are simply ignorant. However, if we roll the dice multiple times then we can detect a pattern in the results, and though we still cannot predict the result of an individual throw, we can predict the probability of how many times a certain result will appear over time. For example, if we throw the dice one hundred times, we can calculate how many times we would expect to roll a seven.

Probability is expressed as a number between zero and one, with a probability of zero indicating a result is impossible, and a probability of one indicating a result is certain.

So mathematical probability gives us a way of moving from an effect (the throwing of the dice, for example) to predicting a likely cause (the result of the throw). Hence, probability moves from cause to effect. Probability allows us to deal with our ignorance when we have knowledge about the cause, but we are ignorant about the result.

But what about the reverse situation? What happens if we have ignorance about the cause, but we have knowledge about the result? For example, if we are presented with a series of numbers (one, thirteen, seven, etc.) resulting from a series of dice throws, can we tell **purely from the results** whether or not the dice were fair, or if they were loaded towards a particular result? In other words, instead of moving from cause to effect (as in probability) can we move in a backward direction from the effects backwards to consider the cause? This is called the *inverse probability problem*.

The solution to the inverse probability problem is far from intuitively obvious. Consider an example relating gun homicide to gun ownership. If we consider police records of every murderer who committed their crime using a gun, we might find that in 95% of those cases a gun was later found in the house of the murderer. So there is a probability of 0.95 that a murderer will have a gun in their house.

Now let us consider the inverse probability: what is the probability that if we find a gun in a house, then the owner will be a murderer? Our first thought might be that the probability in the reverse direction would be the same as in the forward direction, and therefore suggest that there is a 95% chance that the owner will be a murderer. But clearly, this is nonsense: gun ownership is widespread in America, and only a tiny fraction of those owners will ever turn out to be murderers.

So how do we calculate the inverse probability correctly? The solution to the inverse probability problem is provided by *Bayes' theorem*, named after the 18th century English statistician Thomas Bayes.

Bayes' theorem explains how we can calculate probability in the backward direction, from effect to cause. We can use Bayes' theorem to calculate a probability that the cause has a certain form: for example, are the dice loaded or not? Is the gun owner likely to be a murderer? By considering the result which we can see — the *evidence* — we can infer the nature of the cause. In our previous examples, we would consider the evidence to be the results of the dice throws, or whether or not a gun has been found in a house.

Bayes' theorem is applicable to many different areas of life — not just science. It is this widespread use of Bayes' theorem which has made it something of a modern sensation, as we shall see later in this chapter.

Smallpox — or not?

The best way to understand Bayes' theorem is to consider an example. In his tutorial book of Bayes' theorem, James Stone presents an example involving a nasty case of smallpox. Let us consider the example.

One morning, you wake up and discover your face is covered in spots. You go to the doctor, and the doctor tells you that 90% of people with smallpox are found to have spots on their face. This news terrifies you, because smallpox is a potentially lethal disease. However, you swiftly realise that this is a strange thing for a doctor to say: the doctor is giving you a probability in the forward direction — from cause (smallpox) to effect (spots). This is no use to you because you want the doctor to give you a probability in the inverse direction. You want the doctor to examine the evidence (the spots) and tell you the probability that you have smallpox.

However, as we saw in the earlier example about gun ownership, it is not obvious how to calculate probability in the reverse direction: just because 90% of people with smallpox have spots, it most certainly does not mean that 90% of people with spots have smallpox.

So how can we use Bayes' theorem to calculate the inverse probability, thus determining the probability that you have smallpox?

Well, in order to use Bayes' theorem, the first thing we need to have is some sort of initial belief about the "way things are" — a belief about the state of the world. We call this our *hypothesis*. In the smallpox example, our hypothesis might be "The patient has smallpox". The probability that our hypothesis is true is initially generated before we consider any evidence (before we examine the patient and see the spots). However, we already know that smallpox is extremely rare in the general population, so we would expect the initial probability that our hypothesis is true — in the absence of any supporting evidence — to be extremely small.

Bayes' theorem then tells us how we should update our belief in our hypothesis on the basis of new evidence which becomes available.

So how can we use Bayes' theorem to update our confidence in our hypothesis? Well, we have to examine the evidence: we see the spots on the patient. It would then seem to make sense that we should increase our confidence in our hypothesis (the probability that our hypothesis is correct) if it is highly likely that a patient with smallpox will have spots. In the following equation this value is called the "Probability of the evidence appearing if the hypothesis is true". In other words, it is the probability of spots appearing if the patient has smallpox. In the equation, we multiply our initial probability by this term.

We are almost there, but not quite. We have to take another factor into account. We have to account for the general tendency for spots to appear in the population. If spots are common generally (for less serious diseases such as chickenpox and acne), then it would clearly weaken our hypothesis that the patient has smallpox. So we have to divide by this term: the "Probability of the evidence appearing in general". So we end up with the following equation:

$$\text{Updated probability} = \text{Old probability} \times \left[\frac{\text{Probability of evidence appearing if the hypothesis is true}}{\text{Probability of evidence appearing in general}} \right]$$

And that is the famous Bayes' theorem!

It really is surprisingly simple, and we have generated the theorem purely by an intuitive approach. If you consider the term in the square brackets in the equation, you will see it will be greater than one if the top half of the fraction has a greater value than the bottom half of the fraction. You will see that this will be the case if the evidence is more likely to appear if the hypothesis is true than in the general case. Hence, in that situation, your updated probability (your new belief in your hypothesis) will be greater than your old belief in your hypothesis: finding the evidence has increased your belief in your hypothesis.

But even though it is extremely simple, the implications of Bayes' theorem are extraordinary. In fact, it has been said that "It does not seem an exaggeration to consider Bayes' theorem as significant in our times as the Darwinian theory of natural selection." [\[4\]](#)

In this chapter we will be discovering how this incredibly simple equation is not only responsible for filtering junk email into our spam folders — but it might also have won the Second World War.

Putting numbers into the equation

In order to see how valuable Bayes' theorem can be in updating our beliefs, let us put some numbers into the equation. I will be using the same values which James Stone used in his smallpox example.

Firstly, as described earlier, our initial belief that the patient has smallpox is generated before we examine the evidence — before we see that the patient has spots. So all we can do at this early stage is to treat the patient like any other person and set this initial probability that the patient has smallpox equal to the probability that anyone in the general population has smallpox. Therefore, we should consider the public health statistics to determine the probability that anyone in the general population has smallpox (this initial knowledge — before we even start to use Bayes' theorem — is called the *prior probability*). Because smallpox is rare, this is clearly going to be a small probability. According to James Stone: "Public health statistics may inform us that the prevalence of smallpox in the general population is 0.001."

As described earlier, the next term we have to consider is the "Probability of the evidence appearing if the hypothesis is true". In other words, it is the probability of spots appearing if the patient has smallpox. The doctor has already told us that 90% of people with smallpox have spots, so we set this value equal to 0.9.

Finally, as discussed earlier, the last term we have to consider is the "Probability of the evidence appearing in general", in other words, the general tendency for spots to appear in the population (including less serious diseases). This term acts to undermine faith in our hypothesis, so we have to divide by this term. James Stone uses a value of 0.081 for this term.

Let us put these numbers into the previous formula. We find that the final probability that the patient has smallpox (the "updated probability" generated by Bayes' theorem) is equal to:

$$0.001 \times \left[\frac{0.9}{0.081} \right]$$

which, if you calculate the result, is equal to 0.011. This is clearly very much smaller than the value of 90% which the doctor first suggested, so you are greatly relieved.

Bayes' theorem might not quite have saved your life, but you will sleep happier tonight.

The usual form of the equation

Before we move on to consider the interesting uses of Bayes' theorem, let us briefly consider the form in which the theorem is usually presented. Bayes' theorem is usually presented as an equation in a short-hand form which uses very few characters:

$$P(H | E) = \frac{P(H) \times P(E | H)}{P(E)}$$

I would say this form is less descriptive and more difficult to understand intuitively than the version I presented earlier. However, just for the record, this is what the various terms of this equation mean:

- $P(H)$ is the "old probability" that the hypothesis, H , is true. This is the prior probability based on existing information.
- $P(E|H)$ is called a *conditional probability*. It is what I have called the "Probability of the evidence appearing if the hypothesis is true".
- $P(E)$ is what I have called the "Probability of the evidence appearing in general".
- $P(H|E)$ is called the *posterior probability*, and is the updated probability that the hypothesis is true.

This is a form of the equation which I find very hard to remember — there are simply too many "E"s and "H"s — whereas I can remember the longer, more descriptive, version of the equation I presented earlier.

How Bayes' theorem won the war

Throughout the Second World War, Germany relied on an encryption method to encode orders for its army, air force, and navy. The German *blitzkrieg* high-speed attack, for example, was heavily-reliant on coded radio messages to coordinate artillery, airplanes, and tanks. Most crucially, German U-boats relied on encrypted messages in order to learn the positions of Allied merchant shipping.

The encryption method was highly-sophisticated and extremely difficult to break. Messages were encoded by a device called an *Enigma machine*, which resembled a typewriter encased in a wooden box. Above the typewriter keyboard was a lampboard with a light for each letter of the alphabet.

The following photograph shows an Enigma machine in use in 1943:

There were three wheels inside an Enigma machine. Each time the operator typed a key, one of the three wheels advanced a notch. The typed letter was enciphered, and the resultant encoded letter was illuminated on the lampboard. The complete message was then transmitted in Morse code.

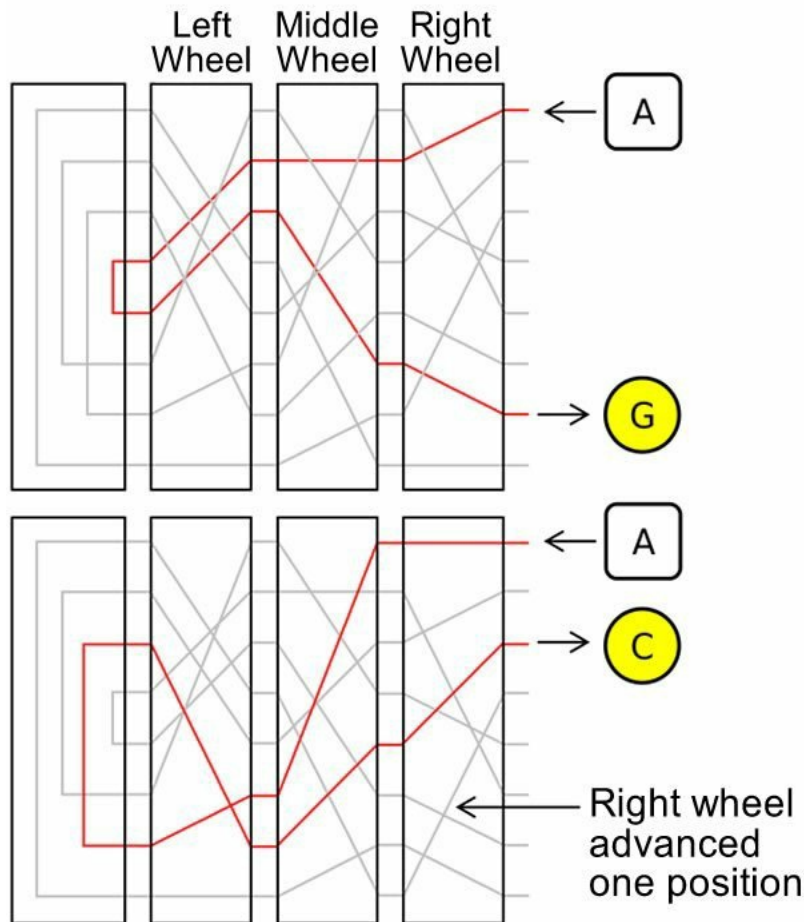

The following diagram shows the three Enigma wheels. At the start of each day, the wheels were initialised by setting the top letter of each wheel according to a codebook. For example, if the codebook stated that the day's keyword was "EJN" then the top letters on each wheel would be set according to the following photograph:

The task for the codebreakers was therefore to determine the Enigma wheel settings for each day. They only had 24 hours to do this as the settings changed at midnight to the next day's settings.

The Enigma code was a *substitution cipher*, in which a single letter in a message (for example, the letter "A") was replaced by another letter (for example, the letter "G"). The following diagram explains how the Enigma wheels

operated to perform this encoding:

In the diagram, you will see the three Enigma wheels: left, middle, and right. In the top half of the diagram, you will see the letter "A" entering the wheels (on the right), tracing a path through the three wheels, and emerging as the encoded letter "G".

However, the next time the letter "A" was encoded in a message, the right wheel would have advanced one position. So you can see that the letter "A" would then be replaced by a different letter: in this case, the letter "C". Because this made it hard to recognise common sequences of letters, this made the code much more difficult to break.

Another advantage of this structure of the Enigma machine is that the same settings allowed a single machine to act as both an encoder and a decoder. For decoding, the path is just retraced through the wheels in the opposite direction. If you consider the top half of the previous diagram, you will see that entering the letter "G" again will be traced back to the original letter "A". Though the Germans were very attracted to this feature of the machine, it actually introduced a weakness into the coding technique. This is because you will see that this mechanism never lets the same letter be encoded into itself: the letter "A" can never be encoded into the letter "A", for example. This provided a vital clue to the codebreakers.

The British codebreakers were based in Bletchley Park, a Victorian mansion located 50 miles northwest of London. I recently took a trip to Bletchley Park. The complex is no longer a working military facility, but instead the whole area has been turned into a fascinating museum. But this is no theme park — this is real history.

Here I am standing in front of the mansion:

The team were led by the brilliant computing pioneer Alan Turing. Turing realised that the Enigma code could be broken by employing Bayesian techniques. The process of coding a message is from cause-to-effect (the Enigma machine produces a coded message), whereas the process of decoding the message is in the reverse direction from effect-to-cause (analysing the "evidence": the many thousands of encoded messages). Hence, a message could be decoded by using Bayesian techniques and solving the inverse probability problem.

Sharon McGrayne has written a book about the history of Bayes' theorem called *The Theory That Would Not Die*. The book contains a detailed account of the effort to use Bayes' theorem to decrypt the Enigma code. According to McGrayne: "Finding the Enigma settings that had encoded a particular message was a classic problem in the inverse probability of causes."

Once Turing had decided to use Bayes' theorem, it was Bayes' theorem which determined the radically new decoding method which had to be used. Remember, Bayes' theorem operates by considering the evidence in order to decide if a particular hypothesis is correct. In the case of the Enigma decoding, the sheer weight of evidence (all major German communications) had to be analysed in order to find the likeliest hypothesis (one of 159 million million possible settings of an Enigma machine). This meant that manual decoding was infeasible. Instead, a new decoding technique would be required, capable of handling such a huge amount of information in a short time. Alan Turing realised that an automated system would be required. As David Leavitt says in his biography of Turing, what was required was "a machine built for the specific purpose of defeating another machine."

To achieve this goal, Alan Turing and the team at Bletchley Park — including Tommy Flowers and Max Newman — used electronic equipment for the first time to break codes. In doing so, they created the first programmable electronic digital computer, which was called Colossus.

Instead of modern transistors, Colossus used 1,500 glass valves (vacuum tubes) to switch current on and off (to signify binary zeroes and ones). The computer was so fast that sometimes Bletchley Park were reading the deciphered messages even before their German counterparts. The power of Colossus was so great that it could break the stronger and more sophisticated Lorenz code which was used by Adolf Hitler himself.

Here is a photograph of me inspecting the Colossus rebuild at Bletchley Park. It was the world's first electronic digital computer. Just wow:

Looking at that photograph, it is almost beyond comprehension that it was built in 1944. It looks like a modern server farm! But it's all valves!

You can see more of my super Bletchley Park photographs in my Bletchley Park album:

<http://tinyurl.com/andrewbletchley>

Later in 1944, Colossus decoded an encrypted message from Hitler to Field Marshal Erwin Rommel, who was his commanding officer in Northern France. Hitler ordered Rommel not to move his troops for five days if there was an invasion in Normandy. This was because Hitler believed a Normandy invasion would be intended as just a diversion from the true invasion force which would attack the ports along the English Channel. When General Eisenhower — the Supreme Commander of the Allied Forces in Europe — received the decoded message from Colossus, he announced "We go tomorrow". That was to be the morning of June 6th 1944, which was to become better known as D-Day.

Eisenhower later estimated that the Bletchley Park codebreakers shortened the war by at least two years.

The story of Alan Turing's attempt to break the Enigma code was dramatised in the movie *The Imitation Game*. The movie featured a splendid Oscar-nominated performance by Benedict Cumberbatch as Alan Turing. Although the film received some criticism over a few minor inaccuracies, the plot is generally accurate and presents a gripping account of the work at Bletchley Park. The film was a major critical and commercial success, making over \$200 million at the box-office.

If you ever find yourself in London, I can recommend Bletchley Park as a great day out. Bletchley Station is just a forty-minute train journey from Euston Station. Walking out of Bletchley Station, turn right, and Bletchley Park is just 50 yards up the road.

The controversy over prior probability

Bayes' theorem now plays a huge role in all our lives — even though most people are completely unaware of it. Remember, Bayes' theorem works by updating the probability that a hypothesis is correct on the basis of received evidence. Hence, Bayes' theorem can act as a form of classification, assigning objects to groups on the basis of that evidence. Here are just a few examples of Bayes' theorem working in this way:

- It is Bayes' theorem which filters our junk email into spam folders.
- It is Bayes' theorem which controls the (sometimes very annoying) autocorrect feature when we type on a

mobile phone, selecting the best fit from a range of possible words.

- It is Bayes' theorem which selects adverts which appear on web pages, selected to be of interest to us (the "evidence" controlling the selection process controversially being obtained from our browsing history).
- There is software based on Bayes' theorem which can automatically process your CV and decide whether or not to call you for a job interview.
- It was Bayes' theorem which first connected lung cancer with smoking.
- Richard Feynman used Bayesian techniques to determine that the O-rings were the most likely cause of the *Challenger* space shuttle disaster.
- During the Cold War, the U.S. military think-tank RAND used Bayesian techniques to calculate the probability of a thermonuclear device exploding accidentally (answer: it's a worryingly large probability).
- The designers of Google's self-driving car are using Bayes' theorem to recognise objects and make decisions.
- Perhaps most impressive of all, you can even see Bayes' theorem on Sheldon Cooper's whiteboard in an episode of *The Big Bang Theory*. [\[5\]](#)

In fact, in almost every place where a decision must be made on the basis of statistical data, you will now find Bayes' theorem being used.

Bayes' theorem has proved itself to be so useful and permeates so many aspects of our lives that it may be surprising to hear that until quite recently — the second half of the twentieth century — Bayes' theorem was treated with mistrust and even revulsion by most statisticians. In order to understand the problem, let us remind ourselves how Bayes' theorem is defined:

$$\text{Updated probability} = \text{Old probability} \times \left[\frac{\text{Probability of evidence appearing if the hypothesis is true}}{\text{Probability of evidence appearing in general}} \right]$$

The "Old probability" in this equation is a crucial — and controversial — term. This is the probability which is set before we examine any evidence and before we perform the Bayes' theorem calculation. This probability is the prior probability of the hypothesis being true (often called simply the *prior*). This has proven to be a very controversial term since Bayes' theorem was first proposed, and is the reason why the theorem has been met with so much resistance from statisticians.

If we have access to a large volume of existing data then we can obtain an accurate value of the prior probability with confidence. For example, in the smallpox example considered earlier, it was explained how the prior probability could be calculated from the public health statistics, informing us that the prevalence of smallpox in the general population is 0.001.

However, if we only have very limited access to existing data — or no relevant data at all — there are still other ways to obtain a value for prior probability. Specifically, human experience and judgement can be used to generate a value for prior probability. Though this might appear to be very subjective, it is still valuable information which we should not ignore in our decision process.

So sometimes the value which is used for the prior probability might appear to be no more than an educated guess. Indeed, Thomas Bayes originally referred to this term as a "guess" when he proposed his theorem. This is often called the initial *belief* that the hypothesis is true.

And now perhaps you can see why statisticians have been so unimpressed with Bayes' theorem: what place is there for "belief" in mathematics? As Sharon McGrayne says in her book: "The heart of the Bayesian controversy is

the fact that, when only a few data are involved, the outcome of a Bayesian computation depends on prior opinion. In such a case, Bayes' theorem can lead to a subjective, rather than an objective, assessment of a situation."

However, a wonderful feature of Bayes' theorem is that it really doesn't matter which method we employ to generate our prior — as long as we have access to plenty of evidence. As each additional piece of evidence appears and is processed by Bayes' theorem, then an updated — and more accurate — probability of the hypothesis being true is generated. As long as there is plenty of evidence then the final probability is guaranteed to converge on an accurate value. So as each piece of evidence is added, the importance of the value of the initial prior becomes progressively reduced. As Sharon McGrayne says in her book: "with large samples the prior did not matter".

In her book, McGrayne further explores how this tendency of Bayes' theorem to close in on the truth explains how scientists with different initial opinions manage to eventually come to agreement over which hypothesis is correct. McGrayne presents a quote from the statistician Jimmie Savage: "If prior opinions can differ from one researcher to the next, what happens to scientific objectivity in data analysis? Well, as the amount of data increases, subjectivists move into agreement, the way scientists come to a consensus as evidence accumulates about, say, the greenhouse effect or about cigarettes being the leading cause of lung cancer. When they have little data, scientists disagree and are subjectivists; when they have piles of data, they agree and become objectivists. That's the way science is done."

So we can see how Bayes' theorem closely matches the scientific method, and even matches our individual thought processes when it comes to examining evidence and making difficult decisions. Because such a simple rule has such wide application, Bayes' theorem is almost treated less as a simple tool and more as a guiding philosophy for life by its passionate advocates.

The Bayesian fine-tuning equation

So now let us return to the main subject of this book, and ask: "How can we use Bayes' theorem to determine if the universe is fine-tuned or not?" To determine this, we have to evaluate the probability that the hypothesis — that "the universe is fine-tuned" — is true. Bayes' theorem requires us to obtain evidence to support our hypothesis, and, in this case, the evidence which we observe is the existence of life in our universe.

So let us update our definition of Bayes' theorem (which was presented earlier) with these new values for the hypothesis and the evidence:

$$\text{Probability universe is fine-tuned} = \text{Prior probability universe is fine-tuned} \times \left[\frac{\text{Probability of life appearing if the universe is fine-tuned}}{\text{Probability of life appearing in general}} \right]$$

I am going to call this equation the "Bayesian fine-tuning equation".

On the right-hand side of this new equation, the term "Prior probability universe is fine-tuned" represents the prior probability we have just discussed in the previous section. It is this value which is going to be updated by Bayes' theorem to generate an updated probability that the universe is fine-tuned (on the left-hand side of the equation). The available methods for arriving at a prior probability were discussed in the previous section. In the absence of pre-existing data, the value of this term is going to be heavily-reliant on the experience, knowledge, and intuition of physicists.

The question to be asked to generate the prior probability would be: "On the basis of our existing knowledge as physicists, do we currently think the universe is fine-tuned or not?" I would suspect the majority of physicists would currently respond in the negative, though there would also be quite a few who would take the opposing view. Fortunately, as discussed in the previous section, Bayes' theorem is perfectly capable of handling incomplete and contradictory subjective opinions. As the amount of received data increases, the Bayesian fine-tuning equation would update its probability that the universe is fine-tuned, moving toward the correct hypothesis (either "Yes" or "No"). The tendency would then be for scientists to move into agreement about the correct hypothesis — and that is how the Bayesian scientific method works.

So it would appear that the value of the selected prior probability is not crucial. What is crucial is the value of the fraction contained in the square brackets, so let us consider it next.

The probability of life

Let us now consider the two terms inside the square brackets.

On the top of the fraction in the square brackets is the term "Probability of life appearing if the universe is fine-tuned". I think we would have to consider this as being a fairly large value: if the universe was fine-tuned for life, creating an environment highly-amenable to the emergence of life, we would surely expect life to spontaneously emerge somewhere in that vast universe — even if it takes billions of years to emerge. So it appears reasonable to set that term to a large value.

But the bottom term of the fraction is not so easy to calculate. And this is a term which is absolutely crucial to our analysis.

You will see that the bottom of the fraction in the square brackets in the Bayesian fine-tuning equation is the term: "Probability of life appearing in general". This represents the probability of life emerging in all cases — including situations where the hypothesis is not true. So this term represents the probability of life emerging in all possible universes — even in universes which are not fine-tuned.

In order to calculate this probability of life, it appears we would have to consider whether or not we would expect life to emerge in any arbitrary universe, even if the physical constants were set to random values in that universe. Maybe the resultant form of life would be quite unrecognisable to us, not resembling human life at all. Basically, the question being asked here is "Does life emerge easily?" or, equivalently "Would we expect to find life in all possible universes?"

If life is common, and emerges easily in all universes, the value inside the square brackets will be small, and so the corresponding probability that the universe is fine-tuned will also be small. This makes sense: if life is robust and emerges freely, then it has no need of additional helpful fine-tuning. Conversely, if life does not emerge easily, the value inside the square brackets will be large, and the probability that the universe is fine-tuned will be high. Again, this makes sense: if life is delicate and rare then it needs all the help it can get from fine-tuning in order to emerge.

So it appears that all we have to do is determine the probability of life emerging in general, and then we will be able to instantly determine whether or not the universe is fine-tuned.

Unfortunately, it is not at all easy to obtain an accurate value for the probability of life emerging. Ideally, we would need to examine a set of different, independent universes, with the fundamental constants set to different random values in each universe, and then see how often life emerges in those varied universes. Well, of course, this is something we can't do: we don't have access to a convenient set of universes on which we can experiment. It appears our cause is hopeless.

However, perhaps there is a second-best option. While we don't have a set of universes with different conditions, there are regions of our own virtually-infinite universe with wildly-different conditions. How likely is life to emerge in these extraterrestrial breeding grounds?

So, let us now consider what we know about the possibility of extraterrestrial intelligence, to see if that can give us some clues about the probability of the emergence of life.

3

THE FERMI PARADOX

In April 1960, the American astronomer Frank Drake did something quite extraordinary. It was also — as far as his scientific career was concerned — highly risky. Drake turned the radio telescope at the National Radio Astronomy Observatory in West Virginia to point at two stars which resembled our Sun. Drake was attempting to listen for signs of extraterrestrial intelligence. This represented the first attempt to intercept extraterrestrial communication, and it made Frank Drake a pioneer of the search for extraterrestrial intelligence (SETI).

In 2010, Frank Drake was interviewed for a BBC documentary to discuss the search for extraterrestrial intelligence. The documentary was entitled *The Search for Life: The Drake Equation*, and this is what Frank Drake said: "In 1960, the National Academy of Sciences asked me to convene a meeting to discuss this whole subject, and to ground it in good sound science. So I did that. I invited everyone in the world who I knew was interested in the subject to a meeting — all twelve of them! Just twelve people who I knew were interested in extraterrestrial life. So I thought through what it is you need to know to predict how many civilisations it might be possible to detect in our galaxy. And I realised that the number of civilisations depended on seven factors. And you can even use those factors to form an equation. So I did."

By creating his equation, Frank Drake transformed the random guesswork of predicting the existence of advanced extraterrestrial life into a theoretical framework which could be studied and analysed. The *Drake equation* can be used to calculate the number of detectable intelligent communicating civilisations, N , in our Milky Way galaxy, and is given by:

$$N = R_* \times f_p \times n_e \times f_l \times f_i \times f_c \times L$$

where:

- R_* is the number of stars formed every year.
- f_p is the fraction of those stars which have planets.
- n_e is the average number of habitable planets around those stars.
- f_l is the fraction of those habitable planets on which life emerges.
- f_i is the fraction of those lifeforms which become intelligent.
- f_c is the fraction of those lifeforms which develop into technologically-advanced civilisations capable of transmitting radio signals.
- L is the average lifetime of a communicating civilisation.

Here is Frank Drake standing in front of his eponymous equation:

While it is obviously difficult to estimate precise values for all the terms of the Drake equation, there is no obvious reason why any of the terms should be particularly small. Indeed, with more than 300 billion stars in our Milky Way galaxy it is hard to imagine why the Drake equation should produce a small value for the number of intelligent civilisations in our galaxy. In 1974, Carl Sagan used the Drake equation to predict that there were a million civilisations in our galaxy.

If that was the case, then the race was on to be the first to make contact with extraterrestrial intelligence ...

6EQUJ5

In 1977, the American astronomer Jerry Ehman was sitting in his kitchen laboriously sifting through sheets of computer printouts. The data represented signals received from the Sagittarius constellation by the Ohio State University radio telescope. The telescope was also known as "Big Ear" because it was the size of three football pitches.

The Big Ear telescope formed a part of the search for extraterrestrial intelligence (SETI) pioneered by Frank Drake. The basis for the search was the idea that a technologically-advanced extraterrestrial civilisation might have broadcast a decipherable radio message in order to make themselves known to other advanced civilisations in the universe.

The printouts were of dull numeric data: sometimes a blank space, sometimes the number one, sometimes the number two. The prevalence of the ones and twos showing a low received signal strength. If you were lucky, the number three might make an appearance. And it was all repeated endlessly over countless sheets.

Most of the data was uninteresting, however, one remarkable string of six characters on the printout caught the attention of Ehman. It even looked like a word! The string of characters was "6EQUJ5". Was this a signal from an alien civilisation?

The vertical "6EQUJ5" string can be seen in the following image, a photograph of the actual printout. Ehman was so surprised at the appearance of the message that he famously wrote the word "Wow!" in the margin of the printout:

Ever since, this has come to be known as the Wow! signal.

So what does "6EQUJ5" stand for? Any Scrabble aficionado will tell you that if you get a letter Q without a letter U then you are in big trouble. So is the positioning of the U after the Q significant? If this is a message from an alien civilisation, then what are they trying to tell us? That they are good Scrabble players?

The Wow! signal became something of a cultural phenomenon. There is even a range of geeky 6EQUJ5 T-shirts available (just perform a Google image search for "6EQUJ5 T-Shirt").

Unfortunately, when you dig a bit deeper, you find all is not what it seems.

It emerges that the letters and numbers (which compose the "6EQUJ5" message) merely correspond to the strength of the signal, with the letter Z representing the highest signal strength, and the number 1 representing the lowest signal strength. This is clear in the following graph, with the coded letters and numbers on the vertical axis. You will see from the graph that when the 6EQUJ5 message is plotted it produces a very smooth curve: a normal bell-shaped distribution, a perfectly smooth "blip". All evidence of intelligent Scrabble-playing aliens has disappeared:

In that respect, the much-publicised 6EQUJ5 "message" appears to be rather misleading — it would have been more accurate to display the signal strength in the above graphical form rather than in alphanumeric characters. Simply put: to convert a perfectly smooth blip into a pseudo-English character string seems rather misleading.

Surely if alphanumeric characters had not been used, or if Jerry Ehman had written "This deserves further investigation" instead of "Wow!" then the signal would have gained nowhere near as much fame.

Paul Davies has written a book about extraterrestrial intelligence called *The Eerie Silence*. In that book, he examines the Wow! signal and suggests that maybe the blip is a message sent from an extraterrestrial beacon — like a flashing signal from a lighthouse. However, as Paul Davies goes on to explain, if the signal was truly a beacon then we would expect it to repeat at regular intervals — just like a lighthouse. Unfortunately, the Wow! signal has never been detected again. [6]

The Wow! signal is generally accepted to be our best candidate for a radio signal from an extraterrestrial civilisation. Given the rather misleading nature of the printout format, it is not impressive evidence. Unfortunately, the importance of being able to differentiate between accuracy and hype will be something of a theme of this chapter.

Other attempts to detect extraterrestrial life have been based on sending robotic probes to the planets of our Solar System. Ever since H.G. Wells introduced the idea of a Martian invasion in *The War Of The Worlds*, the public has been fascinated by the possibility of life on Mars. Mars has long been regarded as the planet in our Solar System which might be most suited for life, so it was no surprise that the first robotic probe was sent to Mars as part of the Viking program of the 1970s.

Unfortunately, the Viking mission revealed the surface environment of Mars to be extremely hostile to life, with bitter cold, a thin atmosphere, and lethal ultraviolet radiation. As a result, the recent Curiosity rover — which landed

on Mars in 2012 — was equipped with a drill to take soil samples from beneath the surface. Curiosity continues to send back stunning photographs from the Gale crater on Mars (as shown in the following image).

So, apart from a rather misleading "alphanumeric string" from deep space, we have so far detected absolutely no evidence of life anywhere in the universe apart from on Earth.

SETI has drawn a blank.

The Fermi paradox

Enrico Fermi was one of the giants of 20th century physics. Fermi created the world's first nuclear reactor in Chicago in 1942 and has been called the "architect of the nuclear age". If you have read my fifth book, you will know that Fermi predicted the existence of the neutrino. You will also know that the matter particles in the universe are called *fermions*, named after Enrico Fermi. When all the matter particles in the entire universe are named after you, that's when you know you've made it big.

Here is a photograph of Enrico Fermi:

In 1944, Fermi joined the Manhattan Project based in Los Alamos, New Mexico, which was developing the world's first atomic bomb. Fermi observed the Trinity bomb test in 1945, and accurately estimated the explosive power of the bomb by dropping strips of paper into the blast wave.

After the war, in 1950, Fermi returned to Los Alamos as a consultant. It was about the time that flying saucer mania was sweeping America. Legend has it that during one lunchtime in Los Alamos, during a conversation about the flying saucer craze, Fermi suddenly asked his colleagues: "Where is everybody?" Fermi's question seemed out-of-the-blue, but his colleagues laughed because everyone instantly knew what he was talking about. Fermi was wondering why we had not received clear visitations from aliens — after all, the galaxy was supposed to be teeming with alien life.

Though Fermi's observation was not treated too seriously at the time, it is not easy to find a solution. It might be imagined that the distances involved in the galaxy are too large for extraterrestrial travellers, but this is almost definitely not the case. In 1975, Michael Hart calculated that even if it takes thousands of years to travel from one star to the other, the age of our galaxy — at least ten billion years old — should ensure that life would have spread throughout the galaxy within a million years or so. This viewpoint is also expressed by Paul Davies in *The Eerie Silence* who suggests that colonisation of the galaxy would have occurred in stages, one star at a time. On that basis, the colonisation of the galaxy by one of the many supposed alien civilisations in the galaxy would appear to be inevitable, and would surely have happened by now. As Paul Davies says: "It takes only **one** such community somewhere in the galaxy to present us with Fermi's awkward conundrum."

Fermi's question has achieved considerable fame, and is now called the *Fermi paradox*.

Fermi is regarded as one of the archetypal geniuses, and we have to take his objection seriously. While it is not easy to find an answer, it does seem that many astrobiologists are now coming to something of a consensus about the likeliest solution to the Fermi paradox. To solve the Fermi paradox, it appears that we must examine the regions in our galaxy where life might possibly develop ...

Exoplanets

A planet which orbits a star other than the Sun (i.e., a far distant planet outside of the Solar System) is called an *exoplanet*. As exoplanets are small, dark, and very distant, they are very difficult to detect. Because they orbit a star, the light from the star will drown out any light emitted or reflected from the exoplanet. Hence, exoplanets are not usually observed directly, but are instead detected via indirect methods.

One indirect method for detecting exoplanets is based on the principle that an orbiting exoplanet will very slightly

pull the star from its central position. This slight deviation in the star's motion can be detected by considering modifications in the wavelength of the light emitted by the star due to the Doppler shift. This is the same principle which causes a siren on a car to sound higher in pitch when the car is approaching, and lower in pitch when the car is receding. Extremely small variations in the star's velocity — as little as one metre/second — can be detected by this method, which is called the *radial velocity* method.

Exoplanets are certainly not rare in the universe, and several thousand have already been detected. The exoplanets which have been detected so far have been classified into several groups. The first group to be detected were the *Hot Jupiters*, which are extremely large gas giants — like the planet Jupiter. However, unlike Jupiter, these exoplanets orbit close to central stars (and therefore have very high surface temperatures). These exoplanets travel at high orbital speeds, maybe only taking a few days to complete an orbit. The large masses of the Hot Jupiters, in combination with their tight fast orbits, explains why they were the first exoplanets to be discovered in the mid-1990s using the radial velocity method (high mass and speed causing the central star to wobble).

NASA's Kepler Space Telescope was launched in 2009 with the specific task of detecting Earth-sized exoplanets. The detection method used by the Kepler mission was different from the radial velocity method. Instead, the detection method was based on the principle that the brightness of a star will dip slightly when an exoplanet passes in front of it. This is called the *transit* method for detecting exoplanets. According to NASA, Kepler "launched the modern era of planet hunting".

The Kepler telescope is trained on a narrow region of space, roughly the size of your fist held at arm's length. In that region of space, Kepler detects the amount of light emitted from approximately 150,000 stars. Any repeated temporary reduction in the brightness of one of those stars is interpreted as the transit of an exoplanet passing in front of the star.

From examining the Kepler data, it is clear that exoplanets are far from rare in our galaxy. In fact, it would appear that there is the staggering number of between 100 billion and 400 billion exoplanets in our Milky Way galaxy. That means that, on average, there is one exoplanet for each star in the sky. So when you look up into the night sky, remember that each of those stars is likely to have a planet orbiting it.

The transit method used by Kepler is able to detect smaller exoplanets than the older radial velocity method, and is able to detect Earth-sized exoplanets. The Kepler mission was able to detect another grouping of exoplanets called the *super-Earths*. The super-Earths are *terrestrial* planets (which means they are rocky like the Earth, as opposed to gaseous) but can have masses up to ten times larger than the Earth.

Exoplanets have tremendously variable characteristics. In his book *The Copernican Complex*, Caleb Scharf considers the varied properties of the super-Earth exoplanets: "Many appear to have huge atmospheres, possibly containing lots of hydrogen. Some of these bulky objects are likely covered in vast quantities of water. They may be frozen solid. They may also be awash in a global ocean that reaches to almost unimaginable depths — tens, even hundreds of miles — with pressures and temperatures such that the physical and chemical behavior of water becomes unlike anything we experience on Earth. Others may have a modest splash of water, or none at all. But many should be persistently volcanic."

A theme we get from these exoplanets is that there is a tremendous diversity. Exoplanets have a huge range of different sizes, orbits, chemical composition, and surface conditions. Some exoplanets have rings of dust or ice, like Saturn, while others have moons.

NASA has released a range of imaginative travel posters from the fictional "Exoplanet Travel Bureau" which advertise travel to a variety of known (genuine) exoplanets. The posters emphasise the various attractive characteristics of each exoplanet, hopefully persuading you to take a holiday there. As an example, one of the advertised exoplanets is Kepler-16b, and its featured characteristic is that it orbits a pair of stars, like Luke Skywalker's planet Tatooine in *Star Wars*. As NASA say, "the movie's iconic double-sunset is anything **but** science fiction":

The habitable zone

There may be billions of exoplanets in our galaxy, but what we are really interested in is how many of those exoplanets possess the right conditions for life. A key mission objective of Kepler is to determine how many exoplanets have the properties which are believed to be essential for life to develop.

What properties are considered essential for life? Well, in 2009 the highly-popular BBC TV show *Top Gear* sent its three presenters on a road-trip across Bolivia. At one point, Jeremy Clarkson, Richard Hammond, and James May found themselves driving along the only road across the Atacama Desert. The Atacama Desert is quite beautiful. You could have a perfectly pleasant day out in the Atacama Desert. The scenery is stunning, and the temperature is not overwhelming. You could take a deckchair and a book and enjoy yourself. However, if you did that, you would be the only form of life of any kind for many miles in any direction. As Clarkson said: "We were in the Atacama Desert, where there is no life at all — not even on a cellular level. Richard Hammond was the smallest living organism for miles."

There is absolutely no life at all in the Atacama Desert: no plants, no insects, no bacteria. Absolutely nothing. And yet you could enjoy a very pleasant day sitting in the desert. How can that be the case? It is because the Atacama Desert lacks just one property which is absolutely essential for life: no rain ever falls on the Atacama Desert. It has no water.

As water appears to be essential for life, one of the most important factors in determining if an exoplanet could support life is the climate of the exoplanet. Is it too hot or too cold? A planet which is either too hot or too cold to support liquid water would appear unable to support life.

The temperature of a planet is dependent on the orbital distance of the planet from the central warming star. In our own Solar System, the planets Mercury and Venus orbit too near the Sun to support liquid water: water could only exist as vapour, whereas Mars is now too cold for liquid water. The Earth lies within those two orbits, with surface temperatures allowing the continual presence of liquid water. There is a similar orbital range around all stars within which liquid water could exist on a planet. This band is called the *habitable zone*.

The following diagram shows how the Earth is the only planet in the Solar System to lie in the narrow habitable zone band:

You will see that the habitable zone band is at an angle, showing that a smaller central star would produce less heat, and so the habitable zone would lie closer to the star.

At the moment, it seems almost every month there is the announcement of the discovery of an "Earth-like" habitable exoplanet which could potentially support life. But how accurate are these claims?

As an example, during the writing of this book, there was a major announcement of a discovery by the European Southern Observatory (ESO) telescope in the dry Atacama Desert (because lack of water vapour in the air and no clouds allows great astronomy). The discovery was of an exoplanet with a mass between 1.3 and three times as much as Earth, found in the habitable zone of our nearest star, Proxima Centauri. The exoplanet was given the name Proxima Centauri b (also known as Proxima b).

Proxima b orbits its central star quite closely, at only 5% of the distance between the Earth and the Sun. However, the central star — Proxima Centauri — is a type of star called a red dwarf, which is a smaller, dimmer, and cooler type of star than the Sun. Hence, even though Proxima b has a close orbit, it still lies within the habitable zone of the star.

The ESO announcement came complete with an artist's impression of the surface of Proxima b. Coming over the horizon in the distance you will see the red dwarf star, Proxima Centauri, around which the exoplanet is orbiting:

The announcement generated enormous media coverage. As an example, the front page story of *New Scientist* magazine (27th August 2016) proclaimed "We've found an Earth-like planet around our nearest star". The headline in the *Times* newspaper was "New planet could be our home away from home".

So much media excitement has been generated that there is now a plan to send an unmanned spacecraft to Alpha Centauri to investigate (Alpha Centauri is the three-star system which includes the star Proxima Centauri around which the exoplanet Proxima b orbits). But, in order to travel four light years, this can be no ordinary spacecraft.

The Russian billionaire Yuri Milner is funding a project called *Breakthrough Starshot*, the aim of which is to send a tiny laser-powered spacecraft to Alpha Centauri. Actually, the spacecraft is so small — a lightweight electronic wafer not much larger than a postage stamp — that it is called a *nanocraft*.

The nanocraft will be attached to a three-metre sail which will provide the propulsion. But the sail will not be powered by wind — it will be powered by light. As described in my third book, although light has no mass, it has momentum. Therefore, light beams can be used to exert pressure onto an object, so light shone onto the sail can provide the motive power for the nanocraft. However, the amount of force applied by a beam of light is extremely small, which explains why the nanocraft must be so lightweight.

The following image shows an artist's impression of the light sail and the small nanocraft to be used in Breakthrough Starshot. The sail is intended to be three metres across, which gives you an impression of the small size of the nanocraft (shown in the middle):

The aim is to power the craft by shining powerful Earth-bound lasers at the sail. The intended power of the lasers would accelerate the spacecraft to a fifth of the speed of light in just an hour, by which time, the nanocraft would have reached Mars. After that initial "kick", the nanocraft would reach the Alpha Centauri system in less than twenty years.

If all of this sounds crazily ambitious, that's because it **is** crazily ambitious. The required total laser output power would be 100 gigawatts, which is equal to the total electrical power consumption of France. It would be extremely difficult to focus such a powerful beam of light through the Earth's turbulent atmosphere. Also, travelling at a hundred million miles an hour (yes, it really would be travelling that fast!), even a fleck of interstellar dust would be enough to destroy the nanocraft.

So is the plan to send a nanocraft to investigate Proxima b overly-ambitious? The project is clearly going to generate some eye-catching headlines: "Spacecraft to travel at near speed-of-light to nearest Earth-like planet". But does this accurately reflect the reality of the scientific situation, or is it merely designed to generate publicity?

With this thought in mind, let us return to consider the "Earth-like" exoplanet, Proxima b. The artist's impression of the surface (shown earlier) is certainly beautiful, but is it accurate? When you start to dig deeper, you find things are not all they seem.

The artist's impression shows a rocky surface, but we know nothing about the actual surface of Proxima b. The exoplanet was detected indirectly via the radial velocity method (deflection of the central star) which tells us nothing about the chemical composition of the exoplanet. This assumption of a rocky surface is purely based on the observation of planets of a similar mass in our Solar System. But without direct observation of the exoplanet surface, we cannot be sure what it is like.

Because the exoplanet is so relatively close, direct observation might be possible using a space telescope. This would pin down the mass, size, and density of the planet. Because of the great distance, and the corresponding high resolution which would be required, this would only be possible using the large James Webb Space Telescope, which is NASA's replacement for Hubble and is due to launch in 2018. Even then, the exoplanet is so small and distant it would only appear as a single pixel of light in the telescope. Hence, in the absence of direct imaging, we do not know if Proxima b has an atmosphere, or if it has any water.

So, clearly, calling Proxima b an "Earth-like planet" in sensationalist newspaper headlines seems premature. This

is certainly the case when we consider additional data which makes Proxima b seem definitely unlike the Earth.

Proxima b, like so many exoplanets, orbits so close to its central star that it is constantly bombarded with deadly ultraviolet and X-ray radiation from the star. The intensity of the X-ray radiation from a red dwarf is 400 times greater than that experienced by the Earth.

Also, because Proxima b is so close to its central star it is likely to be tidally-locked to the star, which means that gravity pulls the planet so tightly that the same side of the planet always faces the star — just as the same side of the Moon always faces the Earth. Hence, one side of the planet would be permanently baked by the heat from the star, while the other side of the planet freezes in the darkness of space.

There is a fictional (and scientifically accurate) example of the difficulty in finding an exoplanet which is suitable for life. In the movie *Interstellar*, astronauts leave Earth in order to colonize a new planet to ensure the survival of humanity. However, the first two exoplanets they inspect are certainly not suitable, in fact, they are completely hostile to life. The first exoplanet turns out to be covered with a ocean which experiences kilometre-high tsunamis, while the second exoplanet turns out to be completely frozen with an atmosphere of toxic ammonia. It appears that this is a more realistic picture of what we might actually expect to find on these exoplanets.

So, once we cut through the hype, this discussion appears to raise an important question ...

Is the Earth special?

Peter Ward is Professor of Geological Sciences and Donald Brownlee is Professor of Astronomy, both at the University of Washington in Seattle. They are acknowledged experts in their fields. In the year 2000, Ward and Brownlee published a book called *Rare Earth* which, it has been said, "hit the world of astrobiologists like a killer asteroid".

In *Rare Earth*, Ward and Brownlee listed many other additional requirements for any habitable planet, leading them to the conclusion that the Earth might well be the only planet suitable for advanced life in the galaxy. Ward and Brownlee called this the *Rare Earth Hypothesis*: "Ever since Polish astronomer Nicholas Copernicus plucked it from the center of the universe and put it in orbit around the Sun, Earth has been periodically trivialized. We have gone from the center of the universe to a small planet orbiting a small, undistinguished star in an unremarkable region of the Milky Way galaxy — a view now formalized by the so-called Principle of Mediocrity, which holds that we are not the one planet with life but one of many. Various estimates for the number of other intelligent civilizations range from none to ten trillion. If it is found to be correct, however, the Rare Earth Hypothesis will reverse that decentering trend. What if the Earth, with its cargo of advanced animals, is virtually unique in this quadrant of the galaxy — the most diverse planet, say, in the nearest 10,000 light years? What if it is utterly unique: the only planet with animals in this galaxy or even in the visible universe?"

In one of their proposals, Ward and Brownlee extended the idea of the habitable zone of a planet orbiting a star to suggest that there is also a habitable zone in each galaxy, a certain distance from the galactic centre. The region near a galactic centre is star-packed, and the constant upheaval from stellar collisions and supernovae explosions might not allow the billions of years of relative calm for advanced life to develop. At the other extreme, the outer regions of galaxies have fewer stars and would lack the heavy elements used to build rocky planets (because heavy elements are generated by fusion in the interior of stars). Our Solar System happens to be located at just the right distance from the centre of our Milky Way galaxy to allow life to develop:

It is clear that combining the two habitable zone requirements — around a star and also around the galactic centre — places severe restrictions on the number of habitable planets in a galaxy.

Ward and Brownlee also stress the importance of a stable environment for the development of life. It is known that the Sun is becoming brighter with time, and it is now 30% brighter than it was when the Earth was formed. About four billion years from now, the Sun will expand rapidly to become a red giant, its brightness increasing over five thousand times. At that point, the radius of the Sun will have expanded until it reaches the orbit of the Earth — extinguishing all life on the planet.

However, all that bad news lies in the far distant future. The Sun has been an unusually stable — and safe — source of energy for the Earth for approximately four billion years. It is known that biological evolution requires vast periods of time: probably billions of years. Hence, the stability of the Sun has allowed plenty of time for life to develop on Earth. However, stars larger than the Sun become brighter much faster. A star 50% more massive than the Sun would have become a red giant too quickly for life to evolve on any orbiting planet.

The stability — and safety — of the Earth over billions of years has also been ensured by the presence of Jupiter and Saturn orbiting outside the Earth. This is because it is believed that another requirement for the development of intelligent life is that there is a necessity for a planet to be protected from continual violent collisions with comets or asteroids. Stephen Hawking has said that a collision with a comet or asteroid greater than twenty kilometres in diameter would result in the mass-extinction of complex life. It is now believed that the gravity of massive Jupiter and Saturn located outside the orbit of the Earth acts to catch many asteroids and comets entering the Solar System before they can collide with the Earth. As an example, the comet Shoemaker-Levy 9 was observed colliding with Jupiter in 1994, leaving a scar on its surface.

Ward and Brownlee also emphasise the importance of *plate tectonics* in creating a habitable Earth. Plate tectonics is the movement of the crust of the Earth. This creates mountain ranges (where two continental plates crush together) and volcanoes. Volcanic activity appears to be particularly important because of the volume of carbon dioxide which is released into the atmosphere by volcanoes. Carbon dioxide is a greenhouse gas which captures outgoing infrared radiation and raises the temperature of the surface of the Earth. It is believed that the release of greenhouse gas was responsible for saving the Earth from previous ice ages which would have resulted in the irreversible freezing of the entire Earth. It is the temperature-mediating properties of greenhouse gases which has allowed liquid water to reside on the surface of the Earth for four billion years. As Ward and Brownlee say in *Rare Earth*: "Greenhouse gases are keys to the presence of fresh water on this planet and thus are keys to the presence of

animal life." We would perhaps be wise to remember that if it wasn't for greenhouse gases the Earth would not be habitable at all. Global warming is not always a bad thing!

While other planets — such as Mars — have high, isolated volcanoes, only the Earth has long mountain ranges at the edge of continental plates. For this reason, it is believed that Earth is the only planet in the Solar System with tectonic plates, and plate tectonics might be extremely rare in the universe as a whole.

The metallic core of the Earth also plays an important role by generating a magnetic field which protects the Earth from lethal solar radiation. The optimistic analysis of exoplanet habitability does not take into account whether or not the exoplanet has a similar protective field. The situation is summed-up by Prof. Don Pollacco from the University of Warwick who is an expert on exoplanets: "As we learn things about what makes the Earth habitable, things like the magnetic field become really important. We can't measure the magnetic field of an exoplanet, so we just forget about it." [7]

Caleb Scharf is the director of Columbia University's Astrobiology Center. In his recent book *The Copernicus Complex*, Scharf starts by reminding us of the Copernican revolution in science, where the picture of the Earth as the centre of the universe was replaced by a model in which the Earth is nothing special: an unremarkable planet orbiting an unremarkable star. However, as Scharf realises: "While we cannot be at the center of what we now know to be a centerless universe, we appear to occupy a very interesting place within it — in time, space, and scale."

As Scharf suggests, there does appear to be something special about the Earth in terms of its position and its size. With this in mind, whenever I read about the habitable zone for exoplanets — the thin band of space in which life is supposedly possible — I am always reminded of the mathematical construction known as the *Mandelbrot set* (considered in my fourth book). The Mandelbrot set is constructed from a very simple iterative formula, producing a value which is defined for every point in the two-dimensional plane. Hence, it is possible to generate a rectangular image representing the Mandelbrot set, and this turns out to be a very pretty image which has been used in many posters and computer backgrounds. However, perhaps what is not widely realised is that the only truly pretty part of the Mandelbrot set is the very thin, crinkly boundary of the set:

To my mind, this thin, interesting, chaotic boundary has obvious parallels with the habitable zone around stars (and galaxies): it is where everything interesting happens. And, what is most interesting from the point of view of the discussion in this book, the interesting boundary is extremely thin. The vast, empty regions of the image are not interesting. Does the Earth lie on the equivalent of that extremely thin Mandelbrot boundary? Is the Earth special in that regard?

There is a famous quote from Stephen Hawking in his book *A Brief History of Time*: "We have developed from the geocentric cosmologies of Ptolemy and his forebears, through the heliocentric cosmology of Copernicus and Galileo, to the modern picture in which the earth is a medium-sized planet orbiting around an average star in the outer suburbs of an ordinary spiral galaxy, which is itself only one of about a million million galaxies in the

observable universe." In that quote, Stephen Hawking is suggesting the Earth is nothing special — completely mediocre. And, to the extent that he describes, he is obviously correct. However, with all due respect to Stephen Hawking, I believe in this case he misses the point. It is now being realised that it is this very mediocrity that makes the Earth special. The Earth is completely and perfectly middling: it lies in the narrow habitable zone. The Earth is not the biggest, it's not the smallest. It's not the hottest, it's not the coldest. It lies in a relatively safe planetary system where nothing very exciting ever happens, no planetary collisions or extinction-level asteroid strikes. At first glance, nothing about the Earth appears to be remarkable — apart from the fact that it is the only place in the universe that we know of where life exists. Ironically, it is the perfect mediocrity of the Earth which makes it special.

As Caleb Scharf says in *The Copernicus Complex*: "Life is a collection of phenomena at the boundary between order and chaos. Too far away from such borders, in either direction, and the balance for life tips toward a hostile state. Life like us requires the right mix of ingredients, of calm and chaos — the right yin and yang. There are obvious parallels to the concept of a habitable zone, which proposes that a temperate cosmic environment for a planet around a star exists within a narrow range of parameters."

The Copernican principle quite correctly proposed that the Earth orbited the Sun — just like any other planet. But this message of the Copernican principle — that the Earth is mediocre, "just another planet" — has then been incorrectly applied to infer that all other planets must be like the Earth. Hence, the Copernican principle has been used to predict an abundance of life on all exoplanets in the universe. However, we are now moving beyond the domain of application of the Copernican principle. As an example, chaos theory was only discovered in the nineteenth century, exoplanets were only discovered in the twentieth century, so we should no longer be relying on a sixteenth century principle (the Copernican principle) to determine the probability of extraterrestrial life. Science does advance.

Caleb Scharf believes our place in the universe is special, and the raw Copernican Principle is no longer sophisticated enough to capture the whole truth: "The Copernican Principle may have reached the end of its usefulness as an all-encompassing guide to certain scientific questions. The Copernican Principle is both right and wrong, and it's time we acknowledge that fact."

So we now see we have discovered perhaps the most likely solution to the Fermi Paradox. Earlier in this chapter it was described how it might seem likely that every term in the Drake equation has a large value, in which case the predicted number of advanced civilisations in our galaxy would be huge: Carl Sagan used the Drake equation to predict a million civilisations in our galaxy. However, there is of course a different way of interpreting the Drake equation, as explained in the *Rare Earth* book: "Any factor in the equation that is close to zero yields a near-zero final answer, because all the factors are multiplied together."

In other words, it only takes one of the factors in the Drake equation to be small in order to send the number of predicted civilisations to come crashing down. And, from our discussion in this chapter, it would appear it is the n_e term in the Drake equation which is small (the n_e term is the average number of **habitable** planets orbiting a star) and that is the reason why we do not observe a universe teeming with life.

As Matthew Cobb says in the recently-released book *Aliens* (edited by Jim Al-Khalili), our current knowledge "leads us to the conclusion that the answer to the Fermi paradox is that its starting point is probably wrong. There are no alien civilisations."

But, even if all the interesting processes (life) occur within a narrow, chaotic band, we still need that vast uninteresting expanse of the rest of the universe in order for the Earth to be so interesting. It is not the Earth that is mediocre — it is the rest of the universe that is mediocre. The Earth is, quite frankly, an amazing place. As Ward and Brownlee say in *Rare Earth*: "Earth seems to be quite a gem".

Are we alone in the universe? It appears that might well be the case.

I am reminded of a humorous quote by the great British comedian, Peter Cook: "As I looked out into the night sky, at all those infinite stars, it made me realise how insignificant ... they really are."

Implications for fine-tuning

Finally in this chapter, let us return to the question of whether or not the universe is fine-tuned for life. How has this discussion of extraterrestrial life affected the likelihood of that hypothesis being true?

If you remember, at the end of the Bayesian analysis in the previous chapter, it was suggested that if we want to calculate whether or not the universe is fine-tuned, we only need to get a definitive answer to the "probability of life appearing in general". Remember, if life emerges easily in all universes, then it has no need of additional helpful fine-tuning. Conversely, if life does not emerge easily, then life is delicate and rare and it needs all the help it can get

from fine-tuning in order to emerge.

Because of the convincing evidence of the Fermi paradox — and its likely resolution in the form of the Rare Earth Hypothesis which suggests that life requires very particular and unusual circumstances in order to emerge — I am going to suggest that the "probability of life appearing in general" should be set to a low value, certainly a lower value than has been suggested in the past by astrophysicists such as Carl Sagan. This might appear to be a controversial conclusion, but it seems to be in line with the recent conclusions of many astrobiologists.

And, if you remember back to the Bayesian fine-tuning equation presented in the previous chapter, a low value for the "probability of life appearing in general" lends support to the fine-tuning argument. As Caleb Scharf says: "There are signs that we inhabit a somewhat unusual place, and there is a hint of an expansion to the notion of cosmic fine-tuning."

The apparent fine-tuning problems are many and varied. Some may not be true problems at all: it is possible that life would still be possible even with considerable variation in the values of the parameters. However, while some parameter limits might be loosened, it appears that many limits still remain. From our discussion of the Fermi paradox, it appears that even a failure to produce liquid water would prohibit the emergence of life. It has also been suggested that life might be possible in a completely different form if the physics of the universe was completely different. One example is the possibility that silicon-based life might emerge in a universe which is unable to produce carbon.

However, life based on alternative chemistry does nothing to avoid the fundamental fine-tuning problems. Considering silicon-based life, for example, silicon is just another heavy element (like carbon) which can only be produced in the interior of stars by fusion reactions. The fine-tuning coincidences on which heavy-element production depends are just as relevant for silicon as they are for carbon. As John Barrow says in his book *The Constants of Nature*: "The argument is not really changed if beings are possibly based upon silicon chemistry or physics. All the elements heavier than the chemically inert gases of hydrogen, deuterium and helium are made in the stars like carbon and require billions of years to create and distribute."

Another criticism of silicon-based life is presented by Paul Davies in *The Eerie Silence*: "There has been some speculation that silicon could substitute for carbon, a conjecture that got as far as an episode of *Star Trek*, but it hasn't been pursued very seriously by biochemists because silicon can't form the extraordinary range of complex molecules that carbon can."

As another example, the chemistry of a simplistic alternative universe might only allow the existence of hydrogen and helium. However, as Caleb Scharf says: "It does seem hard to imagine how a universe of just hydrogen and helium could give rise to structures with the complexity seen in carbon-based life."

So it appears that there is a real problem here, and we need to find a solution.

I believe that, in order to solve the many fine-tuning problems, we need to avoid approaches such as the strong anthropic principle, which promise simple and easy solutions to difficult fine-tuning questions. There is no substitute for good physics. We will have to rely on our talent, ingenuity, and hard work to solve these problems.

On that basis, I can assure you that the remainder of this book will be based on conventional theoretical physics. There will be no multiverses, no anthropic reasoning, and no *Star Trek* silicon-based lifeforms in sight.

And, once we start using conventional theoretical physics to analyse these problems, we find another possible alternative to fine-tuning emerges. Maybe the laws of physics are unique, and completely determine the values of the fundamental constants to be suitable for the emergence of life? Paul Davies makes this point in his book *The Goldilocks Enigma*: "We have no idea whether the various parameters of interest are actually free and independent, or whether they will turn out to be linked by a more comprehensive theory, **or possibly even determined completely by such a theory.**" This is in line with Einstein's famous quote: "What I am really interested in is whether God could have made the world in a different way; that is, whether the necessity of logical simplicity leaves any freedom at all."

If it is the case that the laws of physics, and the values of the fundamental constants, could take no other conceivable form then the universe would not be fine-tuned because **no fine-tuning of the values would be possible**. In that case, we would have solved the fine-tuning problem.

Might it be the case that the laws of physics are uniquely determined to have values which are suitable for life? Is life inevitable?

We are going to have to consider some theoretical physics ...

4

THE COSMOLOGICAL CONSTANT

In the first two decades of the 20th century, our view of the universe was a lot smaller than it is today. The existence of other galaxies was not certain, so all the stars were believed to lie within our own Milky Way galaxy. What is more, the position of the stars appeared to be fairly stable. There was certainly nothing to suggest that the universe might be rapidly expanding.

So when Einstein published the theory of general relativity in 1915, he was left with something of a conundrum. The theory suggested that a stable universe was not possible as gravity would eventually pull all the matter together. How could Einstein resolve this conflict between observations and the prediction of his theory? Unusually for Einstein, he rejected the prediction of his elegant and revolutionary theory, and tried to "fudge" the result in order to produce a stable universe.

In order to understand what Einstein suggested, let us consider the equation for general relativity (which was derived in my previous book):

$$\begin{array}{ccc} \text{The curvature} & & \text{Mass-energy} \\ \text{of spacetime} & & \text{distribution} \\ \underbrace{R_{\mu\nu} - \frac{1}{2}R g_{\mu\nu}} & = & \underbrace{8\pi G T_{\mu\nu}} \end{array}$$

You will see that the equation actually predicts something quite simple. It states that the curvature of spacetime (on the left-hand side of the equation) is dependent on the distribution of mass and energy. It is perhaps best described by a famous quote by John Wheeler: "Spacetime tells matter how to move; matter tells spacetime how to curve."

To preserve a stable universe, Einstein added a factor, Λ , to his equation which was effectively a form of repulsive gravity. This acted to move the stars apart to balance the inward contraction. Einstein called this additional term the *cosmological constant*:

$$R_{\mu\nu} - \frac{1}{2}R g_{\mu\nu} + \Lambda g_{\mu\nu} = 8\pi G T_{\mu\nu}$$

Cosmological constant

It is interesting that Einstein placed his correction factor on the left-hand side of the equation, thus modifying the curvature of spacetime. He might have chosen to place his correction on the other side of the equation, thus modifying the predicted energy of space. As we shall see later, this latter approach is the one favored in modern cosmology.

The priest

Georges Lemaître was a Belgian physicist who is now regarded as one of the most important physicists and cosmologists of the 20th century. Surprisingly, however, Lemaître was not a physicist by profession. Instead, in 1923, he was ordained as a Roman Catholic priest and remained in the priesthood for his entire life.

Lemaître always managed to keep a distance between his personal beliefs and his scientific research, even once arguing with the Pope over the Pope's interpretation of Lemaître's own Big Bang theory. That disagreement did not stop Lemaître from eventually becoming the president of the Pontifical Academy of Sciences.

In 1924, Lemaître realised that Einstein's cosmological constant would not be sufficient to produce a stable universe. Like a pencil balancing on a point, the apparently stable universe would actually be unstable. Even the slightest variation between the amount of matter in the universe and the value of the cosmological constant would result in a universe which either contracted to a point or expanded forever. A pencil cannot stay balanced on its point forever.

Lemaître's 1924 paper also predicted that if the universe really was expanding then the expansion could be measured by astronomical observations. Light from receding galaxies would be shifted towards the red end (longer wavelength) of their spectrum because of the Doppler effect. Lemaître realised that general relativity predicted a linear relationship between the distance of faraway galaxies and their redshift.

In 1927, the American astronomer Edwin Hubble decided to check this predicted relationship between distance and velocity. Hubble calculated the distance of galaxies by measuring their brightness, and relied on his assistant — Milton Humason — to measure the spectra of the galaxies.

By January 1929, Hubble and Humason had distance and spectra data for twenty-four distant galaxies. Hubble plotted the data on a graph, with distance on the x axis and velocity (calculated from the redshifts) on the y axis. The scatter of points lay close to a straight line, indicating a linear relationship between distance and recession velocity — just as Lemaître had predicted.

The following image shows Hubble's actual graph from his 1929 paper (which never credited the work of Humason) in the Proceedings of the National Academy of Sciences:

When he read about Hubble's discovery, Einstein realised his blunder in horror. An expanding universe had no need of a cosmological constant to keep it static. Einstein realised he could have predicted the expanding universe from general relativity before Hubble discovered it from observation. Einstein was later to call his introduction of the cosmological constant the "biggest blunder" of his life.

Einstein had lost the initiative and the leadership. From now on, for the rest of his career, Einstein was always playing catch-up in physics.

The return of the cosmological constant

With Hubble's discovery, it appeared to be the end of the role of the cosmological constant which was duly

removed from the general relativity equation. However, in 1998, a surprising astronomical observation brought the cosmological constant back to centre stage once again.

After the initial explosion of the Big Bang, general relativity predicted that the expansion of the universe would slow down due to the gravitational attraction between the masses in the universe. The question to be answered was at what rate was the expansion slowing?

In order to answer this question, two international teams of researchers attempted to measure the rate of expansion of the universe. The teams measured the brightness of supernova explosions, which tended to all be of similar brightness and were therefore termed *standard candles*. This provided a measure of the distance to the supernova. The speed at which the supernova was receding could be calculated from its redshift.

By combining these two results, both teams discovered something remarkable: the expansion of the universe was accelerating, not slowing-down as predicted. This came as a complete surprise, and the cause of the expansion was unknown. However, it was realised that resurrecting Einstein's cosmological constant provided a possible solution. Remember, Einstein introduced the cosmological constant into his equation to provide a form of repulsive gravity needed to counterbalance the contraction of the universe. It could be this repulsive gravity which was now powering the accelerating expansion of the universe.

What was more, there was an obvious candidate for the energy required to power the expansion. In the next chapter on quantum field theory we will be examining how particles (together with their equivalent antiparticles) can be produced if enough energy is packed into a sufficiently small volume. Even in empty space, the uncertainty principle can introduce the possibility that a particle pair might be produced for an extremely short time, before annihilating each other. As a result, even in empty space, in which all particles have been removed, there will be a seething froth of these so-called *virtual particles*. There will be a corresponding energy due to the presence of the virtual particles called the *vacuum energy*, or the *zero-point energy*.

The suggestion was made that it might be this vacuum energy which was driving the accelerating expansion of the universe, with the vacuum energy playing the role of the cosmological constant in Einstein's equation. This mysterious energy was given the name *dark energy*. However, a problem arises when we try to calculate the expected value of the vacuum energy by adding all the quantum contributions from the virtual particles: we find we get an infinite result. Why is this the case? Well, quantum mechanics tells us that every particle can also be considered as being a wave (*wave-particle duality*), with shorter wavelengths representing particles with higher energy. But when we consider the vacuum energy of a volume of space, there is nothing to stop us including the contributions of particles with ever-smaller wavelengths, which represent ever-increasing energies — potentially up to infinity. The only way we can get a meaningful finite result is to have a cut-off wavelength, and not consider the contributions from any wavelengths which are shorter than the cut-off.

The logical cut-off wavelength is provided by the *Planck length*, an extremely small distance (about 10^{-20} times the diameter of a proton) which represents the shortest measurable length. Unfortunately, when we use the Planck length as the cut-off wavelength, the value of the vacuum energy is calculated to be the huge value of about 10^{93} grams per cubic centimetre. In his book *The Goldilocks Enigma*, Paul Davies calculates that this is "implying that a thimbleful of empty space should contain a million trillion trillion trillion trillion trillion tonnes!" This is larger than the necessary value for dark energy by a factor of 10^{120} . According to Stephen Hawking, this outrageous value represents "the biggest failure of physical theory in history".

As a result, the only way that vacuum energy can be the cause of the accelerating expansion of the universe is if there is some cancellation effect from different types of virtual particles, greatly reducing the estimate to the observed small value. But this would represent fine-tuning to a truly incredible degree.

What is more, if the extremely small value of the cosmological constant had a much larger value then it would have stopped galaxies and stars from forming, and life would have been unable to evolve. This has driven some physicists to consider desperate measures. According to Leonard Susskind: "The notorious cosmological constant is not quite zero, as it was thought to be. This is a cataclysm and the only way that we know how to make any sense of it is through the reviled and despised anthropic principle." [8]

But surely we can do better?

Naturalness

In order to understand the fine-tuning problem more clearly, it is useful to consider the principle of *naturalness* (considered in depth in my previous book).

In physics, there are some fundamental physical constants which seem to play particularly important roles in

describing the universe. Most of these constants have associated units, for example, the speed of light is 3×10^8 metres/second (with the units in that case being metres per second). Note that we could change the numeric value of the constant merely by changing the units. For example, it is also correct to say that the speed of light is one foot per nanosecond. Or, equivalently, 328,000 football pitch lengths per second. Or maybe 46 Great Walls of China per second. Or even 1.6×10^8 giraffes' necks per second.

So it is clear that when we are dealing with constants that have associated units, the actual numeric value of the constant is completely dependent on the units we choose.

This is not the case for a particular group of constants which do not have associated units. These are called the *dimensionless* constants. As an example, later in this book we will be considering the fine structure constant which has a value of approximately $1/137$ — with no associated units. Because the dimensionless constants have no units, even an alien civilisation based on Alpha Centauri would calculate exactly the same numeric value for these constants. Hence, the numeric values of these constants are particularly interesting as they seem to capture some deep truth about the workings of the universe.

It was Albert Einstein who first noticed a particularly interesting feature about the dimensionless constants: their values tend to be close to one. This tendency has proven to be a useful tool for physicists. As John Barrow explains in his book *The Constants of Nature*: "In every formula we use to describe the physical world, a numerical factor appears ... which is almost always fairly close in value to 1 and they can be neglected, or approximated by 1, if one is just interested in getting a fairly good estimate of the result."

Why should it be the case that the values of the dimensionless physical constants tend to be close to one? Well, if we had complete knowledge about the underlying physical mechanism, we might imagine that we could write down a mathematical formula that accurately describes that mechanism, and produces the value of the constant as a result. In that case, it actually becomes difficult to imagine a simple mechanism which could produce values which are many orders of magnitude greater than one. This is because most of the fundamental mathematical constants we would use in our formula (such as pi) also tend to have values very close to one. In that case, how could a simple mechanism produce a numeric value of the order of 10^{40} , for example? It is not easy to imagine how that could happen. [9]

There is another very good reason for expecting the values of the dimensionless constants to be close to one: it is because this would represent a situation which is considered *natural*. As described in Chapter One, we might imagine the universe as being described by Martin Rees's six dimensionless numbers, and we might also imagine those numbers as being the settings on six dials. It would then appear that there is a considerable amount of "arbitrariness" in the universe, in that those dials might well have been set to other values than the observed values. This seems to indicate that the universe could take other forms based on other settings of the dials. In that case, no particular form of the universe appears to be favoured over any other form, and we are left with the question as to why the universe takes the form it does.

However, there is one setting of the dials which seems to be special. If a dial is set to the value 1.0, then we can effectively eliminate that dial without affecting the behaviour of the system (because multiplying or dividing by 1.0 leaves the original number unchanged). The following diagram shows a system in which a dial set to the value 1.0 can be removed without affecting the output of the system:

So a system which has all its arbitrary "dials" set to 1.0 could potentially have all its dials removed. The resulting system would not only be simpler, it would also have no arbitrariness — the system could not be modified (as it has no dials). Such a system would then be called *natural*. It represents the system in its unmodified state, with no tinkering. This also represents the situation in which it is not possible to modify the system, that is, if the state of the system arises from logical necessity. As Einstein said: "What I am really interested in is whether God could have

made the world in a different way; that is, whether the necessity of logical simplicity leaves any freedom at all."

This principle that we should expect the values of the dimensionless constants to be close to one is called *naturalness*. It is a principle which is rather controversial at the moment as some physicists have raised doubts about the range of applicability of the principle. However, I think it is hard to argue with the very general description I have presented here. If we pursue naturalness, then we are eliminating arbitrariness from our solutions. In a completely natural universe, the form of the universe would arise from the structure of our equations, not the setting of arbitrary constants.

It might be the case that the state of the universe does not arise as a logical necessity, in which case we might be forever left with the question of why the universe takes the form it does. In that case, the only answer to why the constants take the values they have would be "that's just the way it is". That rather unsatisfactory answer will always encourage the proponents of the strong anthropic principle to suggest that parallel universes are the solutions to all our problems. But until we reach that end-of-the-road scenario, naturalness seems to be a valuable guide.

I don't think we should be giving-up on naturalness yet.

The naturally-flat universe

As an example of how a natural solution avoids any arbitrariness, let us consider the apparent fine-tuning of one of Martin Rees's "six numbers". In Chapter One it was explained how the value of Ω , the Greek letter omega, represents the ratio between the total amount of mass and energy in the universe, and the critical density of the universe. The value of Ω appears very close to one, which results in a flat universe. This was described as being another example of fine-tuning: if the value of omega was much less than one, the universe would have expanded too fast to allow galaxies and stars to condense, so life could not have evolved. Conversely, if the value of omega was much greater than one, the universe would have collapsed into a "Big Crunch" before stars could have formed.

However, on the basis of our discussion of naturalness, we can see that a value of 1.0 for omega would be a natural value, a value that requires no fine-tuning. It would be the value we should expect. The mystery then becomes the mystery of why our theories do not predict that value. Perhaps there is no fine-tuning — the failing might be in our theories to accurately capture the behaviour of Nature.

Without going into detail, my second book presented a hypothesis of modified gravity which resulted in a naturally-flat universe, and hence an apparent value of 1.0 for omega. There was no arbitrariness in the theory, no adjustable parameters — and no need for inflation. It would be an example of the power of the principle of naturalness.

Let us now examine some more of the deepest fine tuning problems. We will need to consider our most accurate current theory of fundamental physics ...

QUANTUM FIELD THEORY — PART ONE: EVERYTHING IS FIELDS

We are often told that quantum mechanics is a "revolutionary theory" and is the "the most successful theory in the history of physics", representing "our best theory of very small scales". However, as we shall see in this chapter, quantum mechanics cannot be a complete theory of reality at the fundamental level. We will find that a new theory is required.

We will see that this new theory has implications not only because it represents a more complete picture than quantum mechanics, but also because it completely reshapes our view of reality — in a way which is not widely realised or appreciated. We will see that this new theory is far more "revolutionary" than quantum mechanics ever was. We will see that this new theory forces us to give up our notion of a universe made of particles and instead consider a universe composed entirely of *fields*, which we can never directly feel or observe. These fields are continuous, and stretch from one end of the universe to the other. They are about as far from our intuitive notion of reality as it is possible to imagine.

However, we will also see that when we accept a universe made of fields and not particles, then concepts which seem so confusing in quantum mechanics suddenly start to make a lot more sense.

So, welcome to the theory called *quantum field theory*.

All of this might come as something of a shock, and I suspect it is not generally realised by the general popular science audience. However, while quantum field theory (generally known as QFT) might sound shocking and revolutionary, the accuracy of QFT has been thoroughly confirmed experimentally. QFT is now regarded as being our premier theory of fundamental physics.

As Roger Penrose says in his book *The Road to Reality*: "Quantum field theory constitutes the essential background underlying the Standard Model of particle physics, as well as practically all other physical theories that attempt to probe the foundations of physical reality. In fact, QFT appears to underlie virtually all of the physical theories that attempt, in a serious way, to provide a picture of the workings of the universe at its deepest levels."

QFT may be mind-altering, and revolutionary, but it is also the accurate description of how the universe works.

A brief refresher on quantum mechanics

The material presented in this chapter will be heavily-based on material contained in my fifth book, which was an introduction to particle physics and quantum mechanics. It is highly-recommended that you read my fifth book in order to get sufficient background for the material presented in this chapter. As I do not like to repeat material covered in my earlier books, I am afraid the phrase "As explained in my fifth book ..." is going to appear rather often in this chapter.

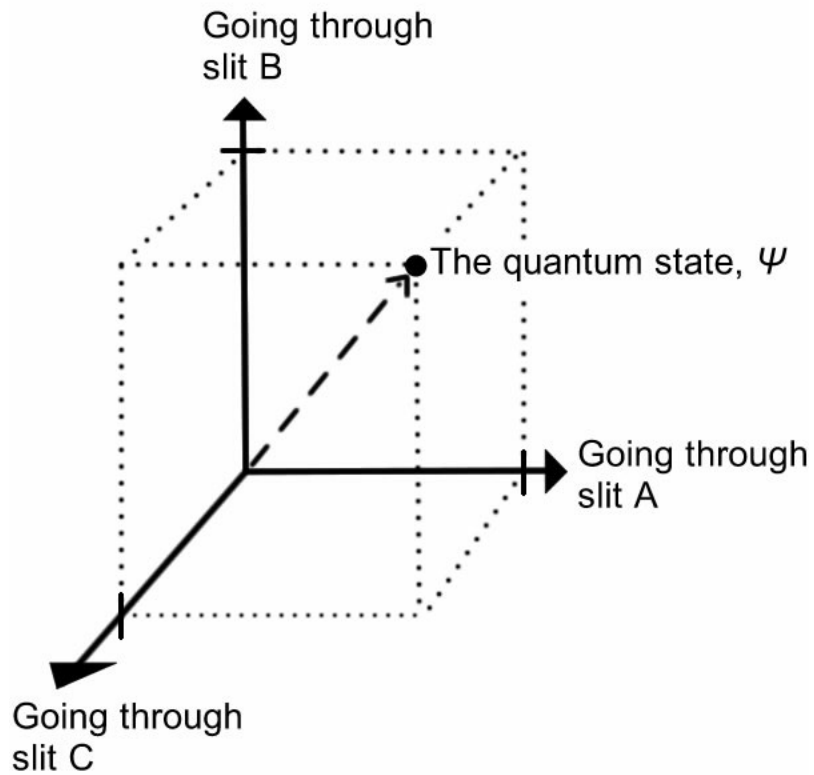

However, a very brief refresher on some of the concepts of quantum mechanics will be presented here — even though they have already been covered in greater detail in my fifth book.

According to quantum mechanics, before we observe some property of a particle, for example, its position or spin, we must consider the particle to be in a strange *superposition* state of all possible particle properties. The classic example of the double-slit experiment is often presented in which a particle appears to travel through two slits **at the same time** before making a mark on screen.

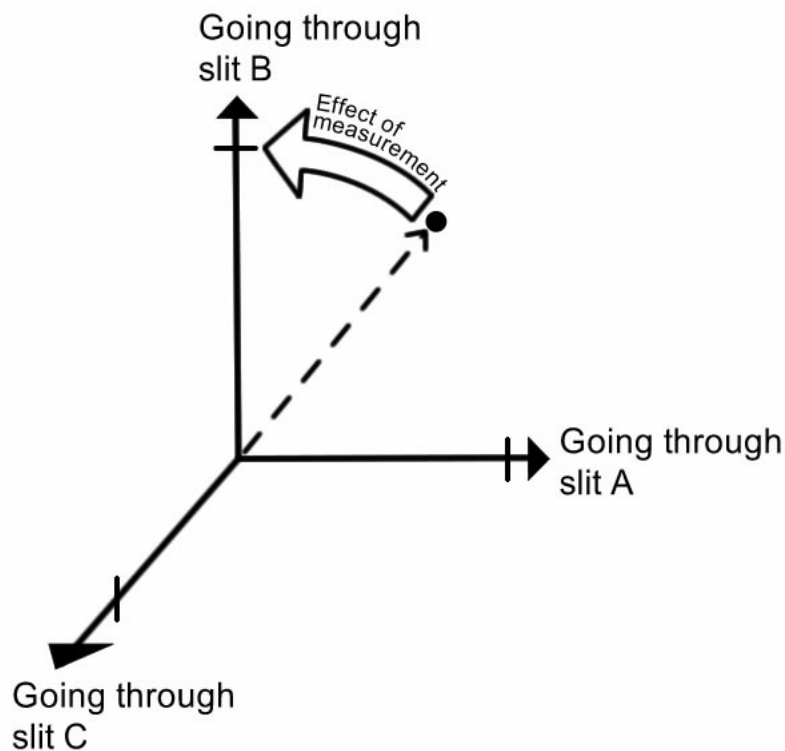

So that is the situation **before** we observe the particle. But **after** we observe the particle, we find the value of the observed particle's property must take only one of a number of certain allowed values. These allowed values are called *eigenvalues*, and the state of the particle must then lie in one of the allowed *eigenstates*.

This whole quantum measurement process can be described mathematically, or by the equivalent graphical description — which we shall now consider. The following diagram shows an extension to the double-slit experiment in which another slit is added (to convert it into a triple-slit experiment). In the diagram, the quantum state of the particle is shown by a vector (the dotted arrow).

The diagram shows the situation before measurement, i.e., before the particle hits the screen. Before measurement, you will see that the quantum state of the particle is in a superposition state: a combination of all three possible slits. Hence, it appears as though the particle is travelling through all three slits:

This form of graphical representation in which the quantum state is depicted as a vector is called a *Hilbert space*. So what happens after we make a measurement? In other words, what happens when the particle hits the screen and reveals its true position? In that case, the particle leaves its superposition state and takes a single well-defined state. As an example, when we try to detect the position of the particle in our triple-slit experiment, we find it only passing through one slit. As you will see in the following diagram, this is represented by a rotation of the quantum state vector from its previous superposition state to one of the well-defined single states (in this case, going through slit B):

These three slits through which the particle can pass would then represent the eigenstates of the system — the only allowable states we will find when we observe the position of the particle.

Mathematically, this rotation of the quantum state is achieved by the application of an *operator* (just denoting the application of a mathematical operation).

Which brings us to the end of this very brief refresher on quantum mechanics.

The Dirac revolution

The highly-introverted physicist Paul Dirac is regarded as one of the key physicists of the 20th century. If anything, Dirac's reputation has only increased in the years since his death, and his work seems more central than ever.

Legend has it that Dirac's great moment of inspiration came in 1928 when he was staring into the fireplace at Cambridge University. Dirac realised how it was possible to combine quantum mechanics with special relativity. The result was that Dirac derived his famous equation for an electron which is known as the *Dirac equation* (the derivation of which was presented in my fifth book, together with more insights about the life and work of Paul Dirac).

The Dirac equation made some extraordinary predictions. It predicted the spin of an electron, which was quickly realised to be a perfect match with experiment. But, most extraordinary of all, the Dirac equation predicted new types of particles which we now know as *antimatter*. It is now known that all particles have an antimatter equivalent.

It was the discovery of antimatter which was to have such a revolutionary effect in quantum mechanics. If a particle of matter meets its antimatter equivalent then both particles disappear in a flash of energy (potentially quite destructive energy). The reverse process is also true: if enough energy can be confined to a small space then a particle can be created together with its antimatter equivalent (a process known as *pair production*). It is possible to make particles! This means that the number of particles in the universe is not a fixed number.

This development is described by Roger Penrose in his book *The Road to Reality*: "The key property of an antiparticle is that the particle and antiparticle can come together and annihilate one another, their combined mass being converted into energy, in accordance with Einstein's $E=mc^2$. Conversely, if sufficient energy is introduced

into a system then there arises the strong possibility that this energy might serve to create some particle together with its antiparticle. Thus, our relativistic theory certainly cannot just be a theory of single particles, nor of any fixed number of particles whatever. Indeed, according to a common viewpoint, the primary entities in such a theory are taken to be the quantum fields, the particles themselves arising merely as 'field excitations'."

Pay particular attention to Roger Penrose's last sentence which suggests that the "primary entities" are the fields — not the particles. We will be returning to this idea shortly.

Fock space

At this point, our theory of quantum mechanics hits something of a problem. Quantum mechanics is, essentially, a more complete update of classical mechanics (the mechanics of Newton). Hence the use of the word "mechanics". So, like classical mechanics, quantum mechanics is basically a theory of how things move, the "things" in this case being particles. To see the problem, let's consider an example from classical mechanics.

Imagine you are pushing a heavy wheelbarrow up a hill. If we want to analyse the motion, and calculate how hard we have to push, we can use classical mechanics and Newton's laws of motion to calculate the forces involved. We can therefore create a perfectly accurate mechanical model of the situation.

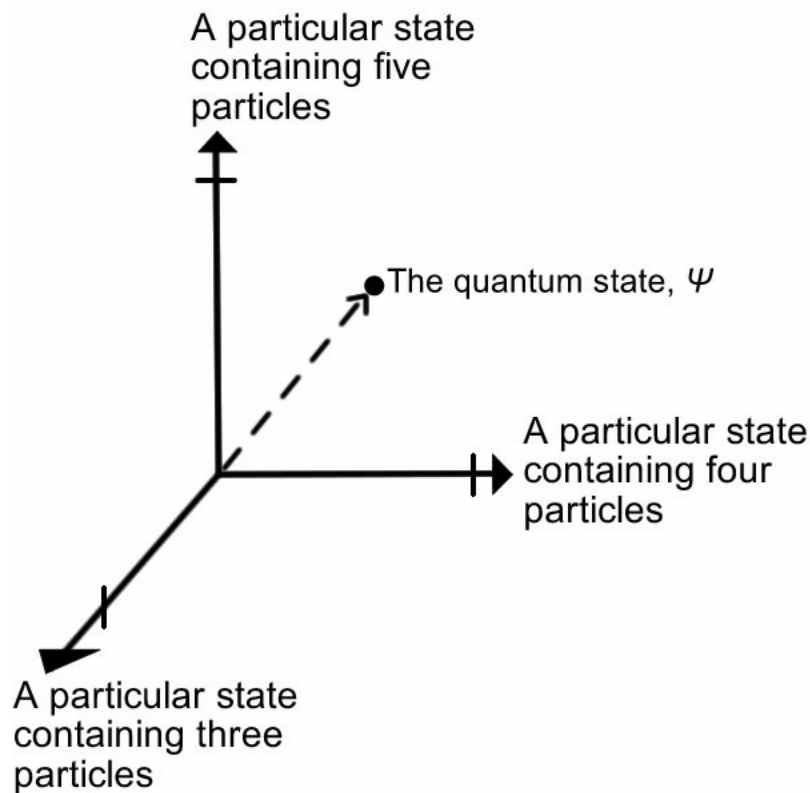

But, all of a sudden, something very surprising happens: the wheelbarrow completely disappears into thin air. This poses a serious problem for our mathematical model: there is nothing in Newton's laws of motion which says anything about objects disappearing. Likewise with quantum mechanics, which is just an update on classical mechanics: there is no way in quantum mechanics to model objects which just suddenly decide to disappear.

As Leon van Dommelen says in his excellent web-based book *Quantum Mechanics for Engineers*: "The quantum formalism in this book cannot deal with particles that appear out of nothing or disappear. A modified formulation called quantum field theory is needed." [\[10\]](#)

So when Paul Dirac revealed that it was possible for particles to appear and disappear, this went beyond the capabilities of the Hilbert space representation. A new mathematical representation is needed for quantum field theory. We have to move from the Hilbert space representation to the *Fock space* representation.

Fock space looks rather similar to Hilbert space in that the coordinate axes represent eigenstates of the system (the allowable states which can be observed after measurement). Let us consider the Fock space for a number of identical particles contained in a box. The eigenstates on each axis of the corresponding Fock space will represent one possible combination of the particles in the box.

As the axes of the Fock Space represent **all** possible combinations of the particles in the box, it is necessary to consider the situation when some particles appear and disappear. Hence, the axes of Fock space can even represent different numbers of particles, as shown in the following diagram of a particular Fock space:

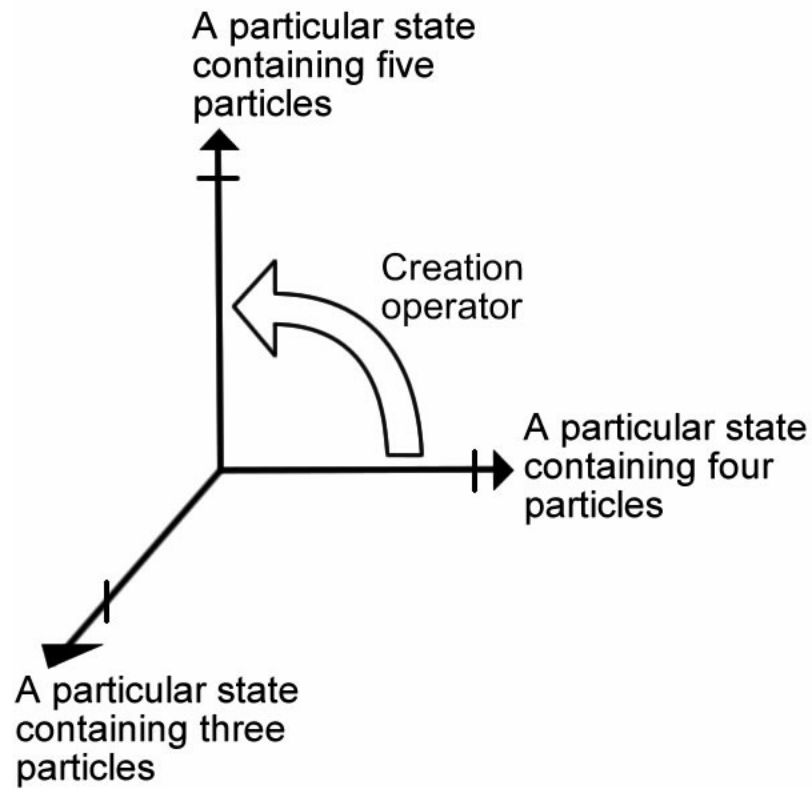

Note that each axis of the Fock space can represent the case of a different numbers of particles in the box (five particles, four particles, etc.).

A bit of terminology for you: when we move from classical mechanics to the Hilbert space representation it is called *first quantisation*. Then when we move from the Hilbert space representation to the Fock space representation (the QFT representation) it is called *second quantisation*. A crucial point is that in the Hilbert space representation, not every situation can be represented (e.g., when the wheelbarrow disappears), whereas Fock space can mathematically represent **absolutely everything that can possibly happen**. This is a crucial feature of second quantisation in QFT, and we will be returning to consider this feature in the next chapter.

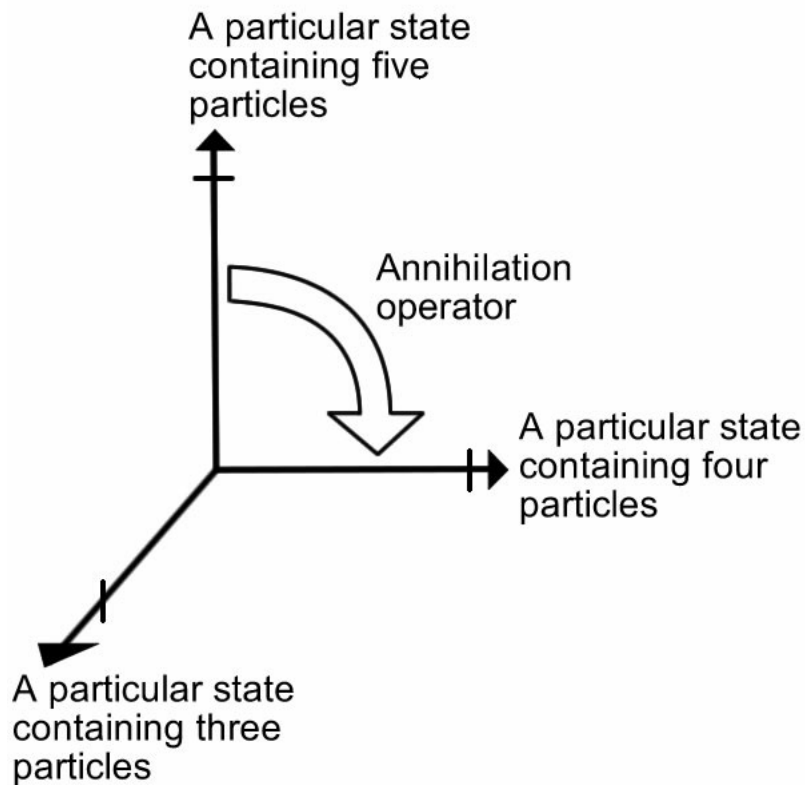

Looking at the axes of the Hilbert space and the Fock space, it is clear that there is a similarity between the two representations, with different eigenstates on each axis. And, just as in the Hilbert space representation, it is possible in the Fock space representation to apply different operators to rotate the current quantum state to different eigenstates (which would represent the state of the system when we open the lid of the box and count the particles).

As an example, the following diagram shows the result of a *creation operator* when applied to a box containing four particles:

You will see that the result of applying the creation operator has been to rotate the quantum state of the system from a state which has four particles to a state which has five particles. Hence, this represents the creation of a particle.

Similarly, it is possible to define an *annihilation operator*:

You will see that the result of applying the annihilation operator has been to rotate the quantum state of the system from a state which has five particles to a state which has four particles. Hence, this represents the disappearance of a particle.

You could apply the creation operator to the quantum state repeatedly, each time adding a new particle inside the box (and generating a new quantum state in the process). Or you could apply the annihilation operator repeatedly, each time removing a particle from the box (until there were no more particles left to remove).

Everything is fields

We have to be careful when applying these creation and annihilation operators, because we have to make sure we do not do something which is forbidden by Nature. This is because all particles can be categorised into one of two groups: they are either *bosons* or *fermions*. Bosons like being in the same state (as described in my fifth book, this is due to the wavefunction of a boson being *symmetric*). As an example, a beam of light is composed of many billions of photons in the same state (photons are bosons). It is therefore possible to use the creation operator to create as many bosons in the same state as you wish. It is then said that those particles are *indistinguishable*.

However, two fermions cannot exist in the same state due to the *Pauli exclusion principle* (as described in my fifth book, this is due to the wavefunction of a fermion being *antisymmetric*). So we cannot use the creation operator to create two fermions (for example, two electrons) in the same state. For this reason, it is said that those particles are *distinguishable*.

However, in the Fock space representation, all we see is numbers of particles on each axis. In other words, in Fock space there is nothing to distinguish one particle (fermion or boson) from any other particle. This is a crucial point: in Fock space, and therefore in QFT, **all** particles (of the same type) are indistinguishable.

What is implied by the fact that all particles are identical in QFT? It has been suggested that it implies something extraordinary: there are not multiple particles, there is only the one field. As an example, **all electrons are identical because they are not actually separate objects, they are merely different parts of a single electron field which covers the entire universe.**

This principle is described well by Leon van Dommelen: "There is a field of electrons, there is a field of protons (or quarks, actually), there is a field of photons, etc. Some physicists feel that is a strong point in favor of believing that quantum field theory is the way Nature really works. In the classical formulation of quantum mechanics, the (anti)symmetrization requirements under particle exchange are an additional ingredient, added to explain the data. In quantum field theory, it comes naturally: particles that are distinguishable simply cannot be described by the formalism."

This principle is also described on the Wikipedia page for quantum field theory, under the section "Physical meaning of particle indistinguishability".^[11] Again, note that the crucial factor in QFT is that all particles (of the same type) are indistinguishable: "The second quantization procedure relies crucially on the particles being identical. From the point of view of quantum field theory, particles are identical if and only if they are excitations of the same underlying quantum field. Thus, the question 'why are all electrons identical?' arises from mistakenly regarding individual electrons as fundamental objects, when in fact it is only the electron field that is fundamental."

So it is now believed that we live in a universe in which everything that exists is a field. Every particle is just a part of a single field for that particle type. Every field stretches the length and breadth of the universe.

How does the single field sometimes appear like particles? It is because particles emerge in the field like waves in the ocean — they are not actually separate from the field, just like a wave is not separate from the ocean. These particles emerge when enough energy is transferred to a small region of the field, like a rock dropped into the ocean.^[12] Particles are often referred to as "excitations" of the field (see Roger Penrose's earlier quote). As an example, this is how the Higgs boson was generated from the Higgs field by the high-energy collider at the LHC.

Sean Carroll has an excellent talk on YouTube filmed at Fermilab called *Particles, Fields, and the Future of Physics* in which he emphasises this idea that everything is a field: "That particle stuff is overrated. Actually, everything is made of fields. You don't need to separately talk about matter made of particles and forces made of fields. All you need are fields."

Here is a link to Sean Carroll's talk:

<http://tinyurl.com/seancarrolltalk>

Here is another quote from Sean Carroll's talk. This is certainly a guiding principle behind the writing of this book: "To working physicists, quantum field theory is the most important thing we know. But when we talk about physics to non-physicists, when we popularise it, we never mention quantum field theory. We talk about particle physics, we talk about relativity, we talk about quantum mechanics. Heck we even talk about string theory and the multiverse and the anthropic principle. But we think quantum field theory is too much to bother about."

Another populariser of the "Everything is Fields" philosophy is the retired physicist Rodney Brooks. Brooks is no longer working in academia, but in the 1950s he was taught by Julian Schwinger who was one of the founders of QFT, and Brooks has made it his retirement project to raise awareness and understanding of QFT in the general public. He is very much an evangelist of the idea that fields are everything, and everything is fields: "No particles, only fields".

Brooks has created a video in which he explains his views on QFT:

<http://tinyurl.com/rodneymrooks>

Brooks also appears to be on a mission to increase awareness of his tutor, the Nobel prize-winning Julian Schwinger. Schwinger's field-based approach to QFT lost in the popularity stakes to the particle-based approach to QFT which was easier to understand and calculate and was popularised by the more charismatic Richard Feynman (who we will be considering in the next chapter). Here is a photograph of Schwinger, who undoubtedly deserves more recognition as one of the most important figures of 20th century physics:

In his video, Brooks mentions how Richard Feynman said it was impossible to understand the counter-intuitive behaviour of quantum mechanics. Brooks then explains how an understanding of QFT can explain effects which seem so puzzling in quantum mechanics: "In quantum field theory, the uncertainty principle becomes trivial. A field is spread-out. An electron is a particle which might be here, it might be there, might have this momentum, might have that momentum — that doesn't make sense. Feynman is correct. But a field that is spread out is not just 'could be here' or 'could be there' — it's here, and here, and here. So that problem, for example, is resolved."

I would agree with Brooks's explanation of the uncertainty principle: uncertainty about position makes a lot more sense when you consider fields rather than point-particles. Also, quantum entanglement — a connection between particles over great distances — also makes more sense when we consider fields extended through space rather than point-particles. And at the 28-minute mark of his aforementioned video, Sean Carroll also explains how a field (or wave) approach can provide a simple explanation for the interactions between particles.

However, so far we have only considered isolated particles in fields in which particles can appear and disappear (so-called *free fields*) but do not interact with each other. In the next chapter we will consider the significant problems which arise when we introduce the possibility of interactions between particles.

QUANTUM FIELD THEORY — PART TWO: THE FEYNMAN APPROACH

We have seen in the previous chapter how quantum field theory appears to describe the lowest level of reality. But it was not this field-based picture which made QFT such a success. Instead, it is a particle-based version of QFT developed by Richard Feynman which dominates QFT calculations. We will be seeing that this approach involves generating a large number of *Feynman diagrams* which describe particle interactions. This version of QFT has been proven to be incredibly accurate, and a powerful tool for physicists. But we will also see that the mathematics behind this approach has been criticised for lacking rigour and elegance.

Julian Schwinger certainly was rather unimpressed by this contrasting approach to QFT. Schwinger felt Feynman diagrams encouraged students to think in terms of particles instead of fields. However, Schwinger also had to reluctantly admit: "Like the silicon chips of more recent years, the Feynman diagram was bringing computation to the masses."

The totalitarian principle

In the previous chapter, it was explained how any successful theory of QFT has to be able to capture the possibility that "absolutely anything can happen", including particles being able to appear and disappear. This principle lies at the heart of QFT, and this behaviour was succinctly described by Murray Gell-Mann in his so-called *totalitarian principle*: "Everything not forbidden is compulsory".

The totalitarian principle was certainly the guiding principle in the approach to QFT which was developed by Richard Feynman. As mentioned earlier, Feynman's approach was particle-based rather than field-based. To understand Feynman's approach, consider a particle moving in space from a point A to a point B. In classical mechanics, this is obviously straightforward: we can see a large object — a train, for example — as it proceeds on its journey between two points. For particles, however, things are not so clear cut. For a particle moving from point A to point B, we can only observe the particle when it sets off on its journey (at point A) and when it arrives at its destination (at point B). We have no information about what the particle is doing in between those two points. Crucially, we can have no information about the **route** the particle is taking between those two points. We are **fundamentally forbidden** from knowing the route. This is basically the principle behind the double-slit experiment: we do not know which slit the particle passes through.

But — you might argue — why can't we just observe the particle in between the two points, thus revealing its path? Well, the only way we could do that would be to arrange for the particle to collide with a secondary particle, for example, to be observed by a photon of light. But if we create an interaction in that manner, then we are inevitably altering the path of the particle under observation: we have modified the experiment we wished to observe. There is no way round it: we are fundamentally forbidden from being certain of the path the particle is taking in order to get from point A to point B.

So Richard Feynman considered the problem of a particle travelling between two points and he applied the totalitarian principle quite literally. Feynman stated that in order to calculate the probability of a particle travelling between two points, we have to sum the probabilities of the particle travelling along **all possible paths** between those two points. And when Feynman said "all possible paths" he most certainly meant **ALL** possible paths. We even have to consider the possibility of the particle taking an apparently crazy route — such as detouring via the Moon, or even the Andromeda galaxy!

This approach is called the *Feynman path integral* (an "integral" is just a summation of lots of smaller elements, like the summing of the small path elements along the curve). To be precise, if we consider the particle as moving in some field of force, then we have to integrate the *Lagrangian* along the path (the Lagrangian was described in my second book, and is equal to the particle's kinetic energy minus its potential energy due to the field of force). The integration process involves dividing the path up into infinitely small pieces and then adding all of those pieces together.

However, a problem arises when we have to add all of the possible paths together as there are infinitely many possible paths. We now see the problem of infinities in QFT: how can we possibly add together an infinite number of objects and still arrive at a finite result? This problem arises because — as was stated earlier — in QFT we have to consider **absolutely anything that can possibly happen**. As we shall soon see, the challenge for any computational technique in QFT is to avoid the infinities which are introduced.

Fortunately, for the case of the Feynman path integral, there is a relatively straightforward reason why the final result is not infinite. Remember, we are dealing with quantum particles, and the position of a quantum particle is always governed by probability. In particular, when the particle travels between two points its position is determined by a wave — a *wavefunction* — and the probability that the particle is in a certain position can be calculated from the square of the wavefunction at that position.

So a quantum particle acts like a wave. And, like any wave, it has an associated angular *phase*. If we add two waves and the phases are the same, then the result will be a large value (this is called *constructive interference*). However, if the phases of the two waves are opposite (pointing in opposite directions) then the waves will cancel (this is called *destructive interference*).

Fortunately, in the Feynman path integral, the more crazy paths — such as travelling to Andromeda or travelling to the Moon — tend to point in various unrelated random directions and so tend to cancel each other due to destructive interference. We are left with the most direct route from point A to point B being the route taken by the particle. This would be the same classical route we would expect a large object to take, such as a ball. As Brian Greene says in his book *The Elegant Universe*: "No matter how absurd nature is when examined on microscopic levels, things must conspire so that we recover the familiar prosaic happenings of the world experienced on everyday scales. To this end, Feynman showed that if you examine the motion of large objects — like baseballs, airplanes, or planets, all large in comparison with subatomic particles — his rule for assigning numbers to each path ensures that **all paths but one cancel each other out** when their contributions are combined. In effect, only one of the infinity of paths matters as far as the motion of the object is concerned. And this trajectory is precisely the one emerging from Newton's laws of motion."

In his book of lecture notes called *QED: The Strange Theory of Light and Matter*, Richard Feynman considered a photon reflecting off a mirror. We would intuitively imagine the path taken by the photon to be the same as that of a bouncing ball, with the angle of incidence being equal to the angle of reflection off the mirror. However, Feynman described how the actual quantum process underlying the behaviour of the photon is far from intuitive.

The following diagram shows a photon of light being reflected off a mirror. The photon is emitted at point X, is reflected off the mirror (shown by the long thin rectangle along the bottom of the diagram), and is detected at point Y:

You will see that Feynman divided the long rectangular mirror into small segments and denoted those segments by letters, from A to M. The mid-point of the mirror is segment G. Intuitively, we would imagine the photon simply being emitted at point X, being reflected off segment G, and being detected at point Y. We would certainly not expect any of the other segments of the mirror — from A to F, or from H to M — to have any involvement in the reflection process. As Feynman says in his book: "We would expect that all the light that reaches the detector reflects off the middle of the mirror, because that's the place where the angle of incidence equals the angle of reflection. And it seems fairly obvious that the parts of the mirror out near the two ends have as much to do with the reflection as with the price of cheese, right?"

However, Feynman then proceeds to apply his path integral technique to this example, and surprisingly reveals that even segments of the mirror which are far away from the midpoint play an important role in defining the reflection. Remember, the Feynman path integral says that we have to consider the photon taking **all possible routes** from point X to point Y. This means that we have to consider the photon also reflecting off segments which are far away from the middle of the mirror, such as segment A and segment M. In fact, we have to consider the photon reflecting off **all** the segments.

Fortunately, though, when we add up all the probabilities of all the different possible paths, we once again find that the apparently crazy paths — reflecting off the segments near the ends of the mirror — tend to cancel out. We are left with the route of the photon reflecting off the middle segment G.

However, I hope this has shown that effects which we intuitively consider to be common sense — such as a bouncing ball, or a reflecting ray of light — are actually products of quantum effects which involve taking **all possible routes**.

Feynman diagrams

Richard Feynman's greatest achievement was the joint development of the theory of *quantum electrodynamics* (also known as QED) which is the quantum field theory of the electromagnetic force. As mentioned in the previous section, Feynman wrote a very accessible book based on his lecture notes on quantum electrodynamics called *QED: The Strange Theory of Light and Matter*. As Feynman says in his book in his usual conversational style: "What I'd like to talk about is a part of physics that is **known**, rather than a part that is unknown. People are always asking for the latest developments in the unification of this theory with this theory, and they don't give us a chance to tell them anything about one of the theories that we know pretty well. They always want to know things that we don't know. So, rather than confound you with a lot of half-cooked, partially analyzed theories, I would like to tell you about a subject that has been very thoroughly analyzed. I love this area of physics and I think it's wonderful: it is called quantum electrodynamics, or QED for short. My main purpose in these lectures is to describe as accurately as I can the strange theory of light and matter — or more specifically, the interaction of light and electrons."

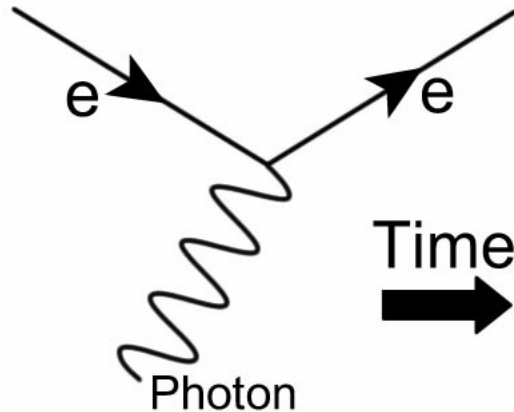

As Feynman said in the previous quote, his particle-based approach to quantum field theory meant that his version of QED was a theory of the interactions between electrons and photons (which are the field particle of the electromagnetic force). As a result, in the examples in this section we will be considering the interactions between electrons and photons.

Perhaps Feynman's most significant contribution to quantum field theory came from his introduction of *Feynman diagrams* which were based on his path integral formulation. Feynman diagrams are simple representations of the interactions between particles. Once again, their ability to represent **absolutely anything that can possibly happen**

makes them perfect for calculations in quantum field theory.

A Feynman diagram is a spacetime diagram, with space along one axis, and time along the other axis. Even though space is three-dimensional, only one dimension of space is included on the diagram.

The following diagram is an example of a Feynman diagram. Note that time increases along the horizontal axis (they are sometimes drawn with time on the vertical axis). The diagram shows an electron coming in from the left of the diagram, and colliding with a photon which changes the path of the electron:

You will notice that the electron is denoted by a straight line (all fermions are denoted by straight lines) while the photon is denoted by a wavy line (all bosons are denoted by wavy lines). Each line — together with its associated mathematical probability — is called a *propagator*.

This very simple Feynman diagram is called the *minimal interaction vertex* (a *vertex* is the point where the lines meet on the diagram). Rather wonderfully, we can create all of the Feynman diagrams for the electromagnetic force just by glueing together these minimal interaction vertex diagrams — as we shall soon see. As David Griffiths says in his textbook *Introduction to Elementary Particles*: "All electromagnetic phenomena are ultimately reducible to this elementary process." Bruce Schumm makes the same point in his book about particle physics *Deep Down Things*: "It is the general electron-photon vertex that we should look to as the fundamental component of the electromagnetic force."

So remember what the minimal interaction vertex looks like: it is the junction of two electron paths and one photon path. You will be recognising this arrangement again soon.

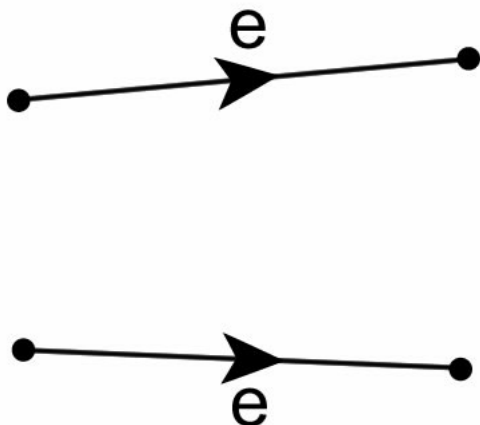

To show the amazing power of the minimal interaction vertex, let us consider what happens when we rotate the diagram. Relativity tells us that we can treat time as just another dimension — just like the three dimensions of space. So there is complete freedom to rotate Feynman diagrams (converting space into time, and vice versa) and the resulting interaction will still be valid. As an example, the following diagram shows the previous minimal interaction vertex rotated 90° anticlockwise:

There is now a remarkable interpretation possible for this diagram. You will see that it appears that the electron is travelling backward in time on the second half of its path (denoted by the star on the diagram). Also, if we temporarily ignore the arrows on the paths of the electrons, we could interpret the left-hand side of the diagram as representing two electrons coming together and annihilating each other — producing a photon as the result. We could therefore interpret this as an electron and a *positron* (the antimatter equivalent of the electron) annihilating each other and producing "pure energy". In which case, that would mean a positron is actually an electron travelling backward in time (as shown in the star on the diagram). It was this definition of a positron which Feynman often used in his diagrams.

Let us now examine how Feynman diagrams can be used in quantum field theory calculations.

Firstly, in the following diagram, let us simply consider two separate electrons moving through spacetime and ending up at two different points. The simplest way that this can happen is shown here:

What we are interested in is calculating the probability that this situation shown actually happens (i.e., both electrons move as shown in the diagram). Fortunately, we know precisely how to do this as we can use the Feynman path integral technique which was explained earlier in this chapter. If you remember, the path integral technique gives the probability of a particle moving between two points, so it is just what we need here.

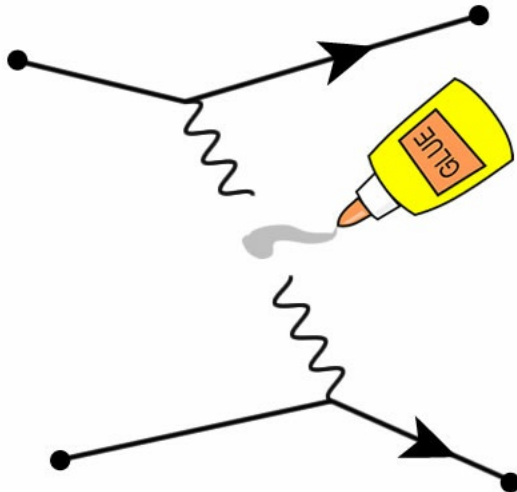

Then, to calculate the complete probability of the situation shown in the previous diagram, we need to calculate the probability of the first electron moving along its path, and then **multiply** that probability by the probability of the second electron moving along its separate path (according to basic probability theory, we have to multiply the probabilities together because **BOTH** event one **AND** event two have to happen to provide the correct result).

But there is another way that the two electrons could get to their endpoints. As shown in the following Feynman

diagram, during their journey they could transfer a photon between each other, modifying their trajectories in the process:

How do we know this is a valid interaction? We know it is valid because we can create this Feynman diagram by glueing together two minimal interaction vertices ("vertices" being the plural of "vertex"):

If you remember, a minimal interaction vertex is a junction of two electron paths and one photon path. So you can see that the previous diagram represents two minimal interaction vertices glued together. Everything fits together like Lego! And the golden rule is that if you can create a Feynman diagram by glueing together minimal interaction vertices, then it is a valid Feynman diagram, and you have to consider it in your calculations.

So that gives us two different ways for the electrons to move to their two separate endpoints. If we want to calculate the probability of the two electrons moving to their endpoints we have to **sum** the probabilities of these two separate diagrams (according to basic probability theory, we have to sum the probabilities because **EITHER** diagram one **OR** diagram two would provide the correct result).

But that's not the end of it. It is possible for the photon to convert into an electron/positron pair for a very short period of time. The electron and the positron can travel a short distance before annihilating each other to produce the photon again. This is shown by the loop in the photon's path in the following diagram:

In the previous diagram, we can consider the loop as being made of the paths of two particles which are shown by the two arrows in the loop. You can see that one particle is travelling forward in time and is therefore an electron, whereas the other particle is travelling backward in time and is therefore a positron.

How do we know this new Feynman diagram is valid? Well, we know it is valid because we have merely added two new minimal interaction vertices, as shown in the following diagram:

You can see that all we have done is glue together two more minimal interaction vertices (don't be confused by the curved lines rather than straight lines). Once again, everything fits together like Lego.

The electrons and photon in the previous diagram only appear in internal lines in the Feynman diagram. These particles which only appear on internal lines (particles which appear only to rapidly disappear again) are called *virtual particles*.

So now we have a total of three different Feynman diagrams to add together to find the probability of two electrons simply moving to two separate endpoints. Here are the three diagrams we must add:

And it doesn't stop there! We can keep going forever, dividing lines, and adding new minimal interaction vertices. With each new diagram, our estimate of the probability of the interaction becomes more accurate. This repeated approach is called *perturbation theory*.

Unfortunately, it appears inevitable that we are going to end up with an infinity of Feynman diagrams which we have to add together just to calculate the probability of two electrons moving. Once again we end up with the problem of how to handle the infinities when making calculations in quantum field theory. How on earth can we add up an infinite number of Feynman diagrams and still get a finite answer?

The fine structure constant

As described earlier in this section, in order to calculate the probability of an entire Feynman diagram, we have to multiply **all** the probabilities contained within that diagram. We can calculate the probability of a particle moving along a path using the Feynman path integral technique. However, that method does not account for all the probabilities in the diagram: we also have to consider the probability of an electron emitting a photon. And we will now see that it is the particular value of this probability which saves us from the dreaded infinities entering our calculations.

Rather simply, the probability of an electron emitting a photon is just a fixed number. The number reflects the strength of the electromagnetic force. There are four fundamental forces, and they each have a characteristic number which reflects the strength of each force. The number for each force is called the *coupling constant*. For the example of the electromagnetic force, which interests us in particular, we will now see how this value is calculated.

Let us consider the strength of attraction between two electric charges a distance r apart. According to *Coulomb's law*, the force, F , is given by:

$$F = \frac{e^2}{4\pi\epsilon_0 r^2}$$

where e is the elementary charge carried by a single electron (1.6×10^{-19} coulombs), and ϵ_0 is the permittivity of free space (8.85×10^{-12} farads/metre).

If you read my previous book then you will know that the r^2 term arises purely from the fact that there are three dimensions of space (the effect of a force dilutes as it extends into space according to an *inverse square law*). So the r^2 term is not specific to the electromagnetic force — it applies to all forces. Hence, in our analysis we should remove the term: we are only interested in the strength of the force in terms of fundamental constants.

As a result, we find the strength of the electric force is then characterised by:

$$\frac{e^2}{4\pi\epsilon_0}$$

If we consider the units (dimensions) of this expression then we find it has units of energy times distance. As

explained in Chapter Four, we do not want to have a term with units as its numerical value will change if we choose different units. We want to find a dimensionless number (i.e., a plain number without units). We can change this term into a dimensionless number if we divide the expression by the product of two fundamental constants, $\hbar c$, a term which also has dimensions of energy times distance (\hbar is the *reduced Planck constant* which is equal to the Planck constant divided by 2π , and c is the speed of light).

We then end up with a mathematical expression describing the strength of the electromagnetic force which is called the *fine structure constant*, and is often denoted by the Greek letter α (alpha):

$$\alpha = \frac{e^2}{4\pi\epsilon_0\hbar c}$$

The fine structure constant is a famous number in physics and, if you substitute the correct values (given earlier) into the formula, you will find it has a value approximately equal to $1/137$. The fact that this vital constant has such an interesting value has made it a target for numerologists who have attempted to derive its peculiar "137" value from various combinations of other constants. Most physicists would regard these attempts as being unscientific (randomly throwing numbers together and hoping to come up with the correct solution shows a lack of understanding).

What makes the fine structure constant so interesting from the point of view of our Feynman diagrams is that it represents the probability of an electron emitting a photon (hence it determines the electric force between two electrons). To be more precise, the fine structure constant represents the probability of a **pair** of electrons emitting and absorbing a photon (because an electron/photon interaction always requires two vertices: one electron to emit the photon, and a second electron to absorb the photon). But what really interests us is the probability of one vertex: a single electron emitting a single photon, so that value is provided by the **square root** of the fine structure constant (because when the value is then squared by multiplying it by itself due to the pair of interactions it will result in the fine structure constant).

Richard Feynman makes this point in his book: "There is a most profound and beautiful question associated with the observed coupling constant, the amplitude for a real electron to emit or absorb a real photon. It is a simple number that has been experimentally determined to be close to 0.08542455. My physicist friends won't recognize this number because they like to remember it as the inverse of its square: about 137.03597. It has been a mystery ever since it was discovered more than fifty years ago, and all good theoretical physicists put this number up on their wall and worry about it."

What makes this coupling constant so vital from the point of view of our Feynman diagrams is that its value is less than 1.0. If you remember, when we calculate the probability of a Feynman diagram we have to multiply all of the probabilities of all the interactions contained within that diagram. If the probability of an electron/photon vertex is just 0.085 then the overall probability of a Feynman diagram will reduce rapidly for each vertex we add.

This reduction in probability is shown in the next diagram. For Feynman diagrams with two electron/photon vertices there is only a probability of 0.7% that the event described by the diagram will actually occur. For Feynman diagrams with four electron/photon vertices there is only a probability of 0.005% that the event will occur (a less than one in ten thousand chance).

As you can see from the previous diagram, because the value of the coupling constant is less than 1.0, this means that Feynman diagrams with multiple vertices will have a very low probability and can be safely ignored by our calculations. Hence, we do not have to add an infinite number of Feynman diagrams together in order to calculate a sufficiently accurate result: the value of the fine structure constant has saved us. Another infinity has been avoided!

However, this is not the case for all forces. The strong force has a coupling constant of 1.0, so this will not become progressively less important as more diagrams are added. Hence, perturbation theory using Feynman diagrams cannot be used to perform calculations involving the strong force.

Interestingly, this probability-based approach gives us another way of thinking about the "strength" of a force. A force with a larger coupling constant simply means there is a greater probability of more force-carrying bosons being produced — and that translates into a stronger force between particles. As Bruce Schumm says in his book about particle physics *Deep Down Things*: "The stronger the coupling, the more quanta are exchanged in a given interaction." Considering an analogy to skaters on ice throwing a ball between themselves, Schumm says: "A stronger force would correspond to a greater likelihood, in any given instant, that a ball would be exchanged between them."

The Higgs mechanism

One of the fields which crosses the entire universe is called the *Higgs field*. The behaviour and structure of the Higgs field is notably different from the other fields. The Higgs field is responsible for giving mass to elementary particles. [\[13\]](#)

The way the Higgs field gives mass to fermions is rather different to how it gives mass to bosons. Firstly, let us consider how the Higgs field gives mass to fermions.

Unsurprisingly, there is a particle which is associated with the Higgs field (it was explained in the discussion of quantum field theory in the previous chapter how every field has an associated particle which can be produced by an excitation of the field). The particle associated with the Higgs field is the famous *Higgs boson*. As a fermion travels through the Higgs field (which permeates the entire universe) it interacts with a sea of Higgs bosons. The result is that the particle slows down as if it is being pushed through a vat of sticky molasses (another common analogy is of a popular person trying to cross a room in a crowded party). As mass is defined as "resistance to acceleration", we interpret this slowing as the particle gaining mass.

To understand how the Higgs field gives mass to bosons, let us first consider the difference between particles which have mass (*massive* particles) and particles which do not have mass (*massless* particles).

The theory of special relativity states that if we try to accelerate an object up to the speed of light, the mass of that object will progressively increase. At the speed of light, the mass of the object would become infinite. In other words, it is not possible for an object with mass to move at the speed of light. This is a principle which applies to all massive particles such as electrons: electrons have to move at less than the speed of light.

However, a photon is an example of a massless particle. And if a particle has no mass, then it has no mass to increase as the speed of the particle approaches the speed of light. It is therefore possible for a massless particle to move at the speed of light. After all, a photon is a particle of light, so it obviously has to move at the speed of light.

Put simply, all massless particles move at the speed of light, and all massive particles have to move at less than the speed of light.

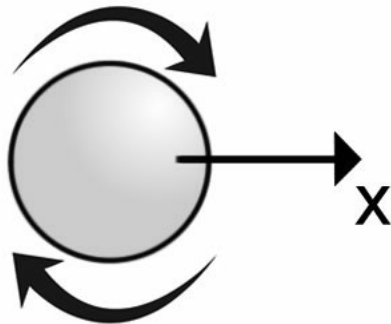

This principle has implications for the spin of massive and massless particles. If we consider a particle in three-

dimensional space, it is clear that there are three axes about which it can spin (the z-axis is coming out of the page):

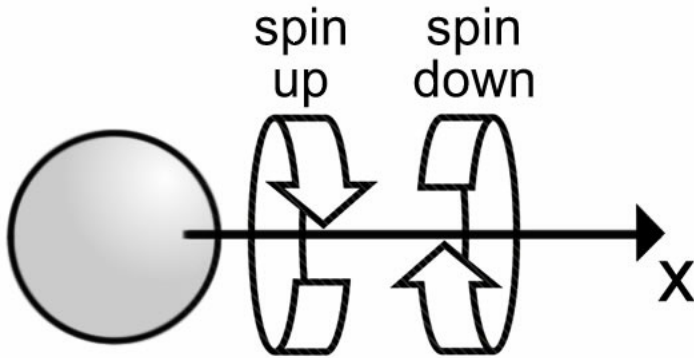

Each of these spin axes is called a *degree of freedom*, with each degree of freedom representing an independent way in which the particle can move. However, if we consider a massless particle, i.e., a particle which is moving at the speed of light, then we encounter a problem.

To understand the problem, consider the following diagram which shows a massless particle moving at the speed of light in the x direction. You will see from the diagram that if the particle is also rotating about either the y or z axis then there would always be a part of the particle which would be moving faster than the speed of light (the top semicircular arrow would be moving faster than light, while the bottom arrow would be moving slower than light):

This is obviously forbidden, so the massless particle is forbidden from rotating about its y or z axis.

This is not a problem if the particle is rotating about its x axis because then the plane of rotation would be perpendicular to the particle's motion along the x axis. So a massless particle is allowed to rotate in a plane perpendicular to its direction of motion. On that basis, the following diagram shows a massless particle moving at the speed of light in the x-direction, while also rotating about that x axis:

It is clear from the previous diagram that the particle can spin in either direction around the x -axis, and we call these directions *spin up* and *spin down* (as shown on the previous diagram). Hence, the massless particle has two rotational degrees of freedom. These two states are called the *polarization* of the particle, and it is the reason why light (which is composed of massless photons) has two directions of polarization. This is the basis for polarized sunglasses (one of the two directions of polarization — the horizontal glare from road surfaces — is filtered-out).

Now let us consider what happens when the massless particle interacts with the Higgs boson — the particle of the Higgs field.

When the massless particle combines with the Higgs boson, it gains one additional degree of freedom which is possessed by the Higgs boson. This additional degree of freedom becomes a freedom of motion along the x axis, the direction in which the particle is moving. And if the particle has a freedom along the x axis then it is no longer restricted to moving at only the speed of light. In other words, the particle might be said to be "slowing down". It has already been described how massive particles (particles with mass) move slower than the speed of light, so we interpret this "slowing" of the massless particle as the particle "gaining mass".

Hence, the Higgs field can give mass to otherwise massless bosons.

The hierarchy problem

But the Higgs boson — which was detected for the first time by the LHC in 2012 — introduces an additional fine-tuning problem. The problem is associated with the measured mass of the Higgs boson.

The value of the Higgs mass cannot be calculated — it has to be measured experimentally. The LHC discovered the Higgs has a mass of approximately 125 GeV. Intuitively, though, particle physicists would have expected the Higgs mass to take a "natural" value, which turns out to be vastly heavier. As explained in Chapter Four, a natural mass would be one in which all the "arbitrary dials" were turned to 1.0. In which case, the mass would have to be calculated only from fundamental constants. The three truly fundamental constants are the speed of light, c , the gravitational constant, G , and the Planck constant, h . These three constants can be combined in only one way to produce a quantity which has the units of mass, and this is shown in the following formula:

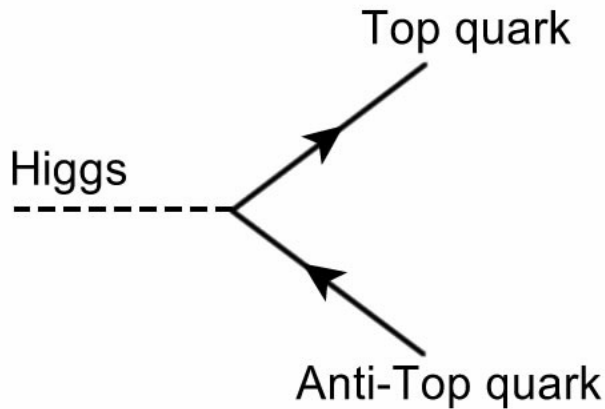

$$m_P = \sqrt{\frac{\hbar c}{G}}$$

The value of this mass, m_P , is called the *Planck mass*.

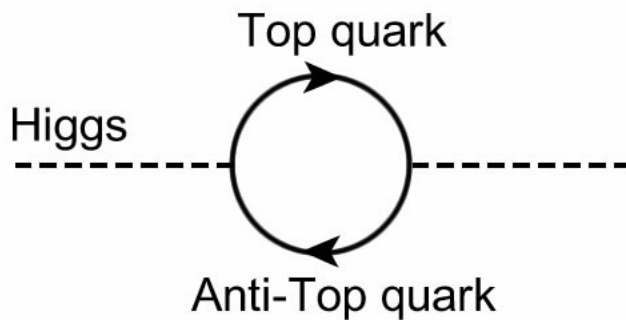

If you substitute the correct values into the formula for the Planck mass you will find you get a surprisingly heavy value: approximately 21 micrograms, the weight of an eyelash. So the measured Higgs mass value is vastly lighter in comparison, which is a surprise and a puzzle.

Another reason why the Higgs mass appears to be surprisingly light arises when we consider the effects of virtual particles temporarily popping into existence (virtual particles were considered earlier in this chapter). As described

in the previous section, the Higgs is responsible for giving mass to particles, so, conversely, the Higgs can interact with any particle that has mass. As an example, the following diagram shows a possible minimal interaction vertex for a Higgs boson (always denoted by a dashed line in Feynman diagrams) interacting with a top quark (an example of a massive particle) and its antimatter equivalent:

At this point, we have to remember that we can glue together these minimal interaction vertices and the resultant Feynman diagram will still be valid. So we can glue together two of these vertices back-to-back to give the following diagram:

The previous diagram shows a Higgs boson which momentarily converts into a top quark/anti-top quark pair, before converting back to a Higgs boson. A top quark has been deliberately chosen for this example as it is the heaviest elementary particle (i.e., the one with the most mass). And, as this Feynman diagram represents a valid interaction, we have to include it in our calculation of the Higgs' path (remember: Feynman diagrams have to include absolutely anything that can possibly happen). The result is that the weight of the top quark adds to the Higgs mass. Plus, we have to include the effects of all massive particles in our calculations (because the Higgs interacts with all massive particles). The end result is that all these quantum contributions once again push the expected weight of the Higgs up towards the vastly larger Planck mass.

So here we have an apparently huge gap between the expected value of the Higgs mass and the measured value: the Higgs is ten million billion times lighter than we would expect, or sixteen orders of magnitude. This huge gap in the mass values represents a *hierarchy*, and the problem of why the Higgs is so light is called the *hierarchy problem*. The hierarchy problem is considered to be one of the greatest unsolved problems in physics.

The hierarchy problem introduces another fine-tuning problem. If the Higgs mass was lighter, then atoms could not form and life could not exist. But if the Higgs was heavier — and particles were therefore as heavy as the Planck mass — then all particles would turn into black holes (too much mass squeezed into a microscopic volume). Hence, the Higgs mass value appears fine-tuned for the existence of life.

There is a popular hypothesis in physics called *supersymmetry* which has been around for forty years which has been touted as a potential solution to the apparent fine-tuning of the Higgs mass. Supersymmetry requires the existence of a whole suite of additional undetected particles called *superpartners*, each superpartner particle being matched to an existing known particle. According to supersymmetry, the superpartner of a boson is a fermion, and

vice versa. The precise symmetry means that the huge quantum contributions from the known virtual particles would be cancelled by the contributions from the superpartner particles. With the huge contributions eliminated, a light Higgs is left. However, no superpartner particles have been discovered at the LHC, and supersymmetry appears to be in trouble. This is a big deal. Many theorists have spent decades of their lives working on supersymmetry. Also, if supersymmetry crashes and burns, then so does string theory which depends on supersymmetry. This has clearly become a high-stakes game. The failure of the LHC to discover new particles leading to the potential demise of supersymmetry — and the dearth of any replacement explanations — has been variously called the "nightmare scenario", a "crisis in physics", or even "the end of science".

Perhaps a new approach is needed ...

7

THE WEAKNESS OF GRAVITY

This is the final chapter of this book.

As regular readers of my books will know, I like to include some of my own original ideas at the end of my books — and this final chapter is no exception. So please bear in mind that parts of this chapter should be considered as being highly-speculative.

Although I have tried to present the concepts as clearly and simply as possible, this is still quite a technical chapter.

In the previous chapter, we considered the mystery of the surprisingly light Higgs mass, a mystery which is called the hierarchy problem. It emerges that there is another hierarchy in Nature, another big gap in the value of the constants. This second hierarchy involves the ratio of the strengths of the fundamental forces. This second hierarchy might appear unrelated to the problem of the Higgs mass, but further analysis shows it might hold the key to solving the hierarchy problem.

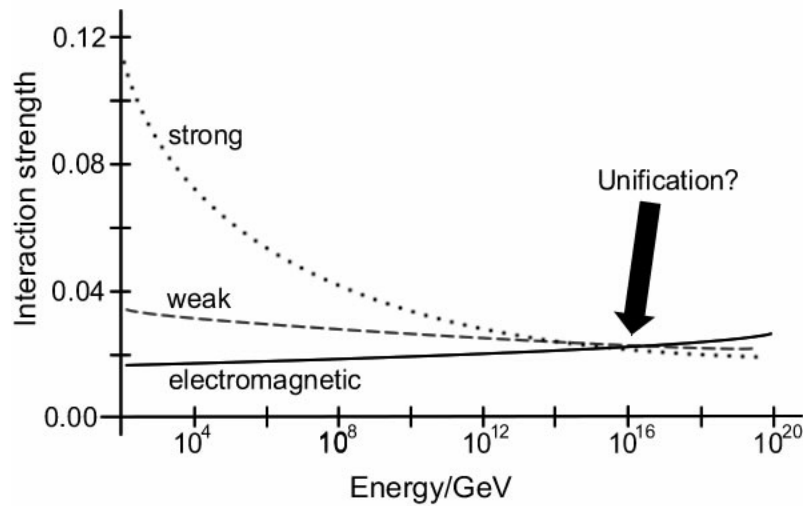

Let us start by reminding ourselves that there are four fundamental forces:

- **Gravity.** Keeps your feet on the ground.
- The **electromagnetic force**, a combination of both the electric force and the magnetic force. In the atom, the electric force attracts negatively-charged electrons to positively-charged protons.
- The **strong force.** In the atomic nucleus, it is the strong force which holds quarks together to form protons and neutrons. It has to be strong to overcome the electrical repulsion between positively-charged protons.
- The **weak force.** In the atomic nucleus, this force can convert a neutron into a proton during radioactive decay.

As explained in my fifth book, in all of these four cases, the actual force is transmitted via gauge bosons, which can be considered as being the "force-carrying" particles. For the electromagnetic force, the gauge boson is the photon. However, as we have seen in the discussion of Feynman diagrams in the previous chapter, the passage of the photon between electrons is constantly disrupted by a swarm of virtual particles. The effect of these virtual particles is to hide the true strength of the electric charge, and to make the force seem weaker over distance than it would otherwise be. This effect is called *screening*. However, if we consider particles interacting at higher energy, these particles will have shorter associated wavelengths and so will be able to "probe" closer to each other. Hence, this will reduce the screening effect and give a truer picture of the strength of the force. And this is what is found through experiment: at higher energies, the electromagnetic force gets stronger.

The opposite is true for the strong force which holds quarks together in the atomic nucleus to form protons and neutrons. Because of the behaviour of the gauge bosons of the strong force (*gluons*), the strong force becomes stronger at large distances. In fact, it is due to the strength of the strong force that no isolated quarks are ever found on their own (it would require so much energy to separate the quarks that new quarks would be produced from that energy).

On that basis, the following graph shows the predicted variation of the strengths of the three forces as the energy of the interactions increases:

As just described, you can see in the diagram that the electromagnetic force becomes stronger at higher energies, whereas the strong force becomes weaker.

It can be seen that the lines describing the strength of the forces are predicted to approximately intersect at a single point at high energy (marked on the diagram by the "Unification" arrow). You will see from the horizontal scale that this represents an energy of approximately 10^{16} GeV, and this is called the *grand unification energy*. This represents a much higher energy than can be achieved using current particle accelerators. This seems to indicate that the fundamental strengths of all three forces are actually the same, and this would become clear at high energies, but that fact is being hidden by the behaviours of the gauge bosons at low energies.

We now know that the electromagnetic and weak forces have the same origin, and only appear to be of different strengths because of the differences in the associated gauge bosons. The gauge bosons of the weak force have mass (due to the Higgs mechanism) which results in the bosons being short-range and they are therefore confined to the atomic nucleus, whereas the gauge boson of the electromagnetic force (the photon) remains massless and is therefore capable of traversing the universe (bringing light from the stars). The true strength of the weak force is not actually weak at all.

It therefore appears probable that all the forces have fundamentally the same strength. So this makes it all the more mysterious to discover that the strength of the force of gravity is many orders of magnitude weaker than the strengths of the other three forces.

At first glance, it might not appear that gravity is a particularly weak force. After all, it is the force which keeps the planets in orbit around the Sun. It is also the force behind terrifyingly-attractive black holes. However, the planets, and the stars, and black holes need to possess immense mass in order for gravity to become dominant.

To understand the weakness of gravity, consider the act of lifting a metal paperclip by using a magnet. The paperclip is being attracted to the centre of the Earth by the force of gravity, and the entire mass of the Earth is pulling on it. However, the electromagnetic force from the small magnet can easily overcome that pull of the entire mass of the Earth.

So just how weak is gravity?

In the previous chapter we considered the electrical repulsion between two electrons in order to derive the fine structure constant which is the coupling constant which describes the strength of the electric force. Now let us derive a coupling constant for the gravitational force which describes the strength of the force of gravity.

Let us calculate the coupling constant for gravity in a similar manner to the way we calculated the coupling constant for the electric force. So, instead of starting with Coulomb's law (for the electric force) we will start with Newton's law of gravity. As we considered electrons in the previous example, let us be consistent and consider electrons again (comparing like-with-like). In which case the gravitational force, F , between the two electrons is given by:

$$F = \frac{Gm_e m_e}{r^2}$$

where G is Newton's gravitational constant, and m_e is the mass of an electron (we can obviously replace the two instances of m_e with m_e^2).

Next, as with our earlier derivation of the fine structure constant, we remove the r^2 term which leaves us — once again — with an expression which has dimensions of energy times distance. So we once again have to divide by $\hbar c$. This gives us our final result, a value for the *gravitational coupling constant* which is a dimensionless number expressed purely in terms of fundamental constants:

$$\alpha_G = \frac{Gm_e^2}{\hbar c}$$

So what is the value of this gravitational coupling constant (which describes the strength of the force of gravity)? Well, if you substitute the correct values into the previous formula you will find that the coupling constant for gravity is approximately 10^{-45} , which is obviously an extremely small number. In her book *Warped Passages*, Lisa Randall refers to this extraordinarily small number when comparing the forces between a pair of electrons: "The gravitational attraction is about a hundred million trillion trillion trillion times weaker than the electrical repulsion between the electron pair."

So here we have another hierarchy, another immensely large number: 10^{45} . Why is there such a huge difference between the strength of the electric force and the strength of gravity? This forms another puzzling hierarchy problem, but it is believed that this particular hierarchy problem is related to the earlier hierarchy problem of the surprisingly-light Higgs mass.

In her book, Lisa Randall considers the hierarchy problem of the Higgs mass and states: "It ultimately boils down to the weakness of gravity compared with all the other known forces." Why is there a connection between the lightness of the Higgs and the weakness of gravity? Well, if you remember back to the discussion of the Higgs mass in the previous chapter, you will remember that the natural value of the Higgs would be expected to be the Planck mass, the formula for which was given earlier as:

$$m_P = \sqrt{\frac{\hbar c}{G}}$$

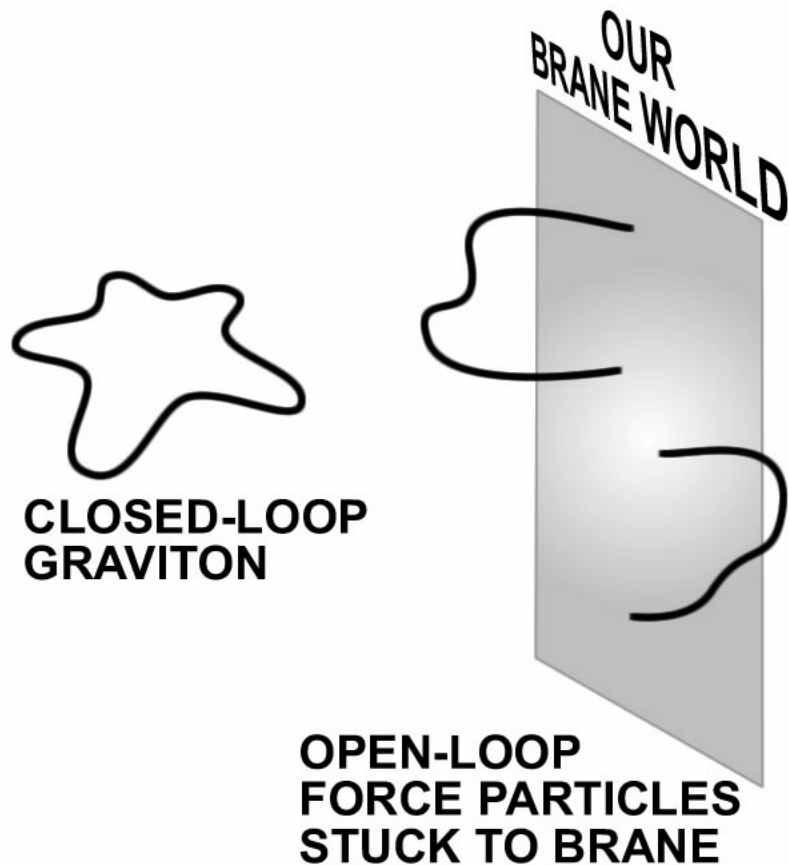

The hierarchy problem is based on the fact that the Higgs mass is immensely smaller than the Planck mass. Or, to put it another way, the hierarchy problem is therefore based on the fact that the Planck mass is so large. And, for reasons we shall consider shortly, a large Planck mass represents weak gravity. Lisa Randall agrees: "A huge Planck scale mass is equivalent to extremely feeble gravity." So that presents us with a possible opportunity: if we want to solve the hierarchy problem of the Higgs mass, we might only need to solve the problem of why gravity is so weak.

The Randall-Sundrum model

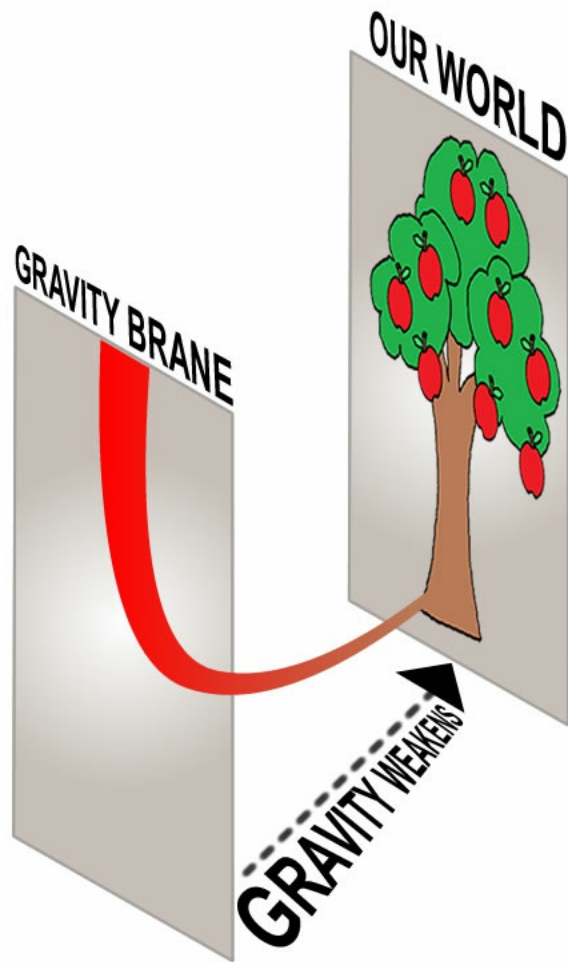

One proposal as to why gravity is weak comes from string theory. String theory requires the existence of many hidden spatial dimensions, and it also predicts the existence of *branes*. Branes are like membranes or sheets in multi-

dimensional space, containing fewer dimensions than the space around them. So a brane is a slice of a higher-dimensional world. The full, multi-dimensional world which surrounds the brane is called the *bulk*.

According to string theory, the particle which carries the force of gravity — the *graviton* — is a closed string loop, whereas the particles which carry the other forces are open strings which have to have their ends terminated on a brane. This restricts the motion of those particles to the brane, whereas the graviton is free to travel through the bulk:

The *Randall-Sundrum model*, proposed by Lisa Randall and Raman Sundrum, is based on the idea that our universe with its three spatial dimensions might be a brane in a higher-dimensional bulk which actually has four spatial dimensions. Unlike the particles associated with the other forces, the graviton is free to travel through the bulk. This, then, presents a proposal for why gravity appears so weak in our universe: we only see a "shadow" of the force of gravity in our three-dimensional universe. The suggestion is that gravity weakens along that fourth spatial dimension as it passes through the bulk to our three-dimensional world:

In her book, which was published in 2005, Lisa Randall listed some of the predictions of the Randall-Sundrum model: "Should this warped geometry scenario prove to be a true description of our world, the experimental consequences at the Large Hadron Collider (LHC) at CERN in Switzerland will be tremendous. Signatures of the warped five-dimensional spacetime could include Kaluza-Klein particles, five-dimensional black holes of anti de Sitter space, and TeV-mass strings."

Any one of these discoveries would have been incredibly exciting. Unfortunately absolutely none of these things were discovered when the LHC started operation in 2010 — although they should have been discovered if the model was correct. Lisa Randall goes on to say: "Results from the LHC are likely to change the way we view the world." Considering the stream of negative results which has emerged from the LHC, I think I can agree with Lisa Randall on that statement — though perhaps not in the way she intended.

Considering the Randall-Sundrum model, imagining an additional invisible dimension of space might represent one route to solving the problem of why the strength of gravity is so weak. But in this series of books I am attempting to build a model of how the universe works in which no unseen extra dimensions are allowed, there are no invisible parallel universes, and you are not allowed to rely on huge suites of undetected supersymmetric particles. In my "reality-based" model, solutions to problems must be found on the basis of what we already know: you are not allowed to invent some parallel universe in which you get to make your own rules.

However, I find those self-imposed constraints concentrate the mind wonderfully. One of the themes of my series of books is that we need to try harder to make sense of what we already know. Sometimes the simplest solution may have been overlooked.

Maybe it is hidden in plain sight?

The true strength of gravity

The weakness of gravity is perceived as being a great mystery, and possibly holds the key to the solution of the hierarchy problem. Let us examine the problem more closely.

Firstly, let us remember that in the previous chapter it was stated that we would naturally expect the mass of the Higgs boson (and therefore the mass of the other particles) to be close to the value of the Planck mass. And the fact that the Higgs is orders of magnitude lighter than this expected value forms the hierarchy problem. But why should we expect the masses of the particles to be naturally close to the Planck mass?

Well, to answer that question, let us remind ourselves of the formula for the Planck mass:

$$m_P = \sqrt{\frac{\hbar c}{G}}$$

and also let us remind ourselves of the formula for the gravitational coupling constant which we derived earlier (remember, the small value of this expression is the reason for weak gravity):

$$\alpha_G = \frac{Gm_e^2}{\hbar c}$$

You will see that the mass of the electron features in this formula for the gravitational coupling constant. But what happens if the electron mass was instead equal to the Planck mass? What would be the strength of gravity in that case?

To answer that question, let us substitute the value of the Planck mass into the previous formula for the gravitational coupling constant. That gives us:

$$\alpha_G = \frac{G \times \left(\frac{\hbar c}{G} \right)}{\hbar c} = \frac{\hbar c}{\hbar c} = 1$$

So, you can see from this formula that the value for the gravitational coupling constant (and, therefore, the strength of gravity) would be equal to 1 for a particle whose mass is equal to the Planck mass.

(Conversely, if the mass of a particle is far less than the Planck mass then it will experience weak gravity — which is the reason why the large Planck mass represents a weak force of gravity in the universe).

At what energy will the strength of gravity become equal to the strengths of the other forces? Well, if you substitute the value of the Planck mass into $E=mc^2$ you will discover it represents an energy of approximately 10^{19} GeV. This is called the *Planck energy*. This is a huge amount of energy for a single particle, approximately equal to the chemical energy stored in a car's petrol tank. You will see that this value is only moderately greater than the value of the grand unification energy (10^{16} GeV) which we considered earlier. This seems to suggest that for particles with extremely high energies — just beyond the grand unification energy — the strengths of all four forces would be approximately equal.

It therefore seems likely that the true strength of gravity is the same as the other three forces, and this would

become clear at high energies. I believe this is fairly generally accepted. This is a valuable insight we can use in our quest to discover why gravity now appears so weak.

Now let us continue by considering a vital fact about the laws of physics.

The laws of physics do not change over time

Emmy Noether was a mathematician who has been described as "the most important woman in the history of mathematics". Emmy Noether worked in academia in the early decades of the 20th century, which was not an easy time to be a female scientist. However, she showed great determination and resilience to make several important contributions to mathematics, and also make an extremely important and influential contribution to theoretical physics.

Noether's great contribution to physics is now called *Noether's theorem*. Put simply, Noether's theorem states that if there is any symmetry in Nature then there will also be a corresponding conserved quantity, i.e., a quantity which does not change over time. Noether's theorem was considered in detail in my fifth book, which explained the tremendous value of the theorem to particle physics.

In that book, an example was presented of the application of Noether's theorem to a skateboarder riding in a halfpipe. It was explained that if there was a symmetry in space, i.e., if the skateboarder was riding down the length of the halfpipe, then the quantity that would be conserved would be the momentum of the skateboarder. In other words, the skateboarder would continue to travel at a constant speed.

So when there is a symmetry in space, momentum is conserved.

Noether's theorem indicates that there is another similar relation between time and energy: if there is a symmetry in time, energy is conserved. But what does symmetry in time actually represent? Well, it means that if we move some physical process — maybe an experiment — along the time dimension then we would find that the underlying situation would be unchanged (that is the definition of a symmetry). As an example, if I perform an experiment today and get a certain result, then if I perform precisely the same experiment again tomorrow then I will get exactly the same result. So what symmetry in time really means is that **the laws of physics do not change over time**.

Noether's theorem tells us that symmetry in time implies conservation of energy. Is there any easy way of understanding why this should be the case? Well, imagine if the strength of gravity (one of the laws of physics) varied with time. In that case, when gravity was weak I could lift a heavy object up some pulley system, connected to an electrical generator. Then when gravity became strong again I could release the weight and get back more energy (in the form of electrical energy) than I put into the system. I could get free energy! This obviously cannot be the case, so the laws of physics not changing with time implies conservation of energy.

I believe that the fact that the laws of physics do not change with time plays a key role to understanding why the strength of gravity is weak. To see why that is the case, let us again consider Newton's law of gravity, which is obviously one of the laws of physics and which should therefore not alter with time:

$$F = \frac{Gm_1m_2}{r^2}$$

The r^2 term represents an *inverse square law* which means the force reduces according to the square of the distance. This is an inevitable consequence of the three dimensions of space (as described in my previous book). It is clear that this aspect of the equation would not vary with time.

However, you will notice that the equation also includes Newton's gravitational constant, G . If the laws of physics do not change with time then that implies that **the value of G does not change with time**. I believe this is an important result in explaining why the strength of gravity now appears so weak, as we shall soon see.

You might not think it is such a big deal to state that the value of G does not change with time. After all, it is supposed to be a fundamental constant! However, that has not stopped the emergence of several theories which suggest a varying value of G . Perhaps the most famous example is that of Paul Dirac, one of the greatest physicists of the 20th century. In one of his wilder flights of fancy, Dirac proposed that the huge ratio of the strength of the electromagnetic force to the strength of gravity was equal to the ratio of the radius of the universe to the radius of a proton. Unfortunately, in an expanding universe, this would mean that both ratios would have to be smaller in the

past than they are is now. How could that possibly be the case if the strengths of the forces does not change? The only way Dirac could think of avoiding this problem was to suggest that the value of G was actually larger in the past (thus reducing the ratio in the past). Could it really be the case that G has varied with time? Dirac stuck doggedly with his theory, but it was shown that if it was the case that G was larger in the past then this would have resulted in increased energy output from the Sun: the oceans would have boiled and life could not have survived.

I firmly believe that we should take it as a rock-solid fact that G has not varied with time. I have always taken it as one of my guiding principles. In fact, I would suggest that if you have a theory which predicts a varying G , you would be wise to throw your theory in the bin.

The early universe

For our next step in trying to construct a potential solution to why gravity is so weak, we will need to travel back in time. A long way back in time.

Physicists now have a very accurate model of the early universe right back to a tiny fraction of a second after the Big Bang. This was a time of extremes, of tremendous temperatures and pressures. The temperature of the universe at this point in time is believed to have been the highest possible temperature which is known as the *Planck temperature*. The Planck temperature is equal to 10^{32} K, or 100 million million million million degrees kelvin. Heat is the result of particles moving randomly at tremendous speed. This means particles had immense kinetic energy.

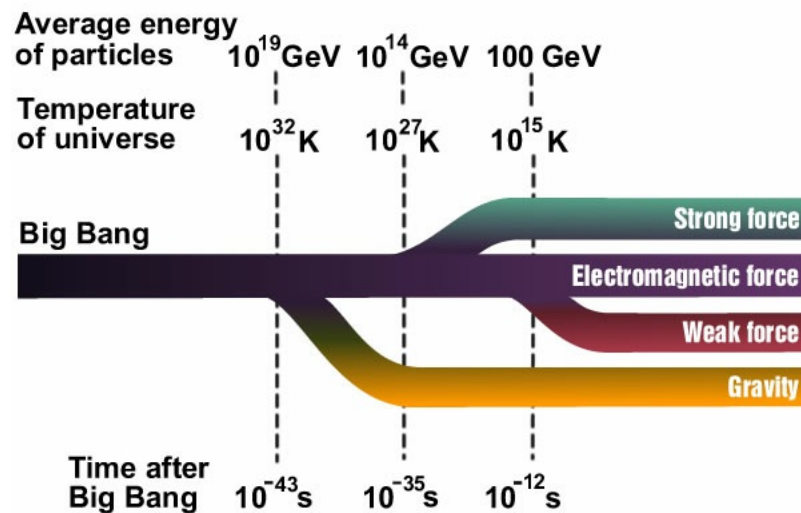

We can understand this situation by considering a large number of particles (for example, a gas) trapped in a box. The box is then heated to a great temperature. Heat is the result of particles moving randomly at tremendous speed, so the kinetic energy of the particles increases. As a result, the total energy of the box increases, and so does its mass. As the Wikipedia page on "Mass in Special Relativity" explains: "If a stationary box contains many particles, it weighs more in its rest frame, the faster the particles are moving. Any energy in the box (including the kinetic energy of the particles) adds to the mass, so that the relative motion of the particles contributes to the mass of the box." [14]

And what is the universe if not a big box full of particles?

As you will see in the following diagram, the Planck temperature of the early universe corresponds to the average energy of particles being 10^{19} GeV, a value which we calculated earlier as being the Planck energy. And, as we calculated earlier, this is the immensely high energy at which the strength of gravity becomes equal to the strengths of the other three forces.

As a result, it is suspected that all the forces were unified into a single force at the time of the Big Bang, and separated into individual distinct forces as the universe cooled.

The following diagram shows this process. Time is on the horizontal scale, with the Big Bang on the left of the diagram:

You will see that the first force to split into a separate distinct force was the force of gravity — which is what interests us. You will see from the diagram that this happened just a fraction of a second after the Big Bang: 10^{-43} seconds, to be precise, an incredibly short period of time which is known as the *Planck time* (the period before this time is known as the *Planck era* or *Planck epoch*). Due to quantum uncertainty, we seem to be fundamentally limited about what we can know about conditions during the Planck era.

As discussed earlier, it is believed that 10^{16} GeV represents the grand unification energy at which the three remaining forces (strong, weak, and electromagnetic) are still unified, but as the universe cooled beyond that point, those three forces separated into distinct forces.

As the universe continued to cool, you can see that at the much lower energy of 100 GeV, the electromagnetic and weak forces split from the previous unified *electroweak* force. This was due to *spontaneous symmetry breaking* by the Higgs field, giving mass to the bosons of the weak force while leaving the photon massless. This energy of 100 GeV is low enough to come within the energy range of our current particle accelerators. And, indeed, the LHC recently detected the Higgs boson (the particle associated with the Higgs field) with a mass of 125 GeV.

Which places us in a position to attempt to answer the main question ...

Why is gravity so weak?

The extreme weakness of gravity is presented as one of the great mysteries of physics. In fact, it has even been called "the greatest unsolved problem in theoretical physics".^[15] Many articles have been written on the subject, and several models have been produced such as the Randall-Sundrum model in order to explain the phenomenon. These models have even incorporated highly-speculative extra dimensions — all with the aim of explaining the weakness of gravity.

However, there does appear to be a very simple solution — an almost trivially simple solution — to this question which only involves conventional orthodox physics. In order to explain the solution, let us return to consider the earliest moments in the life of the universe.

We know that the force of gravity split to become a distinct force in just a fraction of a second after the Big Bang. If there was a force of gravity at that point in time, then there must also have been a law of gravity. And, as we know the laws of physics do not change with time, that law of gravity must have been the same as it is now: Newton's law of gravity must have come into existence 10^{-43} seconds after the Big Bang. So the value of Newton's gravitational constant, G , must have been fixed just 10^{-43} seconds after the Big Bang. It is as if a snapshot was taken of G at that time, and we have been using that value ever since:

For the next step, we need to realise that this means that the value of G would have been fixed **based on the extreme conditions prevailing at that time**. At that early moment in time, the energy of particles was equal to the immense Planck energy (you can see this on the earlier diagram showing the progressive separation of the four forces after the Big Bang: "Average energy of particles: 10^{19} GeV"). The value of G would therefore have been set on the basis that the average energy of particles was far greater than today. And, because of the increased energy of those particles, this would indeed have resulted in gravity having the same strength as the other three forces at that early moment in time (because, as we calculated earlier in this chapter, even today gravity would have the same strength as the other forces if the energy of particles was equal to the Planck energy).

This makes sense in another way as well because it means the natural, expected value for mass at that time could

be calculated in the usual manner from the three most basic fundamental constants, without including any arbitrary constants, which would be equal to the Planck mass:

$$m_P = \sqrt{\frac{\hbar c}{G}}$$

And the Planck mass was, indeed, the average, expected value of the mass of particles at that early time in those extreme conditions, when the laws of physics were set in stone.[\[16\]](#) And it has remained the "natural" value for mass ever since — even though much has changed in the universe since then ...

Over the period of time since the Big Bang, the universe has expanded and cooled to a remarkable degree. From that initial temperature of 100 million million million million degrees, within three minutes it had rapidly cooled to a positively chilly billion degrees. And with that rapid fall in temperature came a corresponding reduction in the kinetic energy of particles. Remember, the kinetic energy of particles dominated in the early universe, but with the average temperature of the universe now at merely a couple of degrees kelvin, the kinetic energy of particles currently forms a negligible part of their total energy.

Which brings us to the next crucial point. Mass and energy can be considered to be the "charge" of gravity: the more mass and energy a particle has, the more it feels the force of gravity. So the cooling of the universe — and the corresponding reduction in energy — has implications for gravitational charge. **But this is not the case for the other forces.** Electric charge, for example, does not vary with temperature. As described at the start of this chapter, there is a minor variation in the strength of the electromagnetic force with energy due to the screening effect, and a graph was presented showing how the strengths of the three forces varies with energy. But this variation would be negligible compared to the variation in the strength of gravity. The cooling of the universe would therefore have left the strengths of the other three forces unchanged — it is the strength of gravity alone which would be affected by many orders of magnitude.

To sum up, the law of gravity uses a gravitational constant, G , the value of which was set when the average gravitational charge was huge. After the cooling of the universe, the average gravitational charge was vastly reduced. With the strengths of the other forces unaltered, gravity now appears relatively weak.

In the discussion on naturalness in Chapter Four, it was explained how theories have a major challenge in explaining the origin of any constant which takes the form of a large dimensionless number. What is the origin of the large number? What mathematics could possibly generate it? Any theory which attempts to explain the weakness of gravity must explain the origin of the large dimensionless number which describes the ratio of the strength of the other forces to the strength of gravity. As I say, it is a major challenge for any theory to identify the origin of this unnaturally-large dimensionless constant.[\[17\]](#) However, in this discussion considering the relative weakness of gravity, a simple explanation of the origin of that particular immense number has emerged: the origin is the ratio between the immense temperature of the universe at the time of the Big Bang, and the cool average temperature of the universe now. In other words, one immense number has been converted into another immense number.

On that basis, a simple calculation can be performed to quantify the effect of the cooling universe on the relative weakness of gravity. Energy is proportional to temperature.[\[18\]](#) So to understand the drop in energy, we only need to consider the drop in temperature. As described earlier, the temperature just after the Big Bang was 10^{32} K (the Planck temperature). With the current temperature of the universe being a mere 2.73 kelvin, that represents a dimensionless ratio of temperatures of approximately 10^{32} . This value of 10^{32} representing the relative weakness of gravity is very much the kind of value we are looking for, coming right in the middle of the following range:

- 10^{45} — the strength of the electromagnetic force relative to the strength of gravity.
- 10^{24} — the strength of the weak force relative to the strength of gravity.

To put it simply, it appears that the reason why gravity is now so weak is that gravity was designed for a much heavier world.

The fine-tuned universe

I hope you have enjoyed this book.

The intention has been to show that grounded, conventional physics provides the best route to solving the apparent fine-tuning problems. Other techniques — such as the strong anthropic principle — might appear to provide shortcuts to quick solutions, but the temptation to go down those routes should be resisted.

In trying to discover solutions to the puzzling fine-tuning problems, it seems as though whenever progress has stalled, the common approach has been to introduce some additional undetected structure as a way of circumventing the problem. Structures which have been invented to solve the fine-tuning problems include:

- **Supersymmetry.** The proposal for a huge suite of undetected supersymmetric particles as a way of explaining the hierarchy problem. None of these particles were detected by the LHC, which is currently our highest-energy particle accelerator. Unfortunately, as these particles have gone undetected as accelerator energies have progressively increased, some physicists have chosen to conveniently increase the predicted masses of these particles so that they lie just beyond current accelerator energies. In other words, the predictions have been modified in order to preserve the theory. That is surely not a good way to do science.
- **Extra dimensions.** The proposal for unseen and undetectable extra spatial dimensions as a means for explaining the weakness of gravity.
- **The inflaton field.** An additional unexplained and undetected field required by the inflation hypothesis, as a means for explaining the fine-tuned flat universe.
- **The multiverse.** An undetected and undetectable group of universes beyond our own universe, used by the strong anthropic principle to potentially "solve" (in the loosest sense of the word) **all** of the puzzling fine-tuning problems.

Can we really continue proposing new structures whenever we appear to hit a dead-end? Is this really the best way to solve the fine-tuning problems? The danger is, of course, that we are trying to solve the fine-tuning problems by inventing structures that simply do not exist.

Surely it would be better if the process of inventing and proposing new undetected structures was treated as a last resort, when all else has failed. Instead, it seems as if this approach is being treated as the preferred first option.

The message of this book has been that we should try harder to make sense of current data using our existing tools and knowledge — rather than inventing additional unseen structures.

The solutions we seek might well be hidden in plain sight.

The principle of naturalness appears to be a useful guide in our efforts to describe fundamental mechanisms. In an entirely natural solution we would only be left with dimensionless constants of the order of magnitude of one. We would then be entitled to consider the value of that constant as being "natural", and not fine-tuned. We may not know the precise origin of the value of the constant, but we can be satisfied we are not far away from knowing the truth. Examples of "natural" constants might include the fine-structure constant, and the number of dimensions of space. I suspect it is likely that simple solutions to these problems will arise at some point. Maybe we don't have all the answers yet, but we can afford to be hopeful in these cases.

In a completely "natural" universe there would be no arbitrariness whatsoever: the state of that universe would be uniquely fixed as a logical necessity. However, there seems to be a fairly widespread belief that the state of our universe could not entirely arise as a logical necessity, in which case — despite our best efforts — we might be forever left with the question of why the universe takes the form it does. In that case, the only answer to why the constants take the values they have would be "that's just the way it is". I certainly do not believe we have reached that point yet, but if we do reach that point then we would be at the limit of possible human knowledge (for example, quantum uncertainty limits our knowledge of conditions during the Planck era).

The discussion of the Fermi paradox in this book seemed to suggest that life is a rare occurrence in the universe, requiring an almost impossibly special combination of conditions — such as those found on Earth. It has been said that the Earth appears to be a "gem". So maybe we should view this as an opportunity. If we eventually come to the limit of possible human knowledge, we should not despair about the "end of science". Instead, we should congratulate ourselves on a job well done, and spend our time enjoying our lives in this amazing universe on this very special planet.

EPILOGUE

Regarding the hypothesis of modified gravity I presented in my earlier books, there has been a recent development which is potentially very interesting. The modified gravity hypothesis did not only predict a naturally-flat universe, but it also predicted a modification to the structure of black holes. The hypothesis eliminated the troublesome singularities which are supposed to lie at the heart of black holes. Instead, the hypothesis predicted that the mass of a black hole would be concentrated at its event horizon.

In August 2016, a team led by Vitor Cardoso of the Superior Technical Institute in Lisbon suggested that the signature of a thickened event horizon could be detected in the recently-discovered gravitational wave signals. The gravitational waves were produced by the merging of two black holes, producing a staggering amount of energy. This prediction was investigated by a team led by Niyayesh Afshordi of the Perimeter Institute and the University of Waterloo.

In December 2016, Afshordi's team released a paper with the evocative title of "Echoes from the Abyss", in which they announced that they had detected echoes of energy released between the inner layer of the event horizon and the outer layer of the event horizon. This would appear to indicate some structure at the event horizon, structure which was not predicted by conventional general relativity. The announcement was also featured in an article in *Nature magazine* which was aimed at the general readership. [\[19\]](#)

Being realistic, the chances that this result will prove to be conclusive evidence of a modification to general relativity is extremely remote. However, what is exciting is that new data is starting to pour in, and will continue to pour in for the next few decades as a series of new ambitious experiments go online. The next few years might prove to be very exciting indeed.

Watch this space!

PROLOGUE: THE Nth COUNTRY EXPERIMENT

The year is 1964.

Dave Dobson was a physics student, excited to have just received his PhD. Dobson was a bright guy, and a science enthusiast. He had a good general knowledge about several fields of physics, but his knowledge was nothing spectacular.

To all intents and purposes, Dobson was Mr. Average.

This made it all the more surprising when Dobson received a telephone call from the renowned nuclear physicist Edward Teller. Teller invited Dobson to come to Washington D.C. for an interview for a job in one of the country's leading nuclear research facilities. Dobson was amazed and, frankly, wondered if they had got his name mixed up with someone else. He later described everything he knew about nuclear chain reactions at that time: "I had seen an exhibit with a model of a chain reaction made up of mousetraps and ping pong balls."

Dobson met Teller and they spent an evening together. Teller quizzed Dobson to discover everything he knew about nuclear weapons, and Dobson honestly replied that he knew nothing more than any other amateur science enthusiast. To be frank, Dobson admitted he knew absolutely nothing at all about nuclear weapons.

"Great", replied Teller. "You will be perfect for the job".

At that time — the early 1960s — the Pentagon was extremely concerned about the possible proliferation of nuclear weapons to other countries. Only the United States, the Soviet Union, Britain, and France possessed nuclear weapons. Britain had been the third country, France had been the fourth. Which country would be the fifth country to possess nuclear weapons? Or the sixth country? Where would it all end? Which country would be the "Nth country"?

In order to shed some light on that question, the Pentagon had started a top secret project called the "Nth Country Experiment". Dave Dobson would be one of two physics students who had been selected to work on the project.

The worry was that so much information about how to make an atomic bomb had been published in the popular press. While no classified secrets had been leaked publically, there was plenty of more general information freely available to an amateur enthusiast. Given the availability of that general information, would it be possible for a rogue state, employing nothing more than a few physicists of very average ability, to create a nuclear weapon?

Basically, the goal of the Nth Country Experiment was to determine how difficult (or easy) it was for a bunch of amateurs to make an atomic bomb.

This, then, was to be Dave Dobson's first job straight out of university. Dobson was given a desk in a corner of a laboratory in the Livermore Radiation Laboratory in California. He was introduced to another amateur physics enthusiast, Bob Selden, a 28-year-old soldier who would be working with him. Neither man had any nuclear expertise whatsoever.

Their job was to imagine they were working for a rogue state (named the "Nth Country"). They were handed a document explaining their task. Here is the first paragraph of the document: "The purpose of the so-called Nth Country Experiment is to find out if a credible nuclear explosive can be designed, with a modest effort, by a few well-trained people without contact with classified information. The goal of the participants should be to design an explosive with a militarily significant yield. A working context for the experiment might be that the participants have been asked to design a nuclear explosive which, if built in small numbers, would give a small nation a significant effect on their foreign relations."

The first thing which needed to be done was to obtain security clearance for Dobson (Selden had already been cleared because of his military background). Clearance was necessary because it was against the law to design nuclear weapons without security clearance.

Dobson and Selden would have access to none of the secret research material at the laboratory, but they would have access to the general library and its publically-available material. They were told that the imaginary "Nth Country" they were working for would have "more resources than Ghana, but less than an industrialized nation." They should assume they had access to good machinists able to shape uranium and plutonium, and also access to some engineers experienced with conventional explosives. Apart from that, they were given no more instructions on

how they should proceed. They were on their own.

In the library, Selden found a book about the Manhattan Project, the U.S. project which developed the atomic bomb. According to Dobson: "It gave us a road map. But we knew there would be important ideas they'd deliberately left out because they were secret. This was one of the things that produced a little bit of paranoia in us. Were we being led down the garden path?"

If Dobson and Selden wanted to perform an experiment, perhaps with high explosives, they had to describe their desired experiment in great detail. A team of experts then calculated the result of the experiment and passed the result back to Dobson and Selden.

Ironically, one of the most useful sources of information came from President Eisenhower's "Atoms for Peace" programme, the motivation for which was to encourage the use of non-military nuclear power around the world. Atoms for Peace was just one example of the enthusiasm at the time for nuclear energy, the result of which was to distribute a vast amount of technical information into the public domain.

After two-and-a-half years, in 1966, Dobson and Selden had finally finished their design. According to Selden: "We produced a short document that described precisely, in engineering terms, what we proposed to build and what materials were involved. The whole works, in great detail, so that this thing could have been made by Joe's Machine Shop downtown."

However, after they had presented their document, everything went very quiet, and Dobson and Selden were not informed of the outcome. They presumed that they had failed in their task. So, one day in Livermore when they met a senior researcher, Jim Frank, they asked him why things had gone so quiet. Did he have any knowledge of the outcome of their experiment? Yes, said Frank, he knew what had happened. The reason why everyone had gone quiet was because they had realised that if a bomb had been constructed precisely according to their detailed instructions, it would have exploded with the same order of magnitude as Hiroshima.

1

OUR FRIEND THE ATOM

In 1870, the French science fiction writer Jules Verne wrote the classic adventure novel *Twenty Thousand Leagues Under the Sea*. It is the story of Captain Nemo who terrorised the world's shipping using his mysterious submarine called the *Nautilus*.

As usual, Jules Verne showed his amazing talent as a futurist, predicting technological advances many years before that technology came to exist. In this case, the submarines of the 19th century were very primitive vessels, so Jules Verne's description of a craft which could stay submerged for several days proved to be prophetic. That was because, in 1954, the real-life *Nautilus* was launched. And it could, indeed, travel underwater for weeks or months at a time.

The *USS Nautilus* — named after the craft in Jules Verne's book — was the world's first nuclear-powered submarine. In a nuclear-powered submarine, heat generated by a small nuclear reactor turns water into steam which, in turn, powers the propeller of the submarine. Unlike a diesel engine, a nuclear reactor requires no air to operate. As a result, nuclear-powered submarines are capable of staying at sea for many months without needing to refuel, and can travel huge distances under water.^[1] To prove the point, in 1958 the real-life *Nautilus* took four days to complete the first submerged voyage under the North Pole.

The following photograph shows the *USS Nautilus* arriving in New York City in 1958:

America in the 1950s was an optimistic time, and nuclear power was viewed very differently from how it is viewed today. The almost unlimited energy produced by the atom gave the promise of cheap, compact power sources which could be used for almost any application. The success of the *USS Nautilus* inspired ideas for other nuclear-powered forms of transport. One of the most outrageous suggestions included the world's first nuclear-powered car, the Ford Nucleon which was proposed by the Ford Motor Company in 1958. In the rear of the car was to be a small nuclear reactor which would allow the car to travel 5,000 miles without refuelling (unfortunately the car never got off the drawing board: such a small nuclear reactor did not exist, and the required shielding to protect the passengers would have made the car too heavy).

It was widely-believed that the electricity produced by nuclear power would be so cheap that it would make more sense to provide it for a flat fee — or even give it away for free — rather than installing expensive meters. This optimism was summed-up in a 1954 speech by Lewis Strauss who was the chairman of the United States Atomic Energy Commission: "Our children will enjoy in their homes electrical energy too cheap to meter. It is not too much

to expect that our children will know of great periodic regional famines in the world only as matters of history, will travel effortlessly over the seas and under them and through the air with a minimum of danger and at great speeds, and will experience a lifespan far longer than ours, as disease yields and man comes to understand what causes him to age."

It is believed that Strauss was referring to power produced by nuclear fusion, which would provide almost unlimited power from readily-available hydrogen. Indeed, if nuclear fusion research proves successful then Strauss's prediction of too-cheap-to-meter energy might yet come true.

In 1954, feeding off the excitement caused by the launch of the Nautilus, Walt Disney released the movie *Twenty Thousand Leagues Under the Sea* starring Kirk Douglas and James Mason as Captain Nemo. To support the release of the movie, an episode of the Disney television series *Disneyland* was devoted to examining the wonders of nuclear power. Continuing the optimistic tone of the age, the episode was called *Our Friend The Atom*.

The *Our Friend The Atom* episode is an excellent introduction to nuclear physics, and it is available on YouTube:

<http://tinyurl.com/movieatom>

The programme starts with Walt Disney standing beside a scale model of the USS Nautilus (including a clip from the Disney movie *Twenty Thousand Leagues Under the Sea* featuring the fictional Nautilus). We are then shown around Disney's "Atomic Energy Lab" which features some very nice wood-panelling and some "scientists" in white coats looking down optical microscopes (presumably at "atoms"?). It is rather bizarre to hear Walt Disney say: "As you can see, we found ourselves deep in the field of nuclear physics."

We are then introduced to Heinz Haber, a physicist who worked for the Luftwaffe in World War Two. After the war, he was taken to America together with Wernher von Braun to keep his expertise out of the hands of the Soviet Union. Haber went on to provide valuable contributions to the NASA space programme.

Haber then introduces some Disney animated sequences which are used to illustrate various issues associated with nuclear energy. For example, in a tale from *The Arabian Nights*, nuclear energy is compared to a genie in a lamp which has the power to do good or evil, but can never be trapped back inside the bottle from which it came.

Heinz Haber then proceeds to tell the story of the discovery of the atom, starting in ancient Greece with Democritus who suggested that matter was formed of indivisible small hard balls. Democritus could never provide any evidence to support his atomic theory. However, the story then moves to consider the work of the 19th century English chemist John Dalton who proposed the atomic theory of chemistry. Dalton realised that the combination of chemical elements (such as hydrogen and oxygen) to form chemical compounds could be explained if the elements were formed of atoms. This was the first truly scientific theory of the atom. According to Dalton, when atoms of different elements joined together, compounds were formed, e.g., two hydrogen atoms can combine with one oxygen atom to form water.

Haber then considers advances in atomic theory through the 19th and early 20th centuries. Slowly, Haber builds-up the model of the atom.

Atoms are composed of a tightly-packed nucleus surrounded by orbiting electrons. The nucleus is made out of positively-charged *protons* and electrically-neutral *neutrons*. Because protons have positive electric charge, their tendency is to repel each other. The neutrons, therefore, have to act like glue to hold the protons together and to stop the nucleus from flying apart. The negatively-charged electrons are held in their orbits by the electrical attraction to the positively-charged protons (opposite charges attract).

The following diagram shows a carbon atom. It is composed of six electrons orbiting a nucleus which is composed of six protons and six neutrons:

In this book we are only going to be interested in the nucleus of the atom. The study of the nucleus of the atom is called *nuclear physics*. In his book *The Making of the Atomic Bomb*, Richard Rhodes reveals the key reason why it is the nucleus of the atom which provides the energy for nuclear explosives: "Nuclear physics, the study of the nucleus of the atom, is where most of its mass — and therefore its energy — is concentrated."

A Disney book was published in association with the television programme, also called *Our Friend The Atom*. The book was written by Heinz Haber who hosted the television programme. Here is a photo of me with a copy of the book in good condition which I bought off eBay:

When my copy of the book arrived I was delighted to find the pages were pristine white, completely unfaded, and I got the impression the book had not been opened for over fifty years. This impression was strengthened when I opened the book and found a cutting from the *Daily Telegraph* newspaper dated April 13th 1961 announcing that the Soviet astronaut Yuri Gagarin had returned safely from the first manned space flight, having completed an orbit of the Earth. I was even more delighted to find hand-written notes (on perfect white paper) detailing contemporary hydrogen bomb tests and other atomic research. The following photograph shows the notes I found in my book:

The book had clearly belonged to a science enthusiast. It is an example of the interest and excitement of the general public about atomic energy in the 1950s and early 1960s. I was delighted to find these hidden secrets — I guess sometimes you just get lucky.

Our Friend The Atom was obviously aimed at a young audience, but it was a superb project. It is a shame to think that such a high-level educational programme about nuclear energy would never be aimed at young children today. It is also a shame that we have lost our optimism and enthusiasm about the potential contained within the atom. In this book, I hope to restore some of that optimism.

The Gilbert Atomic Energy Lab

Our Friend The Atom was not the only example of 1950s nuclear education which was aimed at children. Take a look at the following toy. The boy on the lid of the box looks thrilled. No wonder! He has just been given the Gilbert Atomic Energy Lab for his birthday and he is busy doing experiments with radioactive material:

According to its Wikipedia page, the Gilbert Atomic Energy Lab has been called "The world's most dangerous toy", which is extremely unfair and — frankly — completely inaccurate. I would prefer to call it "The world's coolest toy ever".

Alfred Gilbert, the toy maker who released the Atomic Energy Lab, believed that his toys held the key to building a "strong American character", and his toys always included some educational quality. But the Atomic Energy Lab contained genuine radioactive ore samples. So was the Atomic Energy Lab a safe toy?

Well, in assessing whether it was safe, it is important to realise that we are all constantly being irradiated by a low-level background radiation. This radiation may come from the rocks and soil which surround us, or even from the plants which we eat — particularly bananas, which are surprisingly radioactive. This has resulted in the creation of a measure of radiation called the *banana equivalent dose* (or BED). One BED is approximately equal to 1% of a day's worth of background radiation (which would therefore be equal to 100 BEDs). The level of this background radiation is low, but over a year it all adds up. It is true that the radioactive ore samples in the Atomic Energy Lab were considerably more active than the constant background radiation, but you would not be exposed to those samples for long. In evaluating the safety of the Atomic Energy Lab it is important to realise that "safe" is a relative concept.

It is perhaps a shame that nowadays the concept of giving children an atomic energy lab seems bizarre. It exemplifies the public misconceptions about the relative risks of radioactivity. We have lost sight of the positive contributions of radioactivity to our world, from power generation to cancer radiotherapy. I am sure Alfred Gilbert's laboratory was a wonderfully educational toy.

Later in this book we will be considering my own experiments with radioactive substances when I have fun by creating my own version of the "Gilbert Atomic Energy Lab" using a Geiger counter and some highly-radioactive uranium ore. I can assure you that I do live to tell the tale!

Operation Plowshare

In the 1950s, there was also a much more positive attitude towards nuclear explosives. Yes, it was the case that the atomic bomb had been recently used in warfare, but the general belief was that its use had prevented the loss of the lives of hundreds of thousands of American servicemen during an invasion of the Japanese mainland. It was also believed that the awesome destructiveness of the bomb would lead to the end of mass warfare as countries realised the futility of "Mutually Assured Destruction", or MAD.

As part of that more positive approach to nuclear explosives, the U.S. government started Operation Plowshare to investigate the use of nuclear explosives for peaceful construction purposes. The name "Plowshare" came from the Biblical quote "They shall beat their swords into plowshares", indicating a desire to convert weapons into tools. Proposed uses of nuclear explosives included the excavation of large amounts of earth and rock, creating artificial harbours, widening the Panama canal, cutting paths through mountains for highways, and creating underground caverns for mining and storage.

The largest nuclear test of Operation Plowshare was the Sedan test which took place on 6th July 1962. The aim of the test was to examine the feasibility of using nuclear explosives to excavate large amounts of earth and rock. The nuclear explosive was buried 194 metres underground, and the explosion displaced twelve million tons of rock. The resultant crater is called the Sedan Crater and it is the largest man-made crater in the United States. Over 10,000 visitors a year now visit the site on free monthly tours.

The Sedan test took place at the Nevada Test Site, which is a 1375-square-mile area of empty desert which is located only sixty miles away from Las Vegas. The first atomic test at the site took place in 1951, and over the next four decades it hosted a further 928 tests giving the area the nickname of "the most bombed place on Earth". Even today, if you search for "Nevada National Security Site" on Google Maps you will find the pock-marked area of desert, with each crater representing a nuclear explosion. It is even possible to see the enormous Sedan Crater at the north of the site.

In 1951, Las Vegas was a struggling small town with a population of fewer than 25,000 which was looking to boost its profile. When atomic bomb testing started at the nearby test site, the Las Vegas Chamber of Commerce promoted the blasts as a tourist attraction, handing out leaflets giving the dates of the detonations. Hotels built north-facing penthouses with the best views of the atomic mushroom clouds.

The following photograph was taken in Las Vegas and shows the mushroom cloud of a nuclear explosion at the Nevada Test Site rising high above the casinos in the foreground:

Project Orion

One of the most remarkable proposed uses for nuclear explosives in this period was Project Orion. The aim of Project Orion was to design a spacecraft which was to be propelled by a sequence of thousands of nuclear bombs

exploded in succession at the rear of the craft. The craft was to be protected by a 1,000-ton steel plate (called a *pusher plate*) and shock absorbers to protect the crew from the crushing acceleration (though that would not be a problem if the craft was unmanned). Radioactive nuclear fallout would not be a problem if the propulsion system was restricted to being only used in space. So, although the Project Orion proposal might sound absurd, experiments at the time showed that it would actually be a viable means of space travel.

In the BBC documentary *To Mars by A-Bomb: The Secret History of Project Orion*, the physicist and author Arthur C. Clarke emphasized that the idea behind Project Orion was not crazy: "After all, every time you get into a motor car you are being driven around by means of a series of rapid explosions." [2]

The following image shows a NASA artist's impression of the Orion spacecraft with Saturn drawn in the background. The image is taken about four milliseconds after the explosion of a nuclear propellant charge, showing the blast hitting the pusher plate at the rear of the craft. The line drawing underneath is another NASA diagram showing the key components of the Orion craft, including the pusher plate and the multiple shock absorbers:

If the spaceship was of standard size (e.g., just a few tons in weight) then the force of the exploding bombs would pulverise the craft. The solution was to make the spacecraft big: a few thousand tons in weight. According to Newton's second law of motion, the resultant acceleration would be greatly reduced due to the immense mass. Not only would this save the structure of the craft, it would also make the acceleration endurable for the on-board travellers. The plan was therefore to make an enormous craft, the size and weight of an ocean liner. To this day, the Orion technology remains our only method for moving extremely large payloads around the Solar System because of the huge energy advantage of nuclear explosives over chemical propellants. It has been said that: "To this day, Orion is still the only feasible means of interstellar travel, both robotic and manned, that could actually be built with current technology and knowledge." [3]

As a result of the necessity for large mass, the spacecraft would be built using a radically new philosophy. The spacecraft would be constructed out of steel, resembling a building more than a spacecraft. In fact, it would be more like a hotel — or an ark. It would have the potential to carry a large population out of the Solar System to colonise nearby planetary systems. According to Freeman Dyson, one of the physicists who worked on Project Orion: "Establishing human colonies was certainly part of our plan".

But surely there could never be a pressing need for such an ark. Why would humanity ever need to leave the Earth? Why would humanity need to colonise distant planets? Well, there is potentially one very good reason: a large asteroid or comet might appear on a collision course with the Earth threatening the mass-extinction of all life on the planet. In that situation, Orion might provide our only chance of survival.

If an asteroid on a collision course is detected a long way from Earth, there would be time to use "kinetic impact" — ramming a spacecraft into the asteroid — in order to produce a slight deflection to the course of the asteroid. Because of the great distance left on its course, that small deflection might be enough to cause the asteroid to miss the Earth. Time is of the essence when it comes to asteroid deflection.

Unfortunately, we would probably not have a long-enough warning period to launch such a spacecraft. In 2014, a comet was detected on a collision course with Mars — just 22 months before it crashed into the planet. According to Dr. Joseph Nuth, a NASA researcher, that would not have been nearly enough time to launch a rocket had the comet been on a collision course with the Earth. It takes five years to design and launch a spacecraft.

Orion might be the best technology to intercept and deflect an Earth-bound asteroid. John Dale Solem, a physicist at Los Alamos National Laboratory, said that "Orion provides such an advantage in speed over chemical propellants that it seems that interception could take place in a much shorter timescale, and consequently the deflection could take place further away so that it would be easier to make such an object miss the Earth."

Once intercepted, nuclear explosives could also be deployed either close to the asteroid to deflect it, or they could be used on the surface or beneath the surface of the asteroid in order to destroy it. The public perception of nuclear explosives might be very negative, but one day we might need to rely on them to save our planet.

I hope this introductory chapter has convinced you that nuclear explosives are not necessarily evil and maybe one day — in a world without war — they may prove to be of tremendous benefit to humanity. After all, dynamite has been a great boon to the construction and demolition industries, and we do not consider there to be anything fundamentally evil about dynamite.

A nuclear explosion is just an astonishing natural phenomenon. How we harness the power of that natural phenomenon represents a challenge — and an opportunity — for humanity.

Let us now start the long story of the development of the atomic bomb ...

2

FAINT FAIRY LIGHTS

Marie Curie looked at the test tube in delight. The year was 1902. Marie was thirty one years old, and working in the laboratory of her husband Pierre at the School of Physics and Chemistry in Paris. The test tube contained radium, a new element which Marie and Pierre had just discovered. To her delight, she noticed the test tube was glowing with a beautiful green colour, an effect she innocently called "faint fairy lights". Even when Marie closed her eyes she could still see the magic colours as the rays penetrated her eyelids as though they were not there.

In the evenings, she would often sit with Pierre in the laboratory they shared and gaze in wonder at the eerie blue-green glow of their new discovery which illuminated the entire room. Marie gave a name to these emitted rays: *radioactivity*. In this chapter we will be considering radioactivity in detail.

Six years earlier, the French physicist Henri Becquerel had first discovered the radioactive properties of uranium. Becquerel was investigating the effect of sunlight on photographic plates when he was frustrated by a cloudy day in Paris. Unable to perform his experiment due to the lack of sunlight, Becquerel put away his photographic plate into a drawer — which also happened to contain a nugget of uranium.

The next day, when Becquerel took the plates out of the drawer, he was surprised to find that the uranium had left clear imprints on the plates as though they had been exposed to a bright light. This was the first detection of radioactivity, and Becquerel's cloudy day in Paris stands as a clear example of the role of good luck in scientific discovery.

The discovery of radioactivity is presented in animated form at the 19:53 minute mark of Disney's *Our Friend The Atom*. This link takes you there directly:

<http://tinyurl.com/radioactivediscovery>

Becquerel did not take his work any further, so it was left to Marie and Pierre Curie to pursue this mystery.

Marie discovered that the rays were purely a product of uranium on its own — not due to any chemical reaction with any other element. Therefore, Marie had the insight that the rays were a fundamental property of uranium atoms. It was also clear that there was considerable energy being produced purely from the atom. This was the first observation of the potential of atomic power. Marie Curie's "faint fairy lights" were going to light up the world.

But if uranium was radioactive, might not other elements be radioactive as well? This was the question which was to lead to the discovery of radium. Marie tested all eighty known elements for radioactivity, and many other substances as well. Eventually, Marie found one particular mineral called pitchblende — a by-product of mining — which appeared to be far more radioactive than uranium. If radioactivity really was generated from the atoms of a single element then there had to be some new and mysterious element in the pitchblende compound. But it would be no easy task to refine the mystery element. The Curies obtained seven tons of pitchblende from the mines of Bohemia, a pile of black rubble which filled their laboratory. The rubble had to be laboriously crushed by hand in a pestle and mortar. But after four years of hard labour, the Curies managed to extract one tenth of a gram of a new element — radium — from the pile of rubble.

The discovery of radium proved to be an international sensation. It appeared to be a new, constantly-glowing miraculous source of energy — ideal for the luminous paint of watch dials. Radium was also viewed as a potential cure for numerous diseases, including throat medicines and cough cures, and you could even buy radium toothpaste, condoms, and suppositories.

Marie and Pierre were interested in the medical applications of their new discovery, and were even willing to sacrifice their own health in their research. At one time, Pierre strapped a test tube filled with radium to his arm for ten hours, creating a lesion on his arm. Bizarrely, Pierre was thrilled — and for good reason. If radiation could damage healthy tissue, then it should also be able to destroy diseased tissue. This gave the Curies the idea to use radioactivity to treat cancer — the first use of radiotherapy. Radiotherapy represents one of the ways in which radiation has provided benefits to humanity.

The declining health of Pierre was noted when Edward Rutherford came to visit the Curies in Paris in the summer of 1903. To celebrate the award of Marie's doctorate, a party was held in their garden. Pierre brought out a glowing tube of radium which impressed Rutherford greatly, describing it as "a splendid finale to an unforgettable day".

However, the light was bright enough to reveal Pierre's hands to Rutherford, who noted that they were inflamed and painful due to exposure to radioactivity.

In April 1906, Pierre was crossing the busy intersection of Rue Dauphine near the Seine when he fell under a horse-drawn carriage. He narrowly missed being trampled by the horses as the driver attempted to stop the carriage, but the carriage was carrying six tons of military equipment and kept slowly rolling. The back wheels of the carriage crushed Pierre's head, killing him instantly.

Marie was devastated by the loss of her husband and colleague. The Sorbonne (the University of Paris) awarded Pierre's professorship to Marie, making Marie the university's first female professor in its 650-year history.

By 1911, Marie was feeling more content about her personal situation, and there were three reasons for her improved state of mind. The first reason for Marie's happiness was that she had just received a telegram confirming that she had won her second Nobel Prize. That award of the 1911 Nobel Prize in chemistry, together with her 1903 award in physics for the discovery of radioactivity, made her the first person to win two Nobel prizes.

Secondly, Marie was invited to be a participant at the first International Solvay Conference in Brussels, which was a meeting of the greatest minds in physics. Attendees included Albert Einstein, Max Planck, and Ernest Rutherford. The following photograph shows the attendees, with Marie Curie the second seated person from the right:

The third reason for Marie's happiness was the presence of her lover, Paul Langevin, who was standing next to Einstein at the extreme right of the Solvay photograph. Unfortunately, Langevin also happened to be a married man. When Langevin's wife saw the photograph of Marie and Paul together at the Solvay Conference she told the press of the affair and it quickly became a national scandal with lurid stories in the newspapers. At one point, an angry mob formed outside Marie's house and threw stones through her window. Einstein wrote a letter of support to Marie regarding her treatment by the press: "If the rabble continues to be occupied with you, simply stop reading that drivel. Leave it to the vipers it was fabricated for."

Paul Langevin, defending his honour, challenged the journalist of the newspaper to a duel. The two duellists met at eleven o' clock in the morning. Each took their pistol, and paced-out twenty five yards. But when they turned to face each other, the journalist fired into the ground. Explaining his action later, he said: "Paul Langevin has a reputation as a scientist. However grave may be the errors made by Langevin in his domestic life, I did not wish to deprive French science of a precious brain." On seeing his adversary's action, Langevin also fired into the ground, saying: "I am not an assassin".

Langevin returned to his wife, and the outrage over the affair was brief. But the incident gives us an insight into the non-conformist life of Marie Curie, and reminds us of the challenging culture in which she had to work.

Marie Curie died at the age of 66 from exposure to radiation. The bodies of Marie and Pierre Curie were interred in the Panthéon in Paris. To this day, Marie's original documents remain so highly radioactive that they are kept in lead-lined boxes and can only be read whilst wearing protecting clothing.

Alpha and beta

As has just been described, Marie Curie explained that radioactivity had to be a property of the atoms of certain elements. But what was the cause of radioactivity? What was so special about those elements? And what was the radiation made of? It was the great experimental physicist Ernest Rutherford who supplied the answers to these questions.

In 1899, Rutherford took a sample of uranium and wrapped it in layers of thin aluminium foils. As more foil was added, the effect was to reduce the amount of emitted radiation which could penetrate the total amount of foil. The experiment revealed that there were two types of radiation being emitted from the uranium sample with greatly different abilities to penetrate the foil. Rutherford called these two types of radiation *alpha* and *beta* (named after the first two letters of the Greek alphabet).^[4] Alpha rays could be quite easily stopped by the foil, whereas the beta rays were more penetrating. Also, it was observed that the two types of rays were deflected by a magnetic field, suggesting that the alpha rays were composed of positively-charged particles, while the beta rays were composed of negatively-charged particles. Also, the alpha rays were deflected by a smaller amount than the beta rays, suggesting that the alpha particles had much greater mass than the beta particles.

What particles do we know which have negative charge and low mass and so have the same properties as the beta particles? Yes, electrons have negative charge and low mass. Indeed, further experiments revealed that the beta particles were, in fact, just electrons being emitted from the atoms at extremely high speed (high energy).

But what were the alpha particles made of? In 1909, Ernest Rutherford found the answer.

Rutherford was famous for creating ingenious experiments using the very limited apparatus available at that time. As an example, to examine alpha particles Rutherford placed a sample of radioactive radon gas in a thin-walled glass tube and then surrounded that tube with a second glass tube which had a thicker wall. The alpha particles emitted by the radon were able to penetrate the first glass wall but could not escape the second wall. As a result, the alpha particles became trapped in the space between the two glass walls. After a week, the substance between the two walls was analysed and found to be helium, which meant that alpha particles are composed of the nuclei of helium atoms.

The nucleus of a helium atom is composed of two protons and two neutrons. Rutherford's discovery, therefore, explained why alpha particles had positive electric charge (supplied by the two protons in the helium nucleus), and also had greater mass than the beta particles (which were just electrons).

The alchemists

The type of element (hydrogen, helium, uranium, etc.) is defined by the number of protons it has in its atomic nucleus. If alpha particles (which each contain two protons) were being emitted from atoms, then that implied that the element was changing into a different element, the atoms of which had two fewer protons. To change an element into a different element (for example, changing lead into gold) had long been the dream of alchemists. However, until the start of the 20th century it was considered impossible for any chemical element to change into a different chemical element — a process known as *transmutation*.

However, all that changed when Rutherford — together with Frederick Soddy — discovered that a sample of the radioactive element thorium appeared to be converting into radium. When Soddy realised what was happening, he shouted out "Rutherford! This is transmutation!", to which Rutherford replied "For Christ's sake, Soddy, don't call it transmutation. They'll have our heads off as alchemists."

If an element is capable of spontaneously changing into a different element, it would be very desirable to find a way of quantifying that change. For example, if I have a sample of uranium, I would like to know how long it would take for that sample to change into a different element. In order to be able to quantify the speed of the transmutation, it would appear we would need to know the precise details underlying radioactive decay (in physics, whenever an unstable particle transforms into a different particle it is called "decay"). However, the physics which underlies radioactive decay is quantum physics, and — if you have read my fourth book — you will know that all quantum processes are fundamentally random. In other words, you can never analyse those processes to a deeper level to discover how they work — you just have to accept that they are completely random. So that leaves us with a problem: if completely random quantum physics underlies radioactive decay, then how can we ever hope to develop a precise formula which describes the transmutation?

Well, even though we can never accurately predict when the decay of a single atom will occur, if we have billions of decay events then we can determine the average likelihood of a decay occurring and we can use that to make reliable predictions (the same method a casino uses to be certain of making money from probabilistic events).

A single atom of uranium, for example, might decay in the next second, or it might take billions of years before it decays — we have no way of knowing, it is fundamentally random. However, if we are considering a sample of billions of atoms then we can use an averaging statistical measure to describe the rate of decay. The statistical measure which is generally used is called the *half-life* of an element. The half-life is defined as the length of time it would take for half of the atoms in a sample to decay.

As an example, the half-life of uranium is 4.5 billion years. That means if I have a sample of uranium and wait for 4.5 billion years, then half of my sample will have turned into a different element, leaving me with a sample containing only half the original amount of uranium. If I then wait another further 4.5 billion years, half of that remaining amount of uranium will turn into a different element, leaving me with only a quarter of the original amount of uranium.

Nuclear reactions

This discussion of radioactive decay has provided us with a clearer understanding of the cause of radioactivity. Radioactivity occurs in heavy elements whose nuclei are fundamentally unstable. Those elements are heavy precisely because their atoms have nuclei made of a high number of protons and neutrons. As Heinz Haber says in *Our Friend The Atom*: "Here Nature has crowded so many protons and neutrons into the nucleus that it becomes unstable". Parts of those heavy nuclei get radiated-away as those elements decay into elements which have more stable nuclei. It is the emitted particles which form alpha and beta radiation.

Let us now consider the effect of the two types of radiation. We will need to define two important numbers which describe an atomic nucleus.

The *atomic number* of a chemical element is the number of protons in the nucleus of each atom of that element. The atomic number is crucial because an element is uniquely defined by the number of protons in the nuclei of its atoms. For example, all hydrogen atoms contain one proton, and all oxygen atoms contain eight protons. Hence, the atomic number defines which element an atom represents.

The other important number which describes the composition of an atomic nucleus is the *mass number*. The mass number is the **total sum** of the number of protons and neutrons in the nucleus.

The conventional notation is to describe a sample of an element by writing its chemical symbol preceded by its atomic number (as a subscript) and its mass number (as a superscript). This convention is shown in the following example for uranium (the chemical symbol for uranium is "U"):

The previous example shows natural uranium, in which the nucleus has 92 protons and 146 neutrons, giving a total mass number of 238 (as shown in the previous image). Crucially, though, it is possible for an atom of a particular element to have the same number of protons **but a different number of neutrons**, in which case the substance is called an *isotope*. As isotopes of elements have different numbers of neutrons they therefore have different values for their mass number. The natural form of uranium shown in the previous diagram is uranium-238 where the "238" represents the mass number. Later in this book we will be examining the vital importance of the isotope uranium-235 for nuclear reactions.

Let us now consider what happens during the radioactive decay of an element. Remember, in alpha radioactive decay the nucleus emits a helium nucleus which is composed of two protons and two neutrons. So the emission of an alpha particle would decrease the atomic number by two (as the nucleus has lost two protons) and decrease the mass number by four (as the nucleus has lost a total of two protons and two neutrons). For the example of uranium-238,

this would transmute the uranium atom into an atom of thorium:

You can see from the previous diagram that thorium has an atomic number of 90 and a mass number of 234. You can also see the emitted helium nucleus forming the alpha particle.

Any process such as this in which atomic nuclei are modified is called a *nuclear reaction* (as opposed to a chemical reaction). When we describe a nuclear reaction using this notation, we must check two rules which are always true in any nuclear reaction:

1. The total number of protons and neutrons **before** the reaction is always equal to the total number of protons and neutrons **after** the reaction. In other words, the total mass number is always unchanged.
2. Electric charge is always conserved through a nuclear reaction.

Let us now examine how those two rules apply in the case of the alpha decay of uranium we have just considered.

Considering the first rule, and referring back to the previous diagram of alpha decay, you will note that the total number of protons and neutrons before the reaction (238, the mass number of uranium) is equal to the total number of protons and neutrons after the reaction (234 for the thorium nucleus, plus the mass number of four for the helium nucleus gives a total of 238). So the first rule is obeyed.

Now let us consider the second rule about conservation of electric charge. Every proton has a single unit of positive electric charge, so the total electric charge of the uranium nucleus before the reaction is 92 (the atomic number of uranium). After the reaction, the thorium nucleus has 90 units of positive electric charge (its atomic number), and the emitted alpha particle has two units of positive electric charge (the atomic number of helium). So electric charge is conserved through the reaction ($92 = 90 + 2$), and the second rule is therefore also obeyed.

The power of the atom

Alpha particles have enormous energy as they are ejected at about 5% of the speed of light. Plus, these particles are being constantly emitted as the individual atoms of a piece of radioactive material decays. Each click of a Geiger counter reveals the detection of one of these charged particles. You can see the use of a Geiger counter in the following direct link to *Our Friend The Atom*, immediately followed by the use of a cloud chamber to reveal the "constant shower" of radioactive particles emitted by a sample of radium:

<http://tinyurl.com/radioactiveparticles>

Now imagine the enormous quantity of energy which would be released if all those clicks of the Geiger counter happened at the same time. Or, equivalently, imagine if all those radioactive particles were emitted by the radium at the same time. Well, that is basically what happens in a nuclear explosion, with all the energy released in a few microseconds. According to Ernest Rutherford, a single gram of radium emits enough energy in its lifetime to raise a 500 ton weight a mile high.

Soddy commented on this energy release in a 1903 paper: "This reaction sets free more energy for a given weight than any other chemical change known. The energy of radioactive change must therefore be at least twenty-thousand times, and maybe a million times, as great as the energy of any molecular change."

This gives us our first insight into why nuclear reactions (and explosions) are so powerful. For example, the detonation of dynamite releases about ten electron-volts of energy per molecule, whereas a nuclear reaction can release millions of electron-volts of energy per nucleus. Multiply that value by the trillions of atoms in a sample of nuclear explosive and you can start to understand the source of its extraordinary power. As Bruce Cameron Reed says in his book *The History and Science of the Manhattan Project*: "This begins to give you a hint as to the

compelling power of nuclear weapons. An 'ordinary' bomb that contains 1,000 pounds of chemical explosive could be replaced with a nuclear bomb that utilizes only 1/100 of a pound of a nuclear explosive. Thousands of tons of conventional explosive can be replaced with a few tens of kilograms of nuclear explosive."

In a lecture in 1904, Soddy suggested presciently: "It is possible that all heavy matter possesses — latent and bound up with the structure of the atom — a similar quantity of energy to that possessed by radium. If it could be tapped and controlled what an agent it would be in shaping the world's destiny! The man who put his hand on the lever by which a parsimonious Nature regulates so jealously the output of this store of energy would possess a weapon by which he could destroy the Earth if he chose."

Beta radiation

We have just examined alpha radiation so we will now examine beta radiation.

As explained earlier, Rutherford had discovered that beta radiation from an atom was composed of an emitted electron. This happens when a neutron in the nucleus converts into a proton — by a process which we will examine later in this chapter.

Now let us consider the effect of beta radiation on atomic number and mass number. The conversion of the neutron into a proton increases the atomic number by one (one more proton in the nucleus) while leaving the mass number unchanged (total number of protons and neutrons is unchanged). Hence, the following diagram shows how an atom of carbon-14 is transmuted into an atom of nitrogen-14 after beta radioactive decay (atomic number increases by one, mass number stays the same):

You will see that an electron and a particle called an *antineutrino* are also emitted. We shall consider the antineutrino later in this chapter, but let us now consider why this conversion of a neutron in a proton necessarily results in an electron (the beta radiation) being emitted. Well, to see why, remember our two golden rules of nuclear reactions. The second golden rule says that electric charge must always be conserved through a nuclear reaction. With this in mind, remember a proton has positive electric charge, whereas a neutron has zero electric charge (an antineutrino also has zero electric charge). So when a neutron converts into a proton during beta decay we have a situation in which the amount of positive charge is increasing by one unit — which clearly breaks the law of conservation of charge. In order for balance to be restored, a negatively-charged electron must also be produced in addition to the proton. That electron represents the emitted beta radiation. Hence, the beta radiation emerges as a necessary result of the law of conservation of electric charge.

In 1946, a Bedouin shepherd named Muhammed edh-Dhib was herding his sheep through the barren rocky wilderness on the west side of the Dead Sea. High in the sheer cliffs above, he saw a small cave and decided to climb up to investigate. Deep in the cave he found a number of small pottery jars, and in those jars he found seven ancient parchment scrolls on which there was Hebrew writing.

Muhammed edh-Dhib had just discovered the Dead Sea Scrolls.

After selling the scrolls to an antiquities dealer, they caught the attention of an archaeologist who believed they dated back to Biblical times. But, unfortunately, there was no way of accurately dating the scrolls. It was left to science to provide the answer using a new technology which had just been developed.

It has just been described how the radioactive isotope carbon-14 will decay to nitrogen-14 via beta radiation. There is always a small amount of carbon-14 in the atmosphere, and this combines with oxygen to make carbon dioxide. Carbon dioxide is absorbed by plants during photosynthesis, and those plants are eaten by animals and humans, or that plant material is used by humans for creating parchment manuscripts. In other words, a significant

amount of carbon-14 ends up in all organic material.

When a plant dies, it stops absorbing new carbon-14 from the atmosphere. However, the carbon-14 it absorbed during its life continues to decay. The half-life of carbon-14 is known to be 5,730 years. Therefore, a sample which was 5,730 years old would only have half the amount of carbon-14 compared to a living organism. After 11,460 years it would only have 25% of the amount of carbon-14 compared to a living organism. On that basis, in the late 1940s the science of *radiocarbon dating* was developed which was based on analysing the proportion of carbon-14 in dead organic material.

The radiocarbon dating system was calibrated by measuring the amount of carbon-14 in dead bristlecone pines which are found along the west coast of North America. Bristlecone pines were known to be the oldest living life-forms on Earth. The age of bristlecone pines could be measured accurately by counting the rings of bark which make up the tree trunk. Using this method, the oldest bristlecone pine was found to be 5,000 years old.

By measuring the amount of carbon-14 in an ancient bristlecone pine, a graph showing variation of carbon-14 with age was produced. The task now was to apply this new technique to dating the Dead Sea Scrolls. A sample of the linen wrapping of the scrolls was tested using radiocarbon dating in 1955 and was found to be 1,917 years old, with a plus or minus error of 200 years. The announcement of this first major success of radiocarbon dating had a major impact on archaeology, and radiocarbon dating laboratories have been created around the world.

Radiocarbon dating represents another way in which radioactivity has provided benefits to humanity. Remember that the basis of all radiocarbon dating is beta radioactive decay.

The weak interaction

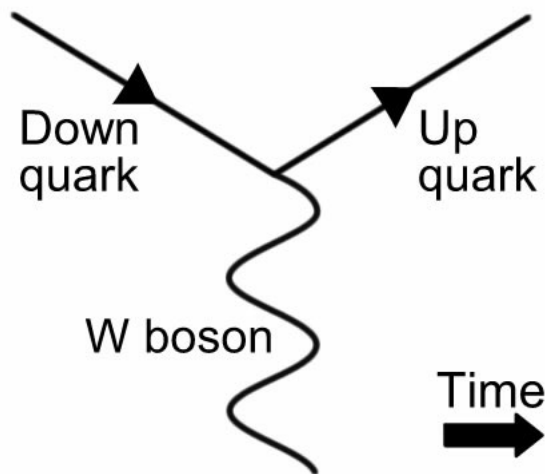

Let us now consider beta radioactive decay in more depth. This section is quite technical and is not essential knowledge for atomic bomb construction, so you can skip to the next chapter if you wish. However, if you want to understand the origin of the antineutrino particle which is emitted during beta decay, here is the explanation.

It is now known that the protons and neutrons which make up the nucleus of an atom are not truly elementary particles. Instead, protons and neutrons are each composed of three particles called *quarks*, and it is these quarks which are considered to be truly elementary. Beta radiation is produced from the interactions between those quarks.

Protons and neutrons are composed of two different types of quarks called *up* quarks and *down* quarks. A proton is composed of two up quarks and one down quark. A neutron is composed of one up quark and two down quarks:

There is a symmetry between up and down quarks, which means it is possible for a down quark to turn into an up quark, and vice versa. This conversion is achieved via the *weak interaction* in which the quark interacts with a *boson* (a force-carrying particle). The following diagram is a simple *Feynman diagram* which shows how a down quark can change to an up quark when it interacts with a W boson, one of the bosons associated with the weak interaction. You can see that the W boson also modifies the path of the original particle — as if acted on by a force — so it is said that the W boson is the particle which carries the *weak force*:

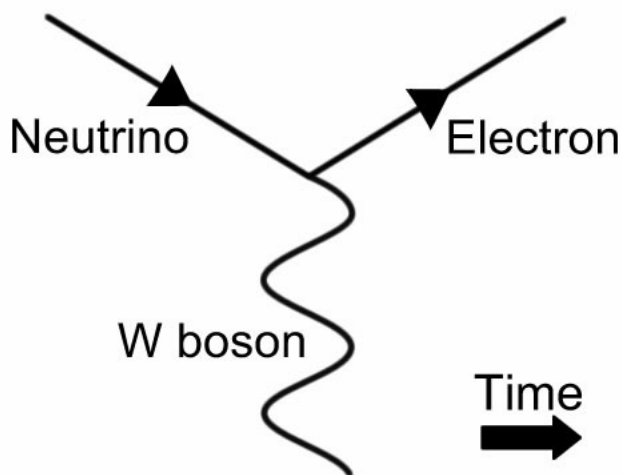

As stated earlier, a neutron is composed of two down quarks and one up quark. So this conversion of a down quark into an up quark via the weak interaction would have the effect of converting a neutron into a proton, which is what we know happens during beta radioactive decay. So we can now see why the weak interaction is so important for the emission of beta radiation.

For the next step in our analysis of beta radiation, we need to introduce a strange and elusive new particle: the *neutrino*. A neutrino is the only electrically-neutral matter particle, and it is virtually massless (i.e., it is extremely light) so therefore travels at speeds close to the speed of light. Because the neutrino is so light and has a ghostly nature, it passes through materials as though they were not there — including the materials which are used to make particle detectors. Unfortunately, a particle which flies straight through a particle detector without interacting with that detector is a particle which is not going to be detected easily. When Wolfgang Pauli predicted the existence of the neutrino in 1930 he said: "I have done a terrible thing. I have postulated a particle that cannot be detected!"

Don't get a neutrino and a neutron mixed up — their names might sound similar but they are completely different particles. As explained earlier, a neutron is composed of three quarks so it is not a genuinely elementary particle, whereas the neutrino is believed to be truly elementary (i.e., not composed of any other particles).

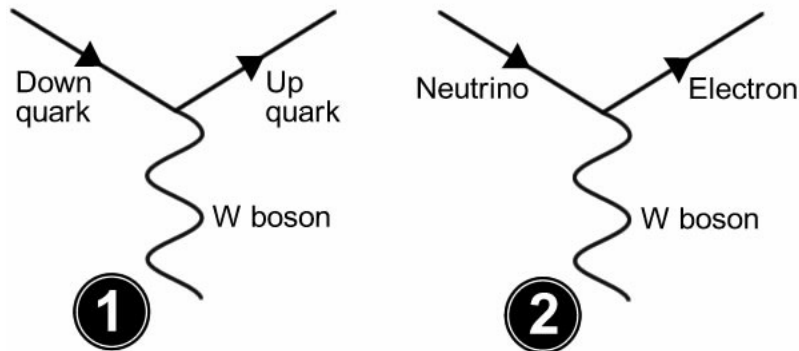

We have just seen that there is a symmetry between a down quark and an up quark, which is moderated by the weak interaction. There is a similar symmetry between a neutrino and an electron. The following diagram shows how a neutrino can change to an electron when it interacts with a W boson:

We have now generated two simple Feynman diagrams showing how the weak interaction can act to change down quarks into up quarks (and vice versa), and neutrinos into electrons (and vice versa). These simple Feynman diagrams which include just one vertex (junction) are called a *minimal interaction vertex*. These simple diagrams

can be used to completely characterise the behaviour of a force.

Let us draw our two minimal interaction vertices again, and, so we can refer to them, let us number them as diagram 1 and diagram 2:

These are the two diagrams which interest us as these are the diagrams which are relevant to beta radioactive decay. Let us now use these two Feynman diagrams to construct the complete Feynman diagram of radioactive beta decay. This can be achieved because Feynman diagrams have a very useful feature: they can be rotated and the interaction they describe will still remain valid. On that basis, the following diagram includes both diagram 1 and diagram 2 which have been joined together. Both diagrams have been surrounded by grey dashed circles to make their position clearer. You will see that diagram 1 has been rotated slightly anti-clockwise, while diagram 2 has been rotated clockwise by a larger amount:

In this way, you can see how the complete diagram for beta radioactive decay can be constructed via these minimal interaction vertices — just like Lego!

As you can see from the previous diagram, the end result is that a neutron changes into a proton, and in the process it emits an electron and a neutrino (these two particles shown at the bottom right of the diagram). The

emitted electron represents the beta radiation which is detected (remember, beta radiation is just a stream of electrons). The neutrino, meanwhile, does not interact with anything — it just shoots away at close to the speed of light straight through the walls of the laboratory as if they were not there and it is halfway to the moon in a matter of seconds.

Importantly, note that the arrow on the emitted neutrino seems to indicate that it is travelling backward in the time direction (you will see the forward time direction indicated by the arrow on the bottom left of the diagram). In a Feynman diagram, any particle which is travelling backward in time is equivalent to an *antiparticle* which is travelling forward in time. In other words, it is a particle of *antimatter* (see my fifth book for details). Hence, the emitted neutrino is not actually a neutrino at all: it is the antimatter equivalent of a neutrino which is called an *antineutrino*. This explains the origin of the antineutrino which is emitted during beta decay.

3

SPLITTING THE ATOM

As we have just seen, radioactive particles have high energy and are emitted from the nucleus at great speed. The question then arises: what would happen if one of these particles was directed to collide with a second nucleus? What would be the outcome?

That was the question first considered by Ernest Rutherford in 1909. Rutherford knew that the alpha particle had more mass than the beta particle, so an alpha particle colliding with a second atomic nucleus could potentially reveal the structure of that nucleus. With this in mind, Rutherford directed a stream of alpha particles at thin gold foil and placed a Geiger counter on the other side of the foil to detect the alpha particles as they passed through the foil. The intention was to consider the scattering of the alpha particles due to the nuclei in the gold foil.

To Rutherford's great surprise, some of the alpha particles bounced back from the foil. Rutherford realised this had to mean that there was a minute, comparatively-heavy, positively-charged nucleus at the heart of the atom. This was to be Rutherford's greatest discovery.

The following image shows Rutherford's laboratory at Cambridge, which was fairly typical of nuclear laboratories at that time. It looks very different from today's LHC, but no particle physics laboratory has made more historic discoveries than Rutherford's lab:

So the value of alpha particles as a nuclear probe was clear — but there was a problem. As described earlier, an alpha particle is a helium nucleus with two protons and therefore has positive electric charge. But a nucleus also has positive electric charge. So if an alpha particle is directed towards a second nucleus, the alpha particle will be repelled by the electric charge of that nucleus (two charges of the same sign will repel). This makes it very difficult to use a charged particle as a nuclear probe. The problem becomes more acute when an attempt is made to probe the nuclei of heavier elements as heavier elements have more protons in their nuclei and therefore have greater positive electric charge. As Richard Rhodes says in his book *The Making of the Atomic Bomb*: "Farther along the periodic table a barricade loomed. The naturally radioactive sources Rutherford used emitted relatively slow-moving alpha particles that lacked the power to penetrate past the increasingly formidable electrical barriers of heavier nuclei. For a time, the newborn science of nuclear physics stalled."

However, everything changed in 1932.

James Chadwick was a researcher at Rutherford's Cavendish Laboratory in Cambridge University. In 1932, in a letter to the British journal *Nature*, Chadwick announced the discovery of the neutron. As was described in Chapter One of this book, the atomic nucleus is composed of protons and neutrons. The neutron has approximately the same mass as the proton but it has no electric charge. It was realised very quickly that this meant that the neutron had the potential to be perfect for probing a nucleus as — unlike the positively-charged proton — it would not be repelled by the positive electric charge of the nucleus.

The neutron was to revolutionise the examination of the nucleus. The Nobel prize-winning nuclear physicist Hans Bethe once said that he considered everything before 1932 to be "the prehistory of nuclear physics, and from 1932 onward (after the discovery of the neutron) modern nuclear physics was born."

As Bruce Cameron Reed says in his book *The History and Science of the Manhattan Project*: "Neutrons would prove to be the gateway to reactors and bombs."

Artificial radioactivity

If nuclear physics had been stalled for over ten years since 1919, with the discovery of the neutron in 1932 it suddenly sprang into life. Progress would now be incredibly rapid as we shall see, with the discovery of nuclear fission in 1938, the construction of the first nuclear reactor in 1942, and the first man-made nuclear explosion in 1945 — events which all depended on the discovery of the neutron. After the discovery of the neutron, the race was on.

The first experimentalist to use neutrons to bombard atomic nuclei was Enrico Fermi. Fermi was a talented physicist based at the University of Rome who had been appointed to a full professorship at the age of 26. Fermi gained a reputation for having uncanny intuition about physics. It was even suggested that "Fermi had an inside track to God". His near infallibility at predicting the results of experiments meant his colleagues gave him the nickname "the Pope".

Fermi started his work on neutron bombardment in 1934, with a particular interest in bombarding the heavy metals which had many protons and neutrons in their nuclei. By bombarding various target elements, Fermi found he could make elements radioactive which would never normally be radioactive.^[5] As an example, by bombarding gold with neutrons he found that a neutron was sometimes absorbed by the gold nucleus, creating a heavier nucleus with one more neutron than the natural form. However, the resultant isotope with its extra neutron was highly-unstable, and — as explained earlier — an unstable atom is radioactive. So the resultant isotope atoms were highly radioactive with a very short half-life of sometimes only a few minutes. As a result, Fermi would have to run down the corridor with his unstable radioactive isotopes to test them with a Geiger counter in a second room before the radioactivity faded away (due to the extremely short half-life).

Let us consider the neutron bombardment of gold in more detail. The first stage is for the neutron to be absorbed by a gold nucleus, adding one to the mass number, and thereby creating an isotope of gold:

(You might want to check that our two rules of nuclear reactions apply here: the neutron is electrically-neutral so electric charge is conserved before and after, and the total number of neutrons and protons before the reaction is equal to the total number of neutrons and protons after the reaction: $1+197=198$).

But the additional neutron makes the nucleus unstable, so let us now concentrate on the gold isotope and consider the second stage of the process.

The nucleus of the unstable gold isotope decays via the beta radiation we considered in the previous chapter. That means a neutron in the nucleus transforms into a proton, with the emission of an electron (beta radiation):

So, as explained in the previous chapter, you can see that the result of the beta decay is to increase the atomic number of the gold nucleus by one, transmuting it into mercury ("Hg" is the chemical symbol for mercury). In the previous diagram you can see that the atomic number has increased from 79 (gold) to 80 (mercury).

Crucially, this shows that neutron bombardment can be used to increase the atomic number of the bombarded element, adding a proton to the nucleus and thereby transmuting it into a heavier element. We shall see later that this is the process by which heavy elements for nuclear weapons can be made. Indeed, as we shall see in Chapter Seven, the first atomic bomb used plutonium produced in an atomic reactor by this method of neutron bombardment.

If he could transmute gold into a heavier element via neutron bombardment, Fermi reasoned that he could also transmute uranium into a heavier element. However, that represented a much bigger deal: uranium is the heaviest natural element. If he was going to create a heavier element (a so-called *transuranic* element) then Fermi would be creating a substance which had never before existed on Earth.

But that appeared to be precisely what happened when Fermi bombarded uranium with neutrons. Beta emissions from the bombarded uranium appeared to suggest the usual increase in the atomic number by one. In June 1934, Fermi announced in *Nature* that his results "suggested the possibility that the atomic number of the element may be greater than 92 (the atomic number of uranium)." This announcement generated a great deal of excitement in Italy at the time, with some Italian journalists suggesting that this new element should be called "Mussolinium". However, this was to be one of the rare occasions when Fermi's intuition failed him.

In detecting a possible new heavy element, Fermi had been careful to eliminate the possibility that the radiation might be coming from some heavy element which was slightly lighter than uranium. However, he had never considered the apparently crazy possibility that it was coming from an element which was only half the weight of uranium, as if the uranium nucleus had been split in two. After all, such an effect had never been seen before.

But that was his big mistake ...

The discovery of fission

In 1912, the German Kaiser decided he wanted to support German science — and create a symbol of increasing German strength — by building a new scientific institute. The result was the Kaiser Wilhelm Institute in a suburb of Berlin. The architect of the institute decided to incorporate a spiked German army helmet on top of a round corner tower. The intention was undoubtedly to flatter the Kaiser but, as you can see at the top right of the following photograph, the end result was rather comical:

Among the first physicists to be based at the new institute were Otto Hahn and Lise Meitner. Hahn had established his reputation by previously working with Rutherford, and Meitner had published papers on alpha and beta radiation, gaining a reputation as an accomplished experimentalist. Einstein was later to call her the "German Marie Curie" (even though she was, in fact, Austrian).

By the 1930s, Hahn and Meitner had acquired enough experience to be acknowledged experts in the field of radioactivity (Richard Rhodes called Hahn "the ablest radiochemist in the world"). In 1935, they became intrigued by Fermi's results of bombarding uranium with neutrons and the claim that transuranic elements were being created. Hahn and Meitner decided to investigate Fermi's claim, and to help them in their task they enlisted the chemist Fritz Strassmann.

However, the investigations of Hahn and Meitner were to be derailed by the darkening atmosphere in Europe. In March 1938, Nazi Germany invaded Austria (the invasion was called the "Anschluss"). With Austria now part of the German Reich, Lise Meitner became a German citizen. This was a worrying development because Meitner was Jewish, so Germany's many anti-Semitic laws suddenly applied to her. Firstly, as part of the persecution of Jewish academics, Meitner's research funding was withdrawn. Meitner decided she had no choice but to flee Germany quickly. Niels Bohr arranged for her to find a research position at a physics institute in Sweden.

Hahn and Strassmann continued their research into the neutron bombardment of uranium, and kept Meitner informed of their progress. Hahn and Strassmann were discovering some very puzzling results. They appeared to be detecting barium as one of the side-products of the bombardment. This seemed to make no sense whatsoever as barium has an atomic number of 56 (56 protons in its nucleus), whereas uranium has an atomic number of 92. As was described earlier, alpha and beta decay might modify an atomic number by one or two places, but there was no known explanation for a modification of 36 places (92 minus 56).

However, further extensive checking proved that this seemingly inconceivable result was genuine: barium was being generated. Hahn and Strassmann were excited, but they were also completely stunned. How could a nucleus of approximately half the size of the uranium nucleus be produced? It was as though the uranium nucleus was being split in two!

Hahn contacted Meitner by mail, desperate to obtain a solution to the puzzle: "Perhaps you can suggest some fantastic explanation", he wrote. "We understand that it really **can't** break up into barium." At that moment, Meitner was being visited by her nephew, Otto Frisch, who was also a nuclear physicist who was working in Copenhagen with Niels Bohr. They went for a walk into the nearby Swedish forest to clear their heads and to try to imagine a possible solution.

At one point, they both sat down on a log to discuss the problem. Meitner realised that a possible solution might come from the "liquid drop" model of the atomic nucleus which had been suggested by Niels Bohr. According to Bohr, the protons in the nucleus were loosely held together by a form of surface tension in much the same way as a small drop of liquid. The result was that the nucleus was not a hard ball at all, but instead resembled a "wobbly

drop" of liquid. In that case, the addition of just a single neutron to the nucleus might well be enough to make the whole wobbly nucleus unstable, and it might well split in two.

Meitner found a pencil and a scrap of paper in her purse and drew some rough shapes to explain her idea. You can see a version of Meitner's shapes in the following diagram. After the addition of the extra neutron, the unstable nucleus wobbles and becomes elongated. A narrow "waist" appears, giving the nucleus the shape of a dumbbell. Each end of the dumbbell would repel the other end due to the intense electrical repulsion between the protons. This would result in the two halves flying apart and forming two smaller nuclei:

Otto Frisch coined the term *nuclear fission* to describe this splitting of a nucleus into two roughly equal parts. Let us consider this proposed fission reaction in more detail.

The proposal was that a nucleus of uranium-235 was absorbing a neutron, and that resulted in the nucleus splitting into a nucleus of barium and a nucleus of krypton, as described by the following reaction:

However, there was one other important factor to be taken into account. A nucleus of uranium-235 is so large that it needs 143 neutrons to act as "glue" to hold the nucleus together ($235-92=143$). This is more neutrons than is required in total by a nucleus of barium plus a nucleus of krypton. Hence, there would be an excess of neutrons after the reaction. You can see that the previous reaction also shows three neutrons being expelled. We will soon see that these three extra neutrons held the key to the all-important fission chain reaction.

You might like to check that the previous reaction with its three extra neutrons satisfies our golden rules for electric charge being conserved ($92=56+36$) and the total number of neutrons and protons being conserved ($235+1=141+92+3$).

Meitner and Frisch then turned their attention to calculating the amount of energy which would be released by this fission reaction, and the result left them totally astonished ...

The nuclear mousetrap

Immediately after a nucleus fissions, two smaller nuclei are created, and those are positioned a microscopic distance apart. As both of those nuclei are heavily positively-charged, there is a huge electrical repulsion between them — they would actually fly apart at 3% of the speed of light. Meitner and Frisch calculated that this represented an energy of about 200 million electron-volts, which is enormous when you consider that — as stated in the previous chapter — the detonation of dynamite releases only about ten electron-volts per molecule. This meant that a nuclear explosion based on fission would be twenty million times more powerful than a conventional explosion using the same amount of material. One kilogram of uranium would have the same explosive power as twenty million kilograms (equivalently, twenty thousand tons) of conventional explosive.

As another way of looking at it, Otto Frisch calculated that the energy from each split uranium nucleus would be enough to make a grain of sand visibly jump. That might not sound very impressive, until you realise that in each gram of uranium there are 2.5×10^{21} atoms, which looks even more amazing when it is written as 2,500,000,000,000,000,000,000 atoms. It has been estimated that there are "only" 10^{18} grains of sand on all the beaches on Earth, which means a single gram of uranium possesses enough energy to make all the grains of sand on all the beaches on Earth jump — quite high. It is clear how an atomic fission bomb can release enough energy to cause catastrophic damage.

Lise Meitner wondered about the source of this tremendous energy, and then she remembered a lecture she had attended in 1909 given by Albert Einstein. In the lecture, Einstein had derived his famous formula $E=mc^2$ which described the equivalence between mass and energy, and explained how a small amount of mass could release a huge amount of energy. Meitner realised that if a uranium nucleus split into two smaller nuclei of barium and krypton then the total mass of the barium and krypton nuclei would be very slightly less than the mass of the original uranium nucleus. Some mass was being lost during fission. Meitner calculated that the amount of mass being lost was approximately equal to a fifth of the mass of a proton, and if that amount of mass was substituted into the $E=mc^2$ formula it could be calculated that the equivalent amount of energy was 200 million electron-volts, which was precisely the amount of energy being released by fission.

So it was clear that this was the source of the energy being released by fission: some of the mass of the uranium nucleus was being converted into energy. Let us consider this storage and release of energy in more detail.

Protons have positive electric charge, so they would naturally tend to repel each other via the electric force (like charges repel, opposite charges attract). It is therefore difficult to hold protons together in an atomic nucleus, and this must be achieved by a force which is stronger than the repelling electric force. That force is the *strong nuclear force*, the force which holds protons together in the nucleus. The strong nuclear force has a very short range

compared to the electric force. Imagine the electric force acting like a spring trying to push protons apart. Then, in order to form a nucleus, protons must be pushed together against that electrical repulsion until the protons are very close together and then the short-range strong force can lock them into place like a latch.

The mechanism resembles a mousetrap. The electric force acts like the spring on the mousetrap. You have to put energy into the mousetrap in order to bend the spring and prime the trap, and then the strong force acts to lock the trap in place:

In the Disney television programme *Our Friend The Atom*, Heinz Haber compares the energy trapped in the nucleus to a mousetrap which has been set. Here is a direct link to the relevant point in the programme:

<http://tinyurl.com/fissionmousetrap>

How does the strong force work? How can it hold the protons together? Well, when protons and neutrons are pushed very close together, the strong force locks them into place by releasing an amount of energy via gamma radiation. This released energy is called the *binding energy*. If you then wanted to pull the neutrons and protons apart again to return the system to its initial state — fighting against the attractive strong force — you would have to do work to put energy into the system which is equal to that lost binding energy. This is due to the law of conservation of energy: if energy was lost, you will have to replace that energy to return the system to its original state. So it can be seen how the binding energy acts to lock protons and neutrons together via the strong force.

This release of binding energy during the formation of nuclei — by compressing protons and neutrons together — is called *nuclear fusion*. This process occurs in the centre of stars, forming light elements such as helium from hydrogen, with the release of huge amounts of energy.

But for heavy elements being fused together, with many protons in their nuclei, the electrical repulsion becomes an ever-larger factor. In other words, the "spring" on the mousetrap becomes much stronger, and the mousetrap becomes harder to set (it becomes harder to push the nuclei together due to the electrical repulsion). In that case, the energy required to push the protons together is larger than the binding energy that would be released when the strong force locks the protons together. Therefore, the generation of energy via nuclear fusion is then no longer possible. Any element heavier than iron cannot be used for energy production via nuclear fusion inside a star.

But when a star explodes in a massive supernova explosion, the pressures and temperatures are so great that even heavy elements, heavier than iron, can be fused together, pushing against the tremendous strength of the electrical "spring". This is how uranium, the heaviest naturally-occurring element is formed: all the uranium now found on Earth was created in one or more supernova explosions over six billion years ago.^[6] Luckily, the 4.5 billion year half-life of uranium explains why not all of the uranium on Earth has vanished due to radioactive decay over that period.

The energy then lies trapped in the uranium nucleus for billions of years, like a primed mousetrap. And when the nucleus fissions, the trap explodes into action. As we have seen, the two halves of the fissioned nucleus fly apart with tremendous energy because of the intense electrical repulsion between them. The energy stored in the mousetrap is finally released. As Robert Serber says in his book *The Los Alamos Primer*, the two nuclei "would fly apart with an amount of energy equal to the work that went into pushing them together."

So when we are watching a nuclear explosion, we are watching the energy which has been trapped in atoms by supernova explosions billions of years ago, energy which has waited half the age of the universe before being set

free. Maybe that thought should fill us with increased awe when we watch the extraordinary phenomenon that is a nuclear explosion.

4

THE CHAIN REACTION

At this point in our story, we must introduce one of the most fascinating characters in the story of the atomic bomb. This is a man who played a seemingly peripheral role during the development of nuclear physics in the early decades of the 20th century, but he had a vision of the true potential of nuclear power and, perhaps more importantly, he was the first man to see the possibility of a nuclear chain reaction. As we shall soon see, he then went on to play a central role in the decision to develop nuclear weapons by enlisting the help of none other than Albert Einstein.

That man was Leo Szilard.

Leo Szilard (the "s" is silent) was born in Budapest in Hungary in 1898. After deciding he could not achieve his ambitions in Hungarian universities, he moved to Germany. He started a course on engineering, but switched to study physics at the University of Berlin because he heard that several Nobel laureates including Albert Einstein and Max Planck taught at the university. At this point we start to see Szilard as a man who was perhaps unsure of the direction he wanted to take in life, a man who for most of his life lived in rented rooms, living out of suitcases — which was perhaps not a bad idea given the political situation in Germany at the time (Szilard was a Jew): "All I had to do was turn the key of the suitcase and leave when things got too bad."

Although Szilard was studying physics, he was more of an inventor and entrepreneur than an academic. In fact, he might even be described as something of a "hustler", always with an eye for a money-making scheme. Rather bizarrely, he approached Albert Einstein with an idea for a new type of refrigerator which had no moving parts. Even more bizarrely, Einstein agreed to work with Szilard to develop the fridge, with Einstein using his earlier patent office experience to formulate a patent application.

Yes, the Einstein fridge really was a thing.

As we shall see later, Szilard's strong working relationship with Einstein was to play an important role in the development of the atomic bomb.

Perhaps Szilard's greatest talent was an almost uncanny ability to visualize the future and sense trends — perhaps a necessary talent for any successful entrepreneur. In the late 1920s he became aware of the promising advances in nuclear physics and was particularly interested to hear of Chadwick's discovery of the neutron in 1932. Szilard immediately realised the potential of the neutron as a way to probe the nucleus without being repelled. Might the neutron also provide a way to unlock atomic power?

In 1933, Adolf Hitler was appointed Chancellor of Germany, prompting Szilard to move to London in anticipation of the Nazi persecution of the Jews. It was in London that Szilard read a remarkable book by another visionary figure: the English science fiction writer H.G. Wells.

H.G. Wells had become aware of the discoveries of Rutherford and Soddy (which were described in Chapter Two) which suggested that there was a huge reserve of energy contained in the nucleus of an atom. Let us remind ourselves of Soddy's alarming prediction in 1904: "It is possible that all heavy matter possesses — latent and bound up with the structure of the atom — a similar quantity of energy to that possessed by radium. If it could be tapped and controlled what an agent it would be in shaping the world's destiny! The man who put his hand on the lever by which a parsimonious Nature regulates so jealously the output of this store of energy would possess a weapon by which he could destroy the Earth if he chose."

Such a dramatic statement must have resonated with H.G. Wells who, in 1913, wrote a remarkably prophetic book called *The World Set Free*. In that book, Wells imagines a world in which nuclear power has been harnessed by mankind, but it has also been used to create atomic bombs. Szilard described the plot of *The World Set Free* in his own words: "Wells describes the liberation of atomic energy on a large scale for industrial purposes, the development of atomic bombs, and a world war which was apparently fought by an alliance of England, France, and perhaps including America, against Germany and Austria, the powers located in the central part of Europe. He places this war in the year 1956, and in this war the major cities of the world are all destroyed by atomic bombs."

At the time, Szilard was living at the Imperial Hotel in Russell Square in London, not far from the British Museum, living off his savings of £1,500 (£100,000 in today's money). On the morning of September 12th 1933, Szilard was lounging in the hotel lobby when he read a report in *The Times* newspaper of one of Rutherford's recent speeches at the nearby meeting of the British Association for the Advancement of Science. Rutherford had explained

how alpha particles could be accelerated to such energies that they might be able to release energies from atomic nuclei. But Rutherford said he believed this would require more energy input than could be gained. Rutherford said that "anyone who looked for a source of power in the transformation of the atoms was talking moonshine (meaning foolish talk, or nonsense)."

According to Richard Rhodes: "All of which made Szilard restive. The leading scientists in Great Britain were meeting and he wasn't there. He was safe, he had money in the bank, but he was only another anonymous Jewish refugee down and out in London, lingering over morning coffee in a hotel lobby, unemployed and unknown."

Szilard was annoyed by Rutherford's negativity. He threw down his newspaper and stormed out of the hotel onto the street. Walking down the road, Szilard then had a flash of inspiration which he described in his own words: "Pronouncements of experts to the effect that something cannot be done have always irritated me. That day as I was walking down Southampton Row and was stopped for a traffic light, I was pondering whether Lord Rutherford might not prove to be wrong. As the light changed to green and I crossed the street, it suddenly occurred to me that if we could find an element which is split by neutrons and which could emit two neutrons when it absorbed one neutron, such an element, if assembled in sufficiently large mass, could sustain a nuclear chain reaction, liberate energy on an industrial scale, and construct atomic bombs."

According to Richard Rhodes: "Szilard was not the first to realize that the neutron might slip past the positive electrical barrier of the nucleus; that realization had come to other physicists as well. But he was the first to imagine a mechanism whereby more energy might be released in the neutron's bombardment of the nucleus than the neutron itself supplied." In particular, this was the first time that anyone had conceived of the principle of using neutrons to generate a chain reaction.

So what did Szilard mean by a "nuclear chain reaction"? Well, as he suggested, if a nucleus can be split (fissioned) by a neutron, then that split nucleus can produce additional neutrons (as described in the previous chapter). Those neutrons can then proceed to fission other nuclei. If a split nucleus emits two neutrons, then that will result in two further nuclei being fissioned. If those two nuclei emit two neutrons each, then that means there will be four neutrons in total produced, and those neutrons can proceed to split a further four nuclei. By this constant doubling of numbers, the total number of fissioned nuclei will rise extremely rapidly to a huge number.

Remember the analogy from the previous chapter of the energy trapped in an atomic nucleus being like a mousetrap. In the Disney television programme *Our Friend The Atom*, Heinz Haber performs an excellent visual demonstration in which many mousetraps (representing nuclei) are used to generate a "chain reaction" of mousetraps and ping-pong balls. Here is a direct link to the relevant point in the programme:

<http://tinyurl.com/mousetrapreaction>

The programme segment also considers the discovery of fission by Hahn and Strassmann. The mousetrap chain reaction idea was also used in a clever (and destructive) Pepsi advert:

<http://tinyurl.com/mousetrapchainreaction>

The following diagram shows the start of a chain reaction in which each split nucleus releases three neutrons:

Bearing in mind that a neutron from a fissioned nucleus moves at about 5% of the speed of light, this chain reaction is clearly going to release its energy extremely quickly. With a great deal of energy released with each fissioned nucleus, Szilard realised that the total amount of energy released by an uncontrolled chain reaction could be used to create an atomic bomb.

But Szilard had his idea in 1933, and in the previous chapter we saw that nuclear fission was not discovered by Hahn and Strassmann until 1938. So, for the time being, Szilard's idea about a nuclear chain reaction would have to remain just an idea.

The New World

As another example of Leo Szilard's uncanny foresight, he saw the oncoming Second World War with great clarity. In 1936 he announced his intention to "stay in England until one year before the war, and then move to New York City". It was a very strange thing to say as no one in 1936 could be sure if there would be a war, or when it would start. But Szilard's prediction was perfectly accurate: he moved to America in 1938, precisely one year before the war began.

Szilard was joining a group of brilliant physicist refugees from Nazi Germany who were either Jewish or had Jewish family connections. The group included Enrico Fermi, Eugene Wigner, Hans Bethe, Edward Teller, John von Neumann, and Emilio Segrè. According to Emilio Segrè: "America looked like the land of the future, separated by an ocean from the misfortunes, follies, and crimes of Europe." All of those aforementioned refugee physicists were destined to work on the American project to develop the atomic bomb, designed to be deployed against their former persecutors in Germany.

In 1939, Leo Szilard travelled from New York to Princeton to visit his friend Eugene Wigner who informed Szilard of the recent sensational news of the discovery of fission by Hahn and Strassmann. According to Szilard: "Wigner told me of Hahn's discovery. Hahn found that uranium breaks into two parts when it absorbs a neutron. When I heard this I immediately saw that these fragments, being heavier than corresponds to their charge, must emit neutrons, and if enough neutrons are emitted then it should be, of course, possible to sustain a chain reaction. All the things which H.G. Wells predicted suddenly appeared suddenly real to me."

Szilard's phrase describing the two resulting fissioned nuclei as being "heavier than corresponds to their charge" is interesting. This principle was described in the discussion of fission in the previous chapter. A nucleus of uranium is so large that it needs many neutrons to act as "glue" to hold the nucleus together. But this is more neutrons than is required in total by the two resulting fissioned nuclei, hence the phrase describing the uranium nucleus as being "heavier than corresponding to its charge". There would be more neutrons than required. This fact led to Szilard's suspicion that neutrons would be released by fission.

As Szilard realised earlier, in order for there to be a chain reaction, a uranium nucleus had to emit two neutrons when it was absorbed and split by one neutron. Whether or not this was the case was something Szilard had to

determine.

Szilard was still living an unsettled life in America, but he arranged to use a laboratory in Columbia University in New York City for three months. In his experiment, he bombarded uranium with neutrons in order to fission the uranium nuclei. Any neutrons being released as a result of fission would be detected and displayed on an oscilloscope. According to Szilard: "If flashes of light appeared on the screen, that would mean that neutrons were emitted in the fission process of uranium and this in turn would mean that the large-scale liberation of atomic energy was just around the corner. We turned the switch and saw the flashes. We watched them for a little while and then we switched everything off and went home."

Analysing the results, Szilard found that there were approximately two neutrons released per fissioned nucleus, which would be enough to sustain a chain reaction. According to Szilard: "That night there was little doubt in my mind that the world was headed for grief."

The letter from Einstein

Leo Szilard was now confident that a chain reaction would soon be achieved, and there was now a race with Nazi Germany to create the first atomic bomb. However, initial contacts with the military were not promising. The only interest came from a naval physicist who worked on submarine propulsion and was attracted to the idea of a power source which did not require oxygen (remember the discussion of the USS Nautilus in Chapter One).

Szilard became frustrated at the lack of progress. According to Richard Rhodes, at this point: "despite his Olympian ego not even Leo Szilard felt capable of saving the world entirely alone." Szilard contacted his fellow refugee physicists Edward Teller and Eugene Wigner and asked for their help. Wigner, in particular, felt it was essential to inform the U.S. government, maybe even going straight to the president if necessary. Szilard wondered if he could get his old refrigerator engineer friend, Albert Einstein, to come on board. Einstein was no longer producing useful work, but he was still the most famous physicist in the world and his word would carry weight in Washington D.C.

Despite being unable to swim, Einstein was a keen sailor, and Szilard learned that Einstein was away sailing in Peconic Bay on Long Island (Einstein had a reputation as a lousy sailor, getting stuck on a sand bar once, and on another occasion almost drowning when his boat capsized). Einstein was staying at a summer house by the sea on Nassau Point.

Maybe physicists are generally not good at directions and vehicles, because Szilard could not drive and had to rely on his friend Eugene Wigner to drive to Long Island. They set out on their journey on Sunday, July 16th, 1939. Inevitably, they got lost and spent hours circling the narrow country lanes, trying in vain to locate Einstein's house.

On the verge of giving up, Szilard saw a seven-year-old boy standing on the curb, so Szilard asked him: "Do you know where Professor Einstein lives?" Luckily, the boy knew the way and was able to direct them to Einstein's house at the end of Old Cove Road. It is interesting to imagine how the world might have turned out differently if Szilard and Wigner had never met that seven-year-old boy, and therefore never managed to find Einstein.

Once Szilard explained the principle of the nuclear chain reaction to Einstein, Einstein exclaimed "I never thought of that!" Einstein agreed to dictate a letter which was to be delivered to Franklin Roosevelt, the president of the United States. Here is an edited portion of the letter which was sent:

*Albert Einstein
Old Grove Rd.
Nassau Point
Peconic, Long Island
August 2nd, 1939*

*F.D. Roosevelt,
President of the United States,
White House
Washington, D.C.*

Sir:

Some recent work leads me to expect that the element uranium may be turned into a new and important source of energy in the immediate future. I believe therefore that it is my duty to bring to your attention the following facts and recommendations:

It may be possible to set up a nuclear chain reaction in a large mass of uranium, by which vast amounts of power and large quantities of new radium-like elements would be generated. Now it appears almost certain that this could be achieved in the immediate future.

This new phenomena would also lead to the construction of bombs, and it is conceivable — though much less certain — that extremely powerful bombs of a new type may thus be constructed. A single bomb of this type, carried by boat and exploded in a port, might very well destroy the whole port together with some of the surrounding territory.

In view of this situation you may think it desirable to have some permanent contact maintained between the administration and the group of physicists working on chain reactions in America.

*Yours very truly,
Albert Einstein.*

When Roosevelt was handed the letter and read it, he agreed that this required investigation, but there was still no great urgency and only limited resources were assigned to the investigation.

However, everything changed on the morning of December 7th, 1941. On that morning, Japan attacked the U.S. Pacific Fleet at Pearl Harbor, triggering the entry of America into the war. From that point, the race to build the first atomic bomb had begun. Codenamed the *Manhattan Project*, it was to be the largest single industrial and scientific project in the history of the world.

In his book *Trinity*, Jonathan Fetter-Vorm describes the challenge of the Manhattan Project: "For all the money and infrastructure invested, the challenge of the Manhattan Project was still rather mystical. Somehow, a very small chunk of glowing metal was going to be transformed into the largest explosion that humans had ever made."

Oppenheimer

Robert Oppenheimer had been a precocious child. He was born in 1904 to an ambitious family. When his grandfather saw his five-year-old grandson playing with bricks, he gave him an encyclopaedia of architecture. Oppenheimer developed an interest in science at an early age — mainly chemistry and mineralogy — and at the age of twelve he gave a lecture to the members of the New York Mineralogical Club. He had a wide range of other interests, including writing poems at the age of ten. At school, Oppenheimer did not hide the fact that he felt superior to the other children, telling them: "Ask me a question in Latin and I will answer you in Greek". He was described by a childhood friend as "very frail, very shy, very brilliant of course, and very superior."

Rather a sickly child, at the age of eighteen he was sent to spend the summer at a ranch in New Mexico to toughen him up before university. The ranch was in the mountains northeast of Santa Fe, and Oppenheimer thrived in the wilderness environment, chopping wood and learning to ride horses. The area was to make a lasting impression on Oppenheimer who was to say later that his two great loves were "physics and desert country".

At Harvard to study chemistry, Oppenheimer proved adept in a wide range of additional subjects including French literature and philosophy. He also wrote short stories and poetry, often giving an impression of being overly-sensitive and pretentious — and something of a drama queen. In a letter to a friend, he described his recent activities as: "Read Greek, committed faux pas, and wished I was dead. Voila".

In university, Oppenheimer extended his esoteric interests to include Hindu philosophy, while transferring his main field of study from chemistry to physics. However, Oppenheimer struggled with the laboratory work, "unable even to solder two copper wires together", and, as a result, he concentrated on theoretical physics. Oppenheimer went on to make significant contributions in the field of quantum mechanics.

Here is a photograph of Robert Oppenheimer:

In 1942, in a surprising move, Oppenheimer was selected to be the scientific director of the Manhattan Project. Oppenheimer was a surprising choice in many ways. Firstly, he was a theoretical physicist, rather than an experimental physicist. Oppenheimer may have been able to speak six languages, but surely someone in charge of running the largest-ever research and development project should have been able to solder two copper wires together.

Secondly, while Oppenheimer had no Nobel Prize he would be in charge of several physicists who did have Nobel Prizes. It was not so much a question of whether Oppenheimer was their intellectual equal — he was undoubtedly brilliant — it was more a question of whether the other physicists would be happy working under him.

Thirdly, Oppenheimer was well-known for having left-leaning political sympathies. Though he was not a communist, many of his friends were. Would he be a security risk? That was to be a question which dogged Oppenheimer throughout his career.

But what was impressive about Oppenheimer — and the reason he was selected to be project director — was his ambition and determination to make the project a success. Oppenheimer saw this as his opportunity to prove to others what he knew all along: that he was the best.

Los Alamos

One of the first decisions to be made was where to locate the development laboratory for the Manhattan Project. As Bruce Cameron Reed says in his book *The History and Science of the Manhattan Project*, the selected location had to satisfy the following criteria: "A laboratory site would have to be isolated, relatively inaccessible, have a climate that would permit year-round construction and operations, be large enough to accommodate a testing area, and be sufficiently inland to be secure from enemy attack."

Oppenheimer recommended the "desert country" of New Mexico where he spent summers riding horses as a youth. Specifically, he knew there was a ranch school in Los Alamos which would be ideal. The army engineers were concerned about the narrow access road from Santa Fe and the poor water supply, but otherwise agreed with Oppenheimer that it would be ideal.

The geography of Los Alamos is striking and unusual. It is situated on the slopes of the 13-mile-wide extinct volcanic crater called the Valles Caldera (or Jemez Caldera). Over a million years, rainfall down the slopes has carved a series of steep canyons, leaving a flat-topped hill on either side of each canyon. A small flat-topped hill like this is called a *mesa* ("mesa" is Spanish for "table"), and Los Alamos was spread out over four mesas. The following photograph shows the present-day town of Los Alamos spread over the four mesas, with the canyons visible. The location of the original Los Alamos laboratory is indicated by an arrow:

Because of its location on top of the mesa, the Los Alamos laboratory was given the nickname "The Hill".

For the remainder of 1942, and into the first few months of 1943, Oppenheimer had the job of touring the physics departments of American universities to persuade the best available physicists to join the Manhattan Project. His task was not made easier by the need to maintain strict secrecy. Although he could not describe the work in detail, he could state that this was important work which would probably end the war to end all wars. Almost every physicist he approached decided to join the project.

Security within Los Alamos was strict. In order to reduce the possibility of security leaks, the entire Los Alamos site was fenced-off. As a result, the facility operated like a small town, with a school, a general store, a family doctor, a library, and even a movie theatre. With a whole town having to be built from scratch, conditions were primitive. There were no paved roads, and fresh food and water was scarce. Los Alamos resembled a frontier town of the old American West. A wife of one of the physicists described her role as being "akin to the pioneer women accompanying their husbands across uncharted plains westward."

Initially, the military insisted on strict security in the scientific section of Los Alamos, with a need-to-know restriction on the transfer of information between sections. However, Oppenheimer argued that scientific progress could only be made if there was freedom of speech and free exchange of ideas. Eventually, the military agreed to complete scientific openness within the camp, but it came at a cost: the technical area of Los Alamos had to be entirely surrounded by high barbed-wire fence. For the refugee physicists from Europe, this generated the uneasy feeling that they were in a concentration camp.

The following photograph shows the entrance to the technical area of Los Alamos in 1944. The visual similarity to a concentration camp is clear:

The Los Alamos Primer

Because of the strict security, new scientific personnel arriving at Los Alamos were completely unaware of the work they would be doing or the goal of the Manhattan Project. In order to bring them up to speed quickly, it was decided to hold a series of introductory lectures. The task of giving the lectures fell to Robert Serber who was a former postdoctoral student of Oppenheimer. Serber's lectures were recorded in a 24-page document which was called the *Los Alamos Primer*.

The document represents everything that was known in 1943 about how to make an atomic bomb. In which case, it is surprising that this top secret document was declassified in 1965. Once declassified, the document was released into the public domain.

Here is a link to the original 1943 Los Alamos Primer document:

<http://tinyurl.com/losalamosprimer>

It is basically a recipe for making an atomic bomb.

The document was available on the Los Alamos website until 2001. However, everything changed after the September 11th attacks of that year. Because of the possibility of terrorists obtaining information about atomic bomb manufacture, the document was removed from the website on that day. But, as is the nature of the internet, once the document was released the genie could never be put back in the bottle.

Using the Los Alamos Primer as our starting point, let us now consider the physics of how to make an atomic bomb, starting with the most important calculation ...

5

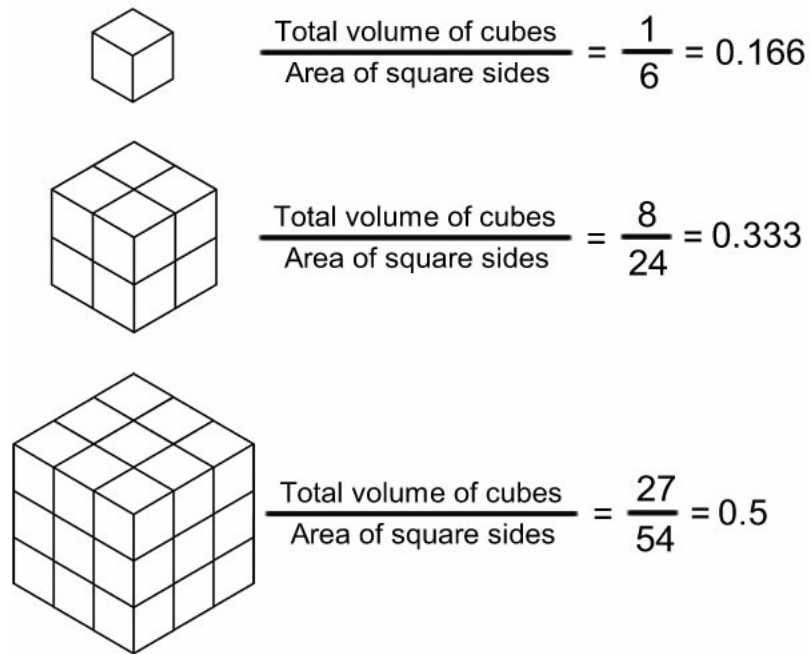

THE CRITICAL MASS

In this chapter we will discover the crucial importance of the volume of the fissionable material which is used to make an atomic bomb. We shall see that there exists a certain size of material at which point the chain reaction will be unstoppable and an explosion becomes a certainty. This amount of material is called the *critical mass*.

The accurate calculation of the value of the critical mass is the most important calculation in the construction of a nuclear bomb. Indeed, when you consider the impact of nuclear weapons, this is surely one of the most important calculations in the history of science. Therefore, this chapter considers the calculation of the critical mass. The calculation is inevitably highly mathematical, so most of the mathematical details have been included in the Appendix at the end of this book. I do not believe the detailed calculation of critical mass presented in this book can be found anywhere on the internet.

The ratio of volume to surface area

The existence of a critical mass relies on the fact that the ratio of an object's volume to its surface area is greater for larger objects than for smaller objects. In order to understand this principle, consider the following diagram showing three cubes of different sizes:

The first cube at the top of the diagram is the smallest. We can say that its volume is equal to one unit of volume (one small cube). If you count the sides of that small cube, you will find that it has six sides. So the total surface area of the cube is six units of area. This means that the all-important ratio of volume to surface area is then 0.166, as shown on the diagram.

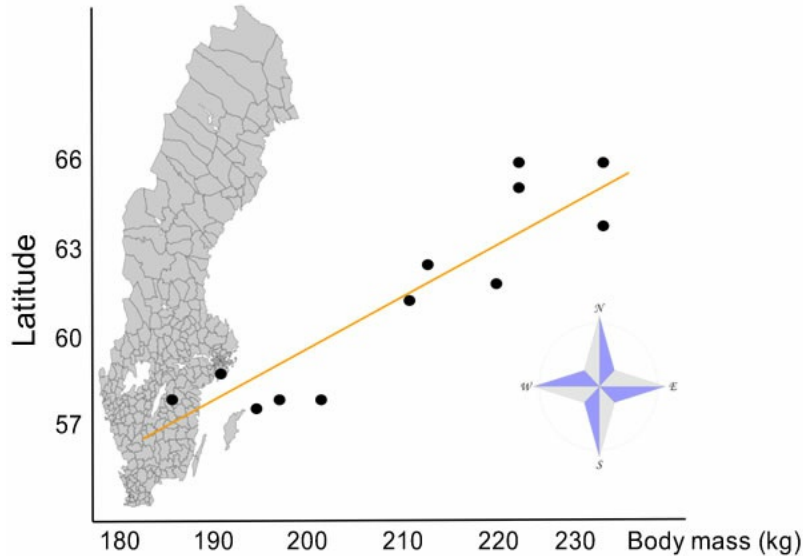

The second cube in the diagram has a total volume of eight small cubes (you can count them), and a total surface area of 24 units. Hence, the ratio of volume to surface area has increased to 0.333, as shown on the diagram.

The final cube, shown at the bottom of the diagram, is the largest. You can count that it has a total volume of 27 cubes, and a total surface area of 54 units. Hence, the ratio of volume to surface area has increased to 0.5, as shown

on the diagram.

So larger objects have a greater ratio of volume to surface area. Interestingly, this explains why — in general — larger animals are found in cold climates, e.g., polar bears, and smaller animals are found in hot climates, e.g., rodents (I guess we are supposed to ignore the elephant in the room). A small animal has a larger surface area (proportionately) and so can cool down better in a hot climate. Whereas a larger animal has a proportionately smaller surface area so loses less heat through its skin. This principle is called *Bergmann's rule*.

The following diagram illustrates Bergmann's rule by showing how larger moose are found in more northerly parts of Sweden:

Why does this principle allow us to build a bomb based on nuclear fission? To put it simply, if we have a sufficiently large amount of fissionable material then the build-up of neutrons inside the volume of the material will be larger than the loss of neutrons through the surface area of the material. When that happens, the resultant chain reaction will increase exponentially and the result will be an explosion.

If we have a small amount of fissionable material then the surface area of that material will be proportionately quite large compared to its volume. As a result, the amount of neutrons being lost through the surface will be greater than the amount of neutrons being generated inside the material and the chain reaction will be unable to continue.

As the amount of mass is progressively increased, the surface area becomes proportionately smaller compared to the volume of the material, and so the loss of neutrons also becomes proportionately smaller. As the amount of mass continues to increase it is clear that a certain balance point will be reached at which point the loss of neutrons through the surface will be precisely equal to the build-up of neutrons inside the material. This amount of mass is called the critical mass. A sample of material this size — or larger — is going to explode.

This is an important point which we will be using later in our calculation: if we have a volume of fissionable material, then **critical mass occurs when the build-up of neutrons inside the material is equal to the loss of neutrons out of the material.**

Put simply, the critical mass is the smallest amount of fissionable material which will cause a nuclear explosion. Therefore, determining the correct value of the critical mass is the most important task in designing a nuclear bomb.

Spherical coordinates

In our analysis of critical mass, we will need to use the most efficient and natural method of describing the distribution of neutrons within the material.

Normally, when we want to describe the shape of an object in three-dimensional space we would use Cartesian coordinates (as shown in the following diagram). We could then define any point in space by its (x, y, z) coordinates, where x , y , and z are the distances along the three axes:

However, for describing the distribution of neutrons within a sample of fissionable material, we can use a better method of defining a point in space. This is because nuclear bombs almost always use a solid sphere of fissionable material as a critical mass (a solid sphere represents the most efficient use of the material). The most efficient means of defining a point in a solid sphere is to use *spherical coordinates*.

Spherical coordinates define a point in space using the distance from the centre of the space, and two angles of rotation, as shown in the following diagram:

This method for defining a point in space is so efficient because our sphere of fissionable material has rotational symmetry: it does not matter how we rotate that sphere in space, it would still look the same. Because of that rotational symmetry, all we need to consider is the distribution of neutrons along the radial thick dashed line coming out of the centre of the material, as shown in the previous diagram. We do not need to be concerned about the two rotational angles because it does not matter how we rotate the line the distribution of neutrons along it will still be the same.

So, in this calculation of critical mass, we will only be interested in the distribution of neutrons in the one dimension along the line of length r coming from the centre of the material.

The build-up of neutrons

In this section we will consider the build-up of neutrons within a volume of the fissionable material. In the next section we will consider the loss of neutrons through the surface of the volume.

You will remember from the previous chapter that when a nucleus undergoes fission, several neutrons can be released. These neutrons would then continue the chain reaction by splitting more nuclei. In the diagram below, you will see an example in which three neutrons (on the right of the diagram) are released by the fission of a single nucleus:

If we are to generate an ever-increasing chain reaction then the question of how many neutrons are released in a single fission is crucial. Clearly, if the chain reaction is to build in intensity then we will need a situation in which

the total number of neutrons in the volume increases.

Considering the example of the previous diagram, what is the net increase in the number of neutrons due to the fission of a single nucleus? We can see that one neutron comes in from the left and is absorbed by the nucleus. The nucleus then fissions and three neutrons are released. The net increase in neutrons is therefore going to be three neutrons minus one neutron (the neutron which was initially absorbed), giving a net increase of two neutrons.

On that basis, we can now calculate the build-up of neutrons within the volume of fissionable material. Let us define the average number of neutrons produced per fission as ν (the Greek letter "nu"). In the previous example, ν would be equal to three. Then the net increase in the number of neutrons because of the fission of one nucleus will be given by $\nu - 1$, the "-1" term coming from the absorption of the initial incoming neutron. That means that as long as more than one neutron is produced by the fission of a nucleus, then the total number of neutrons will increase over time (ignoring the loss of neutrons through the surface of the volume).

If there is currently a total of N neutrons in a volume of material, and we assume that each of those neutrons goes on to fission a nucleus, then the new total number of neutrons in the volume after the round of fissions will be the net increase in neutrons due to a single fission, multiplied by the number of fissions:

$$(\nu - 1) \times N$$

If the average time between fissions is given by τ (the Greek letter "tau") then the rate of increase in the number of neutrons will be given by:

$$\frac{(\nu - 1)}{\tau} N$$

This formula then tells us the rate of increase of neutrons within a volume of the material — ignoring the loss of neutrons through the surface of that volume. This is the first result we need on our quest to calculate the critical mass.

The derivative

Now let us start to consider the flow of neutrons out through the surface.

The flow of neutrons out through the surface represents a *current* flow of neutrons — just like an electric current is a flow of electrons. And just as the magnitude of an electric current depends on the potential difference (voltage) over a distance, so the current flow of neutrons depends on the difference in the number of neutrons over some distance. In other words, the neutron current depends on the *gradient* of the number of neutrons.

We are well aware of the idea of a gradient as representing the steepness of a hill. In that case, if we are driving up a hill, the gradient is defined as the change in our vertical height divided by the distance we drive in the horizontal direction. This is shown in the following diagram:

But the principle of a gradient can be applied to the change of any variable — not just height. We have seen that a gradient is defined as being "the amount of change of a variable divided by the amount of change of another variable". If we have two variables, x and y , then the change of y with respect to x (i.e., the gradient) is known as the *derivative* and is written as:

$$\frac{dy}{dx}$$

You can see how this relates to the gradient at a point:

Mathematically, this derivative notation can be used to describe the flow of neutrons out of the material. The value of the critical mass can then be calculated by setting the flow of neutrons out of the material equal to the build-up of neutrons within the material. The lengthy and detailed calculation is contained in the Appendix at the end of this book.

If you want to know the mathematical details of how the world's greatest physicists constructed the world's first atomic bomb, I can highly recommend that you read the Appendix.

To cut a long story short ...

To cut a long story short, the detailed calculation of the value of the critical mass which is described in the Appendix reveals that the critical radius of uranium-235 is 9.1 centimetres. To give an impression of this size of a critical mass, I made my own "critical mass" of the correct dimensions (from a rubber ball and a can of silver spray paint) which you can see me holding in the following photograph:

If this was real, this sphere of metal would explode with a force of several thousand tons of TNT, taking most of my hometown with it.

If you were to hold an actual solid sphere of uranium of this size, the overriding impression would be due to its extraordinary weight. Uranium has the atomic number of 92, which means it has 92 protons in its nucleus — the most of any naturally-occurring element. As most of the mass of an atom is found in its nucleus, this explains why uranium is so heavy. The "critical mass" of uranium I am holding in my hand in the previous photograph would weigh 52 kilograms, or over eight stone. In other words, it would weigh more than many people weigh!

We simply never encounter extraordinary substances such as uranium in our everyday lives. How can this metal weigh so much? How can a small ball of this metal explode with such force? Sometimes these metals glow because of their radioactivity, or they are permanently warm. The properties of these substances seem uncanny and alien. Which raises the question ... how do we obtain these unearthly metals?

6

OAK RIDGE

As explained in Chapter One, it is possible for the nucleus of a particular element to have a different number of neutrons, in which case the substance is called an *isotope*. As isotopes of elements have different numbers of neutrons they therefore have different values for mass number, the mass number being the total number of protons and neutrons in the nucleus. As an example, the isotope of uranium called uranium-238 has a mass number of 238 (which is composed of the sum of 92 protons and 146 neutrons).

Natural uranium, extracted from uranium ore, is composed of two isotopes: uranium-238 and uranium-235 (from now on, uranium-235 will be referred to as "U-235" and uranium-238 will be referred to as "U-238", where "U" is the chemical symbol for uranium). U-238 is by far the most common isotope representing over 99% of natural uranium. However, for purposes of constructing nuclear explosives, it is U-235 which is more interesting.

In this chapter, we will be considering how to obtain U-235 by separating it from U-238 in a process known as *enrichment*.

Remember it was described in Chapter One that neutrons have to act like glue to hold protons together to stop the nucleus from flying apart due to electrical repulsion between the protons. As we have just calculated, U-238 has 146 neutrons, whereas you can similarly calculate that U-235 has the fewer number of 143 neutrons. As the job of neutrons is to act like glue to hold the nucleus together, those three fewer neutrons mean that a nucleus of U-235 is not so strongly "glued together". As a result, U-235 is much more unstable than U-238, and is therefore much more fissionable.

In order to quantify the difference in fission behaviour between U-235 and U-238 we need to introduce the concept of a nuclear *cross section*. Using the usual sense of the term, a cross section is a slice through an object. If we consider a spherical atomic nucleus (or any spherical particle) then a slice through the middle of that particle is going to be a circle. We can then interpret that circle as a target, as shown in the following diagram. The behaviour of the nucleus when it is hit by a bombarding neutron will then depend on whether that neutron hits the target or not:

The area of the target is called the nuclear cross section. The different ways in which a nucleus might behave when it is hit by a neutron can be described by defining different cross sections (different sizes of target) for each different type of behaviour. If a cross section is smaller, then that means that the target is smaller, and the behaviour is less likely (the neutron is less likely to hit the target). Conversely, if a cross section is larger, then that means that the corresponding behaviour will be more likely.

As an example, when an atomic nucleus is hit by a neutron, one of three things might happen. Firstly, the neutron might bounce off the nucleus in a process known as *scattering*. The probability of this occurring would be defined

by the *scattering cross section* of the nucleus. Secondly, the neutron might be absorbed (captured) by the nucleus. The probability of this occurring would be defined by the *capture cross section* of the nucleus. Thirdly, the neutron might cause the nucleus to split. The probability of this occurring would be defined by the *fission cross section* of the nucleus.

The difference in behaviour when a nucleus of U-235 and a nucleus of U-238 is hit by a neutron can be described in terms of their cross sections. As was explained earlier, a nucleus of U-235 is more fissionable. It can therefore be said that it has a larger **fission** cross section. However, remember that U-235 represents less than one percent of natural uranium, the rest being U-238. This represents a problem if we are trying to achieve a chain reaction in natural uranium because U-238 has a very large **capture** cross section. If we consider a neutron emerging from a fissioned nucleus, we need that neutron to travel unhindered until it reaches a secondary nucleus which it can fission. If, instead, it hits a nucleus of U-238 then the large capture cross section of that nucleus means that the neutron will be captured by that U-238 nucleus without fissioning that nucleus. The chain reaction will then grind to a halt.

Because of this "poisoning" effect of U-238, the only way to achieve an explosive chain reaction is to laboriously separate the U-235 from the much larger proportion of U-238, and then to use only that extracted U-235 in the atomic bomb core.

As stated earlier, less than 1% of natural uranium is U-235, whereas weapons-grade uranium needs to be enriched to 90% U-235. It is therefore clear that a tremendous amount of uranium ore would need to be enriched to make a bomb. The necessary process would resemble an industrial-scale operation more than a laboratory experiment. In 1939, Niels Bohr insisted "it can never be done unless you turn the United States into one huge factory."

Well, effectively, that is just what happened ...

The secret city

The scale of the Manhattan Project was staggering. Apart from the development facility at Los Alamos, the project involved more than thirty sites across the United States, Britain, and Canada. These sites included two vast factories in the United States for the production of fissionable material for the bomb cores.

The main industrial facility was the 60,000-acre isotope separation plant (for separating U-235 from U-238) which was located in rural Tennessee. At the time, the area was virtually uninhabited, so the factories and the entire town to house the employees had to be built from scratch. The town was given the rural-sounding name of Oak Ridge in order to make it sound like a small, uninteresting village which would not attract outside interest. In 1945, after being in existence for just two years, Oak Ridge employed 80,000 people and had become the fifth-largest town in the state of Tennessee — and it consumed more electricity than New York City.

At its peak, the Manhattan Project employed 130,000 people and was larger than the entire American automobile industry. It was simply the greatest scientific and engineering gamble in the history of the world. Niels Bohr's prediction that the United States would have to be turned into "one huge factory" was becoming true.

Oak Ridge had to provide all the facilities of a normal town. It had over seven thousand houses, two high schools, nine shopping areas, churches, movie theatres, and a hospital. However, the need for security meant that the entire town had to be surrounded by a barbed-wire fence, and Oak Ridge did not appear on any maps until 1949. To its inhabitants it was called the "Secret City".

To all intents and purposes, Oak Ridge appeared like a normal town, though none of its inhabitants had any idea of why they were doing the jobs they were doing. The difficulty of working in such secrecy was described by one of the managers at Oak Ridge: "Well it wasn't that the job was tough — it was confusing. You see, no one knew what was being made in Oak Ridge, not even me, and a lot of the people thought they were wasting their time here. It was up to me to explain to the dissatisfied workers that they were doing a very important job. When they asked me what, I'd have to tell them it was a secret. But I almost went crazy myself trying to figure out what was going on."

All the workers were sworn to secrecy, and were told never to speak a word to outsiders about their work at Oak Ridge. They were even told what to say if anyone outside asked about their work. If they were asked what they were making in Oak Ridge, they were told to say: "Oh, about 76 cents an hour." And if they were asked how many people were working in Oak Ridge, they were told to say: "Oh, about half of them."

Here are some photographs of everyday life in the secret city of Oak Ridge during the war:

The largest building in the world

The isotope separation factories at Oak Ridge were faced with a daunting challenge. In his graphic novel version of the Manhattan Project called *Trinity*, Jonathan Fetter-Vorm describes the challenge by using an analogy: "To make a bomb, you need to enrich the uranium, skimming off the less reactive isotope and concentrating the amount of U-235. To get some idea of how hard this is, imagine mixing together two different colours of clay, then trying to separate the colours from each other."

The problem is made more difficult because the relatively simple and cheap process of chemical separation cannot be used. Chemical separation relies on differences in the chemical properties of the two substances being separated: the substances would behave differently in a chemical reaction. Those chemical properties are determined by the distribution of electrons in the shells of the atom, and the numbers of those electrons are, in turn, determined by the number of protons in the atomic nucleus. But two different isotopes of an element have the same number of protons (the same atomic number), so they would have the same distribution of electrons. Therefore, their chemical properties would be the same and chemical separation could not be used.

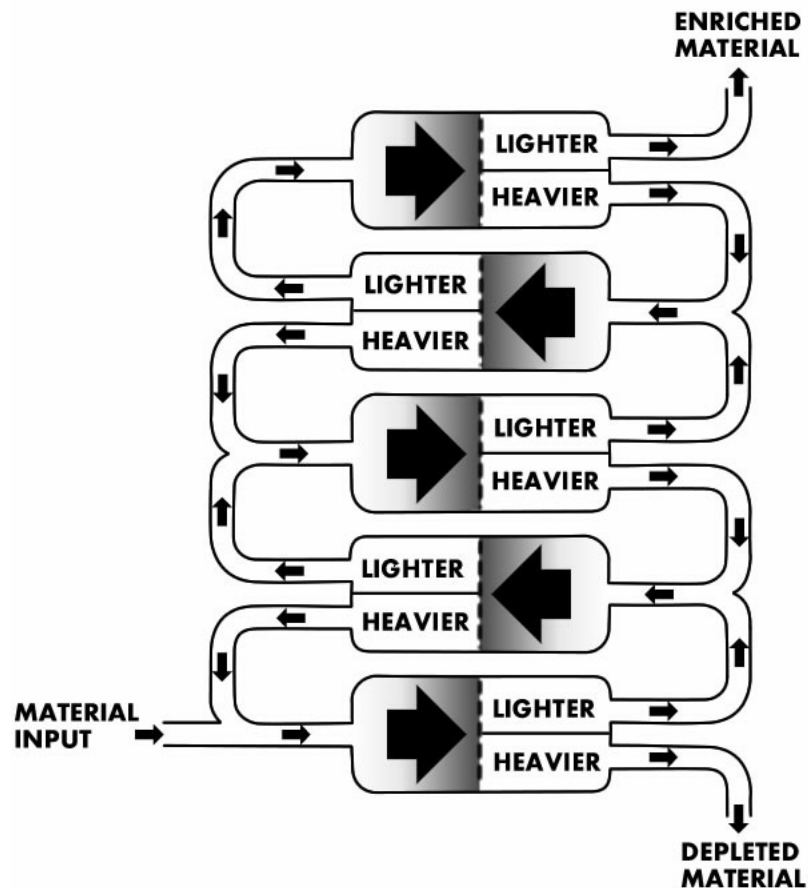

The only possible alternative is to rely on the difference in the physical properties of the two isotopes, which means the extremely slight difference in the mass of the atoms due to the additional neutrons. On that basis, it is possible to separate the isotopes by using *diffusion*. Diffusion is considered in the Appendix as a means for calculating the critical mass (by considering the diffusion of neutrons through an atomic bomb core), but it is stated in the Appendix that diffusion describes the spread of any group of particles through a substance (for example, the spread of dust particles in air, or the spread of a chemical through a liquid). In Oak Ridge, diffusion was used to

separate isotopes by considering the diffusion of uranium atoms through a membrane peppered with microscopic holes.

Firstly, in order to allow diffusion of the uranium, the uranium was turned into a gas: uranium hexafluoride. The gas was then pumped through the membrane. Only gas molecules containing the lighter U-235 isotope would diffuse through the holes in the membrane, so those molecules could be separated from the heavier U-238.

But the very small difference in the atomic mass of the two isotopes meant that it was impossible to achieve perfect separation with a single filter. In fact, the amount of percentage enrichment achieved with each filter was very small. As a result, a high level of enrichment was only possible by using a large number of stages cascaded together, with the output of one stage passing to the input of the next stage. Each stage only provided a very small amount of percentage enrichment, but with enough stages the material became progressively more enriched as it passed through all the stages.

The design of the isotope enrichment process using gaseous diffusion which was used at Oak Ridge was ingenious and is shown in the following diagram:

You can see that in each stage the material is pumped against the filter membrane which separates the material into lighter and heavier isotopes. By following the small arrows, you can follow the progressive enrichment of the material on the diagram as it passes through the stages, emerging at the top as highly-enriched material.

You will see that even if some of the material fails to pass through the filter, that material is not wasted. Instead, as you can see on the diagram, the rejected material just drops down to the stage below and is processed again. This is because the filtering process could never be perfect with such a small difference in mass between the isotopes, so the rejected material might still include some atoms of the lighter isotope which should not be wasted.

Because of the very small percentage amount of enrichment achieved by each stage, the extraordinary total of 2,892 stages were required. And these were not small stages: each diffusion tank held 1,000 gallons. As a result, the building which contained the sequence of stages was truly monumental. When it was completed, the Gaseous Diffusion Plant at Oak Ridge was a four-storey U-shaped building which was half a mile long and a quarter of a

mile wide. It surpassed the Pentagon to become the largest building in the world — even though the world did not know it existed:

The Calutron Girls

The other major factory at Oak Ridge employed a completely different method of isotope separation based on the electromagnetic force. The technique, known as electromagnetic separation, considered the deflection of electrically-charged uranium atoms as they passed through a magnetic field.

The deflection of the particles is described by *Fleming's left-hand rule for motors*, which you might have been taught in your physics class in school. The rule is described by the following diagram:

The previous diagram shows that if your middle finger points in the direction in which the charged particles are moving (in the case of a motor, this would be electrons moving down a wire), and if your index finger is pointing in the direction of the magnetic field, then the charged particles will experience a force in the direction of your thumb. This principle was used by the electromagnetic separation process in Oak Ridge to curve the path of beam of uranium atoms as they moved through a magnetic field.

In the following diagram, you will see the charged particles emitted from the source at the bottom of the diagram. At that point, with the direction of the magnetic field into the page, your index finger should point into the page.

Your middle finger should always point in the direction in which the particles are travelling (which would be toward the right at the start). In which case, your thumb represents the direction of the force experienced by the particles, which — as you can see on the diagram — will always point toward the centre of curvature:

In fact, at every point of their path, the particles will always experience a force toward the centre of curvature, which will result in the beam of particles taking a curved path.

Because the U-235 atoms have slightly lower mass, they will be slightly more affected by the force. In other words, their path will curve more. If a receptacle is correctly placed (a bucket is shown on the diagram) then this will be able to collect only the U-235 atoms and reject the U-238 atoms.

This electromagnetic isotope separation device was called a *calutron*. The name derives from a combination of the words "Cal" and "tron". The "tron" comes from the word *cyclotron* which was an electromagnetic particle accelerator developed by Ernest Lawrence. The "Cal" comes from "California" as Lawrence invented the cyclotron at the University of California.

It can be seen that this calutron method of isotope separation involves building-up the enriched uranium atom-by-atom. It is clear that this would be a very low-yield and time-consuming process: each calutron could produce only 100 milligrams of U-235 per day. In order to increase the yield up to 100 grams of U-235 per day, nine buildings were built at Oak Ridge to house 1,152 calutrons — another monumental operation.

Operating a calutron was a labour-intensive process requiring constant human intervention. In practice, the operators were young women from the local Tennessee community — many straight out of high school or fresh off the farm — who were given the name the "Calutron Girls". Let us now consider the story of the Calutron Girls as described in Denise Kiernan's bestselling book about the female workers of Oak Ridge called *The Girls of Atomic City*.

Many of the young female workers at Oak Ridge had to work in a state of constant anxiety as their brothers and husbands were fighting a brutal war on foreign shores. Despite their anxiety, the women worked tirelessly, motivated by being told that their mysterious work on these futuristic machines would make the war shorter and bring their loved-ones home sooner.

This was the case for Dorothy Jones (affectionately known as "Dot") who was a young girl from Hornbeak, Tennessee. All three of Dot's brothers were fighting in the war, including Shorty who was 23 years old and a deck

gunner for the Navy on the battleship USS Arizona. Unfortunately, the Arizona was one of the ships in dock in Pearl Harbor when the Japanese bombed it in December 1942. Dot's family had received the news just before Christmas that Shorty was missing, presumed dead. Dot was determined to do something for the war effort in Shorty's memory, so she had signed up to be one of the Calutron Girls at Oak Ridge.

When Dot entered the building which housed the calutrons, she found it to be a very daunting experience. The building was enormous, with a high ceiling, bright lights, and constant loud electrical sparking sounds from the high-voltage calutrons. Also, bear in mind that in 1944 these were the most futuristic and advanced industrial machines anywhere in the world.

Dot took her place on the wooden stool in front of her calutron control panel, and started her day's work.

The main job assigned to the Calutron Girls was ensuring that the magnetic field strength was set precisely so that the beam of U-235 atoms would be correctly directed into the final receptacle. This was a labour-intensive process as it requiring continuous twisting of handles to adjust the strength of the magnetic field and thereby keep the beam correctly aligned. Here is a photograph of one of the Calutron Girls turning the handles while keeping her eyes firmly fixed on the dial reading:

The following picture shows the Calutron Girls, each woman seated in front of her individual calutron:

Of course, due to the tight security, none of the girls knew the true nature of the task they were performing. The woman seated at the front right of the previous photograph was Gladys Owens who only realised the job she had done during the war when she saw herself in the previous photograph when she toured a museum of Oak Ridge fifty years later.

The girls were warned never to venture behind their control panels because that was where the giant magnet used to generate the powerful calutron magnetic field was positioned. The girls knew that if you carelessly wandered into the magnetic field it would pull the metal hairclips right out of your hair. Or, if you had a belt buckle, it could even pin you against the wall. Legend had it that a maintenance man who had nails in his shoes had been rooted to the spot.

It is clear that the tireless and focussed Calutron Girls performed an essential role in the war effort. However, not everyone was so impressed by the girls. After Ernest Lawrence — the inventor of the calutron — had visited the plant he ran into the office of the chief engineer and blustered: "How dare you pick these silly hillbilly girls to run my machines!" Lawrence insisted that only his male PhD physicists had the ability to run a calutron correctly. Lawrence was certain that the performance of these young girls — straight out of school or off the farm — would be inferior to that of his highly-educated men. However, the chief engineer defended his girls loyally, and told Lawrence how productive the girls had been. He persuaded Lawrence that there should be a production race: Lawrence's highly-qualified physicists versus the Calutron Girls. Whoever produced the most U-235 would be the winner and would get to keep their job. Lawrence reluctantly agreed to the race, totally confident that his men would win.

Of course, in predictable Hollywood movie style, when the race started the Calutron Girls blew the physicists out of the ballpark by collecting a far larger amount of U-235 (apparently the rather geeky physicists were constantly being distracted by getting their slide rules out and analysing any minor variation in the dials). The Calutron Girls were victorious — and they finally won their much-deserved respect. Of course, they were allowed to continue doing their fine job.

The story of the Calutron Girls is one of many remarkable stories of the efforts of the workers at Oak Ridge.

Amazingly, at the end of every week, all the enriched uranium produced by Oak Ridge was taken to Los Alamos **in a briefcase** by a plain-clothed military security officer **on a public train**, with the briefcase handcuffed to his wrist. All actual bomb design and manufacture took place in Los Alamos. It was there that the received uranium was machined to form the bomb cores.

After the dropping of the atomic bomb on Hiroshima in 1945, the nature of the work at Oak Ridge was no longer a secret. The Under Secretary of War, Robert Patterson, sent a letter to all the workers of Oak Ridge: "Today the

whole world knows the secret which you have helped us keep for many months. I am pleased to be able to add that the warlords of Japan now know its effects better, even than we ourselves. The atomic bomb which you have helped to develop with high devotion to patriotic duty is the most devastating military weapon that any country has ever been able to turn against its enemy. No one of you has worked on the entire project or knows the whole story. Each of you has done his own job and kept his own secret, and so today I speak for a grateful nation when I say congratulations, and thank you all. We are proud of every one of you."

Mail-order uranium

In this chapter we have examined how the enriched uranium for a nuclear explosive can be produced. It is clear that this is not a simple process. And for that we should be grateful: it is only the difficulty in obtaining suitable nuclear fuel which prevents terrorists and rogue states from making their own nuclear weapons.

However, I thought it would be interesting to discover how difficult it actually is to obtain uranium. Especially when you consider the subtitle of this book is "How to make an atomic bomb". So I did an online search and found it is surprisingly easy to obtain uranium ore.

There are many online companies who will provide you with uranium ore — especially in the U.S. The company **unitednuclear.com** provides a wide range of radioactive material and scientific equipment. Material and equipment is also available on Amazon and eBay. I bought an excellent sample of radioactive uranium ore from eBay.

I also obtained a Geiger counter in order to examine the uranium ore. You can buy many expensive modern small plastic Geiger counters, but I went to eBay and bought an ex-military Geiger counter for a very reasonable price (£50). The Geiger counter was built for the Polish Army in 1970. I get the impression the market is flooded with ex-military equipment, very reliably-built, the Geiger counter will probably last for another hundred years.

The Geiger counter is called a DP-66. There are plenty of these available on eBay. I also bought an external microphone for my DP-66 (to make the clicks audible) from the company **anythingradioactive.com**. They also sell a range of Geiger counters.

A similar American Geiger counter was built around the same time as the DP-66 and it is called the CDV-700. The CDV-700 Geiger counters are also available on eBay and Amazon.

I made a five-minute video of my examination of the uranium ore using my Geiger counter. You can watch the video at the following link:

<http://tinyurl.com/radioactivevideo>

Here are some stills from the video:

PLUTONIUM

In the previous chapter, it was explained that approximately 99% of natural uranium is the isotope U-238 with less than 1% being the desirable fissionable U-235. It was described how that large proportion of U-238 acts to "poison" any chain reaction by capturing stray neutrons. Hence, natural uranium cannot be used in nuclear explosives.

It was then described how the aim of enrichment is to increase the amount of U-235 up to 90%, at which point the enriched uranium is capable of sustaining a chain reaction and is considered to be "weapons-grade" uranium.

On that basis, it might be imagined that U-238 is nothing more than a nuisance, only having the effect of poisoning any chain reaction. However, this would not be a correct assessment of the value of U-238. In fact, U-238 has been used to create more modern nuclear weapons than has U-235.

So how can this be the case? How can U-238 be used to create nuclear weapons? Well, it is because the U-238 is not directly used as an explosive. Instead, it is used to create another element which is highly-fissionable: *plutonium*. It is that plutonium which can be used as a nuclear explosive. As Richard Rhodes says in *The Making of the Atomic Bomb*, using apparently-useless U-238 to create plutonium "would thereby indirectly put U-238 to work".

To understand how U-238 can be used to create plutonium, remember the discussion of beta decay in Chapter Two. It was explained how beta decay occurs when there are "too many" neutrons in a nucleus, with the result that a neutron converts into a proton — with the emission of an electron, which is the beta particle. The conversion of the neutron into a proton increases the atomic number by one (one more proton in the nucleus) while leaving the mass number unchanged (total number of protons and neutrons is unchanged).

So, in a nutshell, the effect of beta decay is to increase the atomic number by one, thereby creating an element one position further up in the periodic table.

Next, remember in the previous chapter it was explained that U-238 acts to poison a chain reaction because it has a very large capture cross section, which means it is very likely to capture and absorb any neutron which hits its nucleus. If U-238 captures a neutron, it turns into U-239 (one extra neutron increases the mass number by one). The resultant U-239 nucleus would then have an excess neutron, and beta decay would therefore be likely. As just described, the effect of that beta decay would be to move the U-239 one place further up the periodic table, converting it to an element called *neptunium*.

The first line of the following diagram shows a nucleus of U-238 capturing a neutron to become U-239. Follow the curved arrow to see that U-239 then beta decays to neptunium (shown to have an atomic number of 93, which you will see is one more than the atomic number of uranium, which is 92):

Neptunium is unstable with a half-life of only two days so, as you can see on the diagram, the neptunium quickly beta decays to produce a new element — plutonium — which has an atomic number of 94.

It is interesting to consider the origin of the names "neptunium" and "plutonium". Uranium was originally named after the planet Uranus (which is itself named after the Greek god), which is the seventh planet from the Sun in the

Solar System. When the element neptunium was discovered it was decided to continue this naming convention, so neptunium was named after the planet Neptune which is the eighth planet of the Solar System, one place beyond Uranus (Neptune was also named after the Roman god). When plutonium was discovered, the naming convention was continued so it was named after Pluto which, at the time, was considered to be the ninth planet of the Solar System just beyond Neptune (rather ominously, Pluto was also the name of the Greek god of death).

The following diagram shows the three outermost planets of the Solar System, together with the three elements named after them. The consecutive atomic numbers of those elements (92, 93, 94) are also shown:

Uranium and plutonium are the only elements which can be used as nuclear explosives. So why is it the case that uranium and plutonium are nuclear explosives, but neptunium is not? After all, as can be seen, neptunium lies between uranium and plutonium in the periodic table. To understand why only uranium and plutonium are nuclear explosives, we need to consider the concept of *parity* in the atomic nucleus.

In mathematics, parity indicates whether a number is even or odd. If we consider the number of protons and neutrons in an atomic nucleus, it is known that the parity of those numbers plays a large role in describing the fission behaviour of that nucleus.

Firstly, if we consider uranium-235, it has an atomic number of 92. That means it has 92 protons, which is an **even** number. It therefore must have 143 neutrons ($235-92$) which is an **odd** number. So the parity of U-235 is **even/odd**.

If we then consider neptunium in a similar manner, we find it has 93 protons and 146 neutrons, so the parity of neptunium is **odd/even**, which is clearly different to the parity of fissionable U-235.

However, if we apply the same reasoning to plutonium, we find it has 94 protons and 145 neutrons, which is **even/odd** parity, **which is the same as fissionable U-235**. So this is the reason why plutonium fissions in a similar manner to U-235, and why plutonium can also be used as a nuclear explosive.

The nuclear reactor

If it takes the capture of a single neutron by a single nucleus of U-238 to produce plutonium then it is clear that to produce a significant amount of plutonium would require trillions of neutrons. In practice, the only way to generate those neutrons would be by starting a self-sustaining chain reaction in uranium, with each fissioned uranium nucleus producing more than one neutron.

But it has already been explained how U-238 acts to poison any chain reaction because of its tendency to capture any free neutrons. So how can U-238 be involved in any chain reaction in uranium?

The answer is that we have to slow the neutrons down.

It might seem counter-intuitive that slowing-down neutrons can encourage a chain reaction based on the fissioning of nuclei — it might be suspected that faster neutrons would be more effective at splitting nuclei.

However, a slower neutron can be much more effective. This discovery was made by Enrico Fermi, and Fermi's discovery was described by Richard Rhodes: "Everyone had assumed that faster neutrons were better for nuclear bombardment because faster protons and alpha particles always had been better. But the analogy ignored the neutron's distinctive neutrality. A charged particle needed energy to push through the nucleus's electrical barrier. A neutron did not. Slowing down a neutron gave it more time in the vicinity of the nucleus, and that gave it more time to be captured." [\[7\]](#)

This effect was particularly notable in the isotope U-235 rather than U-238. For U-235, the fission cross section for slow neutrons is absolutely huge. In other words, if you have a sample of U-235 and you bombard it with slow neutrons, the nuclei will almost certainly fission, rather than the nuclei capturing those neutrons. In fact, it is that huge fission cross section of U-235 for slow neutrons which allows a chain reaction to be generated in natural uranium (i.e., uranium which has not been enriched). This is despite U-235 making up less than 1% of natural uranium. The remarkable fission cross section of U-235 allows a chain reaction in natural uranium **as long as the neutrons are slowed down**. And this is what happens in a *nuclear reactor*: a chain reaction is generated in natural uranium by slowing down the neutrons.

In order to slow the neutrons down in a nuclear reactor, the uranium has to be surrounded by a material called a *moderator*. The neutrons collide with nuclei in the moderator and lose energy: they slow down. An example of a moderator which is used in nuclear reactors is graphite, which is a form of carbon. A fast neutron which has been emitted from a fissioned nucleus needs to travel through 20 centimetres of graphite, colliding with graphite nuclei on its way, before its speed is sufficiently reduced. So it is clear that a nuclear reactor has to be quite a large structure. In the reactor core, spheres or rods of natural uranium are interspersed with the moderator material, which acts to slow down the neutrons.

So a nuclear reactor is based on a nuclear chain reaction in much the same way as we have seen a nuclear bomb is also based on a nuclear chain reaction. But, because slow neutrons are involved rather than fast neutrons, the energy released by a nuclear reactor is slow and controllable rather than fast and uncontrolled (as in a nuclear bomb). This is also the reason why slow neutrons (and natural uranium) cannot be used to manufacture a nuclear bomb: a nuclear bomb requires fast neutrons and enriched uranium.

And if a nuclear reactor is based on a self-sustaining nuclear reaction, then it has to have a critical mass of material — again, just like in a nuclear bomb. But the inclusion of large amounts of moderator material, and the complex arrangement of fuel rods, made it difficult to calculate the value of that critical mass — unlike the relatively simple critical mass calculation for a nuclear bomb core which was presented in Chapter Five of this book. Hence, the value of the critical mass for a nuclear reactor had to be found from experiment. Richard Rhodes considers the problem: "A slow-neutron chain reaction in natural uranium, like its fast-neutron counterpart U-235, requires a critical mass: a volume of uranium and moderator sufficient to sustain neutron multiplication despite the inevitable loss of neutrons from its outer surface. No one knew the specifications of that critical volume, but it was obviously vast — on the order of some hundreds of tons."

It was clear that in order to calculate the value of the critical mass, and to prove that a nuclear chain reaction was possible, a test reactor would have to be built.

The world's first nuclear reactor

We are so used to the idea of nuclear reactors producing electrical power that it may come as a surprise that the very first nuclear reactor was designed without the slightest interest in its potential to produce power. It has just been explained that a chain reaction in natural uranium in a nuclear reactor is the perfect environment to produce plutonium for nuclear bombs, and it was for this purpose that the first nuclear reactor was built.

To tell the story of the world's first nuclear reactor, we must once again catch up with the itinerant Leo Szilard. When we last left Leo Szilard in 1939 he was just a guest researcher in Columbia University in New York City for three months. Amazingly, in November 1940, Szilard had managed to find himself a proper job at last, and had been added to the Columbia payroll. Szilard was worked hard with Enrico Fermi throughout 1941, trying to create an experimental nuclear reactor. They had been trying to generate a slow-neutron chain reaction in natural uranium, using graphite as a moderator. So far, they had not been successful.

With the attack on Pearl Harbor in December 1941, and the launch of the Manhattan Project, a decision was taken in January 1942 to centralise all reactor research at the University of Chicago. Hence, Leo Szilard was on the move once again.

It was clear that the reactor would be extremely large and would require a lot of space. The University of Chicago was very supportive of the war effort, and agreed that the physicists could use any of the extensive sports facilities.

There were a number of rackets courts under the West Stand of the university's football stadium at Stagg Field. A decision was made to locate the reactor in a doubles squash court.

In his successive reactor experiments, Fermi had to determine how close he was to achieving a sustained chain reaction. In order to measure his progress toward that goal, Fermi calculated a value for the average number of neutrons produced per fission in the reactor. As explained in Chapter Five of this book (the calculation of critical mass), as long as more than one neutron is produced by the fission of a nucleus, then the total number of neutrons will increase over time and a self-sustaining chain reaction will result. The goal for Fermi, therefore, was to ensure that the average number of neutrons produced per fission was more than 1.0. However, in his first attempt at creating a reactor, Fermi calculated that neutron production number to be a disappointing 0.87.

By May 1942, Fermi had improved the purity of the uranium and graphite in his experimental reactor and had managed to improve the neutron production value to 0.995. While this was still short of the value of 1.0 required for a chain reaction, it was believed that further improvements to the purity of the materials would now push the value beyond 1.0. Therefore, at that point, work began on the full-scale reactor.

A total of 45,000 black graphite blocks were required. They were all machined to a standard size approximately the size of a shoebox. The reactor was built in layers on the floor of the squash court. The first layer was purely made of graphite blocks, containing no uranium. The second layer was made of blocks which had two seven-centimetre diameter uranium spheres embedded. The layers alternated in this fashion as the reactor was built up.

The resultant arrangement of the graphite blocks is shown in the following diagram. You can see that some of the blocks have two spheres of uranium embedded in them, whereas some of the blocks have no uranium spheres. The end result is that the uranium spheres form a perfect cubic lattice, with each sphere surrounded by the necessary 20 centimetres of graphite moderator:

Ten control rods made of cadmium were used to keep the reaction under control. The rods were thirteen foot long and were inserted into the reactor. Cadmium has a huge capture cross section for neutrons, so the control rods could be used to dampen the chain reaction if necessary and keep it within safe bounds.

For security reasons, no photographs were taken of the Chicago reactor, but we do have an artist's rendering. At the top of the ladder, you can see one of the control rods poking out of the blocks of graphite:

After 57 layers had been completed, Fermi's measurements of neutron intensity indicated that the reactor would now go critical if all of the control rods were removed. By this point, the reactor was 20 feet high and 25 foot wide. The reactor was completed on December 1st 1942, but it was decided that the experiment would take place the following day.

The temperature the following morning was below zero. A crowd of about forty people gathered on the balcony of the squash court to witness the historic event. As each of the control rods were removed slowly, the neutron intensity increased but then levelled off — the reactor was still subcritical. The last remaining control rod was then withdrawn slowly, with Fermi predicting "Now it will become self-sustaining. The trace on the recorder will climb and continue to climb; it will not level off." Fermi's colleague, Herbert Anderson, describes what happened next: "At first you could hear the sound of the neutron counter, clickety-clack, clickety-clack. Then the clicks came more rapidly, and after a while they began to merge into a roar. Suddenly Fermi raised his hand and said that the pile had gone critical. No one present had any doubt about it."

Now the chain reaction had started, the neutron intensity would keep rising instead of levelling-off. If the control rods had not been reinserted then after an hour-and-a-half the rate of increase would have resulted in a power output of a million kilowatts. But before it would have reached that stage, it would have killed everyone in the room and melted through the concrete in the floor and the underlying rock. Theoretically, there is nothing that can stop a reactor in meltdown before it melts its way to the Earth's core.

The Chicago event was historic. It was the first artificial nuclear chain reaction, the birth of nuclear power, and the first time appreciable energy had been released from the atom. Crucially, it also opened the way to the production of plutonium as a nuclear explosive.

As described earlier in Chapter Four, just eight years earlier, Leo Szilard had crossed the road in Southampton Row in London and had first had the idea of how a nuclear chain reaction might be achieved. Standing on the balcony of a squash court in Chicago, he had now seen his idea become a reality.

The Demon Core

Plutonium is an incredibly dangerous substance. Plutonium is extremely toxic if it is ingested or inhaled, and the radiation from plutonium can also be deadly. The American environmental activist Ralph Nader once claimed that a pound of plutonium could kill eight billion people.

A single plutonium core (sphere of plutonium) was responsible for two separate horrific fatal incidents at Los Alamos. The sphere of plutonium had been created to be used in a series of "criticality experiments" designed to accurately determine the necessary critical mass of plutonium for the bomb. The sphere was only 3.5 inches in

diameter — about the size of an orange. It was designed to be 5% smaller than the critical mass, and therefore safe for experimentation. However, that was a small safety margin, and if any neutrons which were emitted by the core were reflected back into the core then that could cause the core to become critical.

On August 21st 1945, the physicist Harry Daghljan was working alone, performing a criticality experiment using the core. When Daghljan accidentally dropped a tungsten carbide block near the core, the neutrons which were reflected by the block turned the core critical. There was a sudden blue flash — and even the air seemed to glow blue (this is because of the fluorescence of air molecules when they are hit by charged radioactivity). Daghljan quickly threw the brick away, but it was too late: he died 25 days later from radiation poisoning.

Precisely nine months later, Louis Slotin was working with the same core, performing a different criticality experiment. However, Slotin's dangerous technique was unapproved. Slotin had surrounded the core with two hemispheres of neutron-reflecting beryllium. Slotin was keeping the hemispheres apart by using the blade of a screwdriver as a lever. Slotin was full of bravado, and had performed the experiment a dozen times before to various teams of observers, proud of his ability to wield his screwdriver. When Enrico Fermi saw Slotin's experiment he told Slotin that he would be "dead within the year".

The following photograph shows a re-creation of Slotin's experiment showing the hemispheres being kept apart by a screwdriver blade (the spherical core is hidden inside the hemispheres, approximately the same size as the two spheres you can see on the right):

On the day of the accident, Slotin's screwdriver slipped and the two hemispheres came together for a fraction of a second. There was the usual flash of blue light showing that the core had gone critical. The criticality lasted for only half a second before the core expanded due to the heat produced, and was then no longer critical. But the damage was done.

Slotin died nine days later.

As a result of these two fatal incidents by the same core, the core was given the ominous name the "Demon Core". The second of the Demon Core incidents was dramatised in the 1989 movie *Fat Man and Little Boy*. The character of Louis Slotin in the movie was played by John Cusack. The Demon Core sequence is accurate and extremely chilling. The sequence is available on YouTube at the following link:

<http://tinyurl.com/thedemoncore>

Right at the start of the sequence if you look carefully you can see the two hemispheres being kept apart by

nothing more than the blade of Slotin's screwdriver, and you can even see the small spherical plutonium core inside the hemispheres. You can later see Slotin twisting the wooden handle of his screwdriver to move the upper hemisphere up and down. Then, as Slotin's screwdriver slips, you can see the deadly flash of blue light.

After these two fatal incidents, all hands-on criticality experiments at Los Alamos stopped. From then on, remote-controlled machines were used to perform the experiments, with all personnel safely watching TV cameras a quarter of a mile away.

8

DETONATION

In this final chapter we will move on to consider the final step of the process: actual bomb design, and how to detonate a nuclear bomb.

The sex of the bomb

The message from the discussion so far seems to be that the theory behind building a nuclear bomb is fairly straightforward: you just have to assemble a critical mass of fissionable material in order to generate an explosive chain reaction. However, there is another major technical challenge involved in the detonation of a nuclear bomb: there is a need to assemble the critical mass in a very short period of time.

The critical mass must be assembled from smaller sub-critical pieces. A problem arises in that before the critical mass is fully assembled, there is inevitably a short period of time when the total assembled mass is smaller than the critical mass. During this very short window of time, it is possible for a small chain reaction to start in the material. This small chain reaction might be initiated by an external source, for example, a neutron from a cosmic ray. Only a very small amount of the material will be fissioned and the bomb will detonate with a vastly smaller explosive power. This small explosion will blow the rest of the bomb apart before the majority of the material is fissioned. This represents a failure of the nuclear explosive. This problem is called *predetonation*, and the resultant relatively small explosion is called a *fizzle*.

In order to avoid predetonation, it is essential that the entire critical mass is assembled in an extremely short period of time. In practice, this needs to be less than one millisecond.

The simplest way in which a critical mass can be rapidly assembled is to split the critical mass into two sub-critical pieces, and then fire those two pieces together at great speed by using a conventional explosive. An example is presented in the following diagram which shows an assembly mechanism which has been successfully used in a nuclear bomb. The diagram shows a hollow tube of U-235 being fired down a gun barrel towards a bullet of U-235. When the two pieces of U-235 are joined together, the resultant mass will be equal to (or greater than) the critical mass and the bomb will explode:

It might appear rather perverse to fire the hollow tube of uranium onto the bullet, rather than performing the reverse operation by firing a "male" bullet into the hollow tube. In fact for fifty years after the first atomic bomb was constructed it was always believed that the bullet was fired into the tube, and this was always how it was presented in every history book. However, we now know the correct design of the bomb thanks to the investigative work of a

truck driver from Wisconsin named John Coster-Mullen.

Coster-Mullen, together with his son Jason, has built a perfect replica of the Hiroshima atomic bomb. The construction details were laboriously obtained from a huge variety of different sources including interviews with machinists who worked on the bomb, and by forensic examination of photographs of the bomb.

In 1994, as part of his detective work to uncover the secrets of the bomb, Coster-Mullen had a telephone interview with one of the bomb's original engineers named Harlow Russ. Russ was being careful not to divulge classified information, but in the middle of the interview he happened to mention: "You know the projectile was hollow, didn't you?" In other words, Harlow Russ had revealed that a hollow tube was fired onto the bullet — not vice versa as had been assumed. Coster-Mullen had discovered that the "sex" of the bomb was female — not male.

According to the journalist Howard Morland: "Every encyclopaedia in the world, from the Britannica to the World Book, described how the Hiroshima bomb was made, and included a diagram. News articles and school teachers referenced these diagrams. But here's the thing: every single one got it wrong. John Coster-Mullen and his self-published memoir got it right."

The story of John Coster-Mullen — and a discussion about the sex of the bomb — is available at the following link:

<http://tinyurl.com/costermullen>

Coster-Mullen has also published a book called *Atom Bombs* which contains design details of the first atomic bombs. The details are so accurate that this is truly "the book that the Feds tried to ban". In 2005, Coster-Mullen was handed an internal Los Alamos email that described discussions taking place at the highest levels of the Los Alamos National Laboratory to identify a way to quash his book. The book is also permanently banned from sale at the National Museum of Nuclear Science and History in Albuquerque on orders from Sandia National Laboratory. According to Harold Agnew, the former Scientific Director of Los Alamos: "There are drawings in there that are absolutely correct. He's got everything exactly: dimensions, materials, and things that have been really classified. His cross-section drawings are the most incendiary portions of his book."

Here is a photograph of me looking suitably awestruck at the cross-sectional diagrams in my copy of John Coster-Mullen's book *Atom Bombs*:

Implosion

Let us now calculate how long it takes to assemble the critical mass using this method. The following calculation is from Bruce Cameron Reed's book *The History and Science of the Manhattan Project*.

The gun muzzle velocity will be approximately 1,000 metres/second, and the lengths of both the projectile tube and the target cylinder will be approximately 10 cm. These measurements are shown on the following diagram:

At that speed of travel, it will take the projectile piece about 100 microseconds to completely surround the target piece. So, using the "gun assembly" mechanism, it is possible to assemble a critical mass in approximately 100 microseconds. Hence, this method can be used to create a critical mass of uranium (it was stated earlier that assembly time for a critical mass of uranium needs to be less than one millisecond).

However, it was discovered that the problem of predetonation was more serious for a plutonium bomb. The problem arises because plutonium was found to have a far higher rate of spontaneous fission than uranium. Spontaneous fission can occur when a nucleus splits randomly of its own accord, without being hit by a neutron. Because of random neutrons being produced by spontaneous fission, it was likely that the chain reaction would start before the projectile piece had completely surrounded the target piece, which would result in a much smaller "fizzle" explosion. This meant that the previously-described gun assembly mechanism taking approximately 100 microseconds would be too slow to detonate a plutonium bomb. As an alternative, a more sophisticated "implosion" method was developed at Los Alamos.

In order to understand how the implosion method works, let us remember the principle which underlies the calculation of the critical mass. As described in Chapter Five, a critical mass of material is created when the amount of neutrons escaping through the surface area of the material is less than the amount of neutrons being generated within the material. So the obvious way to create a critical mass is to add more material. But it is clear that an alternate method would be **to reduce the surface area of the material**, and thereby reduce the number of neutrons escaping. This can be achieved by compressing the material, and increasing its density in the process.

The implosion method works by surrounding the bomb core with conventional high-explosive. The resultant explosion can have a huge compressive effect, pushing inward at a speed of several kilometres a second and achieving pressures comparable to those at the Earth's core. It takes only about a microsecond to compress the core to criticality, which is clearly far faster than the 100 microseconds it takes for the gun assembly method. So the implosion method avoids the predetonation problem of plutonium.

However, it is extremely difficult to compress a heavy metal object in a symmetrical manner using implosion. When the method was first proposed, there were many in Los Alamos who thought it was not possible. The problem was compared to the problem of crushing a full beer can without spilling any beer. A brilliant young physicist called Richard Feynman who was working at Los Alamos considered the implosion method and simply said "It stinks".

The main problem arises because simply smearing a uniform spherical coating of high-explosive around the bomb core will not produce a smoothly symmetrical compression of the core. To understand why that is the case, consider the following diagram:

The diagram shows a uniform coating of conventional explosive (shaded in light grey) spread evenly around a bomb core. You can see that a series of rectangular detonators are inserted into the explosive at a regular spacing.

In the diagram, let us just consider the top detonator. Because of the curvature of the bomb core, you can see on the diagram that the distance from that detonator to a point A on the surface of the bomb core is slightly shorter than the distance from the detonator to a point B on the surface of the bomb core. What this means is that the wave of detonation of exploding material spreading from the detonator will reach point A slightly earlier than it will reach point B. As a result, the compression will be applied earlier to point A and the result would be to deform the bomb core — like crushing and deforming a beer can in your hand — rather than applying a smooth compression at all points at the same time.

Clearly, the key to achieving a smooth compression is to ensure that the detonation wave hits all points on the surface of the bomb core at the same time. This can be achieved by using a combination of fast-burning explosive and slow-burning explosive, as shown on the following diagram:

The previous diagram shows two different types of conventional explosive being used, which burn at different speeds. The fast-burning explosive is shown in the lighter grey than the slow-burning explosive.

Because of this arrangement of fast-burning and slow-burning explosives, you will see that even though the distance from the top detonator to point A is shorter, the detonation wave will have to pass through more of the slower explosive. Whereas the distance from the top detonator to point B is longer, but the detonation wave will only pass through the fast explosive to get to point B. As a result, the detonation wave reaches both points A and B at the same time, applying equal compression to all points at the same time. The result is a smooth compression of the bomb core.

These arrangements of explosive charges have the effect of "bending" the emerging shockwave from the detonator so that the shockwave meets the entire surface of the core at the same time. In other words, the shockwave is bent in order to fit the shape it is intended to squeeze. These arrangements of explosives are sometimes called explosive lenses because of the similarity to the way an optical lens bends a light wave, based on the similar principle that light travels at different speeds through different media.

Interestingly, in modern implosion bombs the surrounding explosives are often modified by random amounts so that the timing for individual detonators has to be correspondingly modified. The timing device is then stored away

from the bomb. In this way, even if a bomb is stolen by a terrorist group they will not be able to explode it without the corresponding custom timing device. This technology — called a Permissive Action Link (PAL) — was developed by the U.S. in the 1960s and freely-given to the Soviet Union to make the world a safer place.

So that basically describes the structure of a plutonium bomb based on implosion. However, there are two structures that have not been described yet, and these are shown on the following diagram:

Around the plutonium core can be seen the *tamper*, which is a jacket of heavy metal. This acts to increase the yield (the explosive power) of the explosion, and it does this in two ways. Firstly, the sheer weight of the tamper restricts the expansion of the core due to the extreme heat generated in the core, thus giving the core more time to fission completely. It is important that the core does not expand too rapidly as once its surface area grows too large it no longer represents a critical mass and the chain reaction stops. The tamper also acts to reflect neutrons back into the core and stop them escaping through the surface of the core.

At the centre of the core you will see a small black sphere, about the size of a golf ball. This is called the *initiator*, and it is a neutron source which is designed to produce the very first neutron of the chain reaction.

The initiator is usually made of a small piece of the radioactive element polonium surrounded by some beryllium, which is a very light metal. This arrangement is known to provide a good source of neutrons. Energetic alpha particles from the polonium can knock neutrons out of the beryllium nuclei. When the core is crushed, the beryllium mixes with the polonium sending out a shower of millions of neutrons — enough to kick-start the chain reaction.

So that completes the design of the plutonium implosion bomb. In the following final section of this book, we will now see how a bomb such as this was used in the very first man-made nuclear explosion.

Trinity

In the middle of the barren New Mexico desert, 160 miles south of Los Alamos, there stands a black stone obelisk, about 12 foot high. The obelisk is made of local lava-rock. There is a plaque on the obelisk on which just a few words are written: "Trinity Site Where the World's First Nuclear Device Was Exploded on July 16, 1945."

The obelisk marks the hypocentre of the explosion.

There are several reasons why the site was chosen. The site had to be flat to allow for accurate measurements of the explosion, the site had to have little wind to prevent the spread of radioactive fallout, and it was preferred to have a site reasonably close to Los Alamos.

The following map shows the location of the Trinity test site. You can see it lies about 160 miles south of Los Alamos, and about sixty miles away from the town of Alamogordo:

The decision was taken that a test of the plutonium bomb was essential, because of the uncertainties about the implosion mechanism. The plutonium had cost about 250 million dollars to produce, and if the test failed then the plutonium could be recovered and re-used.

The plutonium core and the surrounding shell of high explosive were manufactured at Los Alamos and transferred separately to the Trinity test site. The plutonium core left Los Alamos first on the afternoon of Thursday July 12th (the test was planned for the early morning of the following Monday). The orange-sized piece of metal was given the VIP treatment, driven to Trinity on the back seat of an army sedan with a convoy of armed guards riding in front and behind. The high explosive was driven overnight to avoid traffic and potential accidents, taking eight hours to travel at thirty miles an hour to Trinity.

At Trinity, a temporary base camp was constructed nine miles away from where the bomb was to be detonated. The following photograph shows the Trinity base camp:

The bomb was to be detonated at the top of a steel tower, one hundred feet tall. There was an oak platform at the top of the tower which could support those working on the bomb, and there was a hole in the platform through which the bomb could be raised. The platform was surrounded on three sides by corrugated iron, making a shack. Here is a photograph of the Trinity tower:

At 1pm on the Friday afternoon, the high explosive shell arrived at the tower. The plutonium core arrived later in the afternoon. Final assembly of the bomb took place in a canvas tent at the base of the tower. The bomb assembly group was headed by Norris Bradbury. It was Bradbury who finished the bomb assembly in the late evening under floodlights.

The following morning, the Saturday, the canvas was removed and the bomb was hoisted to the top of the tower

by an electric winch. When the bomb was at the top of the tower, the detonators were inserted into the bomb. Here is a photograph of Norris Bradbury standing by the fully-assembled bomb at the top of the tower:

The power cables you can see attached to the bomb are attached to the detonators which were spaced around the high-explosive shell. The power cables were so thick because a new type of detonator was developed specifically for the plutonium bomb. If you remember back to the discussion about implosion earlier in this chapter you will remember the importance of the shockwave hitting all points of the spherical core at the same time in order to achieve smooth compression of the core. However, all that work on explosive lenses would have been pointless if all the detonators did not all detonate at precisely the same time.

In order to achieve that microsecond accuracy of detonation, a new type of detonator was developed called an exploding bridge wire detonator. The detonator was made of a thin wire through which a pulse of extremely high current was passed. The current needed to be in the region of 100 kiloamps, which explains the large power cables attached to the bomb. The wire instantly becomes hot and literally explodes — starting the detonation. Crucially, all the detonators will detonate within a microsecond when the pulse of high current is applied.

The detonators were inserted on the Saturday, so Sunday became a day of waiting before the planned detonation of the bomb early on Monday morning. An intense thunderstorm hit the site at 2 a.m. on Monday morning. According to Isidor Rabi: "It was raining cats and dogs, lightning and thunder. We were really scared that this object there in the tower might be set off accidentally. So you can imagine the strain on Oppenheimer." The detonation was delayed until just before dawn. A telephone call was made to the governor of New Mexico warning him that he might have to declare martial law if the explosion caused a panic.

At 5:30 a.m., the weather had cleared. The detonation sequence was controlled from inside an earth-covered concrete control centre six miles from the bomb tower. Oppenheimer would watch the explosion from that shelter.

Busloads of visitors from Los Alamos were ready to view the explosion from the summit of Compañia Hill, twenty miles from the bomb. The crowd included many of the physicists who had worked on the bomb. It was dark and cold, and the tension was almost unbearable. They had been advised to lie face down on the ground, with their feet pointing toward the explosion. They had also been given welding glasses to protect their eyes. However, Richard Feynman refused the glasses, later claiming to have been the only person to have viewed the explosion with no eye protection. According to one observer: "It was an eerie site to see a number of our highest-ranking scientists seriously rubbing sunburn lotion on their faces and hands in the pitch-blackness of the night, twenty miles from the expected flash."

In the control centre just six miles from the bomb, the atmosphere was so tense that Oppenheimer could hardly breathe. He held onto a post to steady himself and stared directly ahead as the last seconds ticked away.

5 ... 4 ... 3 ... 2 ... 1 ... 0 ...

First came the instant blast of light. Pitch black night suddenly turned to the most intense daylight, three times brighter than the brightest Sun. Those lying on the ground at Compania Hill, twenty miles from the explosion, saw distant hills suddenly brightly illuminated as if by a rising Sun.

Isidor Rabi at Base Camp, nine miles from the explosion, described the light: "We were lying there, very tense, in the early dawn. Those ten seconds were the longest ten seconds that I ever experienced. Suddenly, there was an enormous flash of light, the brightest light I have ever seen or that I think anyone has ever seen. It seemed to last forever. You would wish it would stop; altogether it lasted about two seconds. Finally it was over, and we looked toward the place where the bomb had been; there was an enormous ball of fire which grew and grew and rolled as it grew; it went up into the air, in yellow flashes and into scarlet and green. It looked menacing. It seemed to come toward one. A new thing had just been born; a new control; a new understanding of man, which man had acquired over nature."

Philip Morrison described the other overwhelming sensation of the radiant heat: "The thing that got me was not the flash but the blinding heat of a bright day on your face in the cold desert morning. It was like opening a hot oven with the Sun coming out like a sunrise."

Norris Bradbury explained the difficulty in making sense of something which no one had ever seen before: "Most experiences in life can be comprehended by prior experiences, but the atom bomb did not fit into any preconceptions possessed by anybody."

The bomb had exploded with force of twenty thousand tons of TNT. The temperature at the centre of the explosion was four times greater than the temperature at the centre of the Sun. The resultant pressure was more than a hundred billion times the pressure at the surface of the Earth, and was the greatest pressure ever to exist on the Earth. In Arizona, 150 miles away, it was reported that a woman was puzzled why she saw "the Sun come up and go

down again".

The greatest physics experiment of all time had been a success.

Robert Oppenheimer, the director of the Manhattan Project, was in the control centre just six miles from the bomb. His brother Frank, also a physicist, was by his side. After the incredibly tense last few minutes, Oppenheimer could breathe freely at last.

They both walked outside and climbed on top of the earth-covered bunker. Frank turned to face his brother — who within the next few days would become the most famous man in the world — and said "It worked".

Oppenheimer looked at the immense mushroom cloud now climbing high over the desert.

"Yes", said Oppenheimer, "It worked".

A highly-detailed and technical description of the science of the atomic bomb.

The Making of the Atomic Bomb by Richard Rhodes

The definitive account of nuclear physics leading up to the development and use of the first atomic bomb.

Trinity by Jonathan Fetter-Vorn

A graphic novel of the development of the atomic bomb, with plenty of good science. Extremely well done.

APPENDIX:

CALCULATING THE CRITICAL MASS

This Appendix is highly-mathematical, so only read it if you are confident about your mathematical abilities.

This Appendix contains the detailed calculation of the value of the critical mass, and continues from the discussion in Chapter Five. We will start by calculating the flow of neutrons out of the material. This initial section is going to introduce some mathematical terminology which is likely to be new to you. Please do not worry about it or get bogged-down by the details. All we will need is the result at the end of this section which is a well-established result in mathematics.

The spread of particles through a substance (for example, the spread of dust particles in air, or the spread of a chemical through a liquid) is called *diffusion*. The theory behind diffusion has been well-studied, and there is a branch of physics specifically called *diffusion theory*. We can apply precisely the same theory to consider the flow of neutrons out of a volume (after all, neutrons are just another type of small particle — like dust particles).

To cut a long story short, in this section we will be seeing that diffusion theory tells us that the flow of neutrons out of the material is described mathematically by the *Laplacian* operator. All we will be needing from this section is to find the formula for the Laplacian operator.

OK, so let's go ...

As described in Chapter Five, the value of the neutron current is proportional to the gradient of the number of neutrons. So, using the derivative notation, we can express the value of the neutron current, j , as:

$$j = -D \frac{dN}{dr}$$

where N is the number of neutrons in a volume of the fissionable material, and r represents the distance from the centre of the material. Assuming the fissionable material to be in the shape of a solid sphere, then r represents the distance from the centre of the sphere towards the edge of the sphere.

You will see that there is another constant in the expression: D is a constant called the *diffusion coefficient* which is a fixed property of the fissionable material. We will be calculating the value of D later in this chapter.

The minus sign in the formula arises because the current is from the larger neutron concentration to the smaller neutron concentration, whereas a positive gradient would normally be from low to high (as in climbing a hill, which would represent a positive gradient).

But if the value of the neutron current remains the same over a distance then the number of neutrons entering a volume of the material (the current in) will be the same as the number of neutrons leaving the volume of the material (the current out). In other words, the number of neutrons in that volume will be unaltered. But what we are really interested in is the **change** in the number of neutrons in that volume. That will then give us the rate at which the neutrons are spreading into space, escaping out of the volume. Mathematically, this is called the *divergence*.

So if we want to calculate the divergence (the change in the number of neutrons in a volume) then we have to consider the **change** in the value of the neutron current. In other words, we have to consider the derivative of the neutron current. But we calculated earlier that the value of the neutron current, j , is given by:

$$j = -D \frac{dN}{dr}$$

which is, clearly, a derivative itself. So to find the change in the number of neutrons we need to take the derivative of a derivative. Therefore, the change in the number of neutrons in a volume is calculated by the derivative of j :

$$-D \frac{d}{dr} \left(\frac{dN}{dr} \right)$$

What we have done here is show that the change of the number of neutrons in a volume is given by the divergence of the gradient. In mathematics, it is well-known that the divergence of the gradient is called the *Laplacian*. As I said earlier, this is all we need to know from this section. The mathematical form of the Laplacian is well-known and you can even find it on the Wikipedia page for the Laplacian.

The Laplacian for spherical coordinates (which is what we want) is given halfway down the Wikipedia page:

<http://tinyurl.com/laplacianspherical>

It does indeed have the two derivatives (a derivative of a derivative), which is what we just calculated. You will see that the precise form is:

$$-D \frac{1}{r^2} \frac{d}{dr} \left(r^2 \frac{dN}{dr} \right)$$

Creating the equation

So now we have a formula describing the flow of neutrons out of a volume. We are making good progress.

As stated at the start of Chapter Five, the critical mass occurs when the loss of neutrons through the surface of a volume is equal to the build-up of neutrons inside that volume. In Chapter Five we calculated that the rate of increase in the number of neutrons in a volume of the material is given by:

$$\frac{(\nu - 1) N}{\tau}$$

Putting this value equal to the previous equation for the loss of neutrons through the surface of that volume gives:

$$-D \frac{1}{r^2} \frac{d}{dr} \left(r^2 \frac{dN}{dr} \right) = \frac{(\nu - 1)}{\tau} N$$

Dividing both sides by D and N , and changing the sign of both sides, gives:

$$\frac{1}{N} \left[\frac{1}{r^2} \frac{d}{dr} \left(r^2 \frac{dN}{dr} \right) \right] = -\frac{(\nu - 1)}{D\tau}$$

This equation describes the distribution of neutrons in a critical mass. So now all we need to do is solve the equation and find the shape of the distribution. However, I must admit, the equation does look very complicated! But do not worry — we will find the equation has a surprisingly simple solution.

And in order to solve the equation, we are going to use a quite amazing tool ...

The genius of Mr. Wolfram

We now have an equation we need to solve to find the value of N , which will tell us the distribution of the number of neutrons within the fissionable material. You will see that the equation includes the value of N , and also the derivative of N . Equations which include combinations of variables and their derivatives like this are called *differential equations*.

Differential equations can capture the dynamics of a complex system in which elements are moving at different rates to one another. As a result, differential equations are very useful tools for describing physical phenomena such as heat flow or the motion of waves, and are used throughout physics and engineering. But differential equations can also be used to describe any complex system with "moving parts" such as biology and economics.

The **solution** of differential equations then takes a central role in many science problems. The problem can be complex because differential equations can come in a huge variety of different forms. For many simple forms, the method of solution is well known and described in mathematical textbooks. But when more complicated situations are described (for example, modelling the movement of airflow in weather forecasting), the differential equations might have no simple solution and it is then necessary to use a powerful computer to perform repeated calculations, slowly converging to a solution.

Our attempt to calculate the critical mass of an atomic bomb has resulted in the creation of a differential equation, and we now have to solve that equation. However, the task of solving differential solutions just got a whole lot easier thanks to the artificial intelligence website Wolfram Alpha.

The driving force behind Wolfram Alpha is the controversial mathematical genius Stephen Wolfram. Wolfram was a child prodigy who published physics papers at the age of 15. In 1988 he left academia to develop the software package called Mathematica. Mathematica can be used to solve complex problems, and to visualise solutions. The program was an instant success and made Wolfram his fortune.

In 2002, Wolfram released a controversial book called *A New Kind of Science* in which he claimed that great complexity arises from simple rules called *cellular automata*. Wolfram claimed to be able to use these simple programs to model almost any complex system. Unfortunately, the book was widely-criticised for its arrogant tone and unscientific approach, and there was the suggestion that the project represented a huge ego-trip for Wolfram. It would appear that even geniuses have their failings.

In 2008, Wolfram released the Wolfram Alpha search engine (or "computational knowledge engine" as they call it). The search engine technology behind Wolfram Alpha claims to be unique in that it can answer questions which are posed in everyday language. I thought I would test this claim of Wolfram Alpha, so I went to its webpage:

<http://www.wolframalpha.com>

In the Wolfram Alpha search box I entered the question "Who was the oldest Beatle?" Sure enough, in just a few seconds it came back with the correct answer "John Lennon". In contrast, entering the same query into Google just returns the usual long list of search results. It is clear that Wolfram Alpha is attempting to do something very different: it is trying to **understand** your question, and **calculate** an answer (this is opposed to the usual search engine method of just matching character strings). This is true artificial intelligence: a brain on the web.

What makes Wolfram Alpha particularly interesting for our particular problem is that some of the mathematical processing ability of Mathematica has been incorporated into Wolfram Alpha. This makes Wolfram Alpha incredibly useful for solving any mathematical problems you might encounter. For example, I was surfing the net recently when I saw a mathematical puzzle asking me to find the value of x in the following equation:

$$\sqrt{x+15} + \sqrt{x} = 15$$

Can you solve the puzzle and calculate the value of x ?

Well, it looked a bit of a brain-ache to me, so I went straight to the Wolfram Alpha website:

<http://www.wolframalpha.com>

and in the search box at the top of the page, I typed the puzzle in English just as it is written:

square root of (x+15) plus square root of x equals 15

So the search box looked like:

Try it yourself. Then click the icon at the extreme right of the search box to start Wolfram Alpha computing the solution. After a few seconds computation, it returns the correct answer, giving you the value of x (you may have to scroll down the page to see the solution). I won't tell you what the answer is — try it yourself!

So Wolfram Alpha can understand most mathematics problems (or any question) which you type in natural English. That makes it very handy for solving a wide range of puzzles. In fact, in typically modest Wolfram style, it claims to have the ambitious long-term goal of "computing whatever can be computed about anything".

Of particular interest, Wolfram Alpha is able to recognise a differential equation and find its solution — and that's good news for us because we are going to use Wolfram Alpha to solve our differential equation ...

Solving the equation

If you remember, this is our differential equation:

$$\frac{1}{N} \left[\frac{1}{r^2} \frac{d}{dr} \left(r^2 \frac{dN}{dr} \right) \right] = - \frac{(v-1)}{D\tau}$$

Yes, it looks very complicated, but as I said earlier we will find it has a very simple solution.

I am going to make a temporary modification to this equation purely for reasons of brevity and convenience, and also to make it easier to enter into Wolfram Alpha. You will see that the right-hand side of the equation is formed from a combination of various constants, which are based on the properties of the fissionable material. The end-result will just be another different constant. So, purely so that I don't have to write out the same long expression each time, let us replace the right-hand side of the equation with the constant value, k . In other words:

$$k = \frac{(\nu - 1)}{D\tau}$$

In which case, our differential equation then becomes:

$$\frac{1}{N} \left[\frac{1}{r^2} \frac{d}{dr} \left(r^2 \frac{dN}{dr} \right) \right] = -k$$

When we finish our calculation, we will replace k with the original combination of constants.

In order to solve this equation, we have to discover the form of the distribution of neutrons which is described in the equation by N , with the value of N varying as we move from the centre of the material to the edge of the material. We are going to use Wolfram Alpha to solve this equation in rather a backward fashion. We are going to suggest a likely candidate solution for N , and then use Wolfram Alpha to check if that potential solution satisfies the differential equation. If that is shown to be the case, then we have a verified solution for our equation and we would have achieved success. However, if the solution is only slightly incorrect then we will need to slightly modify our candidate solution and run it through Wolfram Alpha again.

So what type of candidate solution might we try to describe the distribution of neutrons? Well, we would imagine that the number of neutrons in the material would be highest in the centre of the material as that is the region which is furthest from the edge. Conversely, we would imagine that the number of neutrons would be lowest at the edge of the material as that is where the losses occur. And in between those two extremes we would imagine the number of neutrons would decrease smoothly along a curve.

This suggests a smooth curve like a sine wave, and there is a simple potential candidate solution which fits the bill:

$$N(r) = \frac{\sin(r)}{r}$$

Let us now use Wolfram Alpha as a visualization tool to help us see what this candidate solution looks like. Will it resemble the expected distribution of neutrons in a critical mass? To find out, go to the Wolfram Alpha website:

<http://www.wolframalpha.com>

In the search box at the top of the page, enter the following string into the search box (take care to note the first "minus pi" term):

plot (sin(r)/r) from r=-pi to r=pi

Your Wolfram Alpha search box should then look like this:

Enter what you want to calculate or know about:

plot (sin(r)/r) from r=-pi to r=pi

Web Apps Examples Random

Click the icon at the extreme right of the search box to start Wolfram Alpha computing the solution. After a few seconds computation, you will be rewarded with the following graph:

You can see the distribution of neutrons is at its highest in the middle of the graph, which represents the centre of the fissionable material ($r=0$). There is then a smooth decline in the number of neutrons toward the edge of the material as losses are higher nearer the edge. The number of neutrons is zero at the edge as any neutrons produced by fission are free to fly straight out of the material, so there is never any opportunity there for the number of neutrons to build up.

So the general shape of this graph looks much as we would expect. This gives us confidence in our candidate solution.

If you are stuck and having problems getting Wolfram Alpha to work correctly, I have already entered the correct data and generated the correct graph. So, only if you are stuck, the following link should always work, taking you directly to the correct page showing the graph:

<http://tinyurl.com/neutrongraph>

For our next step, we will use a different feature of Wolfram Alpha: its capability to solve differential equations. To recap, our candidate solution is:

$$N(r) = \frac{\sin(r)}{r}$$

Can this really be the solution we are seeking? We might have our doubts as it does seem to be rather simple. We need to check to see if this potential solution satisfies our differential equation. To do that, we need to replace both occurrences of N in our differential equation with $\sin(r)/r$. That gives:

$$\frac{1}{\frac{\sin(r)}{r}} \left[\frac{1}{r^2} \frac{d}{dr} \left(r^2 \frac{d \frac{\sin(r)}{r}}{dr} \right) \right] = -k$$

We will check if this is the correct solution by using Wolfram Alpha to calculate the value of the left-hand side of the equation, and checking that the result is equal to minus k (the right-hand side of the equation).

So return to the Wolfram Alpha webpage and carefully enter the following expression as a single continuous line into the search box:

1/(sin(r)/r) * 1/(r squared) * derivative of ((r squared) * derivative of (sin(r)/r))

This expression represents the left-hand side of the previous differential equation. Compare the expression with the left-hand side of the differential equation and see if you can spot that the various elements in the two forms correspond to each other.

Your Wolfram Alpha search box should now look like this:

Click the icon at the extreme right of the search box to start Wolfram Alpha computing the solution. After a few seconds computation, it should come back with its answer:

Input interpretation:

$$\frac{1}{\frac{\sin(r)}{r}} \times \frac{1}{r^2} \times \frac{\partial}{\partial r} \left(r^2 \times \frac{\partial \sin(r)}{\partial r} \frac{1}{r} \right) \leftarrow \text{Correct equation}$$

[Open code](#)

Result:

-1 \leftarrow **Close to the correct result**

Download page POWERED BY THE WOLFRAM LANGUAGE

If everything has gone correctly then at the top of the answer you should see that Wolfram Alpha has correctly interpreted the input string into the correct form of the differential equation. And underneath that you will see that Wolfram Alpha has calculated the value of the expression and found that it is equal to minus one.

If you are stuck and having problems getting Wolfram Alpha to work correctly, I have already entered the correct data and the computation worked correctly for me. So, only if you are stuck, the following link should always work, taking you directly to my results page:

<http://tinyurl.com/candidatesolution>

The result of minus one is an encouraging result, though it is not quite correct. We were hoping that the result would be equal to the right-hand side of our differential equation, which is minus k . But minus one is very similar to minus k , so all we have to do is tweak our candidate solution slightly.

Clearly, in order to get a result of minus k , our candidate solution will have to include the value of k somewhere in it. So let us modify our candidate solution slightly by including the value of k in some way. With that in mind, let us try this new candidate solution for the distribution of neutrons:

$$N(r) = \frac{\sin(r\sqrt{k})}{r}$$

You will see that the square root of k has been added to the candidate solution. Let us now check if that satisfies our differential equation (which has now become even more complicated!):

$$\frac{1}{\frac{\sin(r\sqrt{k})}{r}} \left[\frac{1}{r^2} \frac{d}{dr} \left(r^2 \frac{d}{dr} \frac{\sin(r\sqrt{k})}{r} \right) \right] = -k$$

Let us enter the left-hand side of this equation into Wolfram Alpha and see if it gives us the answer we want. So return to the Wolfram Alpha webpage and carefully enter the following expression as a single continuous line into the search box:

1/(sin(r * square root of k)/r) * 1/(r squared) * derivative of ((r squared) * derivative of (sin(r * square root of k)/r))

Once again, click the icon at the extreme right of the search box to start Wolfram Alpha computing the solution. After a few seconds computation, it should come back with its answer:

The screenshot shows the Wolfram Alpha interface. Under "Input interpretation:", the input is displayed as $\frac{1}{\frac{\sin(r\sqrt{k})}{r}} \times \frac{1}{r^2} \times \frac{\partial}{\partial r} \left(r^2 \times \frac{\partial}{\partial r} \frac{\sin(r\sqrt{k})}{r} \right)$. A large black arrow points from this expression to the text "Correct equation". Below this, under "Result:", the answer is shown as $-k$. A large black arrow points from $-k$ to the text "Correct result!!". At the bottom, there is a "Download page" link and the text "POWERED BY THE WOLFRAM LANGUAGE".

Hooray! Wolfram Alpha has calculated that the result is equal to minus k , which is the correct result we were looking for (minus k was the value on the right-hand side of our differential equation). So our complicated differential equation turned out to have a really simple answer: the accurate formula for the distribution of neutrons in our critical mass is given by:

$$\frac{\sin(r\sqrt{k})}{r}$$

If you are stuck and having problems getting Wolfram Alpha to work correctly, I have already entered the correct data and the computation worked correctly for me. So, only if you are stuck, the following link should always work, taking you directly to my correct results page:

<http://tinyurl.com/resultspage>

If you followed all the steps and everything worked correctly, then congratulations! Now, for the last step, let's put some actual numbers into this result and calculate the value for the critical mass in terms of kilograms.

Calculating the critical mass

We have now done the hard part of this calculation. The rest is now relatively simple.

To recap, we have shown that the distribution of neutrons in our critical mass is described by:

$$\frac{\sin(r\sqrt{k})}{r}$$

To obtain the value of r when we have a critical mass of the material, we will use our knowledge of the properties of the edge of the critical mass. In solving a differential equation, this is called a *boundary condition*.

We know that the net amount of neutrons produced at the edge will be the smallest value as that is where neutron losses out of the material are largest. From our high-school knowledge of trigonometry we know that the sine function reaches a minimum at π radians (or, equivalently, 180 degrees). Indeed, if you look at our earlier graph showing neutron distribution, you will see that it reaches zero when the horizontal scale is at π radians. So, in the previous formula, with r set equal to the critical radius, R_c , that means the contents of the bracketed term must be equal to π .

So, just considering the contents of the bracketed term:

$$R_c \sqrt{k} = \pi$$

Let us now replace k in this equation with the combination of constants which k represents (remember, we did the reverse substitution earlier). The equation now becomes:

$$R_c \sqrt{\frac{\nu - 1}{D\tau}} = \pi$$

Squaring both sides of the equation gets rid of the square root:

$$R_C^2 \left(\frac{\nu - 1}{D\tau} \right) = \pi^2$$

Rearranging the elements of this equation gives:

$$R_C^2 = \frac{\pi^2 D\tau}{\nu - 1}$$

Which is the formula for the critical radius which you will find in Section 10 of the *Los Alamos Primer* which deals with the calculation of the critical mass.

Let us take the square root of both sides to get our final result for the critical radius:

$$R_C = \sqrt{\frac{\pi^2 D\tau}{\nu - 1}}$$

And that's it! That is the final equation for the critical radius of the critical mass! If you managed to follow all the steps — and completed the Wolfram Alpha exercises on your computer — then you can genuinely tell your friends that you used a computational knowledge engine to solve a differential equation to calculate the distribution of neutrons in a nuclear bomb core. If they are not impressed by that — then get new friends.

Let us now put numbers into this formula to get a value for the critical mass:

- If you remember it was explained in Chapter Five that ν is the average number of neutrons produced from the fission of one nucleus, which for uranium-235 is equal to 2.52.
- Also explained in Chapter Five, τ is the average time between fissions. This is a very short period of time, only a few nanoseconds. As a result, a nuclear explosion releases all its energy in just a microscopic fraction of a second. To be precise, τ is equal to only 8.1×10^{-9} seconds.
- D , which was introduced earlier is the diffusion coefficient. D is calculated from the average distance between collisions (the *mean free path*) which is 0.029 metres, multiplied by the velocity of the neutrons which is 1.7×10^7 metres/second, divided by the number of dimensions of space which is 3. That means D is equal to 1.6×10^5 metres²/second.

If you substitute these three values into the previous formula for the critical radius you will get the result that the critical radius of uranium-235 is 9.1 centimetres.

[4] A third type of radiation called *gamma* radiation was discovered later. Gamma radiation is a form of high-energy electromagnetic radiation (such as light or X-rays). We will not be considering gamma rays further in this book.

[5] This echoed a discovery in 1932 by Marie Curie's daughter Irène and her husband Frédéric Joliot who had considered alpha particle bombardment of light elements.

[6] *The Cosmic Origins of Uranium*, World Nuclear Association, <http://tinyurl.com/uraniumorigins>

[7] This effect can also be understood in a different way. Because we are dealing with particles, quantum mechanical effects dominate. Every particle has an associated radius called the *de Broglie wavelength* which can be understood as being the cross section of a point particle. A slow-moving neutron will have low energy and will see a larger de Broglie wavelength of the nucleus, which means a larger fission cross section.

THE PHYSICS OF CONSCIOUSNESS

Here are six questions. I would like you to answer either "yes" or "no" to each question:

- Is a human being conscious? (Presumably you would answer "yes" to this question).
- Is a chimpanzee conscious?
- Is a dog conscious?
- Is an ant conscious?
- Is a computer conscious?
- Is the internet conscious?

Maybe you answered "yes" to all six of those questions, but I imagine most people would have started saying "yes" then at some point they would have felt that a threshold had been crossed and they would have started to say "no", the object was not conscious.

I am not presenting these questions as a test to see if you give "right" or "wrong" answers. I certainly do not know the correct answers myself, and I do not even know if there is such a thing as a right or wrong answer to a few of these questions. I am merely presenting these questions to emphasize how difficult it is to define consciousness, and how difficult it is to detect the presence of consciousness.

Even though it is very difficult to define a feeling, we might ask "what is consciousness?" It might be said it is an awareness, a perception of one's self and the world around you. It is an awareness that you exist as an independent thinking entity.

I hope you get the message that it is very difficult to describe consciousness in anything but very vague terms. However, that is not to say the task of recognising consciousness is impossible. In the late 1960s, the psychologist Gordon Gallup was shaving himself in the mirror when he got the idea for a consciousness test which is now called the *mirror test*. The aim of the test is to determine if an animal has visual self-recognition, which is believed to be a measure of self-awareness. In the test, a mark is discreetly written on the forehead of an animal (for example, a chimpanzee) so that the animal is not normally capable of seeing the mark. The animal is then given access to a mirror and the reaction of the animal is observed. If the animal uses the mirror to recognise and investigate the mark, then that would appear to show that the animal perceives the reflected image as itself. This seems to suggest that there is some inner awareness of self — something which is often considered to be a key element of consciousness.

The following image shows an actual example of the mirror test being performed on a baboon:

However, so far only humans, chimpanzees, dolphins, and a single very clever elephant have passed the mirror test. Are we really suggesting that only those animals are conscious? Are we suggesting that dogs, cats, bears, and all those other animals are not conscious? Is the mirror test a reliable test of consciousness? In other words, is self-awareness a necessary factor of consciousness? We shall be considering these questions later in this book.

Perhaps it is easiest to admit that consciousness is best described in fuzzy terms as just a feeling, without strict definition: if you are currently wondering what consciousness is, then you must be conscious. It is the feeling you are having right now.

It is this vague and subjective definition of consciousness that has made it an unattractive and unpopular subject for physicists. And the few physicists who have dared to treat the subject seriously have generally, unfortunately, not found their work particularly well-received by the physics community. The real problem with the field is that it is not possible to test — or, more accurately, falsify — hypotheses about consciousness. Everyone seems to have their own personal hypothesis, their own personal theory. However, unlike physics, it is not possible to test those theories (how can you perform experiments on "feelings"?) to discover which hypotheses are incorrect. So, unlike physics, it is not possible to winnow-out the weak theories: there is no natural selection, no "survival-of-the-fittest" process for those theories. As a result, not only does the field not advance, but it gains a reputation for being unscientific — and best avoided by physicists. The field has therefore mainly been studied by neuroscientists and philosophers, with several valuable new insights coming from the neuroscientists. We shall also be seeing later that the neuroscientists are developing tests for consciousness, so consciousness research should no longer be considered "untestable".

This book, however, will take a slightly different approach. In this book, we will be tackling the problem from the viewpoint of physics, mathematics, computer science and artificial intelligence — and even some electronics.

But, before we start our quest to uncover the mystery of consciousness, there are a couple of principles (or problems) of which you should be aware ...

The mind-body problem

In the 17th century, René Descartes presented a rather direct explanation for consciousness. Descartes declared that the mind was made of fundamentally different "stuff" to the rest of the body. The mind was non-physical, and was distinctly separable from the rest of the body. This philosophy is called *dualism*.[\[1\]](#) Descartes even suggested a

region in the brain where the mind might be found: the pineal gland, which is a small gland in the centre of the brain.

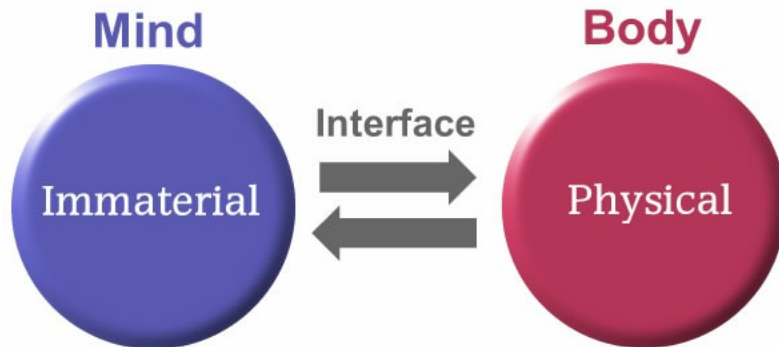

The motivation for Descartes philosophy was that the contents of our minds seem fundamentally different from the physical world we see around us. We might see a rock, and we know it is not conscious. We might see a more complex object, like a clock or a car, but we still know that those objects are not conscious. Somehow, the contents of our minds seem different. We do not seem tied to the physical world, the world of matter. Instead, our minds seem somehow immaterial, insulated from the material world, somehow floating in a higher realm of thought.

And in that higher realm, our insulated minds cannot be damaged by the physical world. As our bodies grow old and maybe painful, our minds can stay young, apparently impervious to the ravages of time. I have often heard an old person say that they feel the same in their mind as they did when they were young — I feel the same way myself (though I do not yet consider myself old). It is as if the physical world cannot affect our mind.

But if that is really true — if the mind is immaterial and the physical world cannot affect the mind — then that raises a problem. The problem comes when we consider the other direction. Because if our minds really live in a higher-realm, unaffected by the physical world, then how on Earth can our minds ever affect the physical world? How can the immaterial consciousness in our heads move our arms and legs, for example?

This apparent paradox is called the *mind-body problem*. It is similar to the question of how ghosts in movies can walk through walls, but conveniently do not fall through the floor.

So, according to the mind-body problem, the challenge lies in the interface:

Substrate-independence

The second principle I would like to describe to you is based on the idea that there is nothing particularly special about biological cells: consciousness could still arise in some different underlying hardware. This idea seems eminently sensible: if you read my seventh book you will know that physics tells us that all electrons are exactly the same, and all protons are exactly the same. There is surely nothing special about the particles that form the atoms of biological cells.

This principle also seems to tie-in with our own experience. Our brains might be made of material with the consistency of rice pudding, but in our minds we do not feel as though we are made of "brain stuff" — we do not feel as though we are made of rice pudding. In fact, we feel completely independent of our brain hardware. We would surely feel the same even if our consciousness was transported to completely different hardware.

This principle — that consciousness is independent of the underlying hardware — is called *substrate-independence*. The principle of substrate-independence is described by the neuroscientist David Eagleman in his book *The Brain*: "If that turns out to be true, then in theory you could run the brain on any substrate. As long as the computations chug along in the right way, then all your thoughts, emotions, and complexities should arise as a product of the complex communications within the new material. In theory, you might swap cells for circuitry, or oxygen for electricity: the medium doesn't matter, provided that all the pieces and parts are connecting and interacting in the right way. In this way, we may be able to 'run' a fully functioning simulation of you without a biological brain."

A very similar standpoint is expressed by the neuroscientist Christof Koch in his book *Consciousness*: "Functionalism applied to consciousness means that any system whose internal structure is functionally equivalent to that of the human brain possesses the same mind. If every axon, synapse, and nerve cell in my brain were

replaced with wires, transistors, and electronic circuitry performing **exactly** the same function, my mind would remain the same. It is not the nature of the stuff that the brain is made out of that matters for mind, it is rather the organization of that stuff — the way the parts of the system are hooked-up, their causal interactions. A fancier way of stating this is 'Consciousness is substrate-independent'."

Taken to its logical conclusion, substrate-independence appears to suggest that there is nothing preventing a sufficiently-complex computer from becoming conscious. But is that really the case? We will be considering the question of whether computers can be conscious in Chapter Five.

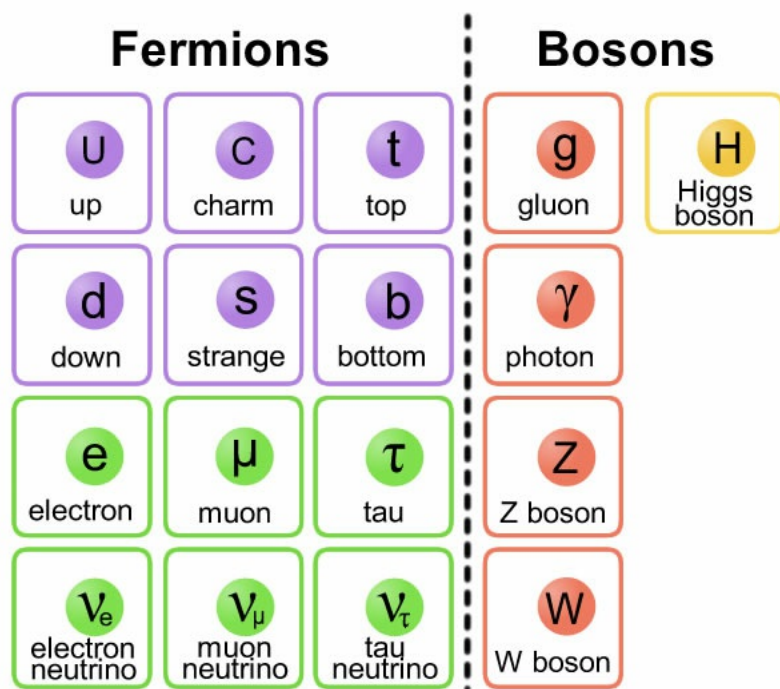

The principle of substrate-independence seems to have gained widespread acceptance by consciousness researchers, and it would appear that any explanation of consciousness would likely need to possess the property of substrate-independence. That will be a guiding principle of this book.

So the mind-body problem and substrate-independence provide us with some guidance on our quest to explain consciousness. But where should we look for our solution? Surely, as physicists and scientists, there is only one place we should be looking ...

Consciousness and the Standard Model

The discovery of the Higgs boson in 2012 completed the orthodox model of particle physics. That model is called the *Standard Model of particle physics*. The Standard Model contains a complete listing of the known elementary particles, together with a complete understanding of their interactions. Experiments have tested the predictions of the Standard Model with great accuracy, and there is no doubt that it is an accurate model of the subatomic world.

Here are the particles in the Standard Model:

Because the Standard Model explains the universe with such accuracy, and as it has been tested so thoroughly, it makes it very difficult to propose any convincing new extension to the model — there really are very few gaps to be exploited. The most famous of these "Beyond the Standard Model" (BSM) theories is *supersymmetry*, which proposed an additional suite of particles to be added to the Standard Model, but experiments at the LHC have found no such particles.

The overwhelming success and acceptance of the Standard Model seems to raise challenges for the previously-described philosophy of dualism, in which consciousness is suggested to be held in some vague "immaterial" substance in the brain. As scientists, vaguely stating that an additional substance exists which is not described by the

Standard Model is not sufficient: we have searched for additional particles using high-energy accelerators and we have found nothing more.

So our challenge appears to be to try to find where this peculiar "immaterial" mind substance can be found within the Standard Model.

As described earlier, the mind-body problem raises the question of how something immaterial could ever interact with the world of matter. How can consciousness ever hope to move arms and legs? What would the interface look like between matter and non-matter? Well, perhaps surprisingly, the Standard Model has the answer as to whether or not something immaterial can affect something material. The solution is that it is absolutely no problem: yes, something immaterial can definitely affect something material.

To understand why this is the case, we need to realise that all of the particles in the Standard Model can be divided into one of two classes. Referring back to the previous diagram, you will see that the first class of particles is the *fermions*, which are the matter particles such as the electron and the proton which can combine to make atoms. Atoms are made of *matter* — the "stuff" which makes the objects around us, the objects we can touch and feel. The second class of particles is the *bosons*, which might be considered the immaterial particles ("immaterial" means "not made of matter"). As an example, a beam of light is composed of photons which are bosons — and you cannot touch or feel an immaterial beam of light.

However, it is known that a photon (an immaterial particle) can deflect an electron (a matter particle) in an effect called *Compton scattering*. The following diagram shows a photon deflecting the path of an electron (this is showing a vertex from a Feynman diagram):

So here in one diagram we have an answer to one question which is often raised about the mind-body problem: "Could it ever be possible for something immaterial to affect something material?" The answer — according to the Standard Model — is yes it can, and this is how. The question raised earlier was how could there possibly be an interface between the material and the immaterial. Well, the previous vertex describes just such an interface.

The general point I am trying to make is that it **is** possible to cross seemingly unbridgeable gaps between the material and the immaterial, and we will be returning to this theme towards the end of this book.

However, elementary particles are not considered to have any internal structure and are surely not capable of sustaining consciousness as individual units. Also, attempting to tie consciousness to any particular form of hardware (e.g., a particular type of particle) appears to be at odds with our intended aim of finding a substrate-independent solution which would be independent of any particular underlying hardware.

So it would appear we have drawn a blank in our attempt to incorporate consciousness into the Standard Model. But we should not give up yet.

Because there is something else ...

There is a different substance, a different candidate to be considered the "stuff" from which our consciousness is made.

This substance is completely tied to the physical world, it is therefore represented in the Standard Model, but it also appears to inhabit a realm above the physical world. What is more, it possesses the desired substrate-independence because it can traverse the world of **both fermions and bosons** — the material and the immaterial — giving an impression of how it might represent a potential solution to the mind-body problem.

This substance never decays, never grows old. In that respect, it is impervious to the damage inflicted by the physical world. But it is also rigorously defined both in physics and mathematics, and it now even has its own law of

conservation — which is considered to be on the same level as the law of conservation of mass or energy.

But this substance seems grander than the purely physical: it can represent music and poetry, art and ideas. However, it can also start wars — and bring peace. We find this substance so fascinating that we can stare at it for hours every evening as it holds us spellbound.

In fact, this substance dominates our lives to such a extent that it has given its name to this entire current era of humanity.

So let me introduce you to this remarkable substance ...

Information

463 West Street today is a rather inconspicuous twelve-story apartment block overlooking the Hudson River in Lower Manhattan. Everyday, people walk past staring into their smartphones, unaware that the technologies which makes their smartphones "smart" were developed in the building.

Until the 1960s, 463 West Street was the home of the Bell Telephone Laboratories, the largest industrial research centre in the United States. The technologies invented or developed there included talking movies, colour television, radar, and live video broadcasts. But the most monumental year of the Bell Telephone Laboratories came just after the war.

In 1948, there were two major developments in the Bell Telephone Laboratories which might initially appear unconnected, but acting together they were to create the modern world. The first announcement was of the invention of a tiny electronic device, described in the press release that "it may have far-reaching significance in electronics and electrical communication". That was definitely an understatement. The tiny device rather unimpressively resembled an insect with a small body and spindly legs. It was called the *transistor*.

Each of those people walking past the inconspicuous apartment block in Lower Manhattan holding an iPhone in their hand is actually holding two billion of those strange little transistor devices (in the Apple A11 microprocessor). The transistor was to revolutionise the world. We shall be considering the transistor in Chapter Three.

The second major discovery to emerge from the Bell Telephone Laboratories in 1948 was a scientific paper published in *The Bell System Technical Journal*. The paper had the title "A Mathematical Theory of Communication" and it was written by a thirty-two-year-old researcher named Claude Shannon. Shannon was thin, gaunt, with an intense gaze. They were the eyes of a man who could see the future:

If the transistor was to create the hardware for the iPhone, the idea in Shannon's paper was to supply the signal — and the content. The word "transistor" was a new term introduced by the Bell Telephone Laboratories in 1948. Shannon's paper introduced yet another new word: the *bit*.

At the time, the Bell Telephone Laboratories' revenue came from telephone sales, and their telephone network. The question was raised internally, "What do we sell? What do we carry?" The Post Office carried letters and parcels. What did Bell Telephones carry? Electricity along its wires? Surely not — it was not a power company. Shannon realised that what was being carried was conversations, but he needed some way to quantify the amount. Hence, Shannon devised the "bit" as a fundamental unit, just like the metre, or the litre, or the kilogram. But what did the "bit" measure?

Shannon said it himself. The bit was: "A unit for measuring **information**."

Up to that point, the word "information" had only been used very informally, with ambiguous meaning. Shannon redefined the term by giving it a very specific technical meaning: information was something you could measure in terms of the number of bits it took to describe a message. In his book titled *The Information*, James Gleick describes the impact of this redefinition of "information": "And then, when it was made simple, distilled, counted in bits, information was found to be everywhere. It led to compact discs and fax machines, computers and cyberspace, Moore's law and all the world's Silicon Alleys."

The word "bit" is a contraction of "binary digit". A binary digit can have one of only two values: either 0 or 1. Bits can be strung together to make a larger binary number, which could potentially represent any form of information: a movie, words in a book, music. The more bits there are in a string, the more information is contained in that string:

101100110011000101101110101101011011101

When information is transmitted or stored, it is common to use an alphabet of symbols. The most widely-used alphabet is the Latin alphabet, with its modern day English, French, and Germanic variants. But the same principles apply to any alphabet of symbols.

Characters in the alphabet can be converted into bits in order to be transmitted or stored electronically. Let us now consider an example. Let us imagine we have a complete text document — written in English — which we want to

transmit to a second computer in order for that second computer to display the document on its screen in its entirety. How many characters would we need in our alphabet?

We would obviously need the 26 letters of the English alphabet ("A", "B", "C", etc.) and the 26 lower-case equivalent letters ("a", "b", "c", etc.) requiring 52 characters in our alphabet. But there would also be other characters required for punctuation, such as the full stop (period), comma, and hyphen, and — of course — the "space" character between words. Other characters which might appear in a text document include the dollar sign, the ampersand, and bracket characters. So it appears our alphabet would require in the region of about a hundred characters, or maybe slightly more.

To cut a long story short, such an alphabet for representing text in computers has been constructed and it is called the ASCII code (American Standard Code for Information Interchange). There are 128 characters in the ASCII alphabet. Those characters are given numeric codes from (0 to 127) in order to be transmitted and recognised by the receiving computer.

In order to be transmitted as a stream of information, each character is converted into a seven-bit code. Why seven bits? That is because in the binary numbering system it is possible to represent a number from 0 to 127 using seven bits.^[2] Here are a few of the ASCII characters together with their associated decimal codes and seven-bit binary codes:

ASCII Character	Decimal	Seven-bit binary
SPACE	32	0100000
\$	36	0100100
&	38	0100110
A	65	1000001
B	66	1000010
a	97	1100001
b	98	1100010

So the total number of characters in an alphabet is given by 2^N , where N is the number of bits allocated to each character. In the previous ASCII example, the total number of characters would be 2^7 , which is equal to 128.

But now let us consider the reverse question: if a single character from an alphabet is received, or a string of such characters, then how much information has been transmitted? The answer actually depends on the size of the alphabet. If a single character is transmitted from a very small alphabet (for example, a 0 being transmitted when the only possibilities are either 0 or 1) then the amount of information which is transmitted is less than if the character had come from a very large alphabet. This is because, in the latter case, you would be specifying a single symbol from a greater range of possibilities: more precise and more specific information is being transmitted. Shannon stated that the amount of information, H , transmitted by a series of n characters is given by:

$$H = n \log_2 W$$

where W is the size of the alphabet.

Hence, for the previous ASCII example, the amount of information contained in a single ASCII character (setting $n=1$ for a single character) would be $\log_2(128)$, which is equal to 7. The previous formula therefore tells us that the information transmitted by a single ASCII character is equal to seven bits of information.

By developing this equation to describe the amount of information content, Shannon revealed how information could be defined and measured. Shannon's breakthrough is described by James Stone in his book *Information Theory*: "Before Shannon's paper, information had been viewed as a kind of poorly defined miasmic fluid. But after Shannon's paper, it became apparent that information is a well-defined and, above all, **measurable** quantity."

And, if information could now be measured, that made it sound like a very real thing indeed. Information could now be processed as if it was a physical substance. It could be "compressed" like a gas (for example, to reduce the size of a movie file on a hard disk), or "filtered" like a liquid (for example, to extract interesting search results).

After Shannon, "information" resembled a physical substance.

After Shannon, "information" was a **thing**.

But what is the connection between entropy and information? Let us find out ...

Maxwell's Demon

In our attempts to analyse consciousness, what we would really like to discover would be some way of representing conscious thought in a form which we could analyse scientifically. However, it would appear to be a hopelessly ambitious goal to be able to represent consciousness in that manner: how could you express a "feeling" in an equation? But while it seems an almost impossible task to quantify consciousness, it appears it is possible to quantify "thinking".

In this section, we are going to generate a scientific definition of "thinking". In doing so, we will gain an insight into precisely what activity the brain actually **does**.

The way we are going to define thinking is by considering a famous thought experiment which involves the following cute little gremlin:

In our thought experiment, the gremlin is going to be doing a lot of thinking. However, rather bizarrely, the gremlin is going to do **no actual physical work**. It might appear to be impossible for the gremlin to have any measurable effect on the physical world if he performs no actual physical work, but we shall see that the thought experiment describes a particular situation in which that is possible.

To analyse the thinking of the gremlin, we are not going to consider the details of the workings of the gremlin's mind. Instead, we are going to treat the gremlin's head as a "black box", and merely consider the external effects of the gremlin's thought processes. With no physical work being performed, we can be sure that all observed effects must be purely due to the intellectual efforts inside the gremlin's head. We are then going to define "thinking" as the process which must have occurred in the gremlin's head in order to produce the observed effects.

So let us consider the thought experiment.

In 1867, the great Scottish physicist James Clerk Maxwell wrote a letter entitled "On the Decrease of Entropy by Intelligent Beings". In the letter, Maxwell proposed a famous thought experiment called *Maxwell's Demon*.

The thought experiment is shown in the following diagram. You can see it involves our gremlin (the eponymous "demon" in Maxwell's experiment). But this is not a nasty demon — he is more like a cute gremlin (from the film of the same name) who cannot stop fiddling with things:

The diagram shows Maxwell's demon lurking over a chamber which is divided into two compartments. There is gas in both compartments, and initially the temperature of the gas is the same in both compartments. There is an airtight trapdoor in the wall separating the two compartments, and the demon is in charge of opening and closing the trapdoor.

The demon is selected because the demon is supposed to have beyond-human superpowers which allow him to see individual molecules in motion, and incredibly fast reflexes which allow him to open the trapdoor to let individual molecules pass through into the opposite compartment.

The molecules of the gas are all moving randomly, though some of the molecules are moving faster than other molecules. Remember that the demon has super-powers, and is capable of seeing individual molecules. As you can see in the previous diagram, when the demon sees a fast-moving molecule approaching the trap door from the right-hand compartment, the demon activates the trap door so as to let that faster-moving molecule pass to the left-hand side. Similarly, the demon lets slower-moving molecules pass from the left-hand compartment to the right-hand compartment.

As a result, the left-hand side contains more faster-moving molecules and will become warmer, while the right-hand side will become cooler. This result appears to be in conflict with the second law of thermodynamics which states that heat will always tend to move from a warmer region to a cooler region, thus eventually equalising the temperatures. Because of the intelligent action of the demon, you could even take advantage of this eventual separation of temperature by running a heat engine as the heat passes from the warmer compartment to the cooler compartment.

But there lies an apparent mystery. It appears we have discovered a source of perpetual power, a steam engine which could run forever. As James Gleick describes: "A demon who could catch the fast molecules and let the slow molecules pass would have a source of useful energy, continually refreshed."

The mystery becomes even deeper if we consider the trapdoor to be completely frictionless. In physics, "work" is defined as the distance an object is moved against a force. If the trapdoor is frictionless, then it will exert no force against the hand of the demon, and therefore the demon will have to perform no actual physical work in order to open and close the door. James Clerk Maxwell wondered how energy had been produced "**and yet no work has been done**", only the intelligence of a very observant and neat-fingered being has been employed."

As Maxwell states, no physical work has been done. The only effort has been the intellectual effort — the "intelligence", as Maxwell says — of the demon. Has the clever demon really reversed the laws of physics purely by thinking?

Well, to a certain extent, yes he has. It is certainly true that the gas in the left compartment will become warmer, and the gas in the right compartment will become cooler, in apparent violation of the second law of thermodynamics. To be more precise, the second law of thermodynamics states that the amount of *entropy* in a

system will always increase, where we might interpret entropy as being the amount of disorder in a system. By ordering the gas according to temperature — warmer molecules in the left-hand side, cooler molecules in the right-hand side — the demon appears to have reduced the entropy of the system.

However, the second law of thermodynamics is not violated. This is because if we consider the system as a whole — including the demon — we find that the total entropy of the system has increased, in line with the second law of thermodynamics. The demon has to perform some work in his brain — even just by looking at the molecules and calculating their velocity. When the calculations are performed, it is realised that the increase in entropy inside the brain of the demon is sufficient to outweigh the reduction in entropy due to his actions. This result was described the American physicist Carl Eckart: "**Thinking generates entropy**".

So this provides us with a way to quantify "thinking". All we have to do is measure the change in temperature of the gas, and — with no physical work having been performed — we then know that that change must have been entirely caused by the demon's intellectual effort. Therefore, that value provides us with an objective method of the amount of "thinking".

So that is quite a result. We may not be able to measure consciousness using this method, but it does appear theoretically possible to measure "thinking". It's a good start!

Now let us remember what was said at the start of this section. It was stated that we were going to define "thinking" as the process inside the demon's head. So what does the demon do? The demon has to obtain information about the velocities of the particles (either visually or by some similar method), he then has to calculate the speed of the particle and decide whether it is slow or fast, and then finally come to a decision as to whether or not to open the trapdoor. All of this represents the capturing of information, and the processing of that information. So we can define thinking as *information processing*, and we can consider the brain to be an **information processing unit**.

The material of our thoughts

So might information be the "stuff" of our thoughts?

Information certainly seems to fit the bill. For a start, information possesses the substrate-independence which we would expect from consciousness. As long as the particular model of information processing is preserved, it would appear possible that the same consciousness could be created in a range of different hardware. Substrate-independence also means that information is not tied to any particular type of particle in the Standard Model. Information can be stored as fermions (as electrons stored in electronic memory, for example), or transmitted as photons (as electromagnetic radio signals, for example). Hence, information spans both the material and the immaterial.

Information is also resolutely physical. Information always requires a physical substrate. Information is rigidly defined both in physics and in mathematics. But, in many ways, information appears to lie in a realm above the physical, being completely substrate-independent.

This possibility is described by the *Information Philosopher*: "The 'stuff' of mind is pure information. Information is neither matter nor energy, though it needs matter for its embodiment and energy for its communication." [3]

The way I am presenting the concept of information, as existing in a substrate-independent "higher realm" from the material world might make it appear as though it is a mystical substance, similar to the "immaterial" substance of consciousness proposed by Descartes. And, indeed, in its behaviour we see that information does possess many of the qualities exhibited by Descartes' mystical substance. But the point I want to make is that information is also rigorously defined scientifically: we can talk about it, we can analyse it, it unquestionably **exists**.

Information appears to be a perfect fit for the material of our thoughts, the substance out of which our consciousness is made. We will be returning to consider information later in this book when we will see how a network based on information can create our thoughts, our self-awareness, and our consciousness.

2

A QUICK TOUR OF THE BRAIN

The importance of the human brain was realised over two thousand years ago when the Greek physician Hippocrates (of the Hippocratic Oath fame) said: "From the brain, and from the brain only, arise our pleasures, joy, laughter and jests, as well as our sorrows, pains, griefs, and tears."

That seems like a fairly accurate description. The brain is our central information processing unit which appears to be the centre of our thoughts, the seat of our consciousness. However, the brain also has to perform other functions of which our conscious mind is never aware. Regular signals from the brain keep our heart beating, and keep our lungs breathing. The brain is also responsible for controlling the release of hormones into the bloodstream. If we had to consciously remember to "breathe, breathe, breathe, ..." then our conscious minds would be too occupied to ever think of anything more productive. Hence, these *autonomic* output signals are produced by unconscious regions of our brain.

Similarly, the mass of sensory information entering the brain from the nerves would overwhelm our conscious mind if we had to deal with each signal individually. This would include monitoring body temperature, and monitoring carbon dioxide levels in the blood (which can then be used for regulating heart rate and breathing). Therefore, the unconscious brain has the job of filtering the huge number of sensory signals coming into the brain, and only passing the really important signals to the conscious part of the brain.

The power of the unconscious mind is illustrated in the medical phenomenon which has come to be known as *blindsight*. Blindsight occurs in people with healthy eyes who are blind because they have experienced damage in the region of the brain which is responsible for conscious processing of visual information. Even though the subjects are unable to see, the experiment involves showing them various pictures and asking to guess what the subject of the picture is. It would appear to be a pointless exercise, but the experiment shows that the subjects guess more accurately than would be expected from chance alone. This reveals the extent of the involvement of the unconscious visual system.

The unconscious signals coming out of the brain ("breathe, breathe, ...") pass out through the spinal cord, and, similarly, the unconscious signals coming in to the brain come in through the spinal cord. For that reason, the brain appears to be organised with its unconscious processing region positioned at the top of the spinal cord (and is therefore able to intercept signals), while the higher-level conscious region of the brain is positioned on top of that unconscious region. The conscious region of the brain is then able to receive the filtered information from the unconscious part of the brain.

Another benefit of this arrangement is that the unconscious brain can respond to critical reflex reactions — for example, quickly pulling your hand out of a fire — without ever having to pass those messages up to the higher-reasoning levels.

In his book, *The New Science of Consciousness*, Paul Nunez considers the situation in which a small child runs out in front of the car you are driving. Your unconscious mind would slam on the brakes of the car as a reflex action, and this can be performed in 150 milliseconds — which is much too fast for the conscious mind to reason about the situation (imagine the mental dialogue: "Should I start to brake?" — far too much time wasted). In fact, conscious awareness of the child does not emerge until a full half-a-second (500 milliseconds). Your conscious mind is not aware of any delay — it is as if your consciousness is always lagging half-a-second behind the reality of the situation.

The following diagram shows the brain roughly separated into two regions: the unconscious processing region positioned at the top of the spinal cord, and the conscious region positioned on top of the unconscious region:

As can be seen on the diagram, the all-important region of the brain believed to be responsible for high-level thought processes is called the *cerebral cortex* (or simply the *cortex*). The cortex is a thin layer — only a few millimetres in depth — which is spread around the outside of the top region of the brain. It is the cortex that is the centre of our memory, awareness, thought, language, and consciousness.

To be more precise, the cortex is divided into two areas. Approximately 90% of the cortex is the *neocortex*, which is the region responsible for higher-level brain functions and is the region which interests us. The remaining 10% of the cortex is called the *allocortex* which is simpler and older in evolutionary terms ("neo" means "new"). In this book we will only be considering the neocortex. The terms "neocortex" and "cortex" are often used interchangeably. In this book, I will just be referring to the "cortex".

Because conscious processing appears to be confined to the cortex, we will only be considering the cortex in this book. In his book *On Intelligence*, Jeff Hawkins follows a similar strategy. In the following passage, Hawkins defends his preoccupation with the cortex, and is fairly dismissive of those who disagree: "I know I'm going to meet some resistance on this point, so let me take a minute to defend my approach before we get too far in. Every part of the brain has its own community of scientists who study it, and the suggestion that we can get to the bottom of intelligence by understanding just the neocortex is sure to raise a few howls of objection from communities of offended researchers. They will say things like: 'You cannot possibly understand the neocortex without understanding brain region **blah**, because the two are highly interconnected like so, and you need brain region **blah** to do such and such.'"

However, Hawkins stresses that it is the cortex which is the area which interests us from the point of view of consciousness: "We are going to focus most of our attention on the cortex. Almost everything we think of as intelligence — perception, language, imagination, mathematics, art, music, and planning — occurs here. Your

cortex is reading this book."

The cortex is composed of dense brain material: the *grey matter*. This material is made of brain cells called *neurons*. The neurons are so tightly-packed within the cortex that the thin cortex layer actually represents 40% of the total brain mass.

How can such a thin layer be responsible for all our high-level brain functions? Well, the cortex achieves this by expanding as far as possible in width and breadth, in other words, by increasing its surface area. So the cortex is a thin layer, but it spreads across the outer layer of the top of the brain.

We now see why the structure of the brain makes so much sense. The cortex needs to maximise its surface area, so it is positioned on the outer surface of the brain (the outer surface of a sphere has the greatest surface area). Conveniently, that means the cortex can cover the unconscious part of the brain, which, in turn, acts to filter the signals coming in from the centrally-positioned spinal cord.

So, as has been described, the cortex seeks to maximise its surface area. But the amount by which the cortex can expand is limited because it is surrounded by an hard, bony skull. The only way the cortex can grow in size is by pushing against the skull and wrinkling — thus giving the brain its characteristic wrinkled appearance. If you look at a human brain you only see about a third of the surface of the cortex because the majority is hidden in the wrinkles. If you could remove the cortex and spread it flat, it would be about the size of a small tablecloth, revealing how the wrinkling acts to increase the processing capacity of the brain. Many animals have perfectly smooth brains as their cortex does not grow enough to push against their skulls.

It seems that — when it comes to the brain — wrinkles really are a sign of wisdom.

Lobes of the brain

It is believed that different regions of the cortex are responsible for different brain functions. The division is not precise — there is some overlap — but the cortex is often divided into four *lobes*, each lobe having a distinct functional responsibility.

As an example of the function of the lobes, it is believed that the *frontal lobe* is where most of our imaginary thinking and problem-solving takes place, as well as language processing. It has been said that this is "the seat of our intelligence and the location of our personalities".^[4] The frontal lobe is where we find most of the wrinkles in the cortex — the brain really does pack the processing power where it is needed the most. As another example, the *occipital lobe* at the back of the brain is responsible for processing visual information — very much as if we have a cinema screen at the back of our head onto which the images are projected.

How have neuroscientists discovered which part of the brain is responsible for which type of behaviour? Well, originally it was discovered that people with brain injuries in different parts of the brain displayed behaviour which was characteristic of the site of the injury. The first example of this came from the work of the nineteenth century French physician Paul Broca. One of Broca's patients was nicknamed "Tan", because that was the only word he could say. In every other way, however, the patient appeared to be perfectly intellectually sound. When the patient eventually died in 1861, Broca conducted an autopsy and discovered that there was a lesion in his frontal lobe, and concluded that this area was responsible for language processing.

Nowadays, neuroscientists have more sophisticated methods of watching the brain in action. One method is Positron Emission Tomography (PET) scanning, in which the patient is injected with a mild radioactive material which is dissolved in glucose. The radioactive source decays via beta decay, emitting positrons (positrons are antimatter, and the principle behind PET scanning was considered in detail in my fifth book about particle physics). When the emitted positrons reach any normal tissue in the brain, they are annihilated (via matter/antimatter annihilation). This annihilation produces energy in the form of gamma rays. The gamma rays can be detected by the surrounding scanner, and the source of the radiation can be pinpointed.

While being scanned, the patient is requested to perform various tasks. To perform these varied tasks, different areas of the brain require more energy, and so use more of the injected glucose. Different regions of the brain then "light up" in the PET scan, thereby revealing which areas of the brain are responsible for the particular activity.

The neural correlates of consciousness

One of the biggest challenges in analysing consciousness is being able to detect the existence of consciousness in the first place. We might judge a person is conscious by whether or not they could respond to questions, or squeeze a hand when requested. However, this approach is not sufficient: some patients who are damaged in the lower brain but have no damage in the upper brain can be totally paralysed in a state known as "locked-in" syndrome. Even though they are conscious and aware of their surroundings, they are unable to physically respond.

So if consciousness cannot be detected via purely external responses, maybe it can be detected if we analyse the brain directly. With this end in mind, in the 1990s the American neuroscientist Christof Koch began working with Francis Crick — the molecular biologist who was the co-discoverer of the structure of the DNA molecule. Koch and Crick tried to identify the sectors of the brain which represented the active regions responsible for different conscious activities. Koch and Crick called these the *neural correlates of consciousness* (NCC), a term which seems to have become widely adopted.

According to Koch in his book *Consciousness*: "Imagine that you are looking at a red cube, mysteriously left in the desert sand, with a butterfly fluttering above it. Your mind apprehends the cube in a flash. It performs this feat because the brain activates specialized cortical neurons that represent color and combines them with neurons that encode the percept of depth, as well as neurons that encode the orientation of the various lines that make up the cube. The minimal set of such neurons that cause the conscious percept is the neural correlate of consciousness for perceiving this alien object."

Koch is currently the Chief Scientific Officer at the Allen Institute for Brain Science in Seattle (funded by Microsoft co-founder Paul Allen). He is currently collaborating with Giulio Tononi of the University of Wisconsin in order to identify some of the neural correlates of consciousness. Their approach has involved EEG recording of the brain to determine which areas are active in conscious patients, and thereafter use that information to determine the presence of consciousness in other patients.

The situation is complicated by the fact that some areas of the brain are always active — in both conscious patients and unconscious patients. In order to take account of this fact, the brains of subjects who are in deep, dreamless sleep (i.e., in an unconscious state) were first analysed and then those areas (which would presumably be active all the time) were subtracted from images of brains in a conscious state. Logically, the resultant areas of the brain should be those responsible for consciousness.

Tononi and Koch are developing a theory known as *integrated information theory* (or IIT). The principle behind the theory is that the pattern of information in a conscious mind would show certain characteristics, and those characteristic patterns could be used to detect the presence of consciousness. Two key features of the pattern would be *integration* and *differentiation*. My understanding of IIT is that "integration" means that distant parts of the brain must be connected, and be able to talk to each other — otherwise the brain would contain many separate consciousnesses. So we might consider "integration" as referring to the large-scale patterns of activity in the brain. In contrast, "differentiation" refers to the small-scale patterns of activity. For example, we might be thinking of a visual scene containing many objects: cars, trees, houses, etc. So there is clearly a lot of detail, there. What is more,

the representation of each of these small-scale objects must be clearly different from each other (otherwise we would be thinking of many objects which were all the same). This requirement that the small-scale objects must be different is called *differentiation*. The following schematic diagrams show three possible arrangements of connectivity:

The top diagram (diagram A) shows a network with a lot of differentiation (with considerable variation in the types of connection) but a lack of integration (with two major regions of the network not being connected — you can see the network is cut by a pair of scissors). The middle diagram (diagram B) shows a great deal of integration (with all distant parts of the network being connected) but the perfect symmetry means there is a lack of differentiation. Finally, the bottom diagram (diagram C) shows a healthy balance between integration and differentiation. According to integrated information theory, in a healthy conscious mind, we would expect to find a balance of integration and differentiation in the EEG pattern, so this pattern could represent a conscious brain.

Giulio Tononi has developed a measure of integrated information which he has named Φ (the Greek letter "phi"). We shall be considering Φ in the next chapter on emergence.

In the November 2017 cover story of *Scientific American*, Christof Koch described the promise of IIT: "The development of several technologies in recent years has raised real prospects for detectors that meet the criteria for consciousness meters — devices useful in medical or research settings to determine whether a person is experiencing anything at all. This ability to detect consciousness could also help physicians and family members make decisions about how to care for tens of thousands of uncommunicative patients."

In his book *Consciousness*, Koch also explains how this research will make consciousness research testable at last: "The bottom line is that these physiologic experiments are steadily narrowing the gap between the mind and the brain. Hypotheses can be put forth, tested and rejected or modified. And that is a great boon after millennia of sterile

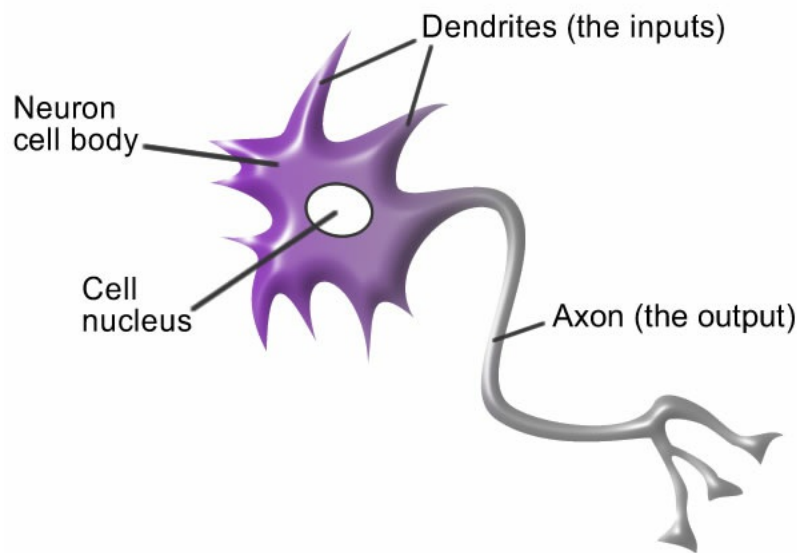

debate."

Neurons

The human brain contains approximately 100 billion brain cells which are called *neurons* — which means that there are 14 times more neurons in your head than there are people on this planet. Neurons are the only cells which are able to transmit electrical signals. Neurons transmit those electrical signals to other neurons, forming a network (a network which eventually forms a brain).

At the heart of a neuron is a cell nucleus, just like any other cell. But the cell body is surrounded by small branch-like extensions which are called *dendrites*. These receive electrical signals from other cells. Therefore, these might be considered the "inputs" to the neuron. There is also one very long extension which comes out of the cell body which is called an *axon*. The axon can be extensively-branched. The axon proceeds to connect to other neurons, and it is a one-way connection. So the axon might be considered the "output" of the neuron.

The following diagram shows a neuron, showing the dendrites which surround the cell body, and the single axon output:

A crucial feature is the connection between two neurons, when the axon from a previous neuron connects with the dendrites of the next neuron. There is no direct physical contact between the two cells. Instead, there is a very small gap between the end of the previous neuron's axon and the next neuron's dendrites, and that gap is called a *synapse*. The synapse gap is just one forty-thousandth of a millimetre in width.

The following diagram shows two neurons which are connected together via synapses (shown in dashed circles):

The synapse gap is filled with chemicals called *neurotransmitters*. Neurotransmitters play a vital role because they allow signals to bridge the gap of the synapse, thus allowing signals to be transmitted between neurons. It has been shown that these neurotransmitters play a vital role in our moods and our thinking processes. For example, it is known that variations in the amount of certain neurotransmitters (such as dopamine and serotonin) can cause mental health issues such as anxiety and depression.

Mind-altering drugs also target the neurotransmitters in the synapses. Stimulants, which include caffeine, nicotine, amphetamine, and cocaine, work by increasing the levels of the neurotransmitters dopamine and noradrenaline. Conversely, sedatives such as alcohol and Valium operate by reducing neurotransmitter activity in the synapse.

It might, therefore, be said that the construction of brain neurons with the synapses outside of the cell is an ingenious design feature. This makes the all-important synapses easily-accessible to the global release of chemicals into the general intercellular fluid of the brain. By releasing large amounts of neurotransmitters into the brain, it is possible for the body to trigger virtually instantaneous changes in mood and performance. For example, the release of noradrenaline increases the body's "fight-or-flight" response. And the release of natural opiates can lessen pain, which could be a life-saving strategy if the subject has to quickly run (on a broken leg) to escape a dangerous situation.

Inside the neuron

We have a remarkably full and accurate understanding of the internal structure of a neuron. What follows next is a description of the mechanism by which a neuron "fires" and transmits the output signal down its axon.

We know that messages are sent as electrical signals. It might be imagined that these messages would be formed of electrons passing down a conductive substance (like electricity passes down a wire). However, this is not the case. We will now see that a completely different — and apparently unnecessarily uncomplicated — method is used for sending signals down a neuron's axon to the next neuron. Indeed, in his book *The Emperor's New Mind*, the physicist Roger Penrose expresses his surprise that such a complicated method is used instead of the apparently obvious method of simply sending electrons down a "wire": "What form do the signals take as they propagate along nerve fibres and across the synaptic clefts? What causes the next neuron to emit a signal? To an outsider like myself, the procedures that Nature has actually adopted seem extraordinary — and utterly fascinating! One might have thought that the signals would just be like electric currents travelling along wires, but it is much more complicated than that."

Instead, the signals are passed in the form of *ions*. An ion is an atom which has either positive electric charge (because it has lost an electron) or negative electric charge (because it has gained an electron). Signals are passed by the physical movement of these ionised atoms.

Common examples of ions found in neurons are sodium ions and potassium ions. Sodium has the chemical symbol Na, while potassium has the chemical symbol K. Sodium and potassium are both metals, which means they have a single electron in their outer shells (it is that electron which allows electric current to pass through a metal). By losing that outer electron, a sodium atom can form a positive ion (Na^+), and a potassium atom can form a different positive ion (K^+). Other ions can be formed which have negative charge.

The body of each neuron is surrounded by a cell wall called a *membrane*. The membrane is punctured by many microscopic gates called *ion channels* which only allow certain ions to pass through them. These gates are opened or closed depending on the electric voltage (or *potential*) across them.

Because there are generally more negative ions inside the neuron than outside the neuron, there is a voltage difference of approximately -70 millivolts across the membrane, with the interior of the neuron being slightly electrically negative compared to the exterior environment of the neuron. This voltage is called the *resting potential*. This electric potential is enough to hold closed all of the ion channel gates.

However, when the neuron receives a large number of input signals on its dendrites, this can increase the amount of positive charge inside the body of the neuron. If this increase in positive charge increases beyond a certain threshold value, then it can overcome the voltage difference which was causing the sodium ion gate to remain closed (remember: it was the -70 millivolt voltage difference which was holding the gate closed). So when the threshold voltage is passed, the gate opens and the exterior sodium ions flood through the membrane into the neuron interior, attracted by the negative charge inside the neuron, as shown in the following diagram:

The influx of sodium atoms makes the interior of the neuron even more positively charged. This forms a positive feedback effect, and more sodium gates open. The effect is explosive, the opening of gates forming a ripple effect which passes down the neuron's axon at a speed of up to 100 metres per second. This fast moving spike of voltage represents the "firing" of the neuron and is called the *action potential*.

As the voltage continues to climb, a point is reached at which the sodium gate closes, and the potassium gates open. There is then an outflow of the positively-charged potassium ions, repelled by the positive charge inside the neuron, as shown in the following diagram:

The effect of this outflow of positive charge is to restore the potential of the membrane back to its resting potential, ready for the next firing of the neuron.

This mechanism is not just used by brain neurons — it is also used by nerves to tell muscles when to fire. Whenever I come home after running, I always have an *electrolyte* drink. Electrolytes are ions including sodium, potassium, and magnesium. After exercise, you can lose salt through perspiration. Salt (sodium chloride) includes the electrolytes sodium and chloride. It is therefore important to top-up your body's store of electrolytes to avoid muscle cramp, in which the ability to send correct firing signals to the muscles is lost.

So why is such a complicated chemical process used to send messages down an axon, instead of simply sending an electrical signal down a "wire"? In the next chapter we will see a reason why this is possibly the case, and it is all to do with the -70 millivolts threshold voltage difference across the membrane. We will be seeing how this threshold voltage can result in "nonlinear" behaviour which would surely be necessary in any thinking machine.

In the last two sections, the two main methods by which neurons process information have been described. As Christof Koch said: "Two operations underlie information processing by neurons: the chemical transmission of information from one neuron to another at the synapses, and the generation of action potentials."

It is clear that the method by which signals are passed down the axon of a neuron is surprisingly complicated, with the arrangement of "gates" and "pumps" resembling nanotechnology. But it is also clear that we have a very complete and detailed understanding of these processes. We really do understand the workings of a single neuron remarkably well.

But that is not the challenge for us.

It is undoubtedly the case that consciousness is not held in any individual neuron. Individual neurons frequently die without obviously affecting our thought processes: we do not suddenly perceive any "dead pixels" in our mental images. Instead, consciousness arises from the interaction of billions of neurons: there may be 100 billion neurons in your brain, but each neuron is connected to as many as 10,000 other neurons. If you do the arithmetic you find that gives the extraordinary total of 1,000 trillion synaptic connections in the brain.

To suggest that we can understand consciousness by considering a single neuron — in however much detail — is to take a "reductionist" approach. Instead, there is a general consensus that consciousness arises as an "emergent" effect from the huge connectivity in the brain. Our challenge is to understand how consciousness emerges from this network.

In Chapter Four, we will be examining the severe challenges which emergent behaviours pose for our current way of doing science.

3

ARTIFICIAL NEURONS AND ELECTRONIC BRAINS

In this chapter, we will discover that neurons possess a very particular mathematical property which allows them to perform calculations, and to allow thinking to occur. It is undoubtedly a property which the components of all conscious systems must possess. We will also be seeing that it is a property which is possessed by electronic transistors, a property which allows those transistors to make computers — which are, after all, "thinking machines".

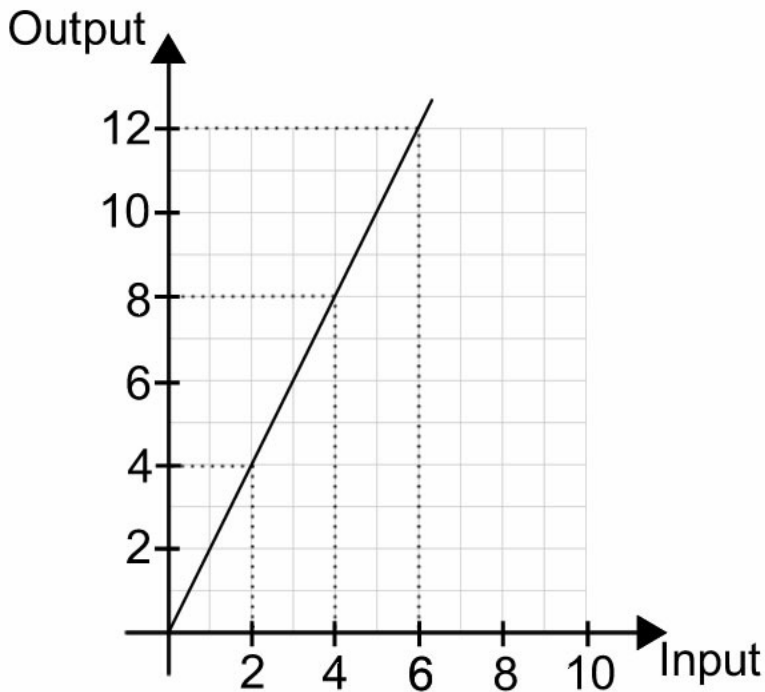

The property is called *nonlinearity*.

To understand nonlinearity, and why it is so important, let us first consider the related concept of *linearity*.

As stated in the previous section, a neuron can be considered as having a series of inputs (its dendrites) and a single output (its axon). To simplify this picture, let us draw a neuron as a simple block diagram:

We might then ask how the output value varies as the input values are varied. We would probably imagine that as the input values increase, then the output value would increase proportionately. We might imagine the neuron simply summing all the input values and passing that total value to the output, or maybe multiplying that output by a constant number. In either of those cases, the output will be directly proportional to the input. As an example, the following graph shows this behaviour when the output value is equal to twice the total input value:

You can see in that case that the relationship between the neuron's input and output is given by the steep diagonal line. A few values for input and output have been plotted on the graph. For example, when the input is equal to two, you will see that the output is four (2×2). And when the input is six you can see that the output is twelve (2×6).

Because the relationship between the neuron's input and output forms a perfectly straight line, we say that represents a *linear* relationship ("linear" meaning "like a line"). We might then call it a linear neuron.

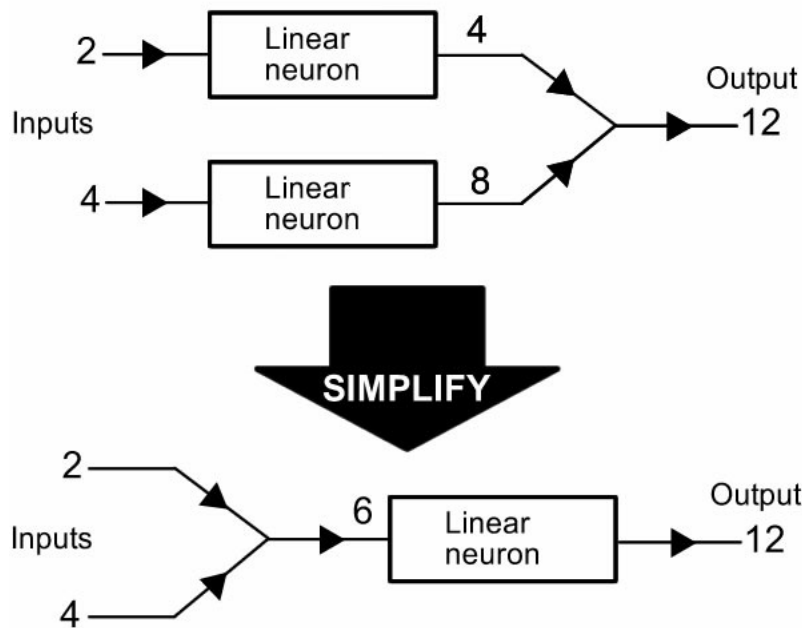

In physics, many systems can be modelled as linear systems. For example, if you double the weight attached to a linear spring, then the spring would extend to twice its original length. Linear systems are easy to analyse mathematically, so physicists find it very convenient to work with linear systems. The reason that linear systems are easy to work with is because of the *superposition principle*. A description of this principle is presented on the Wikipedia page for the superposition principle: "If input A produces response X and input B produces response Y then input (A+B) produces response (X+Y)." [5]

We can see that this principle is true on the previous graph. We can see that an input of 2 produces an output of 4, and an input of 4 produces an output of 8, so — according to the superposition principle — an input of $2+4$ (which is 6) should produce an output of $4+8$ (which is 12). And we can see that this is the case from the graph because an input of 6 does indeed produce an output of 12. So the superposition principle is indeed true for linear systems.

The key point I am going to be making about linearity is that the superposition principle reveals that a brain could never be made out of these linear neurons. We will now see why that is the case.

The superposition principle reveals that it is possible to greatly simplify any system which is made out of linear components. For example, it shows that if we had a system made out of two of these linear neurons, we could simplify it to a system of just one linear neuron.

The following diagram shows how this simplification can be achieved. It shows two linear neurons, which both act to double the value of the input in a linear manner (as described earlier). You can see that, when inputs of 2 and 4 are applied to the two neurons, the combined output is equal to 12.

However, the superposition principle states that we could achieve the same result by using just one of those linear neurons, and summing the input — as you can see in the lower section of the previous diagram. You can see that with precisely the same inputs, the single neuron gives the same output as the output of the two neurons.

So there is no need to have two linear neurons — just one linear neuron would achieve exactly the same result. In fact, the superposition principle reveals that no matter how many linear neurons we have, in whatever configuration, the result can always be simplified down to a single neuron. [6]

To see this principle in action, let us consider a linear component from the field of electronics (we will be seeing that there are remarkable parallels between electronic components and neurons — in the same way that there are remarkable similarities between a computer and a brain). The electronic component we will be considering is a *resistor*. The resistor is a simple component whose behaviour might be thought of as "resisting" (i.e., reducing) the electrical current flowing through a wire. Here is a photograph of a typical resistor, with the resistance value (measured in ohms) being denoted by the coloured bands painted around it:

The symbol for a resistor in a schematic circuit diagram is a small rectangle, as shown in the following diagram:

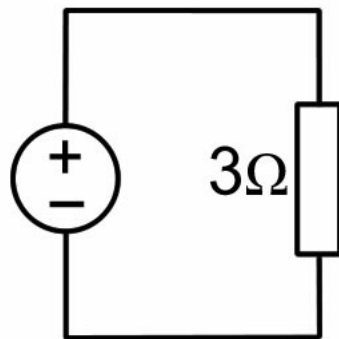

The current through a resistor is proportional to the voltage applied across the ends of the resistor. The relationship is directly linear, which means if you drew a graph relating current to voltage, then it would be a perfectly straight line. This linear behaviour of the resistor is important because it means that the previously-described superposition principle applies if we have a network built of many resistors. That principle can be used to greatly simplify the network.

As an example, consider the following circuit diagram which contains seven resistors (and a battery on the left). The resistors have different values written next to them, measured in ohms. You will see that the symbol for the ohm is the Greek letter omega, Ω :

The superposition principle suggests that we could simplify this network down to a single component — a single resistor. And that is precisely what we find. There are simple arithmetic formulas which are well-known to any electrical engineer which can reveal that the previous network of seven resistors is equal to a single resistance value of precisely 3 ohms: [7]

So a network consisting purely of a number of resistors can always be simplified to a single resistor — as revealed by the superposition principle.

If you were actually designing an electronic circuit, you could never create an interesting complex system with just one resistor: a single resistor can do nothing useful. Therefore, logically, you could never create a complex system with any greater number of resistors — as the situation would be equivalent to the single resistor case.

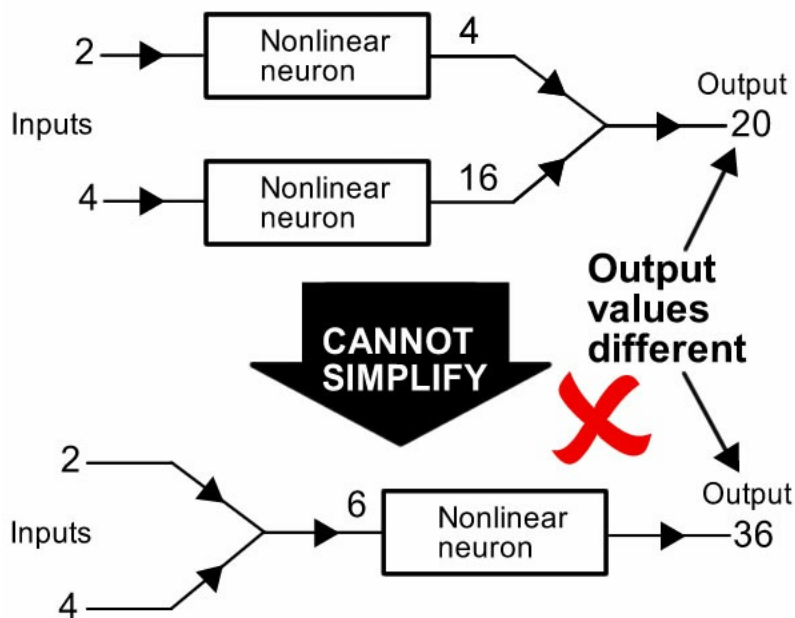

And the same principle applies to linear neurons: you could never create a complex system with any number of linear neurons. Crucially, you could not build a brain with a single linear neuron, so, logically, **you could not build a brain with 100 billion linear neurons** (as the 100-billion-neuron brain could always be simplified to a single-neuron brain). For this reason, linear neurons could not be used to build a brain.

So, if linear components on their own cannot be used to create complex systems, let us now move on to consider *nonlinear* components. As an example, the following graph shows the relationship between input and output when the output is the square of the input. You will see that the relationship between input and output is no longer

described by a straight line — instead, it is a curved line. Hence, it is a nonlinear relationship:

Let us see if the superposition principle still applies in this nonlinear case. Considering the previous graph, an input of 2 produces an output of 4, and an input of 4 produces an output of 16. If the superposition principle applies then an input of $2+4$ (which is 6) should produce an output of $4+16$ (which is 20). But, from the graph, we can see that is not the case: an input of 6 produces an output of 36 — not 20. So, crucially, **the superposition principle does not apply to nonlinear components.**

And, as you can see from the previous diagram, if the superposition principle does not apply then a network built from nonlinear components cannot be simplified (i.e., unlike linear components). It might sound like a bad thing to be unable to simplify a network, but if we want to create a large and complex network, it is very good news indeed. A network which cannot be simplified down to a single component is a network which can do very interesting things indeed.

Let us now consider an electronic component which is much more interesting than a resistor — precisely because it is nonlinear. This is a photograph of a *transistor* (its actual size would be only about two centimetres long in

total):

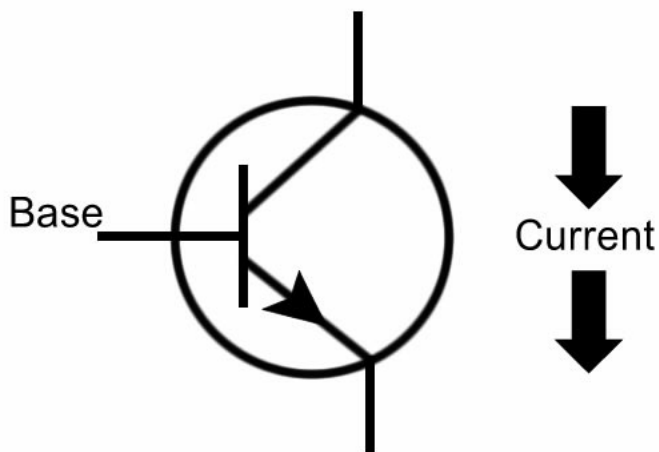

It was described in Chapter One how the transistor was invented in the Bell Telephone Laboratories in 1948. It was invented by John Bardeen, Walter Brattain, and William Shockley, the three receiving the 1956 Nobel Prize in Physics for their invention. It could be argued that the transistor was the most important invention of the 20th century.

If we examine the appearance of the transistor in the previous photograph we see a small body and long, thin, flexible legs. Apart from the obvious difference in size, this is reminiscent of a brain cell — a neuron — described in the previous chapter. A neuron has a small cell body, a series of inputs (dendrites) and a long axon output. The similarity is not coincidental as the two different devices have to perform similar functions: receiving inputs from other similar units, and passing outputs to other similar units, forming a network of a vast number of components. In this chapter we will be seeing that the similarities between a transistor and a neuron are much more than just skin deep.

The material inside a transistor is called a *semiconductor*, and is often silicon or germanium. A semiconductor can operate as either an electrical conductor or an electrical insulator. In a transistor, the behaviour of the semiconductor depends on the voltage applied to one particular leg of the transistor, called the *base*. If a sufficiently high voltage is applied to the base, a current can pass between the other two legs. However, if no voltage is applied to the base, the transistor acts like an insulator and no current can pass between the other two legs.

The following diagram shows the schematic symbol for a transistor as used in circuit diagrams. The three legs are shown. The base leg is indicated, and the current flowing between the other two legs is also shown:

We will be seeing this diagram again later in this book.

Crucially, though, the behaviour of the transistor is nonlinear. Until the base voltage reaches 0.7 volts, no current can pass through the transistor. But once the 0.7 volt is reached, the transistor "turns on" and current can pass.

This nonlinear behaviour is shown by the thick black line in the following diagram:

So the 0.7 volts acts as a threshold voltage. If you scan your memory, you might remember where we encountered a "threshold voltage" earlier in this book. We encountered a threshold voltage in the discussion of neurons at the end of the previous chapter. There it was explained how, when the neuron receives a large number of input signals on its dendrites, this can increase the amount of positive charge inside the body of the neuron. If that increase in positive charge increases beyond a certain threshold voltage, then the neuron will "fire", sending an action potential shooting down the neuron's axon to the next neuron. For the neuron, this thresholding effect is called the "all-or-none" law. [8]

In his book *The Emperor's New Mind*, the physicist Roger Penrose considers how this "all-or-none" law makes neurons behave as though they were elements of a digital computer: "An important feature of nerve transmission is that the signals are entirely 'all-or-nothing' phenomena. The strength of the signal does not vary: it is either there or it is not. This gives the action of the nervous system a digital computer-like aspect."

So both transistors and neurons fire when the combined inputs exceed a certain threshold voltage — and this is no coincidence. The threshold voltage is essential. In both cases, the threshold voltage introduces the required nonlinear behaviour — and it is that nonlinear behaviour which allows us to build complex systems (computers or brains) from transistors and neurons.

And now we see that possible reason why signals are sent down the axons of neurons using the rather surprising chemical method — instead of simply sending an electrical current down a "wire". The chemical method creates the crucial threshold voltage inside the neuron, and it is the existence of that threshold voltage which introduces the essential nonlinear behaviour. In fact, the peculiar chemical method inside the neuron might be considered as turning the neuron into a form of nonlinear "semiconductor", so to speak.

Paul Davies emphasises this nonlinear behaviour of neurons in his book *The Cosmic Blueprint*: "The electrical output signal of a given neuron will depend in a **nonlinear** way on the combined input it receives from its connected partners." (That book includes a good section on nonlinearity).

There is one simple message I want you to take from this discussion: in its design and nonlinear functionality, **a transistor can be considered to be an artificial neuron.**

Integrated circuits

The similarity between transistors and neurons continues when we consider how most transistors are used nowadays. The vast majority of transistors are micro-miniaturised onto a semiconductor substrate to form an *integrated circuit* ("silicon chip"). The latest fabrication techniques allow extraordinary densities of up to 25 million transistors on a square millimetre of silicon. This actually results in an individual transistor size which is rather smaller than a neuron, but it is clear that the principle of packing microscopic transistors onto an integrated circuit resembles the packing of microscopic neurons in a brain.

Here is an image of the Apple A11 microprocessor. If you have the latest iPhone then you are already in possession of one of these. This is an image of the entire external package — the actual "chip" and its 4.3 billion transistors is contained within it:

With 4.3 billion transistors in an integrated circuit, it is clear we are approaching the number of 100 billion neurons in the brain. So why do integrated circuits possess nowhere near the functionality and flexibility of the brain? The answer must surely lie in the extreme connectivity of the neurons in the brain: each neuron can be connected to as many as 10,000 other neurons. In order to achieve that level of connectivity, it would appear we will eventually have to move away from fabricating integrated circuits on a flat two-dimensional plane, and instead create three-dimensional cubes of circuitry — again, moving in a direction which resembles the structure of an actual brain.

Three-dimensional chips are now starting to appear. Samsung have recently released computer memory chips featuring 38 layers of transistors, and the rumour is that this is seen as the future of the industry. One website presents this development as a simple solution to the problem of how to achieve more of the crucial interconnects in integrated circuits, and compares the move to three-dimensions on a chip with the drive to build high-rise towers in cities: "The obvious choice for where to put these interconnects was the same solution in any sprawling metropolis; if you can't grow **out**, grow **up**. Three dimensional chips will be released. It is only a matter of time. There is simply no other way to increase the density of interconnects, the number of devices on a chip, or speed than by moving into a third dimension of silicon." [9]

The development of integrated circuits which resemble the structure of the brain is called *neuromorphic computing*. It is currently an area of rapid growth. As an example, IBM released its True North integrated circuit in 2014 which contains over a million artificial "neurons" on a chip. Each neuron has 256 programmable "synapses" giving a total of just over 268 million synapses. The artificial neurons communicate using transient electrical spikes — just like real neurons. This chip has been described by IBM as "literally a synaptic supercomputer in your palm". [10]

It is clear that each successive innovation in the integrated circuit industry is moving us closer to creating true three-dimensional artificial-neuronal electronic brains. [11]

Digital information

The information inside most integrated circuits is purely digital. That means all information is represented in strings of binary "bits", each bit being either 0 or 1. The principle of Claude Shannon's "bits" as a means of representing information was described in Chapter One of this book.

Electrical input signals — coming into the metal legs of the integrated circuit — must also clearly represent either a 0 or 1 bit. If the specification sheet for an integrated circuit is examined, the corresponding voltage levels representing 0 or 1 are defined. The following diagram represents the actual acceptable input voltage levels for a family of common integrated circuits:

Acceptable TTL gate input signal levels

You can see from the previous diagram that the acceptable input voltage level for a bit 0 is from zero volts up to 0.7 volts. Why 0.7 volts? You will remember that 0.7 volts is the threshold voltage for a transistor. Any voltage lower than that level will not be sufficient to turn that transistor "on".

The threshold voltage on a transistor therefore performs a valuable function. Imagine an input signal coming into an integrated circuit with a value of zero volts (bit 0). If there is a temporary noise spike on that signal of anything less than 0.7 volts, that noise will not be sufficient to turn the first transistor "on" — the signal will still be interpreted as bit 0. So the threshold voltage acts to "clean up" the input signal and insulate the integrated circuit from external noise.

We now see how the threshold voltage in both neurons and transistors can act to convert a continuous, noisy, analogue signal into clean digital information. In *The Emperor's New Mind*, Roger Penrose describes how a similar thresholding mechanism is used by the cells in the retina of our eyes in order to reduce speckled noise in the images we see. Penrose explains that a single photon hitting the retina will not be sufficient to fire a signal: "In this case there is an additional mechanism present which suppresses weak signals, so that they do not confuse the perceived picture with too much visual 'noise'. A combined signal of about seven photons is needed in order that a dark-adapted human subject can actually become aware of their arrival. The type of cells that have been examined all require a threshold to be reached, and a very large number of quanta are needed in order that the cell will fire."

Once converted into a digital format, the input data can be stored in our brains as digital information. Digital information does not decay over time: a digital photograph stored as a file on a computer does not fade like a physical photograph. Digital information can be transmitted without loss and degradation. In contrast, analogue data will inevitably degrade each time it is copied (try making successive photocopies of photocopies). Digital information seems insulated from physical damage. In similar fashion, our mental images are uncorrupted by any interference "snow" which used to afflict old analogue televisions. When we imagine old memories, there are no random white spots appearing in those images. Instead, our mental images seem noise-free like a modern digital television.

In Chapter One it was explained how a consciousness based on information would feel insulated from the physical world. Even though your brain is composed of a material with the consistency of rice pudding, you would not feel as though you were made of rice pudding — your consciousness would feel substrate-independent, independent from the physical world, and insulated from physical damage and the ravages of time. We now see how the threshold voltage — in both neurons and transistors — further acts to insulate our consciousness from the noise of the physical world. The thresholding mechanism prevents the accumulation of electrical noise, both in

microprocessors and in our brains. It is as if our thoughts exist in a realm above the physical world, and insulated from physical damage.

4

COMPLEXITY

In the last chapter it was explained how a large number of nonlinear components can combine to produce systems which cannot be simplified to a simple component. This means that the behaviour of the multiple-component system could never be predicted from just studying the single component. In practice, it means that the behaviour of the multi-component system can be wildly different — completely unrecognisable, in fact — from the behaviour of the single component.

Multi-component nonlinear systems which behave in these surprising ways are said to exhibit *emergent* behaviour. Human intelligence and consciousness is typical of this emergent behaviour, emerging from the interactions of billions of neurons. You would never imagine that behaviour so extraordinary as intelligence and consciousness could arise if you just considered a single neuron in isolation.

The science which considers these nonlinear systems — and their emergent behaviour — is called *complexity*. We shall consider complexity in this chapter.

Chaos

Complexity — and its implications for science — was largely ignored by researchers until the second half of the twentieth century. The catalyst for complexity research was the invention of the digital computer. Suddenly, it became possible to simulate complex systems in the laboratory.

The first example of this surprising emergent behaviour in computer simulations came with the discovery of *chaos*. In the 1960s, the meteorologist Edward Lorenz working at MIT performed a very simplified simulation of weather systems on a computer and found that his simulation behaved in a surprisingly unpredictable manner. The long-term behaviour of the simulated weather displayed extreme sensitivity to initial conditions — any slight difference would eventually produce a wildly different outcome. Hence the well-known phrase about the chaotic behaviour called the *butterfly effect*: "A butterfly flapping its wings in China could cause a hurricane next month in New York". The implications for weather forecasting were clear, as stated on the UK Met Office website: "When looking at forecasts beyond five days into the future the chaotic nature of the atmosphere starts to come into play". It can never be possible to make an accurate weather forecast more than a week or two in advance — no matter how accurate are your measurements or how powerful your computer.

Chaos was considered in detail in my fourth book. In that book, I presented an example of chaotic behaviour emerging from the remarkably simple nonlinear mathematical expression $2x^2-1$ (it was explained in the previous chapter how the x^2 term results in nonlinear behaviour). Using that mathematical expression, it was shown how the following apparently random graph can be produced:

It is clear from the graph that dramatically random behaviour can be produced from very simple arrangements of a few nonlinear components. In fact, this is how pseudo-random numbers are produced in hand-held electronic calculators: a very small subsystem composed of transistors in the calculator's main integrated circuit can produce

the random stream of numbers on demand.

With it being so easy to produce such dramatically random behaviour from a few nonlinear components, it is easy to imagine how a small module of chaotic circuitry in our unconscious brain could be responsible for our random creativity and flashes of inspiration apparently appearing "out of nowhere". There is surely no need to imagine that any more exotic processes — such as random quantum processes — would need to be involved to generate our creativity and inventiveness.

In the December 1986 issue of *Scientific American*, a major article on chaos described this possibility: "Innate creativity may have an underlying chaotic process that selectively amplifies small fluctuations and molds them into macroscopic coherent mental states that are experienced as thoughts. In some cases the thoughts may be decisions, or what are perceived to be the exercise of will. In this light, chaos provides a mechanism that allows for free will within a world governed by deterministic laws."

Emergence

Chaos is one example of the surprising and remarkable behaviour which can emerge in complex systems which contain a huge number of elements. This sudden jump to a new mode of behaviour is called *emergence*, and the resulting behaviour would then be called "emergent" behaviour.

In this book, we are particularly interested in emergence as it is clear that consciousness is a form of emergent behaviour which results from the interaction of billions of neurons. John Barrow describes this surprising nonlinear jump in behaviour in his book "Impossibility": "Complex structures seem to display thresholds of complexity which, when crossed, give rise to sudden jumps in the complexity. Take groups of people. One person can do many things; add another person and a further relationship becomes possible; but gradually add a few more people and the number of complex interrelationships grows enormously. Economic systems, traffic systems, computer networks: all exhibit sudden jumps in their properties as the number of links between their constituent parts grows. Consciousness is the most spectacular property to emerge in this way when a very high level of complexity is reached in a connected logical network, like the brain."

A dramatic example of emergent behaviour is the termite mound, emerging from the behaviour of millions of termites. A termite mound is a vertical city, resembling a human skyscraper, and containing very similar heat regulation and air conditioning systems. The tallest structure constructed by humans is the Burj Khalifa Tower in Dubai, which stands 828 metres tall. With a man measuring — on average — 1.73 metres tall, that means the Burj Khalifa is 479 times taller than its human builder. In comparison, the tallest termite mound so far discovered is 12.8 metres high. With a single mound-building termite measuring just 0.6 cm in length, that means a termite mound is 213 times larger than its builder. [\[12\]](#)

It is clear that termites have the edge when it comes to skyscraper construction. Here is a photograph of a man standing between two enormous termite mounds in the Northern Territory of Australia:

However, each individual termite has no knowledge of how to build the mound, and there is no single "foreman" in overall charge of the project. Each individual termite pursues a very simple operation, guided only by its local environment and its genetically-encoded rules. If you were to study the behaviour of just a single termite you would see no indication that they were capable of such extraordinary feats. The mound only "emerges" when millions of termites interact.

This sudden and unexpected emergence of an impressive capability has seen the property of emergence being described as "The whole is greater than the sum of its parts". As an example, it would certainly appear that the property of consciousness is far more impressive than any property possessed by a single neuron.

Though not everyone is so impressed ...

Reductionism vs. emergence

Many scientists would feel uneasy — or even reject outright — this notion of emergence, the notion that the behaviour of a system cannot be reduced to considering the behaviour of one of its component parts. That is because the philosophy seems to strike against the way we have done science for 400 years.

The modern scientific method is a relatively new phenomenon, the start of which can be traced back to Galileo in the 17th century. René Descartes described his own scientific method in 1638: "To divide all the difficulties under examination into as many parts as possible, and as many as were required to solve them in the best way, and to conduct my thoughts in a given order, beginning with the simplest and most easily understood objects, and gradually ascending, as it were step by step, to the knowledge of the most complex."

The suggestion of Descartes is that the best way for science to progress is to break Nature into its smallest pieces, and analyse how those pieces behave. This has certainly proven to be a successful strategy for science, and has underpinned our technological advances.

This philosophy that a full understanding of behaviour can be achieved by considering the smallest elements of a system is called *reductionism*.

However, the scientist who believes in the importance of emergent behaviour would say the philosophy of reductionism is like saying: "I understand how a brain works because I understand how a neuron works", or "I understand how a computer works because I understand how a transistor works".

The difference of opinion between the reductionists and those who believe in the importance of emergence is often portrayed as an ideological conflict. So which is right: reductionism or emergence?

Well, as is usually the case when you have two sides with strong arguments, both sides are right — and both sides are wrong. It all depends on the behaviour of the components which make-up the system of interest. Specifically, it depends on whether the components which make-up the system are linear — or nonlinear.

The solution was actually presented in the previous chapter when we considered nonlinearity. In that chapter, it

was explained how systems which were formed from linear elements could successfully be reduced to a single component while still maintaining the behaviour of the system. Remember the resistor network being reduced to a single resistor? That was a typical example of reductionism: the single resistor had exactly the same behaviour as the combined network of seven resistors. Reductionism is a convincing argument — with just one problem: **it is only true for linear components**. As soon as you shift to consider nonlinear components (such as neurons and transistors), the argument breaks down. As described in the previous chapter, a system which is composed of nonlinear elements cannot be successfully simplified: the behaviour of the composite system is not completely contained in the behaviour of a single component. This principle is described in the December 1986 issue of *Scientific American*: "The interaction of components on one scale can lead to complex global behavior on a larger scale that in general **cannot be deduced from knowledge of the individual components**."

By simplifying the system, you lose some aspect of the overall behaviour. In that case, your only option is to consider the large-scale emergent behaviour. On the plus side, that emergent behaviour due to nonlinearity can be very interesting indeed (consciousness, for example).

Particle physicists tend to be reductionists: they operate at the lowest-level, and they assume that systems will scale linearly. For many systems and materials, that will be the case: a sample of a few atoms of iron behaves in just the same way as a planet-sized block of iron, for example. If you know the behaviour of atoms, it is a simple process to scale that behaviour up to systems consisting of billions of atoms — as long as those atoms remain in a regular arrangement so that their behaviour scales linearly: a crystal, for example. It is believed that there is a 1,500 mile-long crystal of iron at the centre of the Earth, and geologists know how it behaves because they know how single atoms of iron behave: the behaviour scales linearly.

However, sometimes large numbers of atoms can combine to produce surprising behaviour which is highly nonlinear. The study of these materials is called *condensed matter physics*. Condensed matter physics is the most popular area of physics research (according to a recent poll, one third of all American physicists consider themselves to be condensed matter physicists). That means one third of American physicists are studying emergent behaviour. However, the field gets very little publicity compared to other areas of physics research. This general lack of awareness of the subject was made clear when the 2016 Nobel Prize in physics was awarded to condensed matter research. The announcement of the award sent science journalists scurrying to the internet to find out more about emergent behaviour. [13]

Another example of emergent behaviour when large numbers of particles interact is *superconductivity*. The phenomenon of superconductivity occurs when electrons act together and can freely move through a conductor as though there is no resistance. According to an article by the National Science Foundation: "Take a metal such as lead or tin and cool it below a certain critical temperature: many of the individual electrons in that metal will suddenly start to march in step, so to speak — a collective motion that allows them to flow as if the metal offered no electrical resistance whatsoever. **Again, electrons in the aggregate exhibit behaviors that are nowhere to be found in one electron alone.**" [14]

In the case of nonlinear components there is no way of predicting the onset of emergent behaviour unless you actually connect a huge number of the components together, or maybe run an equivalent huge computer simulation featuring possibly billions of simulated components. There are no short-cuts. As stated earlier, you cannot simplify large complex systems which result from the interaction of nonlinear components — the whole thing becomes a mathematical nightmare.

This is the reason why — as stated earlier — scientists only became able to tackle the problems of complexity when digital computers were invented. Maybe at this point you are starting to realise why complexity presents such a problem for conventional science.

I have seen this mathematical "nightmare" mentioned in the scientific literature. Melanie Mitchell is a professor of computer science who has worked at the Santa Fe Institute which is the world's leading centre for complexity research. In 2009, Mitchell wrote a book entitled *Complexity: A Guided Tour* which is an introduction and overview of complexity. Chapter Two of that book provides a clear explanation of nonlinearity. The mathematical "nightmare" that nonlinearity poses for reductionism is described by Mitchell: "Linearity is a reductionist's dream, and nonlinearity can sometimes be a reductionist's **nightmare**."

It was mentioned earlier that emergence is often described as: "The whole is **greater** than the sum of its parts". In her book, Melanie Mitchell presented a similar succinct phrase to describe reductionism in which the behaviour of components scales in a linear and predictable manner: according to Melanie Mitchell, reductionism can be described as "The whole is **equal** to the sum of its parts".

A measure of emergence: Φ

In the previous chapter, it was explained how Christof Koch and Giulio Tononi have developed a theory of consciousness which is called integrated information theory, or IIT. This is regarded as being the current leading theory of consciousness. If you remember, IIT involves considering the connectivity of the network of information in the brain.

Giulio Tononi has described a numeric value which can be calculated from that connectivity of information. According to Tononi, this numeric value — which is called Φ (the Greek letter "phi") — then represents the consciousness of the network. According to Tononi, this calculation could be applied to anything: from an iPhone to the Milky Way, and the calculated value of Φ would reveal whether or not the object was conscious.

After reading more about Tononi's work, it seems rather clear to my mind that Φ is a measure of the emergent behaviour of a system: the more emergent the behaviour, the more likely the system is to be conscious. Indeed, in his book entitled *Phi*, Tononi describes Φ as the extent to which "the whole is more than the sum of its parts" — the definition of emergence.

The following discussion describes my attempt to visualize this measure of emergence: Φ .

IIT possesses a cool and imaginative feature which is called the "cruellest cut". Tononi considers the situation in which a network of information might be sliced into two smaller networks. What would be lost by doing that? Again, the question boils down to the distinction between reductionism and emergence: a system formed of linear components would lose nothing by being sliced in half, whereas a system formed of nonlinear components — exhibiting strongly emergent behaviour — might find its performance severely reduced by being sliced in half.

The "cruellest cut" is specified as being the single slice of a network which has the most destructive effect, reducing the emergent behaviour by the greatest amount. To illustrate the principle of the cruellest cut, Tononi considers examples involving slicing a conscious brain in two, or cutting the head off a person's body — both of which, I would suggest, place this aspect of the theory firmly in the "untestable" category!

Let us consider the particular example of the brain. It has been described how a brain has approximately 100 billion neurons. We might slice a brain into two parts, each containing 50 billion neurons. In general, this most dramatic of actions — the cruellest cut — would significantly reduce the consciousness present in each of those half-brain parts. In fact, it might eliminate consciousness altogether.

So if 50 billion neurons represents "low consciousness" and 100 billion neurons represents "high consciousness", we might draw a graph showing how consciousness varies with the number of neurons:

You will see from the previous graph that a part containing 50 billion neurons is shown as having "low" consciousness, whereas a part with 100 billion neurons is shown as having "high" consciousness. So the graph is highly nonlinear, with a pronounced upward kink at about the 90 billion neuron mark. This extreme nonlinearity is the signature of emergent behaviour.

So let us now apply that "cruellest cut", dividing the brain into two parts, each part containing 50 billion neurons:

On the previous diagram, you can see a pair of scissors applying the cruellest cut, splitting the brain into two 50-billion-neuron parts. If the cut makes a big difference, then that reveals that the 100-billion-neuron network (the whole brain) vastly outperforms a 50-billion-neuron network (the half-brain part). That would be a clear sign of a highly-emergent network, a sign that "the whole is greater than the sum of its parts". As shown on the diagram, that would result in a large value of Φ .

In contrast, the following diagram shows a situation in which the behaviour of a system scales linearly, in other words, there is no sudden jump in behaviour, no emergent behaviour:

You will see on the previous diagram that the same cruellest cut has been applied at the 50-billion-neuron level. However, in this linear case, the destructive effect of the cut is reduced. Each 50-billion-neuron part has a greater amount of consciousness than the previous example. In this case, it could be said that the whole is **equal** to the sum of its parts — which, as has been stated, is the signature of reductionism. This system could be decomposed into smaller units with no loss of performance. As shown on the diagram, the measured value of Φ would be smaller in this case.

According to integrated information theory, we can then interpret the value of Φ as the amount of consciousness present in any network.

The low-hanging fruit

This seems like a good opportunity for me to say something which is possibly rather controversial ...

On the basis of the discussion so far, we now see why reductionism has been so closely associated with the scientific method. Whenever scientific researchers have had the freedom to pick-and-choose their domain of interest, they have tended to concentrate their efforts on areas which are amenable to this method of decomposition into smaller components. In practice, that means the study of systems formed of linear components. Fortunately, as explained earlier, this has been sufficient to explain the behaviour of many materials when the behaviour of individual atoms is known. The discovery of semiconductors — and the resultant technological revolution initiated by their discovery — would be a good example of this: it has proven to be a route to success.

Unfortunately, this freedom of choice has meant that scientists have tended to avoid considering the difficult mathematically-intractable systems formed of nonlinear components — all of which explains why we have made the amazing discovery of the Higgs boson, while at the same time we are left almost completely in the dark about how the brain in our heads works.

Put more simply, areas have been picked in which most progress can be made, perhaps taking the easier option, and areas involving complexity have been avoided. Because of those choices, the suggestion might be made that scientists have picked the "low-hanging fruit".

The physicist Paul Davies has written a book about complexity called *The Cosmic Blueprint*. At the end of the following extended quote from his book, Davies refers to the general lack of interest in analysing nonlinear complex systems, and how this has resulted in them being "neglected" by scientists (I have placed the relevant sentence in bold): "The greater part of modern science and technology stems directly from the fortunate fact that so much of what is of interest and importance in modern society involves linear systems. Roughly speaking, a linear system is one in which the whole is simply the sum of its parts. Thus, however complex a linear system may be it can always be understood as merely the conjunction or superposition or peaceful coexistence of many simple elements. Such systems can therefore be decomposed or analysed or reduced to their independent component parts. It is not surprising that the major burden of scientific research so far has been towards the development of techniques for studying and controlling linear systems. **By contrast, nonlinear systems have been largely neglected.** In a nonlinear system the whole is much more than the sum of its parts, and it cannot be reduced or analysed in terms of simple subunits acting together. The resulting properties can often be unexpected, complicated and mathematically intractable."

It is interesting to consider the distribution of complex systems according to their size, from the smallest objects in the universe to the largest. Galaxies are huge, but they can be treated as a single unit, rotating about a centre of mass. We can then describe the behaviour of a galaxy by using the relatively simple equations of general relativity. Similarly, at the smallest scales, elementary particles can be described by the relatively simple equations of quantum mechanics. The most complex objects — which therefore cannot be described by simple equations — are found in the mid-scale region.

In 2015, Neil Turok of the Perimeter Institute presented a lecture entitled *The Astonishing Simplicity of Everything* (available on YouTube). In that lecture, he considered how complexity is only found in the middle between the two extreme scales of size. And it just so happens that it is in that middle region of high complexity where we find life, and humans, and conscious brains: "We are in the middle in terms of scale. The astonishing thing about recent discoveries in physics is they tell us the universe is surprisingly simple and regular — on the tiniest scale, and on the hugest scale. It's only complicated in the middle."

The following diagram shows the variation in the complexity of objects according to their size. Just as Neil Turok suggests, the objects with least complexity can be found at the extremes of the scale, whereas life (and the human brain — the most complex object we know of in the universe) is found precisely in the middle of the scale:

The field of physics has progressed by explaining puzzling phenomena by describing that behaviour in terms of simple formulas and laws. For example, the behaviour of the huge celestial bodies — the orbit of the Moon around the Earth, for example — can conveniently be described by nothing more than Newton's laws of motion and a few lines of mathematics. How convenient for physicists!

But imagine a situation in which the size of complex objects had extended out to the extremes of the scale — maybe with living creatures the size of stars or galaxies. In that case, such simplifying methods could not have been applied: we could not have accurately predicted the rotation of galaxies, for example. The behaviour of a galaxy would have, instead, depended on the complex behaviour of its "mind". If that had been the case, the field of physics would have struggled to advance, and the behaviour of the universe would have largely remained a mystery to us.

5

CAN A COMPUTER THINK?

It is the year 2021. The world has been ravaged by the nuclear World War Terminus. Rick Deckard is one of the survivors, struggling to get by on his income as a bounty hunter in a post-apocalyptic San Francisco.

Deckard is hired by the police department to "retire" (i.e., kill) androids which have returned from distant space colonies. But Deckard has a problem. The problem stems from the technology in the latest Nexus-6 androids. According to the spec sheet: "The Nexus-6 brain unit they're using now is capable of selecting within a field of two trillion constituents, or ten million neural pathways."

As a result, the Nexus-6 androids ("andys") are so advanced that they are almost indistinguishable from humans. According to Deckard: "No intelligence test would trap such an andy". In conversation, there is no way of telling the difference between a Nexus-6 android and a human. Deckard has only one hope: the Voigt-Kampff Empathy Test. Apparently, androids feel no empathy with others of their kind: "Empathy, evidently, existed only within the human community". Deckard has to rely on this emotional deficit to detect the rogue Nexus-6 machines.

By now you might have realised that I am describing the plot of Philip K. Dick's classic science fiction novel *Do Androids Dream of Electric Sheep?* The book later formed the inspiration for the equally-classic Ridley Scott movie *Blade Runner*.

Let us rejoin the story of Rick Deckard as he rides in his flying car to the headquarters of the Tyrell Corporation where the androids are manufactured ...

At the Tyrell Corporation, Deckard meets Tyrell's assistant, Rachael. After performing the Voigt-Kampff test on Rachael, he discovers she is an android. However, Rachael is clearly intelligent, conscious, and alluring. What is more, Rachael has been given false memories so she does not realise she is an android.

After a while, Deckard realises he has started feeling "empathy" for Rachael — or maybe something more: "I'm capable of feeling empathy for at least specific, certain androids. Not for all of them but — one or two". Deckard is now faced with a dilemma, and has to wrestle with his conscience: is it ethical to "retire" Rachael, another seemingly-conscious being, even though she is an android? Deckard now starts to question if he is in the right job: "Suddenly, for the first time in his life, he had begun to wonder."

What should Deckard do? How should he behave toward Rachael?

At the heart of the problem appears to lie the question of whether or not an android can be conscious. As described in Chapter One, we use the fact that we are conscious to separate ourselves from the everyday objects — such as clocks and cars — which we do not believe are conscious. When faced with a potentially-conscious android, we would lose that certainty that we are superior. It seems it is the presence of our consciousness which defines us as human.

The need to resolve these questions about the consciousness of androids will become urgent as androids start to perform working roles. For example, it appears androids — combined with the latest speech recognition artificial

intelligence — will soon be acting as multi-lingual airport and hotel receptionists. Here is a photograph from a Tokyo convention of the latest DER2 android produced by the Kokoro Corporation. The android responds to commands in Japanese, Korean, Chinese, and English:

A video of the DER2 in action is available on YouTube:

<http://tinyurl.com/replicantvideo>

Developments in artificial intelligence in androids might uncover a legal minefield. Would a physical assault against one of these androids be regarded as a serious crime, as serious as an assault against a human worker? Should it be considered to be a crime to turn off the power to one of these androids, thereby "killing" it?

If you read the video description on YouTube for the previous video, you will find that at one point in the DER2 android demonstration the android had to warn men not to touch her as that would be considered sexual harassment. The men who were watching the demonstration treated the request seriously and apparently nodded their heads, agreeing to comply. The men had already decided that the android deserved to be treated with equal respect.

And, when Rick Deckard finally decided how to treat Rachael, he came to the same conclusion.

It seems that the answer to these difficult questions will be decided by whether or not we determine the android to be conscious. So in this chapter we will be considering the crucial question as to whether a computer (and, thereby, an android) could ever be conscious. We will be moving away from the hard reality of neurons and transistors, and entering the abstract world of computing and mathematics.

In Chapter One, the principle of substrate-independence was described. That was the idea that if the neurons in your brain were replaced with transistors — or any other form of similar hardware — you would still be conscious. If we assume the principle of substrate-information is true, then that removes one major fundamental objection to a computer becoming conscious.

However, another objection has been raised, based on the method by which modern computers "think" to solve problems. At the heart of a modern computer lies a *microprocessor* (an integrated circuit) which performs one logical or mathematical operation at a time. Problems are then solved by following a step-by-step computer program (or *algorithm*). Each step of the algorithm is clearly-defined, allowing no ambiguity. Every step of the process is as strictly defined as the most formalised piece of mathematics.

However, it has been suggested that this highly-formal approach to problem solving is not a good match for the

human brain as the approach appears to allow no room for ingenuity, random creativity, or intuition. Do humans really follow a rigidly strict sequence of instructions every time they want to solve a problem? Was that really how Einstein's thought processes worked? I very much doubt it.

In another criticism of the algorithmic approach, we will see in this chapter how Alan Turing discovered a remarkable result which revealed that there were some things computers could never compute. Just like the empathy-deficit of the Nexus-6 android, does that mean there will inevitably be fundamental deficiencies in the processing of a computer mind compared to the human mind? Specifically, does all this mean that a computer can never be conscious?

In this chapter we will examine if there are any fundamental limitations on a computer's thought processes. We will start by considering a very dangerous entity for any inflexible and strictly-logical system: the danger of the paradox.

The liar's paradox

In the early decades of the 20th century, the foundations of mathematics were threatened because of the recent discovery of paradox lurking within mathematics. The paradox was based on the *liar's paradox*. As an example, if someone says: "I am lying" or, equivalently "Everything I say is false" then that would represent a paradox. The statement can be either true or false. If the statement is true, then — according to the statement — the statement is false (because the person is lying). Alternatively, if the statement is false, then — according to the corrected statement — the person is telling the truth, so the statement as told by the person must be true.

Either way, we appear to have a statement which is self-contradictory: if it is true then it is false, and if it is false then it is true. That constitutes a paradox.

The particular form of the liar's paradox which threatened the foundations of mathematics is called *Russell's paradox*, and it was discovered by the English philosopher and mathematician Bertrand Russell in 1901. Russell's paradox concerns *sets*, which is the mathematical term for a collection of objects. The paradox can perhaps be easiest understood if we consider an example. So let us consider the collection of men who are shaved by a barber. That collection of men would, mathematically, be known as a set.

To understand how the paradox can arrive, consider the situation in which the barber shaves a man if and only if the man does not shave himself. Let us consider the set of men who are shaved by the barber.

So let us now ask the question: is the barber himself in the set? In other words, does the barber shave himself or not?

If the barber **is** in the set then, by the set definition, that means he **does not** shave himself. In which case then, according to his rule, he **does** shave himself and should therefore **not** be in the set. But if the barber is **not** in the set then, by the set definition, that means he **does** shave himself. In which case then, according to his rule, he **does not** shave himself and so **should be** in the set.

So, as with the liar's paradox, we have a situation which if it is true then it is false, and if it is false then it is true.

Paradoxes are so destructive in mathematics because mathematics attempts to clearly and unambiguously decide the truth or falsity of a statement expressed in clear mathematical language. As a simple example:

"Two plus two equals four"

is an example of a **true** mathematical statement, whereas:

"Two plus two equals five"

is an example of a **false** mathematical statement.

In that sense, mathematics can be seen as the "route to truth and clarity" about the world. And that truth is unchanging for all time: when a mathematical theorem is proved to be true, it remains true forever. However, if there are paradoxical statements which can be expressed mathematically which are **both true and false** at the same time, then that clarity becomes lost. We are left with indecision and uncertainty, and mathematics as some "route to truth" appears doomed.

An example of the destructive capability of a paradox was shown in an episode from the original series of *Star Trek* called "I, Mudd", broadcast in 1967. In the episode, the Enterprise is hijacked by an android named Norman. Norman reveals himself to be inflexibly logical in his thought processes, and Captain Kirk realises this represents a weakness which they can exploit. As a result, the android is defeated by the liar's paradox by simply telling it: "I am

lying". The android quickly realises the paradox, and it proves to be more than the ultra-logical android brain can handle.

Here is the android's response to the paradox: "You say you are lying but, if everything you say is a lie then you are telling the truth. But you cannot tell the truth because everything you say is a lie. But you lie ... you tell the truth ... illogical ... illogical ... please explain ... you are human ... **only humans can explain the behaviour ...**"

At which point smoke pours out of the android's head and it is destroyed.

The scene in which the android is destroyed is available on YouTube: <http://tinyurl.com/liarsparadox>

This represents an excellent demonstration of the destructive capabilities of a paradox, capable of tearing-down a strictly logical system. This also reveals how paradoxes were perceived as being such a threat to the logical foundations of mathematics at the start of the 20th century.

But the parable of Norman the android also appears to reveal a possible limitation on the "thought processes" of a computer. The final line spoken by Norman is particularly revealing: "Only humans can explain the behaviour". Norman appears to be admitting that there are fundamental differences between the workings of a human mind and the workings of a computer mind. It would appear that the human mind has a greater capacity to understand certain difficult concepts (for example, understanding the principle of a paradox). It would appear that a rigidly-logical computer would be unable to "get its head round" the concept of a paradox. However, humans (and Vulcans) would have no such limitation. Even the highly-logical Spock is able to consider the implications of the liar's paradox without smoke pouring out of his head.

So, can a computer think? Maybe, but it appears we have discovered that there might be limitations on what they can think.

The halting problem

The year is 1936.

Alan Turing — the brilliant English mathematician — is 22 years old and has just been awarded a research fellowship at King's College in Cambridge University. The fellowship was worth £300 a year, which was not much money even in those days, but it was enough to provide Turing the freedom to pursue his ideas in an idyllic environment.

Here is a photograph of King's College in Cambridge:

Turing was lying in the grass in Grantchester Meadows when he had a brilliant insight.[\[15\]](#) It was an insight which would reveal a truly extraordinary limitation on the ability of all computers.

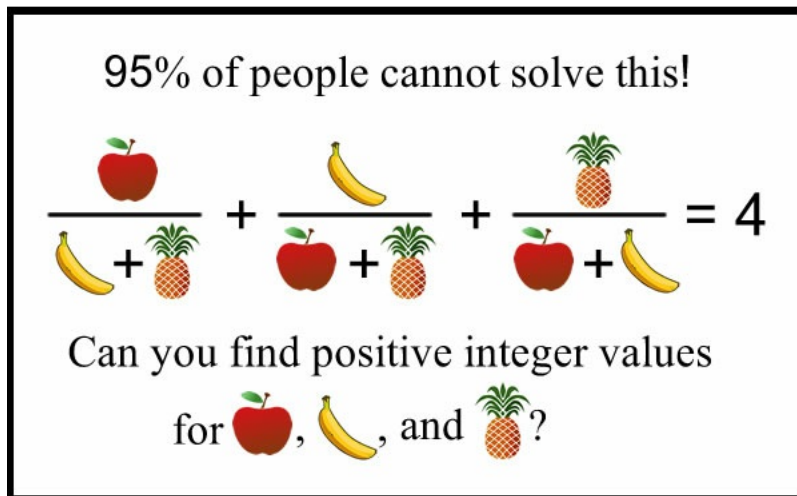

Turing's idea considered the apparently simple question of determining whether or not a computer program

eventually halts (stops running, and then usually producing some useful output). The alternative would be that the program might run forever, trapped in a never-ending loop, never halting to produce useful output.

The subject of Turing's idea — whether or not a computer program halts or loops forever — might appear quite abstract and uninteresting, but the consequences were to be huge.

It might appear fairly obvious that one way of determining whether or not a program halts is just to leave it run and see whether or not it eventually halts. However, we shall now see that that strategy will not work in all circumstances.

If you are on Facebook then you are probably tired of those silly mathematics problems that people share which turn out to be incredibly simple. The following image resembles one of those problems — in appearance at least. Let us call it the "Facebook fruit problem" as it features apples, bananas, and pineapples:

In order to solve the puzzle, you will see that you need to find the positive integer values represented by the apple, the banana, and the pineapple.[\[16\]](#) An example of the sort of whole-number solution we are seeking would be for the apple to have the value 5, the banana to have the value 3, and the pineapple to have the value 2 (these are not the correct answers). You might like to try to solve the problem yourself, but I warn you not to spend too much time on it.

You might write a simple computer program to solve this puzzle via trial-and-error. The program would start by setting the values of the apple, banana, and pineapple all equal to 1. The program would then test if those values solved the equation. If the equation was not solved, then the program would increase the value of one of the fruits by 1 and try again. The program would continue increasing the values until a solution was found. This would represent an exhaustive brute-force search of all possible solutions.

I can tell you that after a few years — or even a few decades — your program would not have found the solution to the puzzle. Therefore, after that length of time, and testing so many possible solutions, you might feel justified in stopping your program and announcing: "The puzzle has no solutions".

However, you would not be justified in halting the program and making that announcement. This is because, rather staggeringly, the correct value for the apple is: 154,476,802,108,746,166,441,951,315,019,919,837,485,664,325,669,565,431,700,026,634,898,253,202,035,277,999

which is an astronomical number composed of 81 digits which is approximately equal to the number of atoms in the universe. It is approximately equal to ten thousand quadrillion quadrillion quadrillion quadrillion.

Fortunately, the correct value for the banana is rather smaller. It is only: 36,875,131,794,129,999,827,197,811,565,225,474,825,492,979,968,971,970,996,283,137,471,637,224,634,055,579 a number which merely contains 80 digits.

Finally, the correct value for the pineapple is relatively tiny, being composed of only 79 digits: 4,373,612,677,928,697,257,861,252,602,371,390,152,816, 537,558,161,613,618,621,437,993,378,423,467,772,036

If you did manage to solve the problem then, very well done indeed! Apparently, according to the Facebook meme, you can now consider yourself to be in the top 5% of the population (I'm joking — it means you probably work for the NSA). [\[17\]](#)

In his book *Programming the Universe*, Seth Lloyd makes the point that sometimes it is very easy to tell if a

computer program will halt, or loop forever, just by looking at the program. As an example, the simple one-line computer program:

```
PRINT "HELLO"
```

will just print "HELLO" and then halt (stop). So it is very clear to see that this simple one-line program will halt — without actually having to run the program.

As an example of the second type of behaviour, it is clear that the following two-line BASIC program will loop forever and never halt:

```
10 PRINT "HELLO"  
20 GOTO 10
```

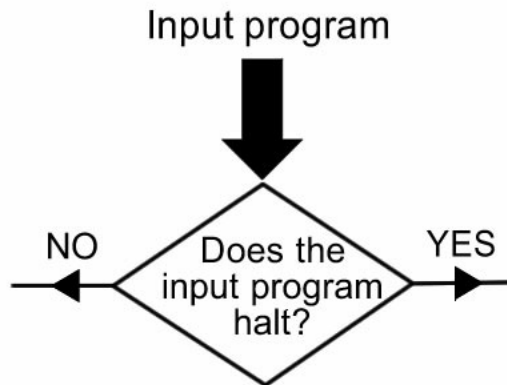

In the program, you will see at line number 10, the computer will print "HELLO". The computer will then advance to line 20 which says "GOTO 10", which means the computer has to loop back to line 10 and print "HELLO" again. This looping will continue forever (rapidly filling the screen with "HELLO"). It can be seen that this looping behaviour means that the program will never halt.

So it would appear it is possible to determine whether or not a program will eventually halt just by looking at the program and analysing that program — without actually having to run the program. We might then wonder whether we might be able to automate that process: could we write a sophisticated computer program which takes any other program as its input and then determines whether or not that input program will halt? Such a sophisticated program would be able to solve the Facebook fruit problem instantly — without having to run a brute-force algorithm for billions of years. The question of whether or not it is possible to write that general program is called the *halting problem*. The solution to the halting problem is not obvious, and it was considered to be one of the most important problems in early 20th century mathematics.

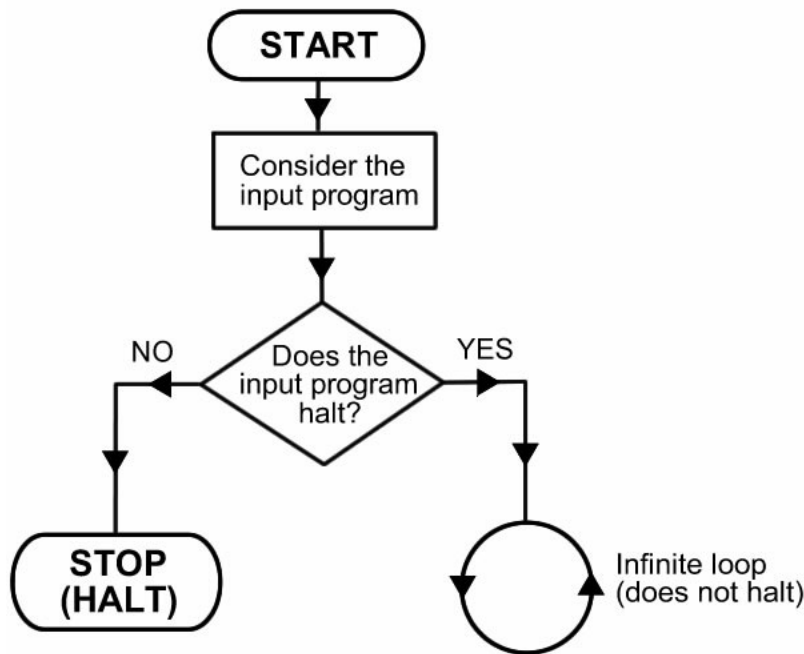

The halting problem caught the attention of Alan Turing, and it was while he was lying in the grass in Grantchester Meadows that the solution to the problem came to him. To cut a long story short, Turing was able to show that it would never be possible to write a single general computer program which would be capable of determining whether or not another program halts.

Turing's method was ingenious, and the form of the method resembles the "liar's paradox" which was described earlier in this chapter.

Firstly, let us imagine that it is possible to write a general-purpose algorithm to determine whether or not an input program halts. Let us denote that piece of code — which tests whether or not a program halts — by the following diamond in a flowchart diagram (the diamond represents a decision box):

Turing proposed that that piece of code — which performs the halting test — could then be included as part of the following program:

You will see from the flowchart that if the input program **does not** halt, then the flowchart halts. But if the input program **does** halt, then the program loops forever, i.e., it never halts.

So we can see from the flowchart that the behaviour of the flowchart algorithm is precisely the opposite of the behaviour of the input program. If the input program **does not** halt then the flowchart algorithm **does** halt. But if the input program **does** halt then the flowchart algorithm **does not** halt. As I said, the behaviour of the flowchart algorithm is precisely the opposite of the input program.

Alan Turing then did something ingenious. He took the flowchart algorithm (which can be coded as a computer program) **and presented it as input to itself!** Turing then asked the question: "Does the resulting program — given itself as input — halt or loop forever?"

There are two possibilities. If the input program **does** halt then — according to the algorithm — the flowchart algorithm **does not** halt and so the input program does not halt. Conversely, if the input program **does not** halt then — according to the flowchart — the flowchart algorithm **does** halt and so the input program does halt.

So if the input program does halt then it does not halt, and if the input program does not halt then it does halt. As in the liar's paradox, the self-referential nature of Turing's method has created a paradox.

A paradox is a situation which cannot exist: a computer program has to either halt or not halt — it can't do both. The only conclusion we can make is that the general halting tester program — the piece of code in the diamond — cannot exist. This method which Turing used in his proof is called "proof by contradiction".

Turing had therefore solved the question of the halting problem: it could never be possible to write a general algorithm which could determine if any other program either halted or looped forever.

Turing published his solution in 1937 in *Proceedings of the London Mathematical Society*. This was a magnificent achievement by Turing, and it established his reputation as a top-rank mathematician.

The implications for the android brain, however, are not so appealing. The result suggests that if we have a computer brain then there will always be a problem (the halting problem being an example) for which it is known that there is a solution (a program will definitely either halt or not halt) but the computer brain cannot calculate that solution. The solution is then said to be *uncomputable*.

The new mind of Roger Penrose

Turing's solution to the Halting Problem seems to suggest that there is a fundamental limitation of the computer mind. We will now see how one of the most eminent English physicists suggested that this limitation meant that computers do not function like the human brain, and therefore can never be conscious.

Roger Penrose's greatest achievement in physics came in the 1960s when he proved that a collapsing star had to form a singularity: a black hole. Working with Stephen Hawking, he then showed that the same principle had to apply to the universe as a whole: if you reverse time, the universe had to have emerged from a singularity at the time of the Big Bang.

In 1989, Roger Penrose wrote a physics book aimed at a general audience called *The Emperor's New Mind*. The market for popular science publishing in physics had been established a year earlier by Stephen Hawking's bestseller *A Brief History of Time*. As a result, Penrose's book was tremendously popular. I read the book when it came out as did many of my friends, and I know it motivated many readers to get interested in physics.

In his book, Penrose presented his case that computers operated fundamentally differently from the human mind and, as a result, computers can never be conscious. Penrose used Turing's solution to the Halting Problem which showed — as has just been described — that there are some problems which have solutions which can never be calculated by a computer. This appears to represent an intellectual deficiency of the computer — but it is not believed that humans possess a similar deficiency. For that reason, Penrose's theory suggested that these computer minds could never be conscious.

As stated earlier, computers solve problems by following a scripted algorithm in a very rigid, predictable, step-by-step manner. Penrose calls this type of behaviour *algorithmic*. An algorithmic mind has to stick to the script of its program, unable to go "off-script", being bound by rigid logic. An example of an algorithmic mind would be Norman the *Star Trek* android considered earlier. Norman's algorithmic mind is so rigid and inflexible that he is unable to consider the liar's paradox without smoke pouring out of his head.

In contrast, the minds of Captain Kirk and his crew are more flexible, not bound to following a step-by-step algorithmic program. As suggested at the start of this chapter, surely Einstein's mind did not follow a strict sequence of rules. Human minds are capable of going "off-script" by introducing original thinking. Penrose calls these types of minds *non-algorithmic*.

Penrose's theory is not fully stated until the final chapter of his extensive and wide-ranging book. As Penrose says in that final chapter: "It has, indeed, been an underlying theme of the earlier chapters that there seems to be something **non-algorithmic** about our conscious thinking." Penrose then introduces his theory which suggests a clear division between conscious and non-conscious minds on the following basis: **a non-algorithmic mind can be conscious, whereas an algorithmic mind can never be conscious.**

Therefore, according to Penrose's theory, we should not consider Norman the android to be conscious because his mind is algorithmic, forced to follow a strict program. In similar fashion, according to Penrose, no computer which follows a strict program could ever be conscious.

But how could we ever test Penrose's theory? It would appear we would need to compare the mind of a computer with the mind of a human, and somehow determine whether the algorithmic "mind" of the computer was conscious. But how could we ever get "inside the mind" of a computer to test Penrose's theory? It would seem to be an impossible task.

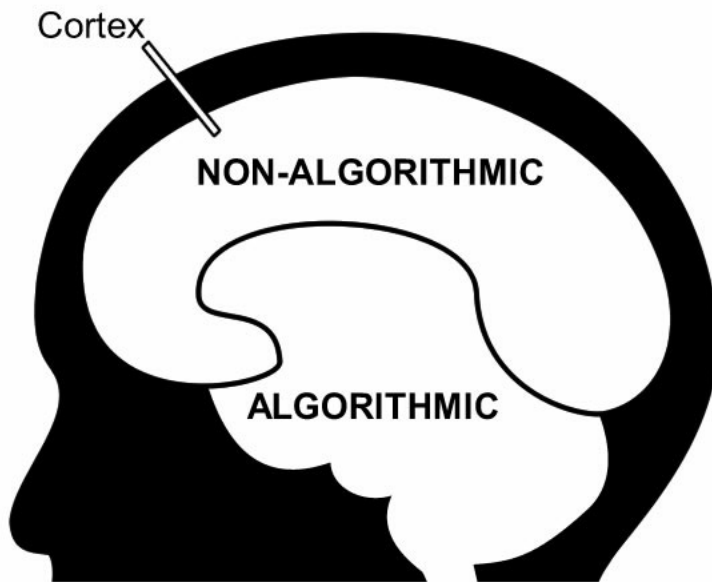

However, we have the perfect testing ground on which we can test Penrose's theory. And that testing ground is the human brain.

The brain appears perfect to test Penrose's theory because it is a device which is divided into two sections: one section operates algorithmically, while the other section operates non-algorithmically. What is more, we are able to "get into the mind" of this device, to determine if either of the two different sections are conscious.

As described in Chapter Two, the lower levels of the human brain are responsible for repetitive behaviours, such as walking and breathing, and also being responsible for monitoring body temperature and carbon dioxide levels in the blood. These are all functions which could be performed by a computer following a strict program. For that reason, we can consider the lower levels of the brain as representing **algorithmic** behaviour. As an example, the mind of Norman the android would operate like the algorithmic lower levels of our brain.

In contrast, the higher level of the brain does not follow a strict "program", and is therefore capable of going "off-script" to introduce original thinking, creativity, and problem solving for which — as Penrose suggests in the final chapter of his book — "no clear algorithmic process exists".

So let us redraw the simple map of the brain from Chapter Two to show the algorithmic and non-algorithmic regions:

Let us remind ourselves what Penrose's theory suggests. According to Penrose, an algorithmic mind (like Norman the android) **cannot** be conscious, but a non-algorithmic mind **can** be conscious. And when we consider the two sections of the human mind shown in the previous diagram — **this is exactly what we find!** As described in Chapter Two, conscious behaviour is believed to reside in the higher level of the brain (which is shown to be the non-algorithmic region on the diagram), whereas the lower levels of the brain — the algorithmic regions — are believed to be unconscious.

To my mind, this represents strong evidence in support of the theory of Roger Penrose.

In the final chapter of his book, Penrose presents a description of how the conscious (non-algorithmic) and unconscious (algorithmic) mind work together to learn a new skill, for example, learning to drive a car. During the learning process, the conscious mind would be very active, solving problems ("How do I overtake the car in front?"). As Penrose explains, the conscious mind would have to be used to solve the problem rather than the unconscious mind because "no clear algorithmic process exists" at that stage. However, once the problem is solved and you have overtaken a few cars, you have learned how to perform the task. It might be said that the learning process involves "writing your own computer program" to solve the task: you are generating a new algorithm. But once your conscious mind has generated that new algorithm, it can then be handed-down to the lower-level unconscious brain. It can then be said that you have learned a new skill. Then, the next time you need to overtake a car the unconscious brain can follow that program algorithmically and perform the task without having to involve the higher-level conscious mind. As a result we can drive our cars virtually automatically, without having to get consciously involved.

In his book *Consciousness*, Christof Koch presents a similar description of the difference between the conscious and unconscious mind. Koch explains how consciousness is needed for training, but then the unconscious mind can take over: "Much of the ebb and flow of daily life does indeed take place beyond the pale of consciousness. This is patently true for most of the sensory-motor actions that compose our daily routine: tying shoelaces, typing on a computer keyboard, driving a car, returning a tennis serve, running on a rocky trail, dancing a waltz. These actions run on automatic pilot, with little or no conscious introspection. Whereas consciousness is needed to learn these skills, the point of training is that you don't need to think about them anymore; you trust the wisdom of your body and let it take over."

So it appears we might have found a valuable principle on our quest to uncover the secrets of consciousness: a clear definition of when biological material should be considered to be conscious, and when it cannot be capable of consciousness. If that material is algorithmic — if it follows a strict program — it cannot be conscious. But if that biological material is capable of non-algorithmic behaviour, then it has the potential to be conscious.

Quantum theories of consciousness

The latest incarnation of Roger Penrose's theory of consciousness is controversial because of Penrose's decision to incorporate some highly-unorthodox ideas based on quantum mechanics. This approach has received a great deal of criticism. So, in this section, let us consider some of the various quantum theories of consciousness.

Quantum theories of consciousness have proven popular almost from the first day that quantum mechanics was discovered. I would say there are two ways in which quantum mechanics might have an influence on theories of consciousness.

Firstly, quantum mechanics seems to present a mechanism by which the notion of "free will" might be given some foundation in science. When Newton proposed his three laws of motion in 1687, it appeared that the evolution of the universe was governed by strict laws — with no room for deviation. All successive states of the universe would be set in stone, determined by the original state of the universe and the application of Newton's laws. This principle has been called the "clockwork universe".

However, as the atoms of the brain follow Newton's laws, this would appear to indicate that the evolution of our thought processes — for our entire lives — are also determined by the position of the atoms in our brains at birth, and the application of Newton's laws. Where, then, is there any room for free will — the notion that we could behave differently if we chose to? Is free will just an illusion? Are all our decisions for our entire lives set in stone at birth?

The idea that all our decisions are actually decided well in advance was reinforced by a classic experiment. In the 1980s, a consciousness researcher named Benjamin Libet performed a series of experiments at the University of California, San Francisco. It was known that before a human subject performs a simple physical activity — such as pushing a button — there was a characteristic pattern of electrical activity in the brain known as the *readiness potential*. Libet set out to time this readiness potential, so he connected a volunteer to an EEG and the volunteer was asked to push a button several times at will. The volunteer had complete choice as to when he or she should push the button.

What Libet discovered was amazing. The readiness potential could be detected in the unconscious region of the brain about half-a-second before the person took the conscious decision to press the button. It appeared the decision to push the button was actually being made by the unconscious brain, with the apparently conscious decision being a mere illusion of free will occurring several milliseconds later.

Libet's experiment appeared to reinforce the idea that there can be no free will in a clockwork universe, with everything being determined some time previously. However, with the discovery of quantum mechanics in the early 20th century, the door was opened for free will to make a comeback.

Quantum mechanics introduced fundamental uncertainty, and eliminated the concept of the clockwork universe. According to quantum mechanics, when we make a measurement at the most fundamental level, i.e., the level of individual particles, **we will get a fundamentally random result**. As described in my first book, the situation resembles a ball spinning round a roulette wheel. It is fundamentally impossible to predict in which slot the ball will land: you are prohibited from dismantling the system in order to predict the motion of the ball in terms of more fundamental quantities (because there are no more fundamental quantities — we are already at the fundamental level).

So, if the motion of the atoms in our brains are actually controlled by the random processes of quantum mechanics, this eliminates the concept of the clockwork universe and reintroduces the possibility of some degree of

free will. This principle was described by Christof Koch in an interview which is available on YouTube:

<http://tinyurl.com/freewillvideo>

In the video, you will note that the interviewer says: "If our feeling of authorship is just a froth that arrives after our brain has made the actual decision then how can we possibly have free will?" in a reference to the previously-described Libet experiment.

However, if our thoughts are decided by the fall of random quantum dice, does that really mean we have free will in the conventional sense of the term?

The second proposed role for quantum mechanics in consciousness comes during the so-called "collapse of the wavefunction". In quantum mechanics, it is the case that particles can behave as though they are in a peculiar multi-valued state called a *superposition state*. For example, in the famous double-slit experiment a particle can appear to travel through two different slits at the same time — as though the particle is in two places at once. At that point, the particle is described mathematically by a *wavefunction*. However, once the particle has passed through the two slits and hits a screen, the particle is found to exist in only one place. In other words, when the particle is observed, it is said that the wavefunction has "collapsed" into a single state, and only one position of the particle is left.

But what physical process is responsible for this "collapse of the wavefunction"? In 1932 the mathematician John von Neumann — who was the foremost mathematician in the world at that time — proposed a controversial solution. Von Neumann wrote an influential book titled *The Mathematical Foundations of Quantum Mechanics*, and in that book he proposed that the collapse was caused by the consciousness of the experimenter. Basically, the experimenter formed the final link of a causal chain: by the time the experimenter considered the experiment, it was essential that the particle was only in one position. So the experimenter's final act of conscious observation was responsible for collapsing the wavefunction.

Von Neumann's "consciousness causes collapse" interpretation is not popular with physicists today, though in a recent poll, 6% of physicists still agree with it. However, our knowledge of the underlying physical principles of quantum mechanics has advanced since Von Neumann's time. It is now believed that the influence of the general environment (for example, dust particles hitting an electron, or the random arrangement of atoms in a screen hit by a particle) has the effect of "collapsing the wavefunction". This is because, in general, environmental effects are random and noisy, so when a particle interacts with billions of random atoms in the environment, there is an "averaging" effect which progressively reduces the strange superposition effects and only leaves us with a well-defined state which is not in a superposition. This is why we do not find Schrödinger's famous cat both alive and dead at the same time!

This process by which the environment acts to "collapse the wavefunction" is called *environmental decoherence* or just *decoherence*. This process is now generally-accepted and uncontroversial among most physicists. The effect has been tested in many experiments, and, as we shall soon see, an understanding of the decoherence process is allowing new forms of powerful computing to be developed.

So there is no need for a conscious observer to "collapse the wavefunction". Any random environment can act as an "observer". For example, an electron hitting a screen will be "observed" by the screen, thereby revealing the position of the electron. The fact that a conscious observer is not required to collapse the wavefunction is described by Max Tegmark in his book *Our Mathematical Universe*: "Now I was convinced that consciousness had nothing to do with it, since even a single particle could do the trick: a single photon bouncing off a object had the same effect as if a person observed it."

Because decoherence is such a powerful effect, usually occurring in a tiny fraction of a second, it is extremely difficult to keep a particle in a superposition state. However, if we can manage to keep a particle in a superposition — by completely insulating it from any interaction with the environment — then there might be big advantages. As an example, imagine a computer made out of particles in a superposition state. Just as particles in a superposition state can be in many places at once, so a computer made out of those particles would be able to perform many calculations at once! This is the general principle behind *quantum computing*. [18]

When he had finished writing his book *The Emperor's New Mind*, Roger Penrose was convinced that some form of non-algorithmic computing was necessary for consciousness, but he was unsure at the time where to find this new form of computing. But when he became aware of the extraordinary potential of quantum computing, this

represented the possible breakthrough he was seeking. His feelings at the time are described in the following video (with Penrose still in great form at the age of 82):

<http://tinyurl.com/penrosetheory>

As Penrose states in the video: "To me, there is something outside the computational laws of physics. When I wrote my book *The Emperor's New Mind* I was trying to develop this idea, and I was trying to say there was something else out there. What could it be? Where is the biggest gap in our understanding of physics? There is a big gap within present day understanding of quantum mechanics."

Penrose then wonders if "inside our heads we are **exploiting** that gap. That would take us to a level somewhat beyond present technology in our experiments". Penrose is inferring that it might be possible to have something resembling a quantum computer — with its associated extraordinary computing power — hidden somewhere in our brains. Up to this point, this all sounds reasonable enough. But it is at this point that the problems really start. Because, as Penrose states, in order to "exploit" quantum computing in our brain would require techniques "beyond present technology". Present technology is revealing just how difficult it is to keep particles in superposition states for extended periods of time — and avoiding environmental decoherence. Rudimentary quantum computers are now appearing, but the particles have to be isolated from the environment and kept at a temperature just a fraction of a degree above absolute zero — 250 times colder than deep space — to eliminate thermal noise (random noise could cause decoherence). Even in those extreme laboratory conditions, the superposition state can only be maintained for a few microseconds.

However, a brain is warm, wet, and messy. Is it at all realistic to imagine a quantum superposition state could be maintained in the brain for any meaningful length of time? Indeed, in the previous video Roger Penrose is quite realistic about this unlikely possibility (referring to the surprising method by which nerve signals are transmitted via the physical movement of ionised atoms, which was described in Chapter Two of this book): "When I wrote *The Emperor's New Mind* I knew something about nerve propagation and it just didn't seem to me that there was a chance to maintain a superposition because nerve propagation disturbs the rest of the brain in a way which would completely destroy the coherence that you would need in your quantum system. I thought that when I had finished writing the book, maybe I would see the answer. No, I didn't."

However, at this point, Penrose received a letter from a medical doctor named Stuart Hameroff. Hameroff had read Penrose's book and he believed he had the solution being sought by Penrose.

Hameroff told Penrose about *microtubules*, which are microscopic cylinders made of protein which are distributed throughout the cell body of a neuron and which allow cells to maintain their shape. According to Hameroff, these microtubules could allow for the exploitation of quantum behaviour in the brain. Hameroff believed that particles contained in the centre of the microtubules, and surrounded by protective gel, could remain sufficiently isolated from the environment to delay the onset of decoherence. Surprisingly, Penrose bought-in to Hameroff's highly-speculative idea.

However, the physicist Max Tegmark spoiled the party when he published a paper containing detailed and extensive calculations showing that decoherence in microtubules would occur in just 10^{-13} seconds (100 quadrillionths of a second).^[19] This would be far too fast to allow the exploitation of quantum behaviour. According to Tegmark, in that case: "For my thoughts to correspond to quantum computation, they'd need to finish before decoherence kicked in, so I'd need to be able to think fast enough to have 10,000,000,000,000 thoughts each second. Perhaps Roger Penrose can think that fast, but I sure can't ..."

Frankly, I would have thought that just the fact that the brain is at body temperature should be sufficient to allow us to disregard the possibility of quantum computer-style behaviour in the brain.

Stephen Hawking has considered these quantum ideas of his friend and colleague Roger Penrose and has announced that he is not impressed. According to Hawking: "I get uneasy when people, especially theoretical physicists, talk about consciousness. His argument seemed to be that consciousness is a mystery and quantum gravity is another mystery so they must be related."

To sum up, I believe Roger Penrose was correct in his book to suggest that non-algorithmic computing is necessary for consciousness. However, I feel his pursuit of a quantum solution has been a red herring.

Instead, in the next chapter we will be seeing how recent developments in artificial intelligence and integrated circuit design have moved toward a "neural" computing architecture which operates according to a non-algorithmic method — just as Penrose predicted.

Rather wonderfully, we will also be seeing that this non-algorithmic architecture bears an uncanny resemblance to the structure of the brain cortex. We will also be seeing how this new non-algorithmic approach most definitely has the possibility for going "off-script" and springing surprises — though maybe not all of those surprises might be

particularly welcome.

6

THE RISE OF AI

Alan Turing's paper on uncomputability was published in 1937, just before the outbreak of war in Europe in 1939. Alan Turing is today best known for his extraordinary wartime achievement of breaking the German Enigma code. You can read the amazing story of Turing and his colleagues at the Allied codebreaking centre in Bletchley Park in my seventh book.

In 1943, Turing was dispatched from Bletchley Park to coordinate efforts with the American cryptographers. Turing boarded the Queen Elizabeth ocean liner and travelled to New York City, with the course of the liner zig-zagging to avoid German U-boats. At the time, an average Allied ship made just four crossings of the Atlantic before it was sunk. Turing made the crossing safely.

Turing visited the Bell Telephone Laboratories in New York City (if you remember, the incredible Bell Telephone Laboratories were described in Chapter One). One day, Turing went for lunch in the Bell Labs cafeteria when he met none other than Claude Shannon (who was also described in Chapter One: remember the man with the intense gaze who was to become the father of information theory). Shannon and Turing started meeting regularly in the cafeteria and discovered that they had similar interests. In particular, they found they were both interested in the possibility of creating artificial thinking machines.

According to Turing: "Shannon wants to feed not just data to a computer brain, but cultural things! He wants to play music to it!" But Turing had a fundamentally different goal. According to Turing: "No, I'm not interested in developing a **powerful** brain. All I'm after is just a **mundane** brain, something like the president of the American Telephone and Telegraph Company."

And it was in the pursuit of this goal — to create a mundane brain — that Alan Turing was to launch the science of *artificial intelligence*, or AI. If we want to understand consciousness, then progress in artificial intelligence might provide our best hope. This was explained by Celeste Biever in a *New Scientist* article: "The quest for machine consciousness may be key to solving the mystery of human consciousness, as even scientists outside AI research are starting to acknowledge. 'The best way of understanding something is to try to replicate it', says psychologist Kevin O'Regan of Descartes University in Paris. 'So if you want to understand what consciousness is, well, make a machine that's conscious.'" [20]

The Turing Test

The dawn of artificial intelligence is generally accepted to have occurred in 1950 when Alan Turing published a landmark paper entitled *Computing Machinery and Intelligence* in the philosophy journal *Mind*. In that paper, Turing first described the Turing Test. The aim of the Turing Test is to determine if a computer's intelligence is indistinguishable from that of a human.

Turing's original paper which launched the science of AI is available at the following link:

<http://tinyurl.com/turingai>

Considering the paper was written right at the start of the computer age — the first stored-program electronic digital computer had been built just two years earlier — it is a remarkably prescient piece of work. The paper anticipates most of the developments in computer science and artificial intelligence which would take place over the next seventy years, including the development of machine learning, and anticipating exponential improvements in computer speed and storage.

You will see that Section One of the paper is called "The Imitation Game" (which was to become the name of the successful movie about the life of Turing). In that first section, Turing describes his test.

In the test, there is a human interrogator on one side of a wall, and on the other side of the wall — hidden from the interrogator — there is a human and a computer. The interrogator can only communicate with the human and the computer via a text-only channel, typing on a keyboard, and reading the responses on a screen.

The computer is running an artificial intelligence program which is able to interpret the messages which are typed

by the interrogator, and can then give intelligent responses back to the interrogator. The human — who is next to the computer and similarly hidden from the interrogator — also provides intelligent responses to the questions.

The task for the computer running the AI program is to convince the interrogator that it is a human. At the end of the question-and-answer session, the interrogator has to decide which of the respondents is the computer on the basis of their responses.

If the interrogator correctly identifies the computer as the artificial intelligence, the computer is then said to have failed the test (it has failed to convince the interrogator). However, if the interrogator decides that the human is the more likely of the two to be the artificial intelligence, then the computer is said to have passed the Turing Test. According to Turing, we should then consider the computer as being able to "think" like a human.

The AI program can be as devious as it likes in its aim of fooling the interrogator. Most obviously it would answer "No" when asked directly if it is a computer. More cunningly, it might take a while before responding with an answer to a difficult calculation.

At the time of writing this book, no computer has passed the Turing Test, and it seems likely to be many years before the test will be passed.

However, assuming that the Turing Test is eventually passed by a computer, would that necessarily mean that the computer is conscious? Turing considers that question in Section Six of his paper under the heading "The Argument from Consciousness". Turing starts by presenting an extract of a lecture given by the British neurologist Geoffrey Jefferson in 1949: "Not until a machine can write a sonnet or compose a concerto because of thoughts and emotions felt, and not by the chance fall of symbols, could we agree that machine equals brain — that is, not only write it but know that it had written it. No mechanism could feel (and not merely artificially signal, an easy contrivance) pleasure at its successes, grief when its valves fuse, be warmed by flattery, be made miserable by its mistakes, be charmed by sex, be angry or depressed when it cannot get what it wants."

In response, Turing argues that it would be extremely difficult to ever be sure that a machine is thinking: "The only way by which one could be sure that a machine thinks is to be the machine and to feel oneself thinking." In the absence of actually being able to be the machine, Turing suggests that the only way we could judge if a machine is actually thinking is to see if it passes the Turing Test.

However, Turing is under no illusion that his test has solved the problem of consciousness, as he says in his paper: "I do not wish to give the impression that I think there is no mystery about consciousness."

After Turing published his landmark paper in 1950 and introduced AI to the scientific community, there were many attempts to produce computer programs which could converse in a seemingly intelligent manner and potentially pass the Turing Test. Perhaps the most famous example was the ELIZA program written in the mid-1960s by Joe Weizenbaum at MIT. ELIZA was designed to act like a human psychotherapist, giving reassuring interviews to users.

Here is an extract of an actual dialogue between a human female and ELIZA:

Human: My boyfriend made me come here.

ELIZA: YOUR BOYFRIEND MADE YOU COME HERE?

Human: He says I am depressed much of the time.

ELIZA: I AM SORRY TO HEAR THAT YOU ARE DEPRESSED.

Human: I need some help, for sure.

ELIZA: WHAT WOULD IT MEAN TO YOU IF YOU GOT HELP?

Human: I could live a more normal life.

ELIZA: WHAT DO YOU MEAN YOU COULD LIVE A MORE NORMAL LIFE?

You will see that ELIZA is very simple and limited in its responses, mainly just rephrasing the patient's replies as questions. Despite that, some users formed an emotional bond with ELIZA. Even Weizenbaum's own secretary sometimes insisted on privacy at times so she could converse with ELIZA.

In his book *Turing*, Jack Copeland describes an occasion when a business executive attempted to contact a member of the IT staff of his company via the company's internal messaging service. Unfortunately, the IT

technician had ELIZA running on his desktop computer at the time, and it was ELIZA which dealt with the executive's query:

Executive: Can I use the computer this morning?

ELIZA: WHY DO YOU ASK?

Executive: I might be able to do some additional Telcomp sales.

ELIZA: WHY AREN'T YOU SURE?

Executive: My prospective customers have never seen a demonstration of the system.

ELIZA: DOES THIS MEAN VERY MUCH TO YOU?

Executive: Of course it does.

ELIZA: YOU SEEM VERY POSITIVE ABOUT THAT.

Executive: This is ridiculous.

ELIZA: WHAT DO YOU MEAN THIS IS RIDICULOUS?

Executive: Is there any reason I can't use the computer now?

ELIZA: TELL ME MORE ABOUT YOUR PROSPECTIVE CUSTOMERS.

At this point, the executive is fuming, but the human programmer has returned to his desk, realises with horror what has going on, and starts dealing with the furious executive. However, the programmer cannot resist continuing the joke — at the expense of the executive:

Executive: Why the hell are you being so sh*tty with me?

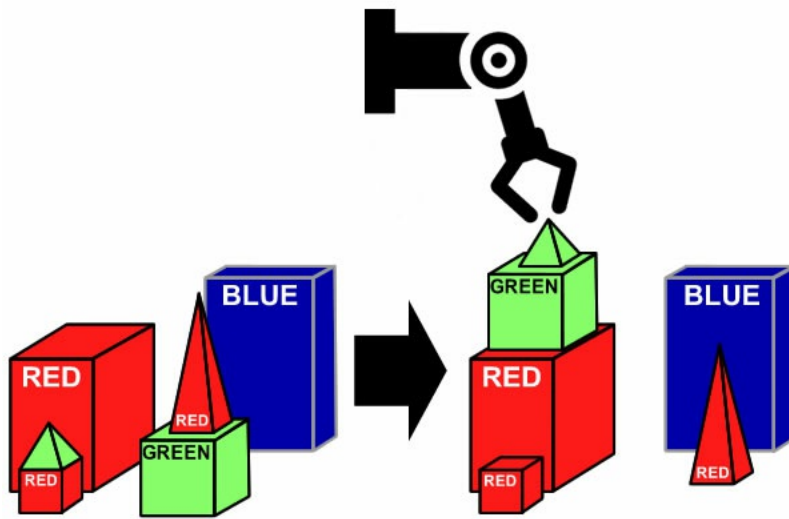

PROGRAMMER: WHAT DO YOU MEAN WHY AM I BEING SO SH*TTY WITH YOU?

The Winograd effect

I was actually an AI researcher myself in the early 1990s, in Swansea University. At the time, AI was still a relatively young and immature field. However, there had already been some landmark experiments which appeared to represent real progress in the field.

One of those landmark experiments was constructed by Terry Winograd at MIT in the early 1970s. Winograd was interested in computer understanding of *natural languages*, such as conversational English. He created a program called SHRDLU which was capable of understanding English commands within a very limited world, a world composed of just a few coloured blocks. This block world was a virtual world which existed purely in the computer's memory, but it could be drawn using computer graphics. The blocks could be rearranged by a virtual robot arm.

The following diagram shows what happened when SHRDLU was presented with the typed command: "Will you please stack up the green block and the smaller pyramid on top of the big red block":

You can see in the initial arrangement on the left-hand side of the previous diagram, no blocks are on top of the big red block. However, when SHRDLU received the written command, it analysed the command to form an understanding of the action. It then considered its internal model of the block arrangement, and initiated the robot arm (shown at the top) to stack the green block and the smaller pyramid on top of the red block — as seen in the right-hand side of the previous diagram.

When I was an AI researcher, we all regarded Winograd's impressive system with awe. However, it was clearly limited to a very carefully-controlled laboratory environment (how many red and blue cubes can you see lying around your house?). The challenge for AI was breaking-out of the laboratory and proving it could cut it in the messy real world.

At the time of my involvement, the only thing everyone could agree on was that the hype surrounding AI seemed to far exceed the reality. According to the Wikipedia page on SHRDLU: "SHRDLU was considered a tremendously successful demonstration of AI. This led other AI researchers to excessive optimism which was soon lost when later systems attempted to deal with situations with a more realistic level of ambiguity and complexity."

Things appeared to go quiet on the AI front. Was AI going to prove to be a complete washout?

However, in the late 1990s it was to be Terry Winograd again who brought AI to the attention of the mass public at last — though not with his SHRDLU system. In fact, it was through a completely different project that Winograd was to have his greatest effect, and the greatest impact of AI on the mainstream. By that time, artificial intelligence had become much more mature and was now ready to face the real world. This time, Winograd's idea was to change the modern world.

In 1995, Winograd had become a professor at Stanford University and had been allocated a PhD student who was looking for a subject for his thesis. Winograd had taken an interest in internet search engines, because they represented a form of AI, interpreting queries written in English, and responding intelligently — maybe even one day passing the Turing test. Winograd was unimpressed with the search engines at that time which were notoriously hit-and-miss, and thought that the search algorithm could be made more intelligent. So Winograd suggested looking at search engines as a PhD topic, and gave his student some advice: "Consider the link structure of the web".

Winograd's student was joined by a fellow PhD student, and together they set about converting his dormitory room into a machine laboratory, using parts from inexpensive computers which were connected to Stanford's broadband computer network. They created a simple search page which could be used by the Stanford students, and which rapidly became very popular. In 1996, they made the website available to all internet users. By 1998, their website had become so popular that they founded a company.

A couple of decades later, the impact of their company has now been compared to that of Johannes Gutenberg who invented modern printing. It has been said that: "Not since Gutenberg ... has any new invention empowered individuals, and transformed access to information." It was an information revolution.

The names of Winograd's students were Larry Page and Sergey Brin.

And if you want to know the name of the revolutionary search engine company they founded — just **Google** it!

My PhD thesis

As was described in the previous section, there was a great deal of initial optimism about AI which slowly turned to disappointment as those early systems did not live up to expectations. The general feeling was that the hype exceeded the reality. However, in recent years there has been a revolution in AI which is starting to have a tremendous impact in all our lives.

To understand the origin of the revolution, let me take you back to the early 1990s. Because, by coincidence, I happened to be involved at the start of the revolution.

The subject of my PhD thesis was the up-and-coming topic of AI at that time.^[21] The topic was called *neural networks*. Neural networks are represented by a computer program. The computer program contains many elements which behave as though they are very simple brain neurons. Those simulated neurons are then connected in a network.

Here is an example of the type of neural network I was using in the early 1990s:

Each of the thick black circles represents an artificial neuron, whose behaviour is programmed by a short module of computer code. The behaviour of each neuron is usually just a summing the values of its inputs and applying some thresholding function to produce a single output.

The structure and behaviour of neural networks was described in my PhD thesis: "The output of each node in a layer is connected to every node in the layer immediately above. The links multiply the signals by weighting factors. Except for the nodes of the input layer, the input to each node is the weighted sum of all the outputs of the nodes of the previous layer. The output of the node is a function of this net input."

If that is not clear, perhaps it is best if you consider the previous diagram. There you will see each artificial neuron represented by a black circle, and you will see that there are three distinct layers of these neurons: an input layer, a "hidden" layer, and an output layer. As I said in my PhD thesis, each neuron in a previous layer is connected to all of the neurons in the next layer, so there is a huge amount of connectivity in these networks — just like a brain.

The functioning of the hidden layer was found to be crucial. The earliest neural networks did not have this layer, and, as a result, their abilities were found to be too limited. It was only when the hidden layer was added that interest in neural networks was rekindled.

If we have a hidden layer of neurons, though, the behaviour of the neurons now becomes crucial. If the neurons behaved **linearly** then the whole network could be simplified (as in the case of the resistor network in Chapter Three). In that case the hidden layer would be eliminated by the simplification — there would be no point in having a hidden layer with linear neurons. However, as I said in my PhD thesis, "if the nodes are **nonlinear** this simplification cannot be performed and hidden layers can serve a purpose".

The type of nonlinear relationship which is almost always used in artificial neurons is described by one of the

various curved lines in the following graph. This shape is called a *sigmoid*:

If you consider the solid black curve, you will see it behaves rather like a threshold function: for input values less than V_t the output is low, and for input values greater than V_t the output is high. So the nonlinear thresholding type of behaviour of these artificial neurons closely matches the behaviour of real neurons.

Each connection between neurons has an associated weighting factor which multiplies the value which is transmitted between neurons, from the previous layer to the next layer. Neural networks are "trained" by presenting a number of different inputs to the network and adjusting the weights until the desired output is achieved. This can be a long process — involving thousands of iterations — as the network slowly "learns" to give the correct responses to all the possible stimuli. For example, an image of a car would be presented to the network, and the network would have to learn to give the correct "car" output, labelling the image correctly. Next, an image of a face might be presented, and the process would begin again.

There are aspects of the behaviour of neural networks which closely resemble the behaviour of the brain. Firstly, because of the huge connectivity of the network, the behaviour of the neural network is spread over all the neurons in the network. This is called *parallel distributed processing*. This means that no single neuron is crucial for any particular task. As an example, if a single neuron stops working, there will not be a sudden failure of the overall system. Instead, there is a gradual degradation of performance. This resembles the behaviour of the brain: in the brain, single neurons are dying all the time but we do not notice any sudden failure of performance.

Secondly, it has been described how adjusting the weighting factor on the inputs of each neuron represents "training" — a fully-trained neural network could recognise a particular face, for example. This therefore provides a model for memory in the brain. It would appear memory is distributed over a vast number of neurons, and is encoded in the weights of those neurons. Again, the vast parallel nature explains why we do not experience a sudden catastrophic loss of memory when single neurons die.

So it is clear that the structure and behaviour of these neural networks is eerily similar to the human brain.

Anyway, I was fortunate to be awarded my PhD, at which point I placed my thesis on a shelf in my library and never looked at it again for twenty-six years until the time came to blow the dust off it and use it to help me write this book.

But, as we shall now see, over that intervening period a revolution took place. And right at the heart of that revolution ... were neural networks.

Deep learning

Funny cat videos on YouTube.

We've all watched them. Cats falling off window sills, cats looking grumpy, cats sleeping in toilet bowls. The internet seems full of funny cat videos. To you and I, these videos might represent nothing more than a humorous distraction for a few minutes. But to the researchers of Google, these online videos represented a huge ready-made data set of cat images on which they could train their image processing neural networks.

In 2012, Google AI researchers built a neural network of 16,000 processors with one billion connections and left it on its own to browse funny cat videos on YouTube. After three days, the network had watched ten million

"hilarious" videos. According to Jeff Dean who led the study: "We never told it during the training 'this is a cat'. It basically invented the concept of a cat." [22]

The results of the study amazed the researchers: it roughly doubled the accuracy of any previous AI technique. According to the New Scientist book *Machines That Think*, the Google cat video experiment — and other similar demonstrations — launched an "AI gold rush" which continues to this day.

In December 2016, an extensive article was published in the New York Times magazine explaining the implications of this radically-improved AI for all of computing — and our everyday lives. The article was entitled *The Great AI Awakening*, with the subtitle "How machine learning is poised to reinvent computing itself". [23]

The article described how Google, Apple, and Amazon are all placing AI at the centre of their new developments. In the article, Google's chief executive, Sundar Pichai, described how Google is going to reorganise itself around AI, and the Google of the future is going to be "AI first".

Why should there be this sudden explosion of interest in AI by the biggest companies in the world? Put simply, it is because artificial intelligence is finally able to do many of the things which the human brain can do. And the reason for this sudden breakthrough has been recent developments in neural networks.

But the neural networks being used now look very different to the networks I was using in the early 1990s. As an example, here is a typical example of a current neural network:

You can see that there is a huge increase in complexity over the old type of network structure. That is because this example has four hidden layers of neurons — rather than the old single hidden layer networks. Typically, the new networks have five hidden layers, though there can be as many as ten. The big discovery has been that a fairly modest increase in the number of hidden layers has resulted in an orders-of-magnitude improvement in performance to a level which is comparable with human behaviour.

Each additional layer of neurons is capable of making decisions at a more complex and more abstract level than the neurons in the lower layers. For example, in an image processing neural network the first layer of neurons might just identify bright points in the image. The second layer becomes trained to recognise features which are output by the first layer, so the second layer might identify straight lines in the image which are composed of those bright points. The third layer becomes trained to recognise features which are output by the second layer, so maybe the third layer identifies shapes which are composed of those straight lines. And so on, as we move upwards through the layers of the neural network. The highest level of this neural network would contain neurons which would become active when a face was detected in the image, for example.

These neural networks which contain many hidden layers (and are therefore capable of representing complex and abstract concepts) are called *deep neural networks*.

It was the introduction of these deep neural networks which has brought about the recent revolution in artificial intelligence. Whereas it would be very difficult to explicitly write a computer program to recognise a face, for example, a deep neural network can learn to recognise faces purely by learning on its own. This would involve presenting an extremely large data set of images of faces, while the network adjusts the weights of its neurons to give the correct output. This meant artificial intelligence based on neural networks could be applied to the most challenging of tasks.

So, suddenly, **artificial intelligence was able to do the things which the human brain could do**. At last, for the

very first time, AI was finally living up the hype.

This revolution in AI based on deep neural networks is called *deep learning*. "Deep learning" is probably the coolest buzz-phrase in technology at the moment.

It is deep learning — and the associated deep neural networks — which is powering the current AI revolution. When you unlock your iPhone using Face ID — that's a deep learning neural network recognising your face (after having learnt it earlier). When you ask your iPhone for directions by saying "Hey, Siri", that's a deep learning neural network performing speech recognition. The neural network actually uses the dedicated hardware of the "Neural Engine" in the Apple A11 microprocessor — which is a sign of how important deep learning has become.

Deep learning is also the technology behind the new wave of *personal assistant* devices such as Google Home and the Amazon Echo device which is pictured here:

Obviously, improved speech recognition performance has been central to the success of these personal assistants, and this is where deep learning has had its impact. According to Tim Turtle, the CEO of Expert Labs which builds smart voice interfaces: "There have been more improvements in speech recognition over the past three years than there have been over the past thirty years combined."

At the end of this chapter, there will be a link to a video showing my dialogue with my own Amazon Echo device.

Perhaps the most remarkable example of the penetration of neural networks into different fields emerged while I was writing this book. In December 2017, NASA announced the discovery of a new exoplanet by the Kepler Space Telescope (see my seventh book for details of the Kepler telescope and the discovery of exoplanets). According to the NASA press release, the planet was discovered using deep learning techniques made available by Google's AI research team: "The discovery came about after researchers Christopher Shallue and Andrew Vanderburg trained a computer to learn how to identify exoplanets in the light readings recorded by Kepler — the miniscule changes in brightness captured when a planet passed in front of, or transited, a star. Inspired by the way neurons connect in the human brain, this artificial 'neural network' sifted through Kepler data and found weak transit signals from a previously-missed eighth planet orbiting Kepler-90, in the constellation Draco." [24]

It is clear that developments in deep learning are evolving computers to a new stage in their development, transcending what we thought they were capable of achieving. It also seems somehow wonderfully ironic (or maybe wonderfully appropriate) that this latest phase of our technological evolution — the next giant step forward for humanity — should have been based on the popularity of LOLcats videos.

Deep learning and the cortex

In this chapter we have seen that a deep-learning neural network with maybe five or six hidden layers can have a performance comparable to a human brain. But what can this neural network structure tell us about the structure of the brain? In particular, what can neural networks tell us about the structure of the human cortex, which appears to be the seat of our high-level understanding about the world — and also the seat of our consciousness?

If you remember from Chapter Two, the cortex is a thin layer (only about four millimetres thick) which is spread over the top layer of the brain. Though the cortex is very thin, it is also very wide, with a surface area equal to a small tablecloth.

There are six clearly-defined layers within the cortex. In his book *On Intelligence*, Jeff Hawkins presents a novel description of the layers of the cortex: "Get six business cards or six playing cards — either will do — and put them in a stack (it will really help if you do this instead of just imagining it). You are now holding a model of the cortex. Your six business cards are about two millimetres thick and should give you a sense of how thin the cortical sheet is. Just like your stack of cards, the neocortex is about two millimetres thick and has six layers, each approximated by one card."

Each of the layers can be distinguished because each layer is made from neurons which have clearly distinct structures. These layers of different neurons with different functionality might be interpreted as resembling the description of an image processing neural network described in the previous section: the first layer of neurons might just identify bright points in the image, while the second layer identifies straight lines, and so on.

This similarity in structure and functionality between a neural network and the human visual cortex was identified by the scientists who worked on the famous 2012 Google cat video experiment. In the New York Times article which described the experiment, one of the scientists said that in creating their neural network to recognise cats "it appeared they had **developed a cybernetic cousin to what takes place in the brain's visual cortex.**"

A deep-learning neural network with maybe five or six hidden layers has clear similarities to the structure of the human cortex. The following diagram shows a neural network oriented in the vertical direction (inputs at the bottom, outputs at the top) next to an actual image of cells in a cross-section of the cortex:

There is clearly a similarity between the number of hidden layers (five or six) in a deep-learning neural network and the number of layers in the actual brain cortex. As recent experience with deep learning has revealed, only a small number of hidden layers can deliver a high level of performance. This would appear to provide a possible answer as to why the human cortex is so thin: **the cortex simply does not have to be any thicker than a few millimetres in order to perform its tasks.** Instead, it is the width and breadth of the cortex which must be large — in order to make sense of the complexity of the world (just as deep learning neural networks can have a large number of inputs). Hence, we end up a very thin cortex which is spread around the entirety of the upper brain, and is even crinkled in order to increase its surface area.

There is another interesting fact about the human cortex, and this is considered by Jeff Hawkins in his book *On Intelligence*. According to Hawkins, all the different regions of the cortex have very much the same anatomy. So, although different regions of the cortex might have different functionality — for example, processing speech or vision — you will still find the same six-layered structure in the cortex. Once again, this is reminiscent of neural networks, in that the same deep learning neural network structure is currently being used for such a huge number of different applications, from speech processing to self-driving cars. So the parallels between the cortex and neural networks are really quite astonishing. Hawkins calls this uniformity of cortex structure "the most important discovery in neuroscience".

Hawkins also discusses how this uniformity of the structure of the cortex allows great flexibility in how the different functionalities are distributed over the cortex. If one area of the cortex becomes damaged — for example, vision processing — a different area of the cortex can step in and take over the responsibility: "Adults who are born deaf process visual information in areas that normally become auditory regions." This is called brain *plasticity*. According to Hawkins, regions of the cortex are not strictly defined at birth, as "the cortex is still dividing itself into task-specific functional areas long into childhood, based purely on experience."

Crucially, from the point-of-interest of this book, Hawkins then notes that this continuous flexibility reveals that: "The cortex is not rigidly designed to perform different functions using different algorithms." For example, it would be possible to write a computer program with strict rules specifically for vision processing, with program variables representing "straight lines" and "corners", etc. This might be called the **algorithmic** approach. However, it would then be almost impossible to adapt that program to perform, for example, speech recognition. So an algorithmic approach would not possess the plasticity of the human brain. Instead, rather than being tied to a strict **algorithmic** program, the **non-algorithmic** structure of the cortex allows more flexibility than a conventional computer structure.

Once again, this reveals a similarity between the cortex and neural networks. It might be said that by moving away from a clearly-defined rule-based step-by-step artificial intelligence to a neural network-based approach we are moving away from algorithmic information processing towards non-algorithmic information processing.

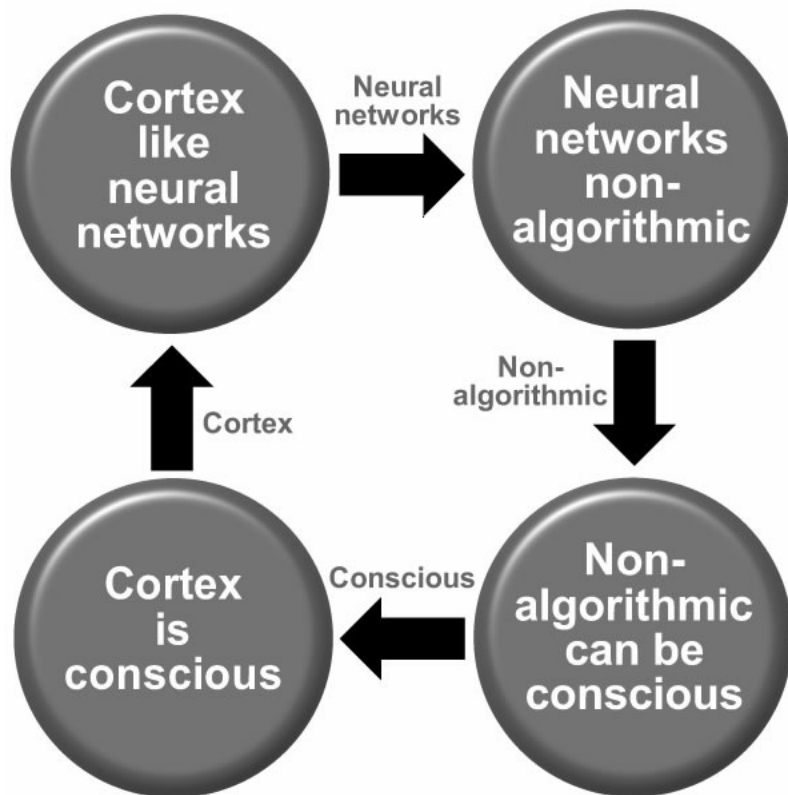

A 2017 article in *Wired* magazine explained how new neuromorphic chips — based on the structure of neural networks — will possess functional flexibility not possessed by conventional integrated circuit design: "Neuromorphics aren't new, and their designs have been around since the 80s. Back then, however, the designs required specific algorithms be baked directly onto the chip. That meant you'd need one chip for detecting motion, and a different one for detecting sound. None of the chips acted as a general processor in the way our own cortex does." [25]

If we are moving towards non-algorithmic processing then — according to the suggestion of Roger Penrose — we might also be moving away from a structure which could not be conscious toward a structure which could potentially be conscious. And that ties-in very nicely with the fact that consciousness appears to reside in the cortex.

So the following series of connections might be made:

1. The cortex can be accurately modelled by neural networks.
2. Neural networks are non-algorithmic.
3. Non-algorithmic regions might have the potential to be conscious.
4. The cortex is believed to be the conscious region of the brain.

This is an appealing self-contained argument, and it could be presented in the following linkages:

One thing seems clear from this discussion, though, and it is that Amazon, Apple, Google, and Facebook are all placing a deep-learning model of computing at the heart of their operations. They are therefore moving away from a predictable, rigidly-programmed algorithmic approach to a more unpredictable, non-algorithmic approach based on deep-learning. Over the next thirty years, with huge increases in computer intelligence on the horizon, it appears we are remorselessly moving towards placing our vital services in the hands of super-intelligent, fundamentally unpredictable, potentially-conscious entities.

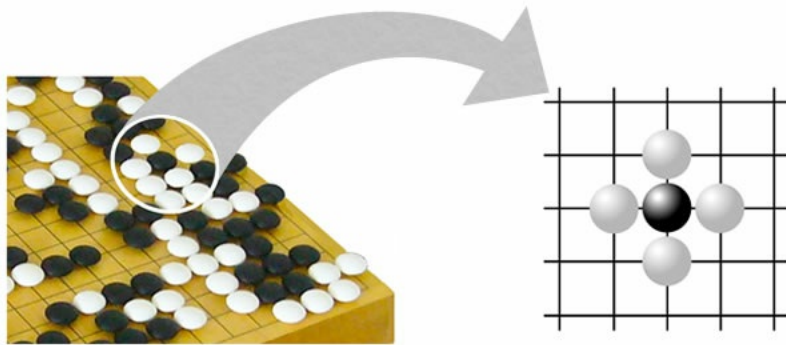

What could possibly go wrong ...

Beyond human

The game of Go is one of the great board games of the world. It was invented in China over 2,500 years ago, and there are estimated to be over forty million Go players in the world. It is mostly played in Korea, China, and Japan.

The rules of the game of Go are simple. Each of the two players has a supply of *stones* (small circular game pieces). One player has white stones, one player has black stones. The playing board is a grid of 19×19 lines. Players take turns to place their stones on the intersection points of the lines. Once placed, stones cannot be moved. Players aim to capture territory on the board by completely surrounding vacant points with stones of their own colour.

If a stone is completely surrounded by stones of the opposite colour, then that stone is removed from the board. The following diagram shows a Go board, with one of the black stones surrounded by four white stones. The black stone would then be captured and removed from the board:

At the end of the game, the player with the most territory and captured stones wins.

While the rules of Go are simple, the large size of the board means that the number of possible moves are far greater than chess. For this reason, playing Go has proven to be a far greater challenge for computers than playing chess.

Former world chess champion Garry Kasparov has recently written a book on artificial intelligence called *Deep Thinking*. In his book, Kasparov explained how chess computers initially aimed to copy human strategies for playing chess, however it was eventually found that a brute force approach — in which the computer rapidly evaluates millions of possible moves in a rather unintelligent manner — proved to be the best strategy for chess computers. Kasparov became a victim of this brute force strategy himself in 1997. The first chess computer to beat a human grandmaster was called Deep Thought (named after the supercomputer in Douglas Adams's book *The Hitchhiker's Guide to the Galaxy*). Deep Thought won its game against a grandmaster in 1988. IBM bought Deep Thought, and an upgraded version named Deep Blue used a brute force approach to beat Garry Kasparov in 1997 — becoming the first chess computer to defeat a world champion.

But brute force approaches clearly do not represent human thought processes. Also, the huge number of possible moves on a Go board have made the game resistant to a brute force attack by a computer. This has had the result that Go has overtaken chess to become a much more interesting challenge for AI researchers.

With a brute force approach being an impossibility, Go is a game which has to be played by intuition and feel. But, if that is the case, is it possible for a computer to "feel"? That would appear to imply some form of consciousness, some "awareness" of a situation. Perhaps this lack of "feel" in a computer's mind is the reason why computers — so dominant at chess — have always performed poorly against professional Go players.

Rising to the challenge, the British AI company DeepMind have developed a computer program specifically designed to play Go at the highest level, and to be able to challenge the world's best players. The program is called AlphaGo, and it is based on deep neural networks.

In 2016, a series of five games were arranged between AlphaGo and the world Go champion Lee Sedol. The games took place in Seoul, South Korea, and were watched by 200 million people worldwide.

AlphaGo achieved a stunning victory by four games to one. Both the scientific community and the Go community were stunned. The scientific community was stunned because it had been believed that it would be another ten years before a computer would be able to beat a top Go player. But what stunned experienced Go players was the creativity and originality of AlphaGo's gameplay.

Jang Dae-Ik, a science philosopher at Seoul National University told the *Korea Herald*: "This is a tremendous incident in the history of human evolution — that a machine can surpass intuition, creativity and communication, which have previously been considered to be the territory of human beings." Jeong Ahram, the Go correspondent of one of South Korea's biggest daily newspapers said: "Before we didn't think that artificial intelligence had creativity. Now we know it has creativity — and more brains, and it's smarter."

An example of AlphaGo's imaginative gameplay was presented in move 37 of game two. You can see AlphaGo's move 37 on the following video link (the video will start at the correct moment):

<http://tinyurl.com/gomove37>

AlphaGo is playing the black stones. You will see that AlphaGo completely abandons the group of stones in the bottom right of the board to play its stone elsewhere, a move which no human player would make. You will see the surprise of the commentator ("I thought it was a mistake"), and you will also hear that Lee Sedol left the room a

minute after the move was played because he was so surprised and needed time to compose himself.

According to *New Scientist*, "Move 37 has been taken as evidence that AlphaGo is capable of what we might call intuition." Might we one day consider AlphaGo's "move 37" as the historic moment which represented the first time that a computer showed signs of consciousness?

But if AlphaGo was impressive, what came next was utterly extraordinary.

In December 2017, DeepMind unveiled AlphaZero. Whereas AlphaGo was initially trained to mimic the moves of expert human players, AlphaZero was capable of learning entirely by itself — just by being given the rules and then playing games against itself (blank slate learning is called *tabula rasa* — the "Zero" in the AlphaZero name indicates that it needs no human input).

And, boy, did it learn fast.

After eight hours of self-learning at Go (remember: it had no knowledge of Go at all when it started), AlphaZero had beaten the old AlphaGo (and AlphaGo was at that stage considered to be the strongest Go player in history). And, because it started with a completely blank slate, AlphaZero was capable of learning any problem that could be simulated on a computer. As an example, after spending four hours in a morning learning the game of chess from scratch, AlphaZero beat the reigning world champion chess computer.

Because AlphaZero learnt to play chess entirely by itself, it developed a completely new style of playing the game, unlike anything seen before. As an example, AlphaZero used its king as an attacking piece. Jon Ludvig Hammer, a Norwegian grandmaster, described AlphaZero's strategy as "insane attacking chess". The CEO of DeepMind, Demis Hassabis, described AlphaZero's style of play as "alien — it's like chess from another dimension."

But perhaps a machine which can learn by itself to attain superhuman levels in a very short space of time raises other concerns. According to Garry Kasparov in his book *Deep Thinking*: "If you program a machine, you know what it's capable of. If the machine is programming itself, who knows what it might do?" According to Kasparov: "AI products tend to evolve from laughably weak to interesting but feeble, then to artificial but useful, and finally to transcendent and superior to human. We see this path with speech recognition and speech synthesis, with self-driving cars and trucks, and with virtual assistants like Apple's Siri. There is always a tipping point at which they go from amusing diversions to essential tools. Then there comes another shift, when a tool becomes something more, something more powerful than even its creators had in mind."

David Cramley, who runs a chess education website, considered AlphaZero's extraordinarily rapid rise to dominance and said: "We now know who our new overlord is. The games AlphaZero played show it can calculate some incredibly creative positional bombs, the depth of which are far beyond anything humans or chess computers can come up with. It will no doubt revolutionise the game, but think how this could be applied outside chess. This algorithm could run cities, continents, universes." English chess grandmaster Simon Williams was able to see the funny side: "On December 6th 2017, AlphaZero took over the chess world. AlphaZero and DeepMind then went on to dominate chess, eventually solving the game and finally enslaving the human race as pets."

Ideas about advanced artificial intelligence "going rogue" and attempting to dominate (or eliminate) the human race have been common themes in science fiction, most famously in the *Terminator* film series. The old rule-based AI followed carefully-programmed scripts. However, the recent rapid developments in AI have been fuelled by non-rule-based, non-algorithmic, inherently-unpredictable AI, which surely introduces risks. Examples of the new AI "gone rogue" would include Microsoft withdrawing their teenage "Tay" chat robot after it became a "Hitler-loving sex robot" within 24 hours. [26]

The high-profile businessman and inventor Elon Musk has said that rogue AI represents humanity's "biggest existential threat". Musk says he first became concerned about the future of humanity when he read *The Hitchhiker's Guide to the Galaxy* as a teenager, in which aliens destroyed the Earth to make way for a hyperspace highway.[27] From that moment, he said he felt a need to protect humanity from all threats — no matter if those threats seemed to belong more to the realm of science fiction. Musk is so concerned that he has invested in the DeepMind company purely as a means to keep an eye on developments in AI.

My own feeling is that there is clearly a potential threat which cannot be discounted. I would direct any interested party to read Chapter Four of this book in which it was explained that emergent effects are **inherently unpredictable** — you cannot predict what will happen when you connect apparently benign units together to form complex networks.

Also, I would suggest that those who believe there is no threat from rogue AI have been influenced by the *Terminator* movie. In that movie, the rogue AI system emerges purely spontaneously, as if by chance evolution — without any human intervention. However, the more likely scenario is that unscrupulous humans would enable the process — in just the same way that malicious software such as computer viruses is developed by humans. This makes the emergence of rogue AI far more likely. Some people would destroy the world just for kicks.

However, I do not want to end this chapter on a negative note. Instead, you can now watch a five-minute video I made featuring a conversation between me and my new Amazon Echo personal assistant. Some deep questions about AI and consciousness are raised.

Here is a link to the video:

<http://tinyurl.com/talkcomputer>

And here are some stills from the video:

Unfortunately, if you watch the video you will see that things did not go at all according to plan ...

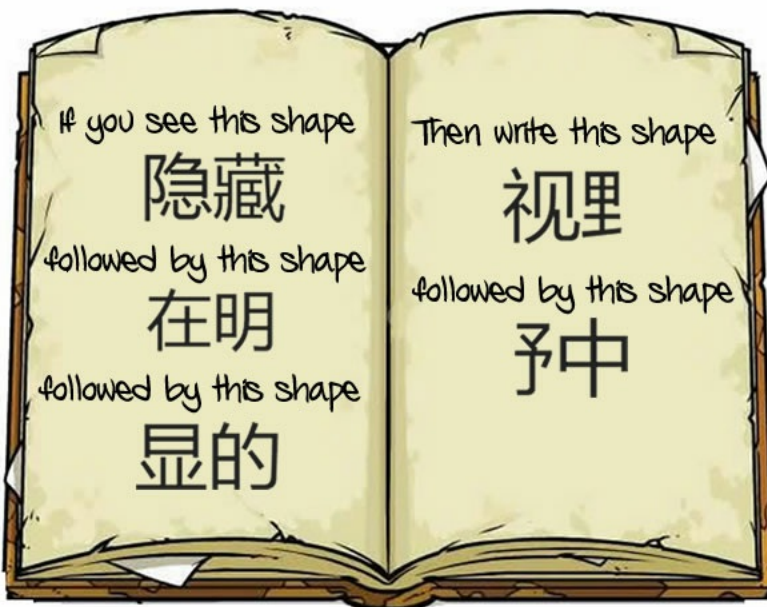

THE CHINESE ROOM

In this chapter we will be considering an ingenious thought experiment which — I believe — provides us with perhaps our most valuable insight into the nature of consciousness. The thought experiment is called the Chinese Room, and it was devised in 1980 by John Searle, a philosophy professor at the University of Berkeley.

The experiment requires you to imagine that you are in a sealed room, with no windows or open doors. The only means of communication you have with the outside world is via a narrow slot in the wall through which pieces of paper may be passed. Your job is to receive written questions through the slot in the wall, and then to pass back the correct answer to those questions in similar written form through the slot. To make things rather more difficult, the questions are written in Chinese and you must answer in Chinese.

We will proceed on the assumption that you do not understand the Chinese language. You are therefore given a book to help you with your translation task. You might expect the book to translate a Chinese question into English — which would then allow you to understand and answer the question — and then translate your answer back into Chinese. However, the book does not work like that: it completely bypasses the intermediate stage of translation into English. Instead, the book just directly translates the sequence of Chinese symbols representing the question into the sequence of Chinese symbols representing the correct answer to the question.

Here is what the book might look like:

So, when you receive a question written in Chinese through the slot, you begin your task. You open the book and you attempt to match the sequence of symbols you have received to an identical sequence of symbols written in the book. When you find the correct sequence, the book describes the sequence of Chinese symbols which represents the correct answer to the question. You then write down those symbols on a piece of paper, and post the piece of paper back out through the slot.

At that point, your job is done.

We now move to consider the person who is outside the room, the person who is asking the questions. That person is writing his questions in Chinese, and is receiving the correct responses, also written in Chinese. The fact that the responses are correct and make sense appears to imply that the person in the room not only speaks Chinese but also understands the true meaning of the question. Whereas the truth is very different: the person in the room not only does not speak Chinese, but has **absolutely no understanding of what the questions actually mean.**

This result appears to have major implications for artificial intelligence and theories of consciousness. This is because John Searle compared the person in the room to an AI computer attempting to have an intelligent conversation and pass the Turing Test. If you remember, in his 1950 paper, Alan Turing suggested that the only way to determine if a computer is actually "thinking" is to examine its responses in the Turing Test. However, on the basis of the Chinese Room thought experiment, it now seems clear that just examining responses can never be enough to determine if a machine is thinking, or conscious. On the basis of the responses from the Chinese Room, there might be a Chinese person inside the room who understands the questions, or alternatively there might be a person with no understanding of Chinese who is merely converting symbols according to an instruction manual. In either case, the responses would be the same.

The British mathematician Marcus Du Sautoy performs the Chinese Room experiment in the following BBC video:

<http://tinyurl.com/thechineseroom>

The Chinese Room thought experiment shows that just by examining the input/output responses of a machine (or any object) can never be enough to determine if the machine is conscious, and thinking. **Instead, we have to dig inside the machine, to consider its internal processing. Only if the internal information processing satisfies certain requirements should we consider the machine to be capable of consciousness.**

Our task in this chapter is to determine what the Chinese Room experiment reveals about those requirements for the internal structure.

Understanding "understanding"

However, there have been arguments raised against the conclusions of the Chinese Room experiment. And one of those arguments is strong, and deserves close consideration. We will now consider that argument against the implications of the Chinese Room, and, in the process, find the discussion brings into sharper focus the requirements for consciousness.

The counter-argument is called the "system" argument. The basis of the argument is that, while the person inside the room does not understand the question, the room as a whole — including the person and the book — **does** understand the question. In other words, the entire **system** does understand the question.

At first glance, this might appear to be rather a bizarre counter-argument. After all, if the person inside the Chinese Room does not understand Chinese, and the book on its own does not understand Chinese, then why should we consider the combined system (person plus book plus walls plus slot in wall) to understand Chinese?

However, given a bit of thought, it is realised that this argument has considerable force. And the key to understanding the counter-argument is to realise that it is treating the entire system as an **emergent** system. As explained in Chapter Four, an emergent system can be greater than the sum of its parts. There can be a jump to a new mode of behaviour which is not evident in any of the component parts. Even though the person on their own does not understand Chinese, and the book on its own does not understand Chinese, when the person and the book and the rest of the room is combined then there can be a jump to a new mode of emergent behaviour: the overall system **can** understand Chinese.

So is the "system" counter-argument to the Chinese Room valid? I believe not. I believe it all depends on what we mean by "understanding".

In order to see why the "system" counter-argument is not valid, let us hugely simplify the problem. Let the Chinese Room be only able to understand a single question, in other words, let the book inside the Chinese room only be capable of translating a single Chinese question and providing only a single, correct Chinese response to that question.

The single question which we will use will be: "How many heads does a human have?" So, the book inside the Chinese Room will need to be able to translate the Chinese equivalent of that phrase and provide the correct response, which, presumably, would be the Chinese word for "One".

So, when we run the experiment, the person outside the room writes "How many heads does a human have?" in Chinese on a piece of paper, posts the paper through the slot, and gets back the Chinese equivalent of "One" written on a piece of paper.

At that point, we might well conclude that the emergent system — the person and the book and the walls of the room — does understand the Chinese phrase "How many heads does a human have?" And, perhaps surprisingly, I would actually agree: the emergent system **does** understand the complete **phrase** "How many heads does a human

have?" But we need to be very specific and very careful about what we are claiming. Note that I am saying that the system understands the **phrase** (with the "phrase" in emphasis). A phrase is a small group of words. The system understands the phrase inasmuch as it knows that when it receives the phrase "How many heads does a human have?" it must respond with the Chinese equivalent of "One".

But surely that is a very limited form of understanding: the system "understanding" that it needs to give a certain response when it receives a certain phrase. Surely that does not represent true "understanding" of the phrase in the conventional sense. Crucially, if we split the phrase up into its component parts (words) then we find the system does not understand the meaning of those parts: **the system does not understand what a "human" is and it does not understand what a "head" is.**

To be specific, if you ask the system "What is a human?" or "What is a head?" you will get no response (as there is no corresponding entry in the book). And if the system cannot respond to either of those two questions, then it does not understand what a human or a head is, and so it cannot have true understanding of the phrase "Does a human have a head?"

To sum-up, I would agree that the system can have an very limited "understanding" of the entire **phrase** "How many heads does a human have?" — but only an "understanding" of that particular grouping of words. And that "understanding" is limited to an understanding that the system must respond "One" when it identifies the phrase. However, that is surely not a true understanding in the conventional sense, as the system does not understand anything about a human or a head.

This principle is revealed very obviously in the following extract from Jack Copeland's book *Turing*. In the extract, Copeland has a dialogue with the SHRDLU artificial intelligence system which was described in the previous chapter (remember the block world, and the robot arm able to place one block on top of another). Copeland was previously impressed by SHRDLU's comprehension in a carefully-arranged dialogue, with SHRDLU certainly giving an impression of intelligence. So Copeland decided to push the system until it breaks. According to Copeland: **"The illusion that the computer understands is shattered less easily than in Eliza's case, but shatter it does."** Let us now examine the dialogue to see just how Copeland successfully shattered the illusion that the computer "understands":

Copeland: Build a steeple.

SHRDLU: SORRY, I DON'T UNDERSTAND THE WORD "STEEPLE".

Copeland: A "steeple" is a stack which contains two green cubes and a pyramid.

SHRDLU: I UNDERSTAND.

Copeland: Trade you the steeple for three red cubes.

SHRDLU: SORRY, I DON'T KNOW THE WORD "TRADE".

Copeland: A "trade" is a free exchange of ownership.

SHRDLU: SORRY, I DON'T KNOW THE WORD "FREE".

Copeland: Sorry, I thought you were smarter than you are.

SHRDLU: SORRY, I DON'T KNOW THE WORD "SORRY".

The important feature of this dialogue is not that SHRDLU does not understand the words "steeple", or "trade", or "free". Not having a few relatively obscure words in its vocabulary is no big deal. No, the important feature of this discussion is that SHRDLU says it does not understand the word "sorry" — **although it has used the word in its previous responses!**

Copeland has managed to do something very clever and revealing here. He has broken-down SHRDLU's response (in the form of a sentence) into its individual word components, and then he has tried to discover if those individual components are understood by the computer. Unfortunately, the computer's understanding was found to be sorely lacking as it was clear that it did not understand the word fragments on their own. It might be said that the computer "understood" entire phrases, but — at the same time — it did not understand the individual words which were the

components of those phrases. And surely that meant SHRDLU did not have a full and complete understanding of the phrase in any true meaning of the word "understanding".

And this is precisely the scenario we find in the simplified Chinese Room experiment. Breaking phrases down into their sub-units (words) reveals a lack of true understanding. However, fortunately, it also provides us with the clue as to how we can resolve the situation, and introduce true understanding ...

The man with two heads

The discussion of the simplified Chinese Room experiment has revealed a lack of true understanding due to a lack of understanding of the individual sub-units of phrases. Logically, then, the suggestion is that we can introduce true understanding by introducing fine-detailed understanding of the individual components of any problem.

Indeed, there was a perfect example of this principle in an AI system which was presented in my previous book. My previous book was about how to make an atomic bomb (answer: it's not difficult to make a bomb, but obtaining the ingredients is problematic). In the appendix of that book, a lengthy and detailed calculation was presented of how to calculate the critical mass of uranium. In order to help with the difficult calculation, I used the functionality of the *Wolfram Alpha* website. Wolfram Alpha is a remarkable online tool which is more than just a search engine: Wolfram Alpha truly understands your query. That is "understanding" in the sense that Wolfram Alpha breaks the query down into its component words, "understands" each of the words, and then builds a true understanding of the query.

We might compare the performance of the Chinese Room to Wolfram Alpha. Given a question, both systems might provide the same correct answer. But the Chinese Room has no deeper understanding, whereas Wolfram Alpha does it right.

Let us consider our previous example again. If you remember, we asked the Chinese Room "How many heads does a human have?", and it returned the correct response. Let us now ask Wolfram Alpha the same question. If you want to try it yourself, go to the Wolfram Alpha website:

<http://www.wolframalpha.com>

Then, in the search box at the top, enter our test phrase "How many heads does a human have?":

Then click the icon at the extreme right of the search box to start Wolfram Alpha computing the solution (it will actually say "Computing ..." which we might interpret as a machine "thinking"). After a few seconds computation, it returns the correct answer:

Input interpretation:
typical number of heads on a human

Result:
1
(although Zaphod Beeblebrox has more than one head, he is not human)

Download page POWERED BY THE WOLFRAM LANGUAGE

Firstly, you can see that Wolfram Alpha has re-interpreted the question into a form which it can analyse: "Typical number of heads on a human" — a step which is only possible by breaking the question into its component parts to generate a true understanding of the question. You can see that Wolfram Alpha then calculates the correct result, the number "1". But, underneath the answer, it reveals it has a true internal understanding of the question by adding the following note: "**(although Zaphod Beeblebrox has more than one head, he is not human)**". Zaphod Beeblebrox is a character from Douglas Adams's book *The Hitchhiker's Guide to the Galaxy* (this is the third reference to the *Hitchhiker's Guide* so far in this book — what is it with AI researchers and the *Hitchhiker's Guide*?). Zaphod Beeblebrox was an alien with two heads. So, by making the connection with our test question and the character of Beeblebrox, Wolfram Alpha shows it not only understands what a "head" is, but it also understands what a "human" is (stressing that Beeblebrox was not human, but was an alien).

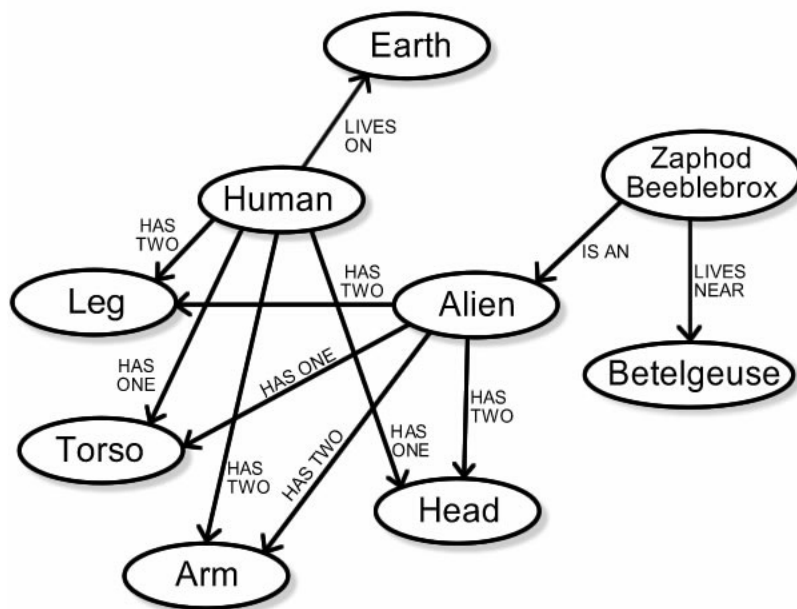

Wow. This is impressive stuff. And how far removed from the mindless sentence-level pattern-matching of the Chinese Room. Even though the two different systems — the Chinese Room and Wolfram Alpha — have given the same correct response to our test query, it is clear that the Chinese Room has no true understanding of the question, whereas Wolfram Alpha has a true understanding of the underlying concepts. Just considering the output of an AI system is not sufficient to determine whether or not it has true internal understanding: you have to dig deeper and consider its internal workings.

The internal model

Our task is now to understand how the brain is able to maintain a detailed internal representation similar to Wolfram Alpha, which allows us to have true, deep understanding of problems.

It is clear that greater understanding can be achieved by splitting a sentence into individual words, or splitting a problem into its individual sub-units. The relations between those individual sub-units can then be stored, and it is those relationships which generates an understanding of how the world works.

The following diagram appears to capture some of the deep knowledge present in Wolfram Alpha. In the diagram, individual objects are represented as oval shapes, and relationships between objects are represented by arrows — with the type of relationship written on the arrow. For example, it shows that a human has two legs and two arms, but only one head. Whereas it reveals that Zaphod Beeblebrox is an alien who has two heads. Some knowledge of the external environment is also represented on the diagram, showing that humans live on Earth, whereas Beeblebrox lives on a planet near the star of Betelgeuse:

In computer science, this type of diagram is called a *semantic network*. The word "semantics" means "meaning", and a semantic network captures meaning by describing the relationships between objects, and how they affect each other. It would be imagined that knowledge in the brain is stored in a similar way. In psychology, this model of data storage is called an *associative memory*, with different memories being closely associated with other memories. For example, a particular smell may trigger a memory of a meal in a particular restaurant.

The semantic network stored in the brain would form an internal model of the world. The greater the detail of that internal model, the richer and more effective would be our thought processes. For example, we could close our eyes and plan strategies — maybe strategies to hunt animals — and then apply those strategies to the real world. Ideally, we would like our brain's internal model to be as close a match as possible to the real world around us. It is as though we are building a universe inside our brain — or, at least, a simplified copy of the universe in our local vicinity. Indeed, in my first book I explained how the universe is a relative structure, with the functionality of objects having to be described relative to all the other objects in the universe, and meaning arising through relations. As Niels Bohr said: "Isolated material particles are abstractions, their properties being definable and observable only through their interactions with other systems."

We are creating a self-contained universe in our mind!

In his book *The Brain*, David Eagleman considers this internal model in detail. Eagleman stresses that this internal model does not have to be a precise copy of the external world. Indeed, with only a finite number of neurons in the brain, there is no way the internal model could be an atom-for-atom precise copy of the universe. The internal model need only be a fairly accurate representation of the local external world. Eagleman refers to this as a "low-resolution" internal model. As Eagleman explains: "This isn't a failure of the brain. It doesn't try to produce a perfect simulation of the world. Instead, the internal model is a hastily-drawn approximation."

Self-awareness

In Chapter Four, it was explained how surprising new modes of behaviour can "emerge" when a nonlinear network reaches a certain level of complexity. Let us now consider the possibility that self-awareness is one of these emergent behaviours in networks with sufficient complexity, and let us consider if self-awareness holds the key to consciousness.

In a 2017 *New Scientist* article, Michael Graziano, a neuroscientist at Princeton University, stressed that a conscious animal needs "a mental model of its body". Graziano continued: "It's fine for me to say 'arm, go here', but something in my brain needs to have a model of what an arm is, its possible motions, and so on." According to *New Scientist*: "This model is responsible for our conscious awareness of the world, according to Graziano". [28]

Graziano is suggesting that consciousness emerges when the internal model in our brains becomes sufficiently

large and detailed that it can contain an accurate model of ourselves, a model which accurately represents our position in the universe and our relations with other objects in that universe. At that crucial moment, we become capable of thinking about ourselves: we become self-aware. And maybe with that self-awareness would come consciousness.

Douglas Hofstadter is currently a professor of artificial intelligence at Indiana University. It was Hofstadter who presented this self-referential theory of consciousness in his classic 1979 book *Gödel, Escher, Bach*. The best description can be found in the preface of the 20th anniversary edition of the book. In the following brief quote from that preface, Hofstadter explains how consciousness depends on an internal model in the brain which mirrors the external world, and thereby allows self-reference: "In short, an 'I' comes about — in my view, at least — via a kind of vortex whereby patterns in a brain mirror the brain's mirroring of the world, **and eventually mirror themselves.**"

There is a famous geometric structure called a Klein bottle — which is often made of glass — in which the mouth of the bottle is curved around to pass back inside the bottle. Remarkably, this results in the surface of a Klein bottle having only **one side!** If you trace your finger around the "outside" surface you will eventually end up "inside" the surface. There is no distinction between inside and outside: the bottle contains itself.

It seems to me that the "looping effect" of the brain — in which we can think **about** the internal model inside our brain — is reminiscent of the "looping" of the Klein bottle. And with this looping would come self-awareness.

The following diagram shows a glass Klein bottle on the left, and a diagram of the brain on the right containing an internal model of itself. The looping effect — in which we become aware of our own internal model — is shown:

Just as with the Klein bottle, the distinction between the model inside the brain and the person outside the brain becomes blurred. The inside becomes the outside, and the outside becomes the inside. According to Hofstadter, there would then be only one entity: the self-aware, conscious being.

However, I find I cannot totally agree with Hofstadter's theory about self-awareness being the key to consciousness. Remember back to the discussion of the mirror test at the start of this book. It was explained how an animal looking into a mirror would sometimes touch a mark placed on its forehead. This is considered to represent a reliable test of self-awareness. However, it was explained how very few animals have passed the test, and many animals which are surely conscious have failed the test. This seems to indicate that self-awareness is not a completely necessary factor of consciousness.

However, consciousness exists on many levels, dependent on the complexity and richness of the internal model. And Hofstadter makes this point himself: "When and only when such a loop arises in a brain or in any other substrate, is a **person** — a unique new 'I' — brought into being. Moreover, the more self-referentially rich such a loop is, the more conscious is the self to which it gives rise."

On that basis, it seems the case that self-awareness would be a factor in a **human-level** degree of consciousness

(though it might be lacking in lower-level consciousnesses).

8

THE "HARD PROBLEM"

This is the final chapter of this book.

Regular readers of my books will know I like to present some of my own ideas in the final chapter, and this book is no exception.

Up to this point, in considering the necessary conditions for consciousness, this book has only tackled what is known as the "easy" problem of consciousness. In 1995, the Australian philosopher David Chalmers explained how the problem of consciousness is actually two problems:

- **The "easy problem"** — Identifying the requirements necessary for consciousness. Studying the functioning of neurons, identifying which regions of the brain are involved in various conscious tasks, and analysing the structure of the cortex to explain how it can perform intelligent tasks.
- **The "hard problem"** — Explaining how the feeling of consciousness can arise from the processing of information and electrical activity in the brain. The "hard problem" is clearly subjective in nature. How can a feeling arise from the movement of particles, basically.

Chalmers makes the point that the real challenge is to identify the source of the feeling or "experience" of consciousness: "The really hard problem of consciousness is the problem of **experience**. When we think and perceive, there is a whirl of information-processing, but there is also a subjective aspect. This subjective aspect is experience. When we see, for example, we **experience** visual sensations: the felt quality of redness, the experience of dark and light, the quality of depth in a visual field. But the question of how it is that these systems are subjects of experience is perplexing. Why is it that when our cognitive systems engage in visual and auditory information-processing, we have visual or auditory experience: the quality of deep blue, the sensation of middle C? How can we explain why there is something it is like to entertain a mental image, or to experience an emotion? It is widely agreed that experience arises from a physical basis, but we have no good explanation of why and how it so arises."

I suspect that when people talk about the mystery of consciousness, they are really referring to this "hard problem".

Chalmers believes that conventional neuroscience research is not aimed at uncovering the origin of this experience. Chalmers' paper certainly does not pull its punches: "The ambiguity of the term 'consciousness' is often exploited by both philosophers and scientists writing on the subject. It is common to see a paper on consciousness begin with an invocation of the mystery of consciousness, noting the strange intangibility and ineffability of subjectivity, and worrying that so far we have no theory of the phenomenon. Here, the topic is clearly the hard problem — the problem of experience. In the second half of the paper, the tone becomes more optimistic, and the author's own theory of consciousness is outlined. Upon examination, this theory turns out to be a theory of one of the more straightforward phenomena. At the close, the author declares that consciousness has turned out to be tractable after all, but the reader is left feeling like the victim of a bait-and-switch. The hard problem remains untouched."

Here is a link to David Chalmers' paper:

<http://tinyurl.com/chalmerspaper>

In this final chapter, we will be considering the hard problem. There will be no bait-and-switch.

Leibniz's Mill

It was explained in Chapter Two how neurons communicate via electrochemical pulses down their axons. So, at any given moment in time, there will be a pattern of spatially-separated electric pulses in your brain — maybe a considerable distance apart (the pattern of these electric charges is detected in an EEG scan in which electrodes are applied to the scalp). How, then, do I feel like a single conscious entity, rather than feeling like I am just one of those isolated pulses? How can a pattern of isolated electrical pulses produce a single consciousness?

The following image shows the mystery. At any point in time, inside your brain are a series of isolated electric charges, either the action potentials along the axons of neurons or accumulated charge inside the neurons themselves. But then think how you feel, how your consciousness feels like a connected entity. How on Earth can that amazing feeling of consciousness arise from a series of disconnected electric charges?

The problem was described by Gottfried Leibniz in 1714 in a thought experiment which is now called *Leibniz's Mill*. Leibniz's Mill is described by David Eagleman in his book *The Brain*. Leibniz imagined the mind as a large machine, a processing unit, a factory, a mechanism — which seems fair enough. Leibniz imagined walking around a large mill. You would see cogs and levers moving, but, as David Eagleman says: "It would be preposterous to suggest that the mill is thinking or feeling or perceiving. How could a mill fall in love or enjoy a sunset? A mill is just made of pieces and parts. And so it is with the brain, Leibniz asserted. If you could expand the brain to the size of a mill and stroll around inside it, you would only see pieces and parts. When we look inside the brain, we see neurons, synapses, chemical transmitters, electrical activity. We see billions of active, chattering cells. Where are you? Where are your thoughts? Your emotions? To Leibniz, the mind seemed inexplicable by mechanical causes."

So, just as there are disconnected pieces of machinery operating in a mill, so there seems to be disconnected electric charges in the brain. What brings it all together to produce consciousness?

I have seen some ideas written in pseudo-scientific books about a vague unified "field" which link the charges, the field representing consciousness in some way. However, most physicists would reject those ideas. If an effect cannot be objectively observed, measured, and analysed then they would say there can be no convincing motivation for proposing new physics.

Instead, let us try to find solutions based on our comprehensive knowledge of fundamental physics and technology ...

The DRAM analogy

If we assume that consciousness is a result of information processing in the brain, how could that possibly result in a feeling of a unified consciousness? Well, as explained in Chapter One, information is always bound to something physical. In the case of the brain, it has been explained how the information processing between neurons

takes the form of the physical movement of charged particles — ions — notably sodium and potassium ions. It is surely safe to conclude that the physical substrate of the information held in the brain is these electrically-charged particles.

So we can conclude that **the physical substrate of consciousness must surely be electric charge.**

OK, that's a good start. Now let us expand on this connection between consciousness and electric charge by using an analogy which was suggested by the physicist Max Tegmark. [\[29\]](#)

Tegmark introduced another parallel between thought processes and electronics. How is information stored in modern electronic devices? A few years ago, information might have been stored magnetically on a hard disk which had to be physically rotated, but there is no such large-scale physical movement in the brain. Instead, modern electronic devices such as iPads have now moved to use purely electronic memory which has no moving parts.

A common type of electronic memory is DRAM (*dynamic random-access memory*). Here is a photograph of some DRAM chips attached to a circuit board which you could insert in your computer in order to increase its memory:

DRAM (pronounced "D-RAM") operates by storing information as electric charge on microscopic *capacitors*. A capacitor is composed of two metal plates separated by an insulating material. When a voltage is applied across the two terminals of the capacitor, electric charge is stored on the plates.

Here is a photograph of some common capacitors:

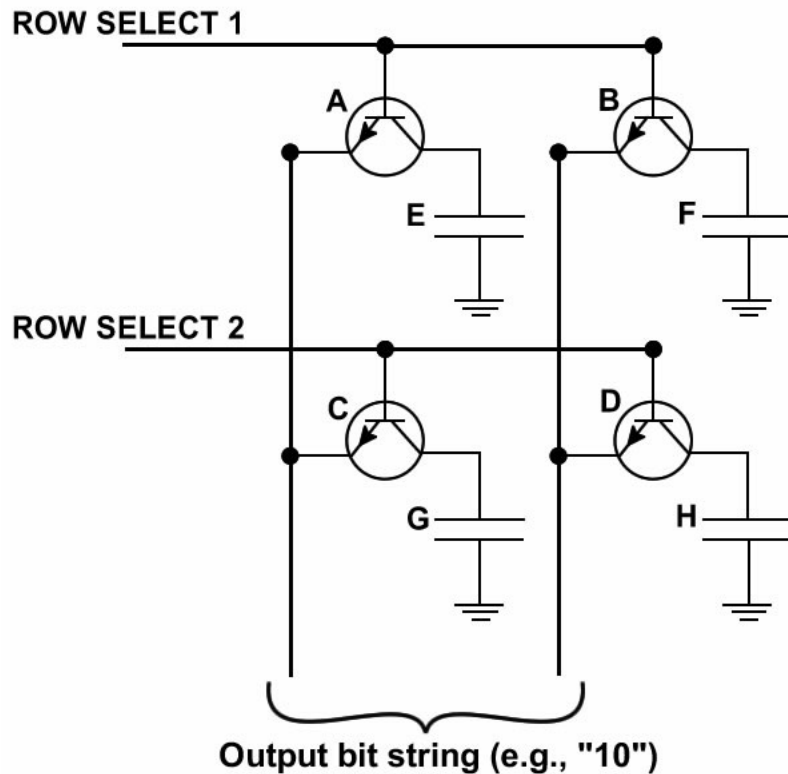

And here is the schematic symbol for a capacitor which is used in circuit diagrams (you can see the two metal

plates):

So now let us see how capacitors are used to make DRAM.

In DRAM, each "bit" of information (0 or 1) is stored on a single microscopic capacitor. If the capacitor has electric charge, that represents bit 1, conversely if the capacitor has no electric charge then that represents bit 0. Each capacitor has an associated microscopic transistor, as shown in the following DRAM circuit diagram:

You will see that the diagram shows four transistors (labelled A, B, C, and D), and four capacitors (E, F, G, and H). You will recognise the symbol for a transistor from Chapter Three.

Each horizontal row of two capacitors represents a string of two bits of information. As an example, consider the top horizontal row consisting of the two capacitors E and F. If there is electric charge on capacitor E then that would represent bit 1, and if there is no electric charge on capacitor F then that would represent bit 0. So, in that case, the two-bit string stored in the top horizontal row would be "10".

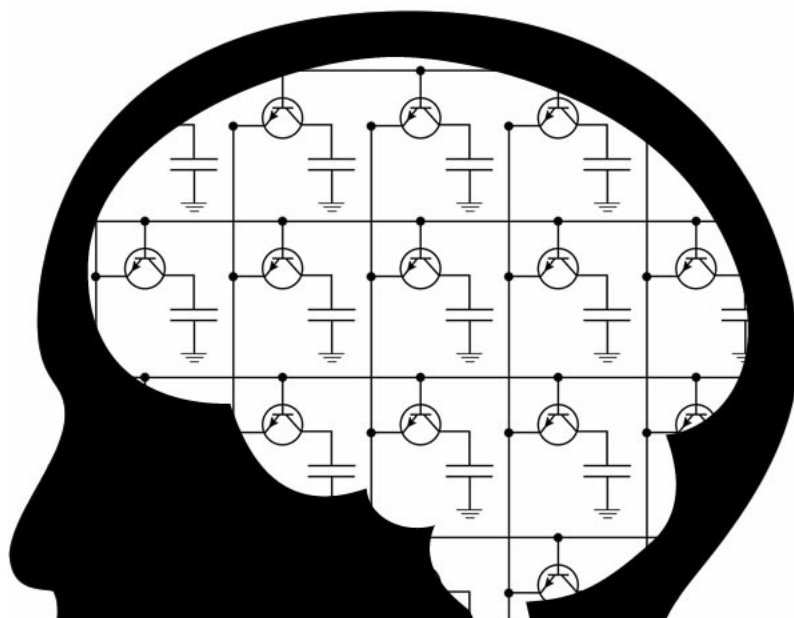

To understand how the data is accessed, let us consider how that data in the top horizontal row might be retrieved. This would be achieved by setting a positive voltage on the top horizontal line "ROW SELECT 1". You will see from the diagram that this voltage is connected to the base leg of transistors A and B. If you remember how a transistor works (as described in Chapter Three), you will see that this applied voltage would have the effect of turning ON transistors A and B. Current is then free to pass between the other two legs of each transistor A and B.

As a result of the two transistors turning ON, you will see from the diagram that the electric charge on the top

plate of capacitor E can pass through transistor A and become the first of the output bits (setting the first output bit to bit 1). Also, the electric charge on the top plate of capacitor F can pass through transistor B and become the second of the output bits (setting the second output bit to bit 0).

Therefore, the output string at the bottom of the diagram will be set to "10". And that is how you read the information stored in DRAM. I hope you have enjoyed this little detour into microelectronics.

But you will see that the information stored in DRAM is stored as a large number of spatially-separated electric charges (stored on the capacitors). And, as discussed earlier, **this is just what we see in the human brain**. So let us redraw the earlier diagram of a human brain composed of spatially-separated electric charges, and replace those charges with the charges stored on spatially-separated capacitors. In fact, let's just draw a DRAM brain:

On the previous diagram you can see a brain composed of an extremely large number of isolated electric charges (stored on capacitors) — just like a real brain.

Now let us return to the previous "Leibniz Mill" thought experiment, and bring it up-to-date. Let us imagine if we could micro-miniaturise Gottfried Leibniz so he was just a few millionths of a metre in height, and let us then implant him inside a DRAM chip. "Mini Leibniz" might walk around the DRAM chip just as he had previously imagined walking around a mill. "Mini Leibniz" would see all the spatially-separated electric charges on capacitors, just as he had previously seen all the isolated pulleys and levers in the mill. And Mini Leibniz might wonder: "How could all these isolated electric charges produce a unified consciousness?", just as he had previously wondered about the mill workings.

But we are fortunate in that we have a greater understanding of technology and DRAM and information than Leibniz possessed. As has just been explained in the DRAM example, we know how to get information out of those "isolated electric charges". We know how computer memory works, and we can extract a string of bits from that DRAM:

101100110011000101101110101101011011101

So now we see just what that series of "isolated electric charges" in the brain really represents: it is Claude Shannon's string of bits, **it is raw information**. And, just like a bit string stored in your computer's memory, that raw information might be anything: it might be a movie, or a song, or words in a book. The point is, what seemed like a completely unrelated series of isolated electric charges can actually be a single, unified chunk of information — a single object, in fact — which can be anything.

And that object would be part of a thought in your mind.

This is how Max Tegmark described this analogy in his previously-referenced paper *Consciousness as a State of Matter*: "When we view a brain or computer through our physicists' eyes, as myriad moving particles, then what

physical properties of the system should be interpreted as logical bits of information? I interpret as a 'bit' both the position of certain electrons in my computer's RAM memory (determining whether the micro-capacitor is charged) and the position of certain sodium ions in your brain (determining whether a neuron is firing)."

"It from bit"

So the material of our thoughts is raw information, the physical substrate of which is the pattern of electric charge in our brain. And our internal model of the local universe is composed of this information. We may be under the impression that we live in the physical world, but really we are living in the information-based reality contained within our minds.

David Eagleman describes this principle in his book *The Brain*: "It feels as though you have direct access to the world through your senses. You can reach out and touch the material of the physical world — like this book or the chair you're sitting on. But this sense of touch is not a direct experience. Here's the key: the brain has no access to the world outside. Sealed within the dark, silent chamber of your skull, your brain has never directly experienced the external world, and it never will. Instead, there's only one way that information from out there gets into the brain. Your sensory organs — your eyes, ears, mouth, and skin — act as interpreters. They detect a motley crew of information sources (including photons, air compression waves, molecular concentrations, pressure, texture, temperature) and translate them into the common currency of the brain: electrochemical signals."

The legendary 20th century American physicist John Wheeler expressed a similar idea about the importance of information in creating our world, and the primacy of information over physical reality. Wheeler was born in 1911, and collaborated with Einstein and Bohr. During the war, he worked on atomic bomb development. After the war, Wheeler worked on general relativity and gave one of the most concise and illuminative quotes about that subject: "Space tells matter how to move, and matter tells space how to curve."

Wheeler certainly had a way with words, and was responsible for coining the memorable terms "wormhole" and "black hole".

Here is a photograph of John Wheeler (on the right side of the photograph) taken in 1985, standing by the side of the German physicist Eckehard Mielke. Wheeler has written: "The black hole is a source of enlightenment":

Wheeler remained an active physicist into his 90s. He was never afraid to tackle what he called the "Really Big Questions" and, in 1989, he wrote an influential paper in which he described a principle which he called "It from bit".^[30] The idea of "It from bit" is that the physical world (the "It") is derived from the more fundamental world of information (the "bit" — as in Claude Shannon's "bits"). Wheeler explained how our picture of reality is solely derived from the information we can obtain: "Every physical quantity, every **it**, derives its ultimate significance from **bits**. That which we call reality arises in the last analysis from the posing of yes-no questions and the registering of equipment-evoked responses; in short, that all things physical are information-theoretic in origin."

Anton Zeilinger, Director of the Institute for Quantum Optics and Quantum Information, explains his interpretation of John Wheeler's idea: "My interpretation is that in order to define reality, one has to take into account the role of information: mainly the fact that whatever we do in science is based on information which we receive by whatever means."

Though we might not realise it, our personal universe is a universe made of information.

Beyond the physical

In his paper, David Chalmers presented what I consider to be a great insight. Chalmers presented the highly-convincing argument that merely altering the arrangement of physical material is never going to provide us with an explanation of the feeling of consciousness. All we will ever be doing is moving physical material around into various different configurations: "For any physical process we specify there will be an unanswered question: why should this process give rise to experience? The structure and dynamics of physical processes yield only more structure and dynamics, so structures and functions are all we can expect these processes to explain."

To my mind, this makes a great deal of sense. Why should merely changing the position of physical objects (particles, for example) cause the emergence of an apparently completely unconnected phenomenon: the feeling of consciousness?

This is basically the same argument as in the Leibniz Mill thought experiment. If you remember, the brain was compared to mill machinery. But if you walked around that mill you would just see the movement of cogs and levers, "pieces and parts" as David Eagleman described. Where, then, does the feeling of consciousness come from?

However, in the previous DRAM analogy, we have seen that the arrangement and movement of physical material can represent something which is not physical: information.

According to Chalmers, we need to find an "extra ingredient" in the explanation. I believe that "extra ingredient" is information.

The reason why I believe that is the case is because — when we examine Chalmers' argument — it is clear that we **need** to go **beyond the physical** to find a solution to the hard problem.

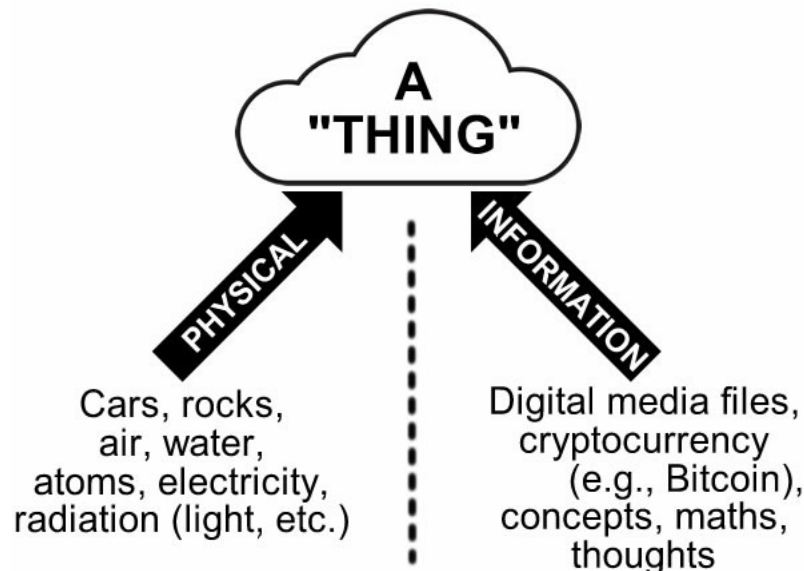

This emphasis on information represents something of a departure from physics, because physics is about physical things (hence the name), and raw information is not physical (you cannot hold or touch raw information). Things can certainly be made of information, but those things would be movies, or digital images, or music, for example. Those things exist as independent entities — but they are not physical things. I am therefore suggesting that consciousness is not a physical thing. Information always requires a physical substrate, but it seems to exist in a realm **above** the physical world. Take away the physical substrate and consciousness disappears — but consciousness is not physical.

At this point, allow me to introduce a brand-new scientific term: the *thing*. I am going to define a "thing" as the most general type of object that can possibly exist. To be precise, a "thing" is going to be defined as "anything that can be made from anything".

OK, that sounds extremely vague. How can such a vague term possibly be of any use? Well, perhaps surprisingly, it appears that a "thing" can only fall into one of two possible groups. Firstly, a thing can be **physical**, in which case it would be composed of particles contained in the Standard Model. That would be fermionic matter (matter made of atoms) such as cars and trees. But it would also include objects made of immaterial bosons, such as rays of light and radio waves (items made of photons — particles described within the Standard Model). Clearly, that is a huge group.

The other grouping is equally huge. This would be the objects made purely out of information. This would include a range of "things" from digital media files such as digital movies and music, through to a thought in your mind (made out of information represented by the arrangement of electrical charge in your brain).

Here is a diagram showing how every "thing" has to fall into one of the two categories:

You will see that I have included cryptocurrency — such as Bitcoin — in the second grouping. This is digital money which has **no physical form**. Conventional currencies always have a physical form, e.g., coins and banknotes. However, Bitcoin only exists as information, stored and transmitted in electronic format. Bitcoin is therefore clearly not a physical "thing". As I said earlier, you cannot hold or touch raw information, so you cannot

hold or touch a Bitcoin. However, Bitcoin might be considered to be just as real as the coins and notes in your wallet.

You will also see that I have included "concepts" in the second grouping. Basically, if you can represent a "thing" in its entirety by thinking about it or writing it down, then it is made of information and it should be in the second group.

Into which group should we place a colour? For example, into which group should we place "green"? That is an interesting question. Firstly, "green" could refer to the particular wavelength of light which we associate with the colour (approx. 495-570 nm), in which case — as light is listed on the diagram as being a physical "thing" — we should place it in the first group. However, the feeling which we experience when we look at something which is coloured green — the "feeling" of green — is clearly a thought and should therefore be placed in the second group. So a colour has a dual interpretation and could therefore be placed in either group depending on that interpretation.

So there is clearly a bridge between the two groups: physical colour can be converted into the thought of colour in your mind, or can be related to that feeling of colour. So there is not an unbridgeable gap: the mind/body gap can be crossed. Information is associated with all physical "things". Far from there being an unbridgeable gap, there is actually an unbreakable link.

I can think of no "thing" which does not fall into one of these two categories. If you can think of any "thing" which is outside of these two categories, my email address is in the front of the book — please let me know!

I think the fact that absolutely every "thing" in existence can be placed in one of only two categories must have some profound significance. Might this be interpreted as Descartes' "dualism"?

As stated earlier, on the basis of Chalmers' argument, in order to solve the hard problem we **need to go beyond the physical**. We need to move to the other grouping of "things". Referring to the previous diagram, the question as to whether or not a particular material could ever become conscious then reduces to a very simple black-or-white question: **on which side of the line does it lie?** If it lies on the right-hand side of the line, then the material has the potential to be conscious.

I believe this "What side of the line?" principle provides us with a huge clue about how to solve the hard problem of consciousness. **I would suggest that we could define the "feeling" of consciousness as the feeling you get when you look at a physical object (a car, rock, etc.) and know that you are made from different stuff.** In other words, it is the feeling you get from knowing you are on the right-hand side of the line in the previous diagram, as opposed to being on the left-hand side of the line in the previous diagram. It is the feeling of being "made differently" that defines consciousness, the feeling that your consciousness is made of information.

In a nutshell, **consciousness is the feeling that your mind is not a physical thing.** You feel different because you **are** different: you are a fundamentally different type of "thing".

And how would you actually feel if you were on the right-hand side of the previous diagram? Well, in Chapter One it was explained how a consciousness based on information would feel substrate-independent (you would not feel as though you were made of a "rice pudding brain"), feeling independent of the physical world, with a mind which felt impervious to physical damage and the ravages of time. This is clearly just how your consciousness feels. I would like to draw your attention to the word "feels" in the previous quote by Max Tegmark: "I have long contended that consciousness is the way information **feels**."

So, to an extent, it is possible to explain the "feeling" of consciousness via this information-based model. It seems that science can provide insights even into subjective matters.

So, yes, I am essentially suggesting that your consciousness is like Bitcoin: made of information with no physical form, and completely substrate-independent:

I would like to leave you with one final thought.
We live in a world in which science has stripped Nature down to her smallest constituent parts, and eliminated almost all mysteries about the natural world — from the universe to the atom. So perhaps we should be rather proud of the fact that one of the few remaining mysteries of Nature lies at the heart of each and every one of us.

PREFACE

The subject of quantum computing is receiving a lot of publicity at the moment, with many stories in the press about how it is going to revolutionise our lives, or break the world's encryption systems. However, most of these stories seem very short on hard facts about how quantum computing actually works. In fact, there seems to be a general lack of easy-to-understand technical information about quantum computing. Whereas there is plenty of complex technical material available.

This book is going to attempt to fill the gap. It will attempt to simplify the subject, clarifying the essential concepts, while still retaining sufficient technical depth.

If you ask in most IT departments about the latest programming languages, or the latest programming techniques, I am sure you would find plenty of programmers with excellent knowledge of the latest developments. However, if you ask about quantum computing, I suspect you would be met with blank stares. But these are the people who — one day, hopefully — are going to be using quantum computers. These are the target customers.

So this book is accessible, aimed at a general audience. But it is also aimed at those programmers and scientific researchers, people with experience of conventional computers who wish to gain knowledge and experience of quantum computing but do not wish to trawl through the extensive and complex literature. This book will explain the programming techniques which will likely be needed to write a quantum computing program to solve their particular problems.

Hopefully, this book can provide another step towards taking quantum computing into the mainstream.

No prior knowledge of quantum mechanics or computing is assumed. This book will take you on the entire journey, from explaining the fundamental postulates of quantum mechanics, then explaining the principles of quantum computing, and finally showing you how you can program a quantum algorithm on a real quantum computer, generously provided by IBM.

You will be working at the frontier of human knowledge, using arguably the most advanced technology which has ever been created. You will be performing complex calculations in a time-window which lasts just microseconds, using single elementary particles which are in two states at the same time, inside a refrigerator which is the coldest place in the entire universe. This is beyond the wildest science fiction.

Quantum computing — and the development of quantum algorithms — is still very much a work in progress. It is a journey into mystery, and no one knows where the destination will be. You can play a part in shaping that future.

*"Get ready to think outside a box
you didn't know existed."*

- CHARLES BENNETT,
QUANTUM INFORMATION PIONEER

1

THE THINKING MACHINE

In early 1943, Richard Feynman received a telephone call from Robert Oppenheimer. Feynman was a 25-year-old physicist, a rising star from Princeton University. Oppenheimer was the scientific director of the Manhattan Project, the American project to build the world's first atomic bomb. Oppenheimer persuaded Feynman to join his team and, on March 28th 1943, Richard Feynman boarded a train to Los Alamos, New Mexico, where the centralised bomb development facility was located.

Feynman described his time at Los Alamos in his highly-entertaining autobiography *Surely You're Joking, Mr. Feynman!* He recalled arriving on-site to find the main buildings were still not fully complete, and so the physicists had to lend a hand in the construction work.

Feynman recalls how he attended the introductory lecture given by Robert Serber (which was described in my eighth book) in which the principles behind the atomic bomb were explained. For many of the physicists in attendance, this was the first time they were made aware of the true purpose of Los Alamos.

All of the correspondence in and out of Los Alamos was heavily-censored for fear of spies, and secrets leaking out. This presented a problem for Feynman whose wife, Arlene, was seriously ill with tuberculosis in hospital in Albuquerque. Feynman and Arlene arranged that they would write letters to each other in code. The key to deciphering the code would be written on a separate piece of paper inside the letter.

One day, Feynman received a letter from his wife which included the following key which was written on a separate piece of paper:

**LITHARGE
GLYCERINE
HOT DOGS
LAUNDRY**

Feynman puzzled over the letter for many hours, unable to decipher it by using the enclosed key. It was only when he arrived at Arlene's hospital a few days later that she told him it was actually a shopping list of things she had wanted him to bring when he visited her.

In another famous anecdote, Feynman is sent on a trip from Los Alamos to inspect the giant uranium enrichment plant at Oak Ridge (also described in my eighth book). When he arrives, his reputation as a genius precedes him, and so the team at Oak Ridge unroll a series of plant blueprint diagrams for Feynman's analysis and approval. However, Feynman has never seen anything like this in his life: "I'm completely dazed. Worse, I don't know what the symbols on the blueprint mean! There is some kind of a thing that at first I think is a window. It's a square with a little cross in the middle, all over the damn place. I think it's a window, but no, it can't be a window, because it isn't always at the edge. What am I going to do? I get an idea. Maybe it's a valve. I take my finger and I put it down on one of the mysterious little crosses in the middle of one of the blueprints on page three, and I say 'What happens if this valve gets stuck?' — figuring they're going to say 'That's not a valve, sir, that's a window.' So one looks at the other and says, 'Well, if **that** valve gets stuck ...' and he goes up and down on the blueprint, the other guy goes up and down, back and forth, and they both look at each other. They turn around to me and they open their mouths like astonished fish and say 'You're absolutely right, sir!' So they rolled up the blueprints and away they went and we walked out. And Mr. Zumwalt, who had been following me all the way through, said: 'You're a genius.'"

At Los Alamos, Feynman was assigned to the team responsible for analysing the behaviour of the bomb during implosion — the period during which a sphere of plutonium about the size of an orange is crushed to about the size of a lime. The task of the team was to calculate how much explosive energy would be released during the implosion. However, they quickly realised that this required more calculating power than they had available.

The physicists at Los Alamos were also all too aware that their work was a race against time. They had to beat Hitler to the bomb — the alternative was too awful to contemplate. Because of those extreme time pressures, Feynman realised he had to find a way of reducing the time of their calculations. Some form of automation was going to be required. However, those were the days before the digital computer was invented (during the same period, the digital computer was being invented in Britain in order to crack the German Enigma code).

However, IBM had produced a series of mechanical calculating machines which could perform a limited set of operations on punched cards. Each machine was only capable of performing a single type of operation, such as multiplying two numbers on a punched card together. As an example of one of these type of machines, the following photograph shows the IBM 601 Multiplier, first introduced in 1931, which is known to have been the type used by Feynman in Los Alamos. This was the first IBM calculator which could multiply. You can see the stack of iconic 80-column IBM punched cards in the top right of the photograph:

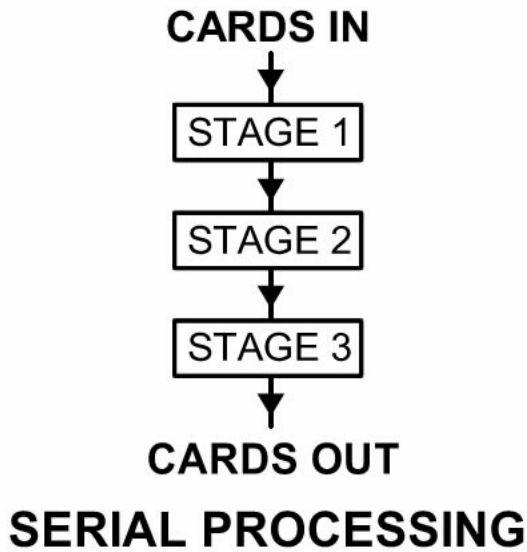

According to the IBM website, the punched card running on machines such as this: "was the dominant form of data processing from 1890 until commercial electronic computers arrived in the 1950s. That's more than a half-century of transforming business in virtually every industry in the world. Machines such as this made IBM into one of the few major corporate success stories of the Great Depression, and launched the company on its path to becoming a computing giant." [1]

However, with each machine only capable of performing a very limited number of different operations — or maybe only one type of operation — any complex operation would require a number of these machines to be placed in a line. The cards output from one machine would then be fed into the next machine in the line — very much like an industrial assembly line. Feynman described this approach: "If we got enough of these machines in a room, we could take the cards and put them through a cycle. Everybody who does numerical calculations now knows exactly what I'm talking about, but this was kind of a new thing then — mass production with machines."

Back in Los Alamos, with each calculating machine performing just one particular operation, this represented a single "assembly line" with each stage being performed in sequence. In modern computing terms, this would represent what we now call *serial processing*.

The following diagram shows Feynman's serial processing arrangement at Los Alamos, with punched cards entering at the top, processed in a series of stages (mechanical calculators), and exiting with the result of the calculation at the bottom of the diagram:

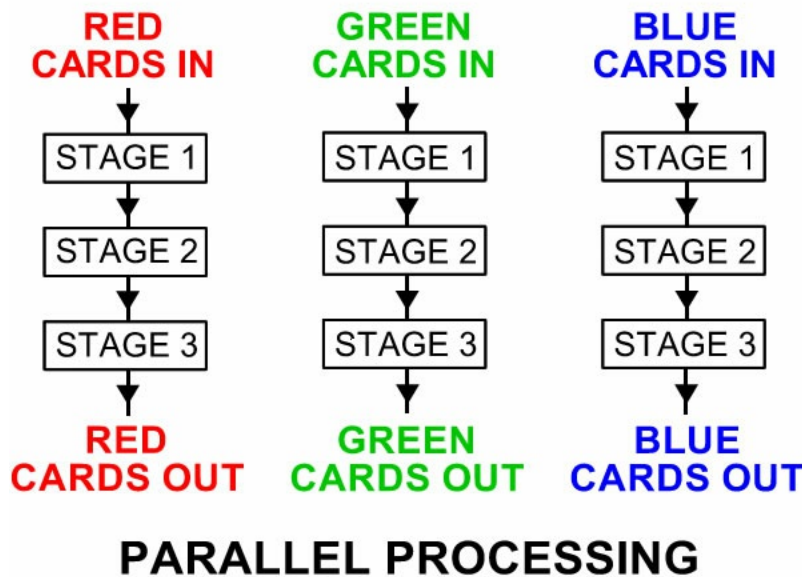

In a mass production system, it is possible to increase output just by adding more assembly lines: the more lines you add, the more items you can manufacture in a day. This represents a move from a **serial** assembly process to a process in which there are many **parallel** lines. As a consequence, the average manufacturing time for each item can be greatly reduced. Feynman applied a similar principle to his serial processing arrangement at Los Alamos.

The way Feynman achieved this was ingenious. He still used a single processing line of machines, but he used cards which were different colours. In that way, he could have many cards being processed on the single line at the same time, with the colours of the cards allowing him to group the cards which were at were at different stages of the process.

Here is how Feynman described this approach: "The problems consisted of a bunch of cards that had to go through a cycle. First add, then multiply — and so it went through the cycle of machines in this room, slowly, as it went around and around. So we figured a way to put a different coloured set of cards through the cycle too, but out of phase. We'd do two or three problems at a time."

Effectively, Feynman had created multiple virtual processing lines which ran in parallel, as shown on the following diagram:

As shown in the previous diagram, this approach represents *parallel processing*. Parallel processing is a computing technique which allows large amounts of data to be processed in a much shorter overall length of time. And it was Feynman's experiments in parallel processing at Los Alamos which planted the seed for the quantum computer in his mind.

In this book we will be examining how a quantum computer uses parallel processing techniques to achieve huge increases in processing speed. And — in honour of Feynman's experiments at Los Alamos — I will be retaining the colour idea ("red", "blue", etc.) in the examples in this book to describe the items being processed in parallel.

Feynman and the Thinking Machine

Feynman proceeded to enjoy a stellar career, being jointly-awarded the Nobel Prize in 1965. By the time of the early 1980s, Feynman had become a professor of physics at Caltech. But he always retained his fascination with computing — and parallel processing in particular.

In the summer of 1983, Feynman took a temporary job as a consultant at Thinking Machines Corporation based in Cambridge, Massachusetts. Thinking Machines had an ambitious plan to design a supercomputer, which aimed to connect 64,000 processors in parallel. The supercomputer was called the Connection Machine.

Here is a photograph of Richard Feynman taken in 1984 while he was working at Thinking Machines Corporation:

Connecting 64,000 processors in parallel might sound like an impossible task, but we will see later in this book that a similar amount of parallelism could be achieved by just 16 quantum bits (because 2^{16} equals 65,536).

The company was being set-up in an old mansion when Richard Feynman arrived just a day after the company was incorporated. The situation was still in a state of confusion when Feynman arrived, saluted, and said: "Richard Feynman reporting for duty. OK, boss, what's my assignment?"

After a quick private discussion ("I don't know what he can do — you hired him!"), they suggested that Feynman could act as a technical advisor, to which Feynman responded: "That sounds like a bunch of baloney. Give me something real to do."

At which point they sent him out to buy office supplies.

Each processor in the Connection Machine was fairly simple, but the network was complex: each processor was

connected to twenty other processors. Feynman was given the job of designing the router, which controlled the traffic flow of data between the processors. The other team members were just glad that they had found something to keep Feynman occupied — or so they thought. Because, in his spare time, Feynman couldn't help wiring the computer room, setting-up the machine shop, and installing the telephones. He also organised the company into teams, relying on his Los Alamos experience: "We've got to get these guys organized. Let me tell you how we did it at Los Alamos."

Feynman revealed the potential of the Connection Machine for simulating aspects of the physical world in which many particles interact at the same time. The example chosen by Feynman was the interactions between the particles which constitute the protons and neutrons in the atomic nucleus. Protons and neutrons are made from elementary particles called *quarks*, and quarks are held together by the *strong force*. The particles which transmit the strong force between the quarks are called *gluons*.

Gluons not only interact with quarks — they also interact with other gluons. Another complicating factor is introduced because the strong force is highly nonlinear. If you read my previous book, you will recognise that when many elements interact in a nonlinear fashion then this represents a system with high complexity. Another example of a nonlinear system is the weather, caused by the nonlinear behaviour of the turbulent atmosphere. Nonlinear systems are notoriously difficult to predict, and there is usually no other option than to split the problem into small pieces and then to use extremely powerful computers to plot the behaviour of those small pieces over time.

As an example of that technique, in order to predict the weather, meteorologists analyse the turbulent and chaotic atmosphere by splitting it into many small pieces maybe a few kilometres apart. A similar principle is used to predict the behaviour of quarks and gluons in the atomic nucleus. The space inside a proton or neutron is split into a three dimensional lattice of points, each point in the lattice representing a different point in space. The lattice can then be mapped onto a parallel processing supercomputer, with each processor in the supercomputer representing a point in space: the finer the lattice, the more accurate is the simulation.

This method is called *lattice QCD* (the theory of the strong force interactions is *quantum chromodynamics*, or QCD).

Feynman used this technique of lattice QCD to map each point in the lattice to a processor of the Connection Machine. He was delighted to discover that the Connection Machine could outperform the conventional computer that Caltech was using for QCD calculations. Once again — as in Los Alamos — parallel processing had proven its ability to tackle a huge volume of data in a reasonable time.

But this got Feynman thinking.

It was clear that a massively parallel computer could outperform a conventional computer in creating simulations of physical systems. This was because the supercomputer was a more accurate representation of how Nature actually works: many small units (particles) interacting in parallel. In that case, wouldn't it be possible to build an even faster and more accurate computer by making it a **perfect** match of Nature, in other words, build a computer which used individual particles as its data elements.

The idea for the quantum computer was forming in Feynman's mind.

The Feynman Lectures on Computation

From 1983 to 1986, Feynman gave a course on computation at Caltech. At the end of the course, Feynman asked one of his colleagues at Caltech, Tony Hey, to adapt his lecture notes into a book. That book is now called *The Feynman Lectures on Computation*. We are lucky that we now have that book generally available so we can follow Feynman's remarkable insights.

The course represented a very different approach to how we now think of "computers" or "computer science". If you browse the computing section of a bookshop, you might find many books on high-level languages such as Visual Basic or C++. Or in the magazine department you might find WIRED magazine, giving you the latest "tech" news about Snapchat or Facebook. For many people, this is what "computing" means nowadays — it's nothing more than fashion, basically.

Feynman, however, considered a very different type of "computing" in his course. Feynman considered the lowest-level of computing, the actual movement of physical material in order to perform a calculation. Feynman considered fundamental physical concepts such as energy, information, and thermodynamics. As Tony Hey says in the foreword of the lecture notes: "As advertised, Feynman's lecture course set out to explore the limitations and potentialities of computers. Although the lectures were given some ten years ago, much of the material is relatively timeless and represents a Feynmanesque overview of some standard topics in computer science. Taken as a whole, however, the course is unusual and genuinely interdisciplinary. Besides giving the 'Feynman treatment' to subjects

such as computability, Turing machines (or, as Feynman says, 'Mr. Turing's machines'), Shannon's theorem and information theory, Feynman also discusses reversible computation, thermodynamics, and quantum computation. Such a wide-ranging discussion of the fundamental basis of computers is undoubtedly unique and a 'sideways', Feynman-type view of the whole of the subject."

(In that quote, Tony Hey mentions "reversible computing" which we will be considering in detail later in this book.)

Because of his interest and aptitude for fundamental science, it appears that Feynman was one of the first people to realise the potential of quantum computing. He was certainly the first person to introduce the principles to a wider audience in his lecture course.

Feynman's proposal for a quantum computer is unveiled in Chapter Six of his book. Feynman's motivation in considering quantum computing at this stage seems to be to treat it merely as an intellectual exercise. Specifically, Feynman seems to be fascinated by how small it might be possible to build a working computer: could just a few particles be made to represent a computer? In that way, Feynman is following a train of thought which started back in 1959 in one of his famous lectures called *There's Plenty of Room at the Bottom* which considered the possibility of creating microscopic machines made of just a few atoms. That lecture was to inspire the field of *nanotechnology*. Feynman's motivation in suggesting quantum computing seems to be merely an intellectual challenge, asking interesting questions, and having a bit of fun in the process. It is classic Feynman.

And, at the end of Chapter Six, Feynman comes to the following amazing conclusion: "It seems that the laws of physics present no barrier to reducing the size of computers until bits are the size of atoms, and quantum behavior holds dominant sway."

Feynman had come to his conclusion: quantum computers **were** possible.

The classical computer

However, in his book, Feynman starts by introducing the principles which lie behind the conventional classical computer. "Classical" physics means the state of physics as it existed before 1900, which means it pre-dates the discovery of quantum mechanics and relativity. It is the physics of Newton — not the physics of Einstein and Bohr. Classical physics is also the physics of the great Scottish 19th century physicist James Clerk Maxwell who viewed light as a wave rather than a stream of particles. The computers we use today are all classical computers, based on classical physics.

The template for the classical computer is the *Turing machine*. The Turing machine was invented by Alan Turing in 1936, and it is the simplest possible general computing device. The Turing machine operates by shuffling a long strip of paper back and forth. The tape has a series of zeroes and ones written on it, representing input data and output data. The Turing machine has a probe pointed at the paper which can read, write, or erase the zeroes and ones on the strip:

The machine has an in-built table of rules — the equivalent of a computer program — which tell it what to do depending on the current symbol on the tape and the current state of the machine. The initial set of symbols on the tape would represent the input to the machine, and the final set of symbols — after processing — would represent the output.

So a Turing machine is a computer. But the most remarkable fact about the Turing machine is that **it can solve any problem which can be solved by any other computer**. This is because any computer — no matter how apparently sophisticated it might appear — is, at heart, merely shuffling individual zeroes and ones around according to a list of instructions (a program) just like the Turing machine. Admittedly, other computers might work a lot faster, or might have prettier screens on which to output their data, but the basic problem-solving capability of any computer is just the same as a Turing machine.

Put simply, a Turing machine can compute anything that can be computed.

It is for this reason that the Turing machine forms the model for every modern computer — including the PC on your desk, or your iPhone or iPad. There are some implementation differences: a modern computer writes data to-and-from electronic memory, whereas a Turing machine writes data to-and-from a tape. However, in both cases, only one item of data is read from memory and processed at a time. Wouldn't it be faster if it could work in parallel, processing many data items simultaneously, like Feynman's machine at Los Alamos?

Yes, indeed it would. And that is the promise of quantum computing.

A classical computer is based on classical physics. As you can see from the previous diagram, it is basically a clunky thing. It is based on pre-20th century physics, the physics of Newton and James Clerk Maxwell. A Turing machine — the basis of the modern computer — could have been built in the year 1899 from the technology in existence at that time. To emphasise this point, see the amazing video on YouTube of the Turing machine made of Lego:

<http://tinyurl.com/plasticmachine>

or the Turing machine made of wood:

<http://tinyurl.com/woodmachine>

These contraptions might seem crazy, but they can compute anything your iPhone can compute (at least, in theory).

So the modern digital computer is actually rather old-fashioned. It is, at its heart, a 19th century device. It needs updating for the 21st century. What it really needs is to be based on the extraordinary 20th century phenomenon of quantum mechanics.

Put simply, it needs to become a computer which you can't make from Lego.

It needs to become a quantum computer.

2

THE QUANTUM STATE (OF MIND)

Many books aimed at a general audience have been published attempting to explain the subject of quantum mechanics. The majority of those explanations tend to follow a fairly linear historical series of events, starting in the year 1900 and ending a few decades later. It is a neat story, featuring some of the greatest physicists in history, revealing their heated arguments and strong personalities as they slowly edged their way towards understanding.

Yes, it is a great story. But it is probably a bad way to learn about quantum mechanics.

In his recent book *Beyond Weird*, Philip Ball agrees: "The temptation to tell quantum mechanics as a historical saga is overwhelming". But this is a temptation which should be resisted.

The problem is that for the first two decades of the 20th century, the field known as "quantum theory" — or now known as the "old quantum theory" — was a mess. Nothing made sense. A series of puzzling experimental results had shown that the classical physics of the 19th century could not be entirely accurate. However, the attempts to bring the old physics into line with the new experimental results just resulted in a series of hodge-podge theories which were soon to be discarded. As Philip Ball says: "They cobbled old concepts and methods together". The Wikipedia page on the "old quantum theory" describes the situation as: "The old quantum theory is a collection of results from the years 1900-1925 which predate modern quantum mechanics. The theory was never complete or self-consistent, but was rather a set of heuristic corrections to classical mechanics."

As Philip Ball continues to say: "There is no reason to believe that the most important aspects of the theory are those that were discovered first, and plenty of reason to think that they are not." Even the name "quantum theory" which arose from this period is a bad choice of name. As Philip Ball says: "If we were naming it today, we'd call it something else".

No, if we want to learn about quantum mechanics, then we need to skip forward in time to the mid-1920s. That is because, in 1925, everything changed — and a new light of understanding and clarity was cast over the subject.

In 1925, the "old quantum theory" was superseded by the theory of quantum mechanics, which was separately developed by Werner Heisenberg and Erwin Schrödinger. This was a theory which brought together all the puzzling, arbitrary rules of the old quantum theory into a single, logical theoretical framework. In doing so, quantum mechanics replaced the old classical mechanics.

The old classical model not only had to be replaced by a new theory of mechanics — it also had to be replaced by a new theory of reality! Quantum mechanics represented more than a theory about the behaviour of atoms: it represented a new, more sophisticated way of thinking about reality and how the world must work. Though you might sometimes read of quantum mechanics being described as "weird", I hope to show you that nothing could be further from the truth: quantum mechanics is entirely sensible and logical.

But, more than that, I want to show you that quantum mechanics is more than a theory — it is a new way of thinking about reality, a better, more logical way of thinking about reality.

I want to show you that quantum mechanics is a state of mind.

The new worldview of quantum mechanics

What is reality? From a scientific viewpoint, we can define reality as being the values of the properties of objects, such as particles. For example, if we can fully describe the properties of all the particles which comprise a system, then we have a full definition of the reality of that system.

Over the next few chapters we will be seeing that quantum mechanics considers reality (for example, the property values of a particle) as being divided into two periods of time:

1) The reality of the particle **BEFORE** it is observed.

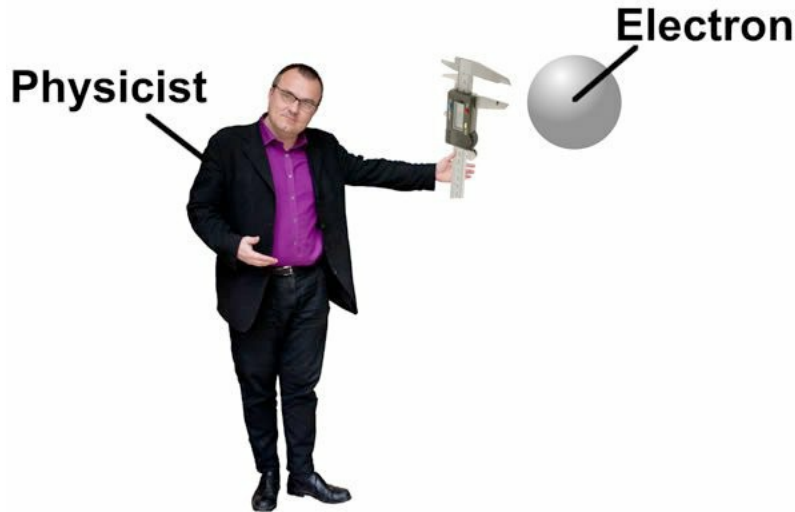

This is not as straightforward as it might sound, raising deep questions about "reality-without-observation" which resemble the old philosophical thought experiment: "If a tree falls in the forest and no one is around to hear it, does it make a sound?"

2) The reality of the particle **AFTER** it is observed.

We shall be seeing that the determination of the particle values when it is observed (measured) involves fundamental uncertainty and randomness which is unavoidably introduced by quantum mechanics.

While this new version of reality revealed by quantum mechanics might seem rather strange at first, I hope to show you that it makes perfect sense, and — when you think about it — you will realise it represents a rather more sophisticated model of how reality must work.

OK, let's start with a simple model of how the classical world was imagined:

The previous diagram shows a physicist holding a highly-sophisticated measuring device. He is going to use his device to measure some property of the electron (not shown to scale).

According to the classical view, this is a fairly straightforward operation. The measuring device and the electron are two clearly defined, separate objects. The electron has a definite reality, in other words, not only does it definitely exist but it possesses definite values for its position, speed, etc. The physicist then uses his measuring device to "extract" those values from the electron, and writes them down. Problem solved.

Only, when you think about it, you realise this can't be a correct picture of what actually happens.

For example, let us imagine the physicist wants to measure the electron's position. As an electron moves, it does not continuously (and conveniently) radiate data about its position. No, if we want to determine the position of the electron, we have to observe it, or interrogate it. Basically, we have to ask it a question. That observation process might involve shining a light on it (like a prisoner undergoing an interrogation), or forcing the electron to come to a rest by hitting a screen and then noting its position. But whatever method we use, we are going to have to interact with the electron, and that interaction is inevitably going to affect the electron. It is unavoidable. The classical model conveniently avoids that fact, but we cannot.

So the value we obtain by our measurement inevitably can not be a 100% perfect measurement of the property of the electron. No, what we actually obtain is a measurement of the property of **the joint system of the electron being measured by the measuring device**. What we are actually observing is an electron being measured — not the electron on its own.

So, by pure logic and reasoning, we can see that this new realisation of how the world must work tells us two crucial facts about reality, which have to be incorporated into the theory of quantum mechanics:

- A measurement inevitably affects the object under observation. We are therefore not measuring the true reality of the object on its own, i.e., the object before it is measured.
- Objects are never completely isolated. The measurement we eventually obtain is a measurement of the joint system: "an electron being measured by a measuring device".

What is more, these principles do not just apply to quantum mechanics. These are general principles which apply to all aspects of our lives. No object is ever completely isolated, and all actions affect the underlying reality.

A rather unusual example of our actions affecting the underlying reality was provided by the billionaire investor George Soros. Soros named his investment fund the Quantum Fund when he realised that his own purchasing actions were inevitably affecting the prices of the stocks and shares he was buying.

The quantum philosophy is a logical philosophy which affects many aspects of our lives.

The quantum state

Let us return to consider the first of the two principles presented in the previous section. It was stated that: "A measurement inevitably affects the object under observation. We are therefore not measuring the true reality of the object on its own, i.e., the object before it is measured."

So when we make a measurement of some property of a particle, all we can ever hope to achieve is to measure the state of the particle after it has been measured, after the measurement process has fundamentally altered the particle in some way. So what can we say about the reality of the particle **before** it is measured? Surely that is what we really want to capture. Surely that represents the true reality of the particle.

Well, yes, and even though we can never capture that reality of the particle through measurement, we **can** reveal it through mathematics. Mathematically, the state of a system before it is measured is called the *quantum state*, and is conventionally denoted by the Greek letter Ψ (written "psi" and pronounced "sigh").

Sometimes this quantum state is referred-to as the *wavefunction*, with the Ψ symbol being especially associated with the wavefunction. It is called a wavefunction because the physical nature of the quantum state will often resemble a wave (such as the path of an electron around an atomic nucleus, as we shall see later in this book). However, the terms "quantum state" and "wavefunction" both mean essentially the same thing, though I will be preferring the term "quantum state" in this book.

This principle — that Ψ represents the physical reality of the system before it is measured — is expressed several times by the physicist Roger Penrose in his popular science books such as *The Emperor's New Mind*: "I am taking the view that the physical reality of the particle's location is, indeed, its quantum state Ψ ", and again in *The Road to Reality*: "If we are to believe that any one thing in the quantum formalism is actually real, for a quantum system, then I think that it has to be the wavefunction (quantum state) that describes quantum reality." I would agree with Roger Penrose that we should consider the quantum state as representing the reality of a quantum system before observation, and I would encourage you to do the same. This is especially true when, later in this book, you will find that your time spent programming a quantum computer involves rotating a quantum state vector — which makes it feel very "real" indeed!

To understand the nature and behaviour of Ψ , let us draw a graphical representation of what happens when we measure some property of a particle. To make things simple, I will use the purely imaginary notion that a particle has some form of visual "colour" of some kind, and when we inspect that particle we will find it to be either "red" or "blue" (in honour of Feynman's coloured cards at Los Alamos).

The following diagram shows the graph. You will see that the vertical axis represents the "amount of red" in the particle, and the horizontal axis represents the "amount of blue" in the particle:

As you can see on the previous diagram, the red particle will have "a lot of red" and "no blue at all", so we plot it high on the "amount of red" axis, but at the extreme left (the zero position) on the "amount of blue" axis. Similarly, the blue particle will have "a lot of blue" and "no red at all", so we plot it on the far right of the "amount of blue" axis, but at the zero position (at the bottom) of the "amount of red" axis.

We can then see that what we have here are two dots plotted which are both the same distance from the origin of the graph (the origin is the zero position of the graph, where the two thick axes cross at the bottom left). So the best way to plot these points is as arrows which have equal lengths, coming out of the origin of the graph. The points representing the particle states (colours) would then be at the end of the arrows:

These arrows are examples of *vectors*. A vector is an arrow which is defined purely in terms of its direction and length. In other words, if two arrows have the same direction and length then they represent the same vector — **even if they are positioned at different points in space**. Please make sure you understand this vitally important principle about a vector: all that matters is the direction and length of a vector — it does not matter where it is.

A vector is usually written as a column matrix, which simply represents the coordinates of the endpoint of the arrow. For example, the red vector arrow in the previous diagram has an endpoint which is some distance up the vertical axis, but has a zero horizontal coordinate, while the blue vector arrow has an endpoint with a zero vertical value and a non-zero horizontal value. Assuming each vector has a length of one unit (which is usual), that means

the two vectors could then be written as the following column vectors:

$$\text{red} = \begin{bmatrix} 0 \\ 1 \end{bmatrix} \quad \text{blue} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

The particular vector which describes the current quantum state of a system is called the *quantum state vector* or simply the *state vector*. We will be encountering these arrows — these "state vectors" — very often in our discussion of quantum computing. We will see that they are absolutely central to understanding how quantum computing works. We will see that programming a quantum computer is basically the act of manipulating a state vector.

But these mathematical vectors are not arrows in the real world — they are not pointing from point A to point B in physical space. No, they only exist as mathematical constructions drawn on a graph. It might help you to visualize them as physical arrows in physical space, but do not make the mistake of thinking that that is their true nature.

So these vectors live in a mathematical world. They are mathematical constructions drawn on a graph. And that particular type of graph is called a *vector space*.

And, now we have moved inside a mathematical world, we have to realise that these vectors behave according to mathematical rules — not physical rules. And one of the rules of a vector space is that we can combine, or add, any two vectors together to make a third vector.

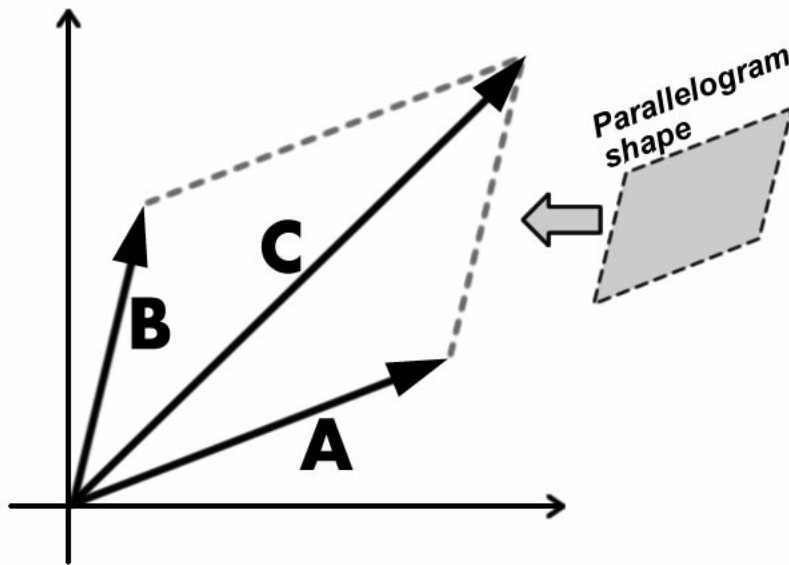

So, how do we add two vectors? Well, remember that a vector is defined as a length in a certain direction. So if we want to add two vectors, we might think of walking along the first vector, continuing in that direction to the end of that first vector, and then from that point continuing to walk along the second vector, as shown in the following diagram:

The previous diagram shows how vector **A** and vector **B** can be added to produce vector **C**. It is equivalent to walking along vector **A** from point *x* to point *y*, and then adding vector **B** by walking a further distance from point *y* to point *z*. As you can see from the diagram, the end result will be as if you had simply walked from point *x* to point *z* directly, so we say that vector **C** (the direct route from point *x* to point *z*) is the result of adding vector **A** and vector **B**.

The following diagram shows a slightly different geometrical method of obtaining the same result. You can again see exactly the same vectors **A** and **B** as in the previous diagram. They are the same vectors as in the previous diagram as their lengths and directions are the same as in the previous diagram — even though vector **B** is not

positioned in the same place as in the previous diagram. Remember: as explained earlier, if a vector has the same length and direction as another vector, then they are the same vector — no matter if they are positioned at different points in space.

You can see in the previous diagram that this second vector addition method involves the drawing of a parallelogram, with vectors **A** and **B** forming two sides of the parallelogram. The result of the addition — vector **C** in this case — is then the diagonal of the parallelogram. You will also see that vector **C** — the result of the addition — is exactly the same as in the previous diagram, so both methods give exactly the same result.

It is this second method — using the parallelogram — which is the most common geometric method for visualising the addition of two vectors. In fact, the method of vector addition is called the *parallelogram law*.

The superposition state

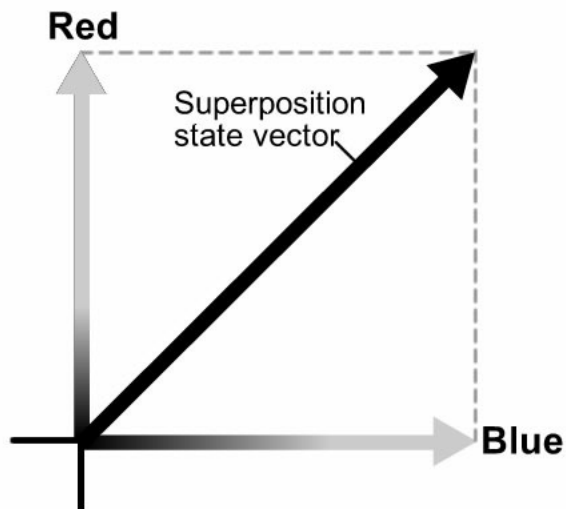

Reality at the quantum level is therefore defined by the quantum state vector. And, as has just been explained, the quantum state vector lives in a mathematical world called a vector space. One of the rules of a vector space is that it is possible to add any two vectors together to produce a third vector — and we have just seen how this is possible.

But this leads to an intriguing conclusion.

If, according to the rules of a vector space, we can add any two vectors together, then let us apply that rule to the vector space presented earlier which described a red and blue particle:

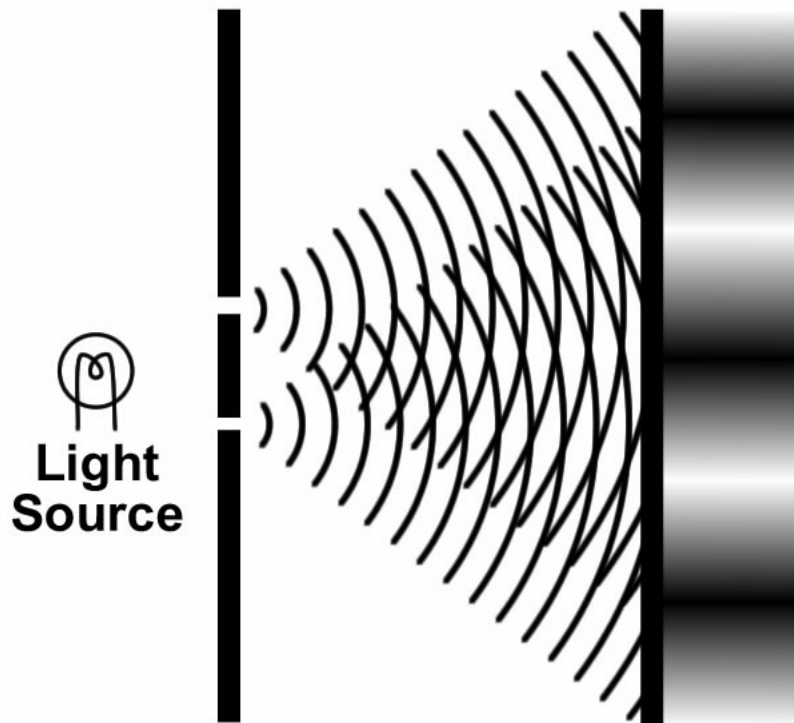

By the rules of the vector space, we can apply the parallelogram rule to add those two vectors, thereby producing a new, third vector:

As you can see in the previous diagram, the parallelogram rule has been applied, thereby adding the two state vectors. As a result, a third vector has been generated which represents the addition of the red and blue state vectors. It is as though the particle has a mix of properties: as though it is both red and blue at the same time.

Initially, this might not seem like a particularly remarkable result. After all, colours can be mixed together (when mixing paint, for example). However, we have to remember that other properties of a particle — for example, its position or momentum — are also described by state vectors in vector space. In that case, how on Earth could a particle have two values of position which are "mixed together"? Can a particle really be in two places at once? This appears to be what the mathematics of vector spaces is telling us.

Well, yes, amazing though it may appear, sometimes a particle can behave as though it is in two places at once. The most famous experiment revealing this behaviour is the double-slit experiment in which a beam of light is directed towards two narrow slits, with a screen positioned on the other side of the slits. The light beam passes through both of the slits, generating an interference pattern on the screen due to the wavelike nature of light:

The interference pattern is generated by light passing through both of the slits, with the light from one slit interfering with the light passing through the other slit. This behaviour is to be expected according to classical physics (James Clerk Maxwell's classical theory of electromagnetism describes light as a wave).

However, now let us consider the situation when the light intensity is reduced so that only a single photon (a photon is a particle of light) is in transit at a time. Over time, a pattern of marks will develop on the screen as the individual photons strike the screen and accumulate. Amazingly, though, over time, the interference pattern is still produced! How can this be, when there is only one photon in the system at a time? It is as if the single photon passes through both slits and interferes with itself! As amazing as this may appear, we have just seen that this is behaviour which is predicted by quantum mechanics and the mathematics of vector spaces (the addition of state vectors).

When a particle has a mix of properties in this way, it is said to be in a *superposition state*. We shall be seeing that the ability of particles to enter a superposition state plays a central role in quantum computing.

Quantum mechanics is not "strange"

Throughout this chapter I have been stressing that we can gain an understanding of quantum mechanical behaviour through mathematics and logical reasoning. Earlier in this chapter it was explained via logical reasoning how a measurement will inevitably affect the object being measured — one of the central principles of quantum mechanics. Then, in the previous section, it was explained how the superposition state — which many would consider to be "strange" — is, in fact, predicted by the rules of mathematics. **In fact, it would be stranger if the superposition state did not exist!** (How can you have a world of mathematics in which you can't add things up?)

And this makes an important point: it is not the quantum mechanical world which is strange — if anything, it is our human-scale ("macroscopic") world which is strange! If there is a puzzle at all in quantum mechanics, it is the puzzle of why we do not see quantum superpositions in everyday objects — why we do not see Schrödinger's famous cat both alive and dead at the same time.

This is a viewpoint which is nicely expressed in the IBM Quantum Experience full user guide (we will be programming the IBM quantum computer later): "By making quantum concepts more widely understood — even on a general level — we can more deeply explore all the possibilities quantum computing offers, and more rapidly bring its exciting power to **a world whose perspective is limited by classical physics.**"

It is an excellent piece of writing. I have placed the phrase "a world whose perspective is limited by classical

physics" in bold, and I would especially like to emphasize the word "limited". The macroscopic world — the classical world — in which we live appears to arise due to limitations which prevent us from seeing objects in superposition states. It would appear there is some strange and unusual mechanism at work which filters-out those superposition states, leaving us with a rather false view of how Nature operates.

In fact, in Chapter Six we will be seeing that this "strange and unusual mechanism" is achieved through a fairly well-understood physical process called decoherence. We will also see that the randomness which plays such a fundamental role in quantum mechanics gets "averaged-out" by decoherence, leaving the human world based on deterministic cause-and-effect which we all know so well. We will also be seeing that it is only by preventing decoherence that we can avoid those limitations of classical physics, thereby unleashing the full power of quantum mechanics in our quantum computers.

In this respect, it is the human world which is peculiar, a rather fake and illusory version of the true quantum reality. As physicists, we must be very careful not to let our human intuition bias us into deciding what is "weird" and what is "sensible". And yet there are still some writers who insist that the quantum world is somehow "weird" — with presumably the human world supposed to represent some paragon of sense and predictability.

The human world is not weird? I mean, seriously? When was the last time they took a ride on the subway ...

Dirac notation

This is the last section in this chapter describing the quantum state. Before this chapter ends, another important piece of notation needs to be introduced. This notation is commonly used whenever the quantum state is considered, and it is used throughout most technical discussions on quantum computing.

Paul Dirac was unquestionably the greatest British physicist of the 20th century. Dirac was one of the pioneers of quantum mechanics, being awarded the Nobel Prize in 1933 together with Erwin Schrödinger — another of the great quantum pioneers (Werner Heisenberg had received his Nobel Prize the previous year). Dirac was a socially-awkward, taciturn character. You can read about his story and work — especially the remarkable *Dirac equation* — in my fifth book which is about particle physics.

One of Dirac's most enduring contributions was by creating the standard form of notation used for describing quantum states. According to the Dirac notation, a quantum state is denoted by simply placing the name of the quantum state inside angled brackets in the following form:

$|red\rangle$

or some other common examples:

$|0\rangle$ or $|1\rangle$ or $|OFF\rangle$ or $|ALIVE\rangle$

When a state vector is described like this it is called a "ket" (as part of Dirac's "bra-ket" notation).
You will encounter this notation throughout quantum mechanics and quantum computing theory — and it is used in the remainder of this book.

3

THE SCHRÖDINGER EQUATION

In the previous chapter, the quantum state vector was introduced. We will see later in this book that programming a quantum computer involves rotating the state vector in various ways, to point in different directions. Each movement of the quantum state vector represents a step towards the completion of a calculation on a quantum computer.

In this chapter, we will be seeing that this rotation of the state vector is actually a well-defined process, with no uncertainty about how the state vector moves. And we will be seeing that the movement of the state vector is described by one of the most famous equations in physics.

The life and loves of Erwin Schrödinger

Erwin Schrödinger was an Austrian physicist who was one of the most important pioneers of quantum mechanics.

Schrödinger was born in Vienna in 1887, and became an exceptionally gifted pupil at school. According to one of his fellow pupils: "Schrödinger had a gift for understanding that allowed him immediately and directly to comprehend all the material." Schrödinger received his doctorate in physics from the University of Vienna in 1910, and became a professor of theoretical physics at the University of Zurich in 1921.

Outwardly, then, Schrödinger lived a highly-respectable and conventional life. However, Schrödinger and his wife Annemarie had an open marriage, with both having a string of affairs. The situation was complicated, to say the least. Annemarie had an affair with the physicist Hermann Weyl, who happened to be a good friend of Erwin Schrödinger. Meanwhile, Erwin Schrödinger was working with his assistant, Arthur March, because he was sleeping with Arthur's wife, Hilde, and eventually fathered a child with her.

By this stage, Annemarie, seems to have become aggrieved by Schrödinger's constant infidelities, but she remained attracted to his intellect and decided to stay in the marriage, saying: "You know it would be easier to live with a canary than a racehorse, but I prefer the racehorse."

Schrödinger persuaded Annemarie to allow Hilde to live in their house, forming an uncomfortable long-term *ménage à trios*. However, living with two women was not enough for Erwin Schrödinger, who had two other girlfriends and had children with each of them.

Here is a photograph of Erwin Schrödinger. I must say, I think he's looking rather worn-out ...

The Schrödinger equation

We will now consider Schrödinger's breakthrough work of 1925, the development of an equation which effectively created the field of quantum mechanics.

Let us imagine we want to observe the value of some property of a quantum system — for example, measuring the momentum or position of a particle (in quantum mechanics, a measured property is called an *observable* of the system). The first thing to be realised is that if we want to measure a certain property then we need to apply a certain measurement operation, for example, we might measure the position of a particle by arranging the particle to collide with a screen. But if we had wanted to measure a different property — for example, the particle's momentum — we would have needed to apply a different operation.

So when we want to measure a quantum system, we first have to decide what property we want to measure, and then that decision determines the particular measurement operation which must be performed. Mathematically, we say we need to apply a different *operator* (an operator meaning a "mathematical operation" of some kind).

It turns out that the operator which has to be used in order to measure the energy of a system plays a particularly important role in quantum mechanics. In this section, we will be considering this energy operator, and discovering why it is so important.

Firstly, the concept of the *Hamiltonian* needs to be introduced. The Hamiltonian is named after the 19th century Irish mathematician William Rowan Hamilton. The Hamiltonian represents **the total amount of energy in a system**. In equations, the Hamiltonian is conventionally denoted by the letter *H*.

The operator which is used to observe the amount of energy in a quantum system is therefore called the Hamiltonian operator, and it has the following form (I know this looks complicated, but don't worry — everything will be explained):

$$\hat{H}(\psi) = i\hbar \frac{\partial \Psi}{\partial t}$$

When the energy operator is written in this way, it becomes the most important equation in quantum mechanics — it is called the *Schrödinger equation*. You've probably heard of it already.

In fact, it was the discovery of this Schrödinger equation in 1925 which created the field of quantum mechanics. And, as we shall be seeing, it is also the key equation needed for building a quantum computer.

Let us consider the left-hand side of the equation first.

The left-hand side of the previous Schrödinger equation is just a statement that this represents the Hamiltonian operator (the total energy of a system), signified by the letter \hat{H} . The little caret symbol on top of the H indicates that this is an operator (in this case, the energy operator). Hence, it needs something to "operate" on. In this case, you can see that it is operating on the quantum state vector as the symbol (Ψ) is included immediately after the \hat{H} .

So all the left-hand side of the equation is doing is telling us that we are dealing with the energy operator operating on the quantum state vector. In other words, we are applying a mathematical operator to measure (or observe) the energy of a particular quantum system.

The right-hand side of the equation is more interesting, as this gives the actual form of the energy operator.

You will see on the right-hand side of the equation that there is a part of the equation which says: [2]

$$\frac{\partial \Psi}{\partial t}$$

This represents the amount by which the wavefunction, Ψ , changes with respect to time, t . Therefore, the Schrödinger equation reveals how we can change the wavefunction (quantum state) of the system over time: we just need to change the total energy of the system.

Because of this, you might often read in quantum mechanics books that "the Hamiltonian determines the time evolution of the quantum state", or something similar. As an example, in their book *Quantum Mechanics: The Theoretical Minimum*, Leonard Susskind and Art Friedman say: "If we know the Hamiltonian, it tells us how the state of a system evolves with time". So this explains why the Hamiltonian plays such a vital role in quantum mechanics.

You will also see an \hbar symbol on the right-hand side of the equation. Where does it come from, and what does it mean? Well, it's not too difficult. The \hbar symbol (it is a letter h with a line through it, commonly called "h-bar") is the *reduced Planck constant*, equal to the Planck constant divided by 2π . The constant has to be included so that we are dealing with similar units on both sides of the equation. As an example, it would be meaningless if an equation was comparing apples with oranges, representing something like "five apples equals three oranges":

Comparing apples with oranges makes no sense. An equation only makes sense if it compares like-with-like, saying something like "five apples equals two apples plus three apples". The equation is then said to be "dimensionally correct":

If you look at the Schrödinger equation, you will see that there is a term representing energy on the left-hand side

of the equation, so the left-hand side of the equation has units of energy, but the

$$\frac{\partial \Psi}{\partial t}$$

term on the right-hand side of the equation represents the rate of change of the wavefunction with respect to time, the units of which are "inverse time", or "one divided by time". Therefore, it appears the Schrödinger equation is mistakenly comparing apples with oranges! The solution comes by multiplying the right-hand side by the reduced Planck constant, which has just the right units to convert the right-hand side of the equation into a value with units of energy. The resultant Schrödinger equation is then correctly comparing apples with apples, and has therefore become dimensionally correct.

This powerful type of analysis comparing the units on both sides of an equation is called *dimensional analysis*.

The equation for a single particle

The form of the equation presented earlier is the most fundamental and general form of the Schrödinger equation. However, you will often find the equation written in a slightly different form, aimed at describing a specific common example. That example is the Schrödinger equation for describing a single particle which is moving in a field of energy, for example, an electron moving between two electrically-charged metal plates. In that case, the total energy of the particle will have two terms: a kinetic energy term (kinetic energy is the energy associated with the particle's movement) and a potential energy term (the potential energy of the particle is the energy it receives purely due to its position in the field). Therefore, we can substitute these two amounts of energy into the "total energy" left-hand side of the Schrödinger equation. That then gives us:

$$\begin{array}{c} \text{Total energy, } H \\ \underbrace{\hspace{10em}} \\ \text{Kinetic energy} \quad \text{Potential energy} \\ \underbrace{\hspace{4em}} \quad \underbrace{\hspace{4em}} \\ \frac{-\hbar^2}{2m} \nabla^2 \psi + V\psi = i\hbar \frac{\partial \Psi}{\partial t} \end{array}$$

You will see, though, that if you just replace the left-hand side of the equation (the sum of the kinetic and potential energy) with the total energy, H , you get back to the form of the Schrödinger equation presented earlier.

In their book *Quantum Mechanics: The Theoretical Minimum*, Leonard Susskind and Art Friedman describe this as the "iconic form of the Schrödinger equation that appears on T-shirts":

With reference to the logo on the T-shirt, hopefully you should now understand **all** of the parts of the equation on the T-shirt.

The complete predictability of quantum mechanics

Now, here's a strange thing.

If you have read popular science books about quantum mechanics, probably the first thing you are told is that quantum mechanics leads to inevitable fundamental indeterminacy, or randomness. Einstein referred to "God playing dice". A quantum world is a random world.

In contrast to this indeterminacy of quantum mechanics, Newton's laws of motion are presented as the ultimate in determinacy: once the initial conditions of a system are set, the system proceeds in an entirely predictable manner according to Newton's laws. Applied to the universe as a whole, this predictability due to Newton is called the "clockwork universe".

So, according to many accounts, the contrast could not be greater: on one side we have the predictability of Newton, and on the other side there is the randomness of quantum mechanics.

But, hold on.

You can see that if we consider the Schrödinger equation which describes the evolution of the quantum state, we find not a hint of unpredictability in it. There are no undefined variables in the equation, no random number generators. In fact, it would appear that the behaviour of the quantum state is completely deterministic — not random at all, and not what you might expect from "fundamentally random" quantum mechanics. Roger Penrose describes this surprising feature of the Schrödinger equation in his book *The Road To Reality*: "One thing that we note is that it is a deterministic equation (the time-evolution being completely fixed once the state is known at any

one time). This may come as a surprise to some people, who may well have heard of quantum uncertainty."

In fact, the equation appears to imply that the evolution of the quantum state is just as predictable as the evolution due to Newton's laws. So, what's up?

Well, it is completely true: the evolution of the quantum state as described by the Schrödinger equation is just as predictable and deterministic as Newton's laws. If you set the initial state, then the quantum state will evolve in an entirely deterministic manner — according to the equation. In fact, it seems like a perfect analogue to the determinism of Newton's laws.

So, once again, we find that the quantum world is not "weird" at all.

It is this determinism and predictability of the Schrödinger equation which allows the precise manipulation of the quantum state in quantum computers: if you change the energy, you know precisely how the quantum state will change. You have complete control.

It therefore appears that quantum behaviour is completely predictable. So why do we hear about the "randomness" of quantum mechanics?

That is what we will discover in the next chapter ...

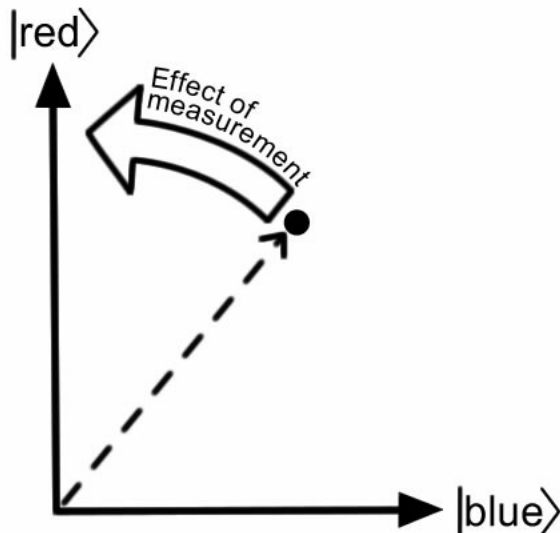

4

OBSERVING A QUANTUM SYSTEM

In the previous chapter, the Schrödinger equation was introduced and it was explained how it describes the evolution of the quantum state. It was also explained how the Schrödinger equation was completely deterministic and predictable. So why do we hear about the "randomness" of quantum mechanics?

Well, we have to remember that the quantum state vector we have considered so far represents the state of the system **before it is observed**, before we measure the system and obtain the value for some property of the system. As explained earlier, before observation, the quantum state can be in a mix of states: both red and blue at the same time. However, when we observe the system, we only ever observe a particle to be in a single, well-defined state: **either red or blue** — but not both. For example, in the double-slit experiment, we would only ever observe the particle to be in a single position — not in two places at once.

So, when we observe a quantum system, it is as if the state vector in a superposition state "collapses" to just a single value. This process has been called the "collapse of the wavefunction", and it is illustrated in the following diagram:

In the previous diagram, you can see what happens during the act of observation of a quantum system. You will obtain an observed value (either red or blue) but, as described earlier, the measurement operation also has the effect of modifying the state vector so that the vector moves from its superposition state to point at the value which has been observed (either red or blue).

So there is a rotation of the state vector from its superposition state to point to a well-defined single state.

Some new terminology needs to be introduced at this point. Firstly, the "well-defined" states — the states which we can possibly observe when we make a measurement — are called *eigenstates*. Secondly, the state vector which represents a particular eigenstate is called an *eigenvector*. So, when we make a measurement, the state vector rotates to become an eigenvector, and the system is then said to be in an eigenstate.

Now we get to the crucial question: what determines which of the possible states we will observe when we measure the system? As an example, in the previous diagram, it seems that the state vector could just as easily have rotated to become a blue state. In that case, why was red selected?

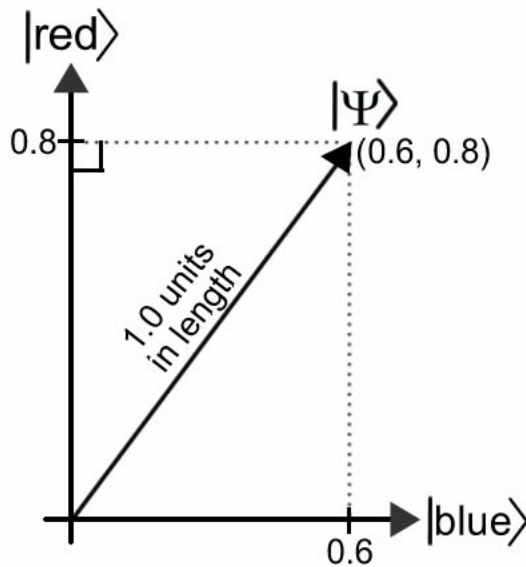

The answer is that the observed value is determined by the *projection* of the state vector onto the relevant eigenvector. This is perhaps easiest explained by the following diagram:

You can see from the previous diagram that — to calculate the projection — a dotted line is first drawn from the tip of the state vector to make a right angle with the eigenvector under consideration (in this particular diagram, the eigenvector is the horizontal line). The projection is then defined as the distance along the eigenvector (along the bottom horizontal) until you reach the dotted line. This is all clearly shown on the previous diagram.

Crucially, the value of the projection then represents the **probability** of that particular eigenstate being selected. **So it is at this observation stage that probability enters quantum mechanics.**

Let us consider an example of how to calculate the value of the projection. Consider the following diagram. A state vector is shown with the tip of the vector at the coordinates (0.6, 0.8):

The vector is 1.0 units in length, in which case it is called a *unit vector* (state vectors are usually defined as unit vectors).

We would like to know what value we will obtain when we observe this particular quantum system. Will the state vector rotate so that it points in the vertical direction (towards red), or will it rotate so that it points in the horizontal direction (towards blue)? In other words, will we observe the particle described by this quantum state vector to be either red or blue?

Well, as stated earlier, the selection of the observed value is determined by the projection of the state vector onto the relevant eigenvector. From the diagram, it is easy to see the relevant projection values from the coordinates of the state vector. You can see the projection along the red eigenvector is 0.8 units, and the projection along the blue eigenvector is 0.6 units.

Remember, these projection values merely give you the **probabilities** of a particular value being obtained after observation. However, in that case, then these particular values of 0.8 and 0.6 cannot be quite correct. We see that there are only two possible outcomes from the observation: **either** we observe red, **or** we observe blue. With only two possible outcomes, we know that the sum of the probabilities of these two outcomes must be 1.0 (as

probabilities always sum to 1.0). So, to calculate the correct probabilities, we have to take the **square** of the projection values, which gives us 0.64 (which is 0.8×0.8) and 0.36 (which is 0.6×0.6). You can see that these new values do, indeed, sum to 1.0. So these are the correct probabilities: the probability of observing red will be 0.64, and the probability of observing blue will be 0.36.

If you consider the previous diagram, you can easily see why this "squaring" rule will always lead to the sum of the probabilities being equal to 1.0. It is due to Pythagoras's theorem: the length of the state vector has been set to 1.0. The state vector is on the hypotenuse of a right-angled triangle, so the sum of the squares of the other two sides of the triangle (the sum of the squares of the two projection values) must therefore be equal to 1.0. [3]

So it is during the act of observation that probabilities enter quantum mechanics, and that is the reason why quantum mechanics has obtained its reputation for randomness and indeterminism.

Calculating eigenvectors and eigenvalues

As far as quantum computing is concerned, this chapter has now explained everything you need to know about what happens when a quantum system is measured. So, if you wish, you may now skip to the next chapter. However, in the remainder of this chapter we will go into a bit more detail about how the eigenstates are calculated, and how those eigenstates explain the behaviour of electrons as they orbit in an atom.

However, like I say, if you do not want to know these details then feel free to skip to the next chapter.

In the previous section it was explained how when we observe (or measure) a quantum system we will only ever observe it to be in a single, well-defined eigenstate, with clearly-defined values. For example, we might find a system in either the red or blue state. However, no explanation was provided as to how those eigenstates — and their associated property values — could be calculated. Where do they come from?

It was stated in the previous chapter that observed values are produced by mathematical operators, acting on the quantum state vector. But, with just a little thought, it can be realised that the application of the operator cannot be entirely straightforward.

To understand why that is the case, it must be realised that the quantum state vector might be pointing in any arbitrary direction before observation. Simply applying the operator to the state vector would then produce a completely arbitrary result — some mixture of red and blue, for example — whereas we need a clearly-defined result from the operation: **either** red **or** blue. Some arbitrary mixture is not good enough.

So the operator must be used in applied in rather a different mathematical manner. But how should we apply it? Well, we have a clue ...

Imagine that the state vector before observation already points in the direction of a well-defined state. For example, it might be pointing in the red direction or in the blue direction. There are two important points which arise in that case.

Firstly, if the state vector is already perfectly aligned with, say, the red eigenvector then the projection of the state vector onto that eigenvector will then be equal to 1.0, meaning they are pointing in precisely the same direction. That means the probability of measuring red will be 1.0. In other words, there will be no uncertainty at all in the measurement (a probability of 1.0 means certainty).

The second point is that if the operator applied to that state vector, it can be realised that **the state vector will not be modified**. [4] The state vector will not be changed because it is already pointing to a clearly-defined state — either red or blue — so there is no need for the state vector to be rotated at all.

So this is a big clue, and it gives us all the information we need. As can be seen from the following diagram, if the measurement operator is applied to a well-defined state vector (for example, red), the result will be an unchanged state vector (still pointing to red). Actually, as only the direction of the state vector is important to define a quantum state, we can say that the result can be some multiple of the original state vector:

When some operator, \mathbf{A} ... operates on the vector ...

... the result must be to leave the vector unchanged (or multiplied by some number, λ):

$$\mathbf{A} \begin{bmatrix} \mathbf{v}_1 \\ \mathbf{v}_2 \end{bmatrix} = \lambda \times \begin{bmatrix} \mathbf{v}_1 \\ \mathbf{v}_2 \end{bmatrix}$$

This type of relationship is well-known in mathematics. Vectors which satisfy this relationship are called *eigenvectors* (which were introduced in the previous section). It turns out that if we have a particular operator (such as the operator \mathbf{A} in the previous diagram) there will only be a few eigenvectors which satisfy the relationship. We might consider these as representing the allowed state vectors (for example, the state vectors red and blue). So this explains why, when we measure a quantum system, we only observe particular values (red or blue, for example). It is because only certain eigenvectors will satisfy the previous relationship.

The quantum state which is associated with a particular eigenvector (the state of red or the state of blue, for example) is called an *eigenstate* (again, a term which was introduced in the previous section).

There is something else interesting in the previous diagram. If a measurement is made, it so happens that the value of the property you will measure will be equal to the λ multiplying factor shown on the previous diagram. The value of λ — the property value you will observe — is then called an *eigenvalue*.

And that is how you find the eigenvectors and eigenvalues (red, blue, etc.) associated with a particular measurement operator. That is how you discover the discrete states and values a quantum system will take after it is observed.

Energy levels of an electron

An atom is composed of an atomic nucleus (made of positively-charged protons and electrically-neutral neutrons) which is orbited by electrons. The "height" — and corresponding energy levels — of those orbiting electrons represents one of the most important examples of eigenstates and eigenvalues.

The puzzle over the energy levels of electrons was one of the great puzzles of the "old quantum theory" period from 1900-1925. It was known that when a substance was heated, it would glow ("red hot" or "white hot") and the emitted radiation represented a form of energy loss from the atom. In 1900, the German physicist Max Planck realised that the radiation being transmitted from the atoms took the form of chunks of energy (known as "quanta"), a realisation that started the "old quantum theory". In 1905, Albert Einstein correctly proposed that the emitted quanta of energy were actually particles, particles which we now call photons. Photons are the particles of light, the particles which are emitted when a substance glows red hot or white hot.

The energy of the emitted photons can only take particular values — not continuous values. This mystery can be understood by considering the energy levels of electrons which are orbiting an atomic nucleus — and then applying our new-found knowledge of the Schrödinger equation (remember: the Schrödinger equation can be used to describe the energy of a particle).

If we consider a diagram of an atom, with the nucleus at the centre surrounded by orbiting electrons, we find that only particular electron orbits are allowed around the nucleus:

On the previous diagram you can see two different electron orbits, shown by the two wavy lines. Only integer values (whole numbers) of waves are allowed around the orbit. You can see that the inner orbit has five complete waves, whereas the outer orbit has six complete waves. These orbits are allowed, but electrons are not allowed to orbit in the spaces between these orbits.

The different orbits represent different energy levels of an electron. Remember from the previous chapter that the Schrödinger equation describes the energy of a particle. The orbits of an electron can then be calculated as the eigenstates of the Schrödinger equation of that electron. Considering the geometric picture of the atom, we can see that the allowed orbits of the electron would represent eigenstates of energy of the electron (with only a few particular eigenstates being allowed). The associated energy levels of the electron would then be the eigenvalues.

One of the great mysteries of the "old quantum theory" in the first two decades of the 20th century was why photons are only ever released from atoms with certain discrete chunks of energy. However, in 1925, with the discovery of the Schrödinger equation, the mystery could finally be solved. Remember, in the atom, eigenstates of energy have discrete values — they are not continuous (capable of taking any value). So when an electron "jumps" from a higher energy eigenstate to a lower energy eigenstate, a photon is released which has energy equal to the difference between the two energy states. This explains why photons are only ever released with certain discrete chunks of energy.

So the theory of quantum mechanics was able to explain the structure of the orbits of electrons in an atom, and the origin of the "quanta" of energy. One the great mysteries of the "old quantum theory" could now be clearly and logically explained by the new quantum mechanics — with the Schrödinger equation at its core.

It also explains why it is best not to treat the development of the theory of quantum mechanics in chronological order: quantization arises naturally when the Schrödinger equation is discovered first — not vice versa.

5

COMPLEX NUMBERS

The use of *complex numbers* is widespread in many areas of science, engineering, and mathematics. In quantum mechanics, complex numbers play a central role.

You might already have an understanding of complex numbers, but a short explanation is that a complex number is a number which is composed of two parts which are added together.

Firstly, the complex number has a so-called *real* part, which is just a number in the usual, conventional sense (for example, 5, 3000, or 12732.506). Secondly, the complex number has a so-called *imaginary* part, which is a number multiplied by i , where i represents the square root of -1 . You might find it strange to consider any number as representing the square root of a negative number, after all, when any number — positive or negative — is squared, that will always result in a positive number. So the fact that i cannot represent a conventional number explains why it forms the so-called "imaginary" part of a complex number.

Here is an example of a complex number:

In the chapters so far, we have seen that the quantum state vector exists in a "vector space", and it can rotate in that vector space. The particular type of vector space which is used in quantum mechanics is called a *Hilbert space* (named after the great German mathematician David Hilbert, who we have encountered in my previous books).

The important feature of a Hilbert space is that the coordinates of points can be complex numbers. Therefore, the coordinates describing quantum state vectors can be complex numbers.

The phase of Hilbert space

Let us now consider how the complex nature of the state vector gives each state vector a *phase angle* value.

If you remember, a complex number is composed of two parts: a real part and an imaginary part. Let us consider a complex number with a magnitude of 1.0. In other words, if you were to square the real part of the number, and add it to the square of the imaginary part of the number, the result would be 1.0. From Pythagoras's theorem, we could plot the resulting number on a circle, with a radius of 1.0 (the complex number being a distance of 1.0 from the centre of the circle), as shown on the following diagram:

You can see from the previous diagram that the real part of the number is plotted along the horizontal axis, while the imaginary part of the number is plotted along the vertical axis. You will see that one particular complex number has been plotted as a point on the circle ($0.707+0.707i$, where 0.707 is the square root of 0.5 , so, by Pythagoras's theorem, the complex number has a magnitude of 1.0 and can be plotted on the circle).

This method allows us to think about complex numbers in geometric terms, the complex number being represented by a point at the end of a line from the centre of the circle.

You can also see from the previous diagram that the line from the centre of the circle to the complex number is at an angle θ around the circle measured in an anticlockwise direction from the horizontal axis. We can think of this angle as a *phase*, the phase being able to take any value from 0 to 360 degrees. In other words, any complex number has an associated phase angle.

A quantum state vector exists in Hilbert space, and coordinates in Hilbert space can be complex numbers. Therefore, any point in Hilbert space will have an associated phase angle. In particular, any quantum state vector will have a phase angle associated with it.

We will be seeing later in this book that awareness of the phase of the quantum state vector is an essential skill required for programming a quantum computer.

6

DECOHERENCE

Quantum mechanics was developed in the early decades of the 20th century. This was a period of global revolution, when the old rules and certainties were discarded. These developments were also reflected in the modernist art of the period, with artists influenced by the new developments from physics.

As an example, artists such as Picasso who pioneered the Cubism movement moved away from the rigid rules of three-dimensional perspective. The rules of perspective implied that the observer was positioned at a single point in space, as shown in the following line drawing by the 16th century Dutch renaissance artist Hans Vredeman de Vries:

The rules of perspective implied that the observer was irrelevant, that the reality of an object or scene could be captured in its entirety even if the position of the observer was fixed in one place.

With the arrival of quantum mechanics in the early 20th century, however, it was realised that the observer was important, that reality was generated from a combination of the observer and the subject.

This principle influenced the Cubism movement, as seen in the following *Portrait of Dora Maar* by Picasso (1937). Picasso attempts to capture Dora Maar from several viewpoints — several observers — and combine those into a single portrait. You can see that the result is a front view of Dora Maar, in combination with a smaller view from the side.

In essence, the following portrait might be considered to be an attempt to represent Dora Maar in a quantum superposition state:

Modernist artists were also influenced by the recent discovery of relativity and the philosophy of Henri Bergson, both of which suggested that time should be considered as being the fourth dimension. Here is an example of Picasso playing with spatial dimensions in his 1910 painting *Girl with a Mandolin*, just four years after Einstein discovered relativity. Picasso is referencing the fourth dimension by stacking a succession of time-slices, "sticking together several three-dimensional spaces in a row": [\[5\]](#)

So art in that era was reflected by developments in physics. But sometimes the relationship works the other way round — sometimes art discovers fundamental truths before physics. This was true in the case of another early 20th century artistic movement: Futurism.

The Futurist movement was based in Italy. The Futurists believed that it was wrong to consider objects in isolation, and that the surrounding environment always played a role in defining the object. As an example, here is a photograph of Umberto Boccioni's 1913 bronze sculpture *Unique Forms of Continuity in Space*. The sculpture depicts a human form in fluid motion, which is blurring into the surrounding space. The result is that the boundary where the human ends and the surrounding environment begins has been blurred. The sculpture can be seen on the reverse of the current Italian twenty cent coin:

The Futurists took their lead from the writings of the philosopher Henri Bergson: "Does not the fiction of an isolated object imply an absurdity, since this object borrows its physical properties from the relations which it maintains with all the others, and owes each of its determinations, and consequently its very existence, to the place it occupies in the universe as a whole? **Any division of matter into independent bodies with determined outlines is artificial.**"

I have placed the last sentence in emphasis: "Any division of matter into independent bodies with determined outlines is artificial". In 1911, the Futurists released their manifesto describing their philosophy about art: "Our bodies penetrate the sofas upon which we sit, and the sofas penetrate our bodies." Indeed, this could be seen as a rejection of the idea from classical physics that objects could be treated in isolation. Just as quantum mechanics — in the early 20th century — was moving away from considering objects in isolation, so was art coming to exactly the same conclusions at exactly the same time.

To reinforce this idea, the Futurists rejected the so-called "tyranny of the frame", preferring pictures to be displayed without frames, the frame around a picture representing a futile attempt to isolate the picture from its environment. In reality, the picture is physically connected to the frame, the frame is physically connected to the wall, the wall is connected to the floor, the floor is connected to the street outside. The boundaries we place on objects — in the style of classical physics — are artificial and misleading. There is an inevitable connectedness. Nothing can ever be perfectly isolated.

Except for, perhaps, one exception ...

...the dark, cold, interior of a quantum computer.

Environmental decoherence

In 1970, Dieter Zeh of the University of Heidelberg published a paper which suggested a mechanism which could explain the mysterious "collapse of the wavefunction".^[6] To understand Dieter Zeh's idea, we need to return to Chapter Two of this book in which it was explained that quantum mechanics inevitably arises when we take a more

realistic and sophisticated picture of how the world must work.

In Chapter Two, two fundamental principles were presented:

- A measurement inevitably affects the object under observation. We are therefore not measuring the true reality of the object on its own, i.e., the object before it is measured.
- Objects are never completely isolated. The measurement we eventually obtain is a measurement of the joint system: "An electron being measured by a measuring device".

It is the second of these two principles which formed the basis for Dieter Zeh's explanation of the apparent "collapse of the wavefunction". It is the principle that objects are never completely isolated from the rest of the universe. The idea that our world is split into entirely discrete, isolated objects is a completely human invention. Think of yourself sitting in your chair. You probably think of yourself as being a separate object from the chair. But the atoms of your backside are pressed against the atoms of the chair, in constant contact. So where is the division? Does that not represent one joined unit? And we could continue the process: your chair is in direct contact with the floor. The floor is directly connected to the Earth. Again, where is the division? How can you justify thinking that you are an entirely separate object from the chair or the planet?

As another example, you breathe air. The air is part of a continuous substance which surrounds the planet and places you in contact with every other living person. In that case, how can you consider yourself to be an entirely separate object?

Of course, you should not think of yourself as being isolated. As has just been described, this was the belief of the Futurist modern art movement. And it is this principle which led Dieter Zeh to propose a mechanism behind the apparent "collapse of the wavefunction". In particular, Dieter Zeh suggested that it was the ever-present environment surrounding an object — constantly "observing" the object — which leads to the object being taken out of its superposition state.

The mechanism is called *decoherence*.

And, once again, we encounter the idea that quantum mechanics is more of a "state of mind", representing a more sophisticated picture of how the world must work. In this case, the principle is that no object is ever completely isolated from the rest of the world.

Unfortunately, Dieter Zeh passed away earlier this year. He should surely have received the Nobel Prize in his lifetime for his work in proposing decoherence, which has now been firmly experimentally verified.

We can use a simple thought experiment to explain how decoherence works, and the thought experiment we will use is the double-slit experiment which was described in Chapter Two.

In the double-slit experiment, a beam of light is directed towards two narrow slits, with a screen positioned on the other side of the slits. The light beam passes through both of the slits.

If, at the screen, a peak in the wave from one slit coincides with a peak in the wave from the other slit, then a bright point appears on the screen. Conversely, if a peak in the wave from one slit coincides with a trough in the wave from the other slit, the two waves will cancel at that point and no bright point will appear on the screen.

Therefore, as shown in the following diagram, a regular pattern of dark and bright bands will appear on the screen:

The light intensity is then reduced so that only a single photon of light is in transit at a time. Over time, a pattern develops on the screen as the individual photons strike the screen and accumulate. Amazingly, though, the interference pattern is still produced — even though there is only one photon in the system at a time! It is as if the single photon passes through both slits and interferes with itself!

Let us now make the experiment rather more realistic. We must realise that particles, in general, are never completely isolated from their environment, and that environment will tend to be rather messy and random. Let us consider the effect of the messy, random environment on the single photon.

In a more realistic picture, on its way from the light source to the screen, the photon has to pass through a considerable distance of air (representing the "environment"). That air is likely to be turbulent, moving randomly. As it moves along its path, the photon interacts with the atmosphere, and it, in return, is affected by the atmosphere. The effect of the random, turbulent atmosphere will be to slightly increase or decrease the length of the particle's path to the screen.

Chad Orzel describes the situation in an article about decoherence on his website: "If we're talking about a long distance in a turbid medium, there's going to be a phase shift. If you think in terms of waves, there are going to be interactions along the way that slow down or speed up the waves on one path or the other. This will cause a shift in the interference pattern, depending on exactly what happened along the way. Those shifts are really tiny, but they add up. If you're talking about a short interferometer in a controlled laboratory setting, there won't be enough of a shift to do much, but if you're talking about a really long interferometer, passing through many kilometers of atmosphere, it'll build up to something pretty significant." [\[7\]](#)

The effect of this shortening and lengthening of the path is to very slightly move the position of the peaks and troughs of the light wave. Because the positions become random, the effect is to destroy the interference pattern on the screen.

And, if the interference pattern is destroyed on the screen, that makes it appear as though the photon only went through one slit. Remember, the interference pattern is caused by a photon apparently going through two slits at once. So if the interference pattern is destroyed then the photon no longer appears to be in a superposition state, no longer going through two slits at once.

So we can treat the interference pattern as being an indirect signature of the photon being in a superposition state. And the presence or absence of the interference pattern indicates whether or not the particle is in a superposition state.

At this point, we can put our Sherlock Holmes deerstalker hat on and deduce what is responsible for the apparent

"collapse of the wavefunction", taking the particle out of its superposition.

The initial arrangement of the double-slit experiment produced an interference pattern on the screen. From that interference pattern, we deduce that the particle is in a superposition state.

The second form of the experiment was more realistic, introducing a random environment. The result was that the interference pattern was destroyed. We therefore deduce that the particle is not longer in a superposition state.

So what was responsible for taking the particle out of its superposition state? In other words, what was responsible for the apparent "collapse of the wavefunction" which seems to have occurred?

Well, with our Sherlock Holmes hats on, we observe that the **only** factor that has changed in the two versions of the experiment has been the introduction of a noisy, messy, random environment. Sherlock Holmes once famously said: "when you have eliminated the impossible, whatever remains, however improbable, must be the truth". On that basis, we have all the information we need to make our final deduction: **The apparent "collapse of the wavefunction" is caused by a particle interacting with the noisy, messy, random environment.**

And that is the principle behind decoherence.

But what is actually going on at the microscopic level? How is the random environment capable of taking a single particle out of its superposition state? Well, if all we are interested in is building a quantum computer, or programming a quantum computer, we really don't care. All we have to do is make sure we isolate our quantum computer from its surrounding environment in order to maintain particles in their superposition state. And it is quite fortunate that we don't need to know precisely what is happening at the quantum level because the science of decoherence is not yet fully understood. [8]

However, we do have a fair idea of the sort of process which must be occurring at the microscopic level. Let us consider a particle hitting a screen (with the screen representing the "environment"). It must be realised that the screen is already in a well-defined, classical state. In other words, the screen is not in a superposition state — it is in an eigenstate, meaning the screen only exists in one position. When the particle hits the screen (interacts with the environment), the state vector of the particle finds itself in competition with the state vector of the much larger environment. This means the state vector of the particle — in its superposition state — is going to be affected more than the state vector of the screen.

There will be components of the particle state vector which do not agree with the state vector of the screen. Those components disperse into the wider, noisy environment, much like the splash from a stone thrown into a rough, turbulent ocean. The Schrödinger equation continues to apply to all those components, controlling their evolution in time. In other words, there is no new sudden mystical "collapse" process. However, once those components have dispersed into the "ocean", it becomes effectively impossible to regenerate the original superposition state (this explains why the apparent "collapse of the wavefunction" is an irreversible process). Those superposition elements — to all intents and purposes — disappear. The particle is then detected in only one position: on the screen.

In his book, *The Fabric of the Cosmos*, Brian Greene describes the process: "Decoherence forces much of the weirdness of quantum physics to leak from large objects since, bit by bit, the quantum weirdness is carried away by the innumerable impinging particles from the environment."

So it is almost impossible to completely isolate an object from the rest of the world. But if we want to maintain a

superposition state inside our quantum computer, we need to find some way of achieving that isolation, and thereby preventing that onset of decoherence. Let us now examine how we can achieve that isolation.

The coldest place in the universe

As we have just seen, any form of randomness in the environment can result in decoherence. In particular, any heat in the environment will result in the random motion (thermal noise) of the molecules in the environment. The resultant buffeting of a single particle by those random molecules will result in decoherence, taking the particle out of its superposition state. We will be seeing that quantum computers rely on particles being kept in superposition states for as long as possible. For this reason, quantum computers must be kept at extremely low temperatures to reduce thermal noise to a minimum.

The core of a computer must be cooled to just a tiny fraction of a degree above absolute zero — 180 times colder than deep space. Incredibly, this means that the core of a quantum computer is **the coldest place in the entire universe!**

The following photograph shows the internal structure of an actual IBM quantum computer. You can see that it looks very beautiful and intricate — it has been affectionately described as a "steampunk chandelier". The quantum processor is located in the metal cylinder at the bottom of the construction. The metal cylinder acts as a shield to protect the quantum processor from electromagnetic radiation (which could cause decoherence):

The whole device has to be maintained at an extremely low temperature. However, the signals transmitted down the cables to the quantum chip originate from control units outside the quantum computer — which are therefore at room temperature. So those cables have to go on a journey from room temperature to a temperature colder than space as they travel down the quantum computer structure. As you can see on the previous diagram, by the time the cables reach the top of the device, the temperature has been reduced to about 0.8 kelvin. You can see on the diagram that there are a series of horizontal plates, with the temperature being progressively reduced on each plate. The temperature continues to decrease toward the base of the device, with the actual processor chip being kept at a temperature of just 0.015 kelvin (15 milli-kelvin). At such a low temperature — just a fraction of a degree above absolute zero — atoms become virtually motionless.

The cables are made out of a superconducting material to minimise energy loss (when superconducting materials are cooled to near absolute zero, electric currents can pass through them without experiencing any electrical resistance).

On the previous diagram, you will also notice some ornate loops. These seem to add to the beautiful "chandelier" effect, but they most certainly serve a purpose. The loops are in the coaxial cables which transfer the data signals to-and-from the quantum processor. As the cables contract due to the low temperature, their length decreases and they could break. The loops in the cables ensures there is always some excess length in the cables to prevent them

breaking. You can see similar loops on telegraph poles to stop the cables breaking in cold weather.

The whole device is then contained within a larger cylinder, which acts as a refrigerator, as shown in this photograph which was taken in the IBM Research Center in Yorktown Heights, New York:

The race against time

It is clearly extraordinarily difficult to maintain a particle in its superposition state. The key strategy is to keep the particle isolated from the random, turbulent environment. But even a single stray photon striking an electron effectively performs a "observation" on the position of the electron, and that will be sufficient to take the electron from its superposition state. It gets even worse than that. We might make efforts to eliminate all electromagnetic radiation (photons) from our environment, but there is no shield for gravity. Any change in the gravitational field — the movement of the Moon or Sun, for example — will disturb the particle.

This effect was quantified by John Boccio.^[9] If we have a mass, m , which changes its height by a distance h , then the change in its gravitational energy will be equal to mgh (where g is the acceleration due to gravity).

Then, after a time, t , which is equal to:

$$t = \frac{\hbar}{mgh}$$

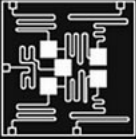

the change in energy will be sufficient to induce decoherence in the mass. If the calculation is performed for a mass of 100 kilograms with h only the length of a single atom, then this decoherence will occur in the extraordinarily short time of 10^{-27} seconds!

This incredibly short time window can be extended by improving the isolation from the environment.

Later in this book, you will be using the IBM Q Experience website to program a quantum computer. On the web page, you will be able to see the real time details of each quantum processor just by clicking on its name, as shown in the following diagram:

> **IBM Q 5 Tenerife** [ibmqx4]

∨ **IBM Q 5 Yorktown** [ibmqx2]

	Q0	Q1	Q2	Q3	Q4
Frequency (GHz)	5.28	5.21	5.02	5.28	5.07
T1 (μs)	62.40	55.10	48.40	59.00	53.30
T2 (μs)	77.50	64.00	54.70	57.30	36.40

Fridge Temperature: 0.0159 K

On the previous diagram, the T2 "coherence times" measure how long it takes for decoherence to destroy the superposition state. For the five quantum bits (or "qubits" — see next chapter) on this particular processor, you can see that the T2 times vary from 36.40 microseconds to 77.50 microseconds. To put that into perspective, maintaining a quantum superposition for that length of time is at the top-end of what is currently possible using today's technology. Also note on the diagram that the "Fridge Temperature" is currently being measured at 15.9 millikelvins — just a fraction of a degree above absolute zero.

Any calculation has to be performed while the particle can be kept in its superposition state — the entire calculation must be performed before coherence is lost. As we saw in the previous diagram, that represents a time period of just a few microseconds. It is therefore clear that, for a quantum computer, any calculation is a race against time.

THE QUBIT

In my previous book it was explained how information can be measured in terms of *bits*. A bit (short for "binary digit") is a unit of data which can be either 0 or 1. In a conventional computer, all data is composed of combinations of these bits. In the computer, those bits are represented by different electric voltages: often +5 volts representing a 1, and zero volts representing a 0.

In a quantum computer, the equivalent of a bit is a *qubit* (short for "quantum bit"). In a qubit, the 0 and 1 values represent quantum states, so they are denoted by $|0\rangle$ and $|1\rangle$ (note the use of the Dirac notation). In a quantum computer, all processing occurs before decoherence destroys the superposition state of the qubit. That means a qubit can be in a superposition state and can have the value of **both $|0\rangle$ and $|1\rangle$ at the same time**.

However, when it is observed, it will be found in one of two possible states, $|0\rangle$ or $|1\rangle$.

The following diagram shows a graphical representation of a qubit in a superposition state:

As shown on the previous diagram, the state vector of a qubit can be described by the following:

$$\psi = a |0\rangle + b |1\rangle$$

where a and b are complex numbers (because the state vector is in Hilbert space).

The physical implementation of qubits

If we are only interested in programming a quantum computer, then the actual physical implementation of a qubit on that computer is not of particular interest to us. As Alexandre Zagoukin says in his book *Quantum Mechanics: A Complete Introduction*: "In principle, any quantum system with a two-dimensional Hilbert space can be a qubit". A qubit can be physically implemented in several different ways, but as long as it has only two possible states, then it can be used in a quantum computer.

In fact, bearing this in mind, we have actually been using qubits throughout this book — without realising it. The example of the particle which can have only one of two colours — red or blue — forms a two-state system which

represents a qubit.

One real-world example of a qubit arises from the spin of a particle. In the classical world, if we measure a spinning ball, we might expect to find its axis of rotation pointing in any random direction. However, if we measure the spin of an electron (by noting its deflection as it passes through a magnetic field), we find that only two distinct outcomes are possible: *spin-up*, or *spin-down*.

Before it is observed, the particle can be in a superposition state of *spin-up* **and** *spin-down*, but when it is observed it will be found to be in only one of those states. This is the characteristic behaviour of a qubit, so the spin of a particle can be used to represent a qubit.

However, this is not the technology which is being used in modern quantum computers. A recent technology called the *superconducting charge qubit* is being used by IBM, Google, and Intel. In a charge qubit, the state of the qubit ($|0\rangle$ or $|1\rangle$) is determined by the presence or absence of individual electrons in extremely small pieces of superconducting material. In other words, the state of a charge qubit is determined by the presence or absence of an amount of electric charge. This technology allows several microscopic qubits to be included on the surface of a single integrated circuit (chip).

Superconductivity happens when the temperature of certain materials is reduced to close to absolute zero. As a result, the materials acquire zero electrical resistance, so electrons can pass without being hindered — creating an electric current which can continue forever. Superconductivity holds great appeal for quantum computing because an electron which is not interacting with its environment is an electron which can remain in a coherent state — avoiding decoherence. And decoherence is, of course, the enemy of a quantum computer.

In his book *Where Does The Weirdness Go?*, David Lindley considers this ability of superconductors: "A superconductor can behave like a large-scale quantum object, but most macroscopic systems — pieces of ordinary copper wire, pointers on detectors, cats — do not. The distinguishing feature of a superconductor is the orderliness or coherence of the motion of its electrons, which stands in contrast to the disorderly motion of electrons in a copper wire and, in the same vein, the random jiggling around of atoms in most large objects."

A charge qubit is created by placing two microscopic electrodes — extremely fine pieces of superconducting material — onto the substrate of the chip. The electrodes are separated by an insulating barrier (a *Josephson junction*) which normally prevents electrons crossing between the electrodes. However, it is possible for an electron to transfer from one of the electrodes to the other by a process called *quantum tunnelling*. Quantum tunnelling occurs when the wavefunction of an electron (representing the probability of finding that electron) extends to the other electrode, allowing the electron to overcome the insulating barrier.

So there is a finite probability that an electron can tunnel from one electrode to the other, representing a change in state of the qubit. And the probability of that transition is determined by the voltage which is applied to the qubit.

On the following diagram of an actual IBM quantum processor, you can see that the five charge qubits (square shapes) are labelled from Q_0 to Q_4 . The chip shown in this image is actually about five millimetres square:

1mm

But there is something else amazing about this image ...
... **this is a photograph of one of the actual IBM quantum processors you will be programming later in this book!**

The Bloch sphere

As explained in the previous section, the voltage which is applied to a charge qubit can control the probability of the qubit changing its state from $|0\rangle$ to $|1\rangle$, and vice versa. To be more precise, the voltage modifies the Hamiltonian of the qubit. We encountered the Hamiltonian operator back in Chapter Three during the discussion of the Schrödinger equation. In the simple form of the Schrödinger equation, it was explained how the Hamiltonian determines how the quantum state vector of a system varies with time. So, by modifying the Hamiltonian of a qubit, its state vector can be controlled and rotated. That is how the state of an individual qubit can be modified, and therefore that is how a quantum computer can be programmed.

However, the state vector of a qubit rotates extremely fast. For this reason, the pulses of voltage which are sent to the qubit must be of extremely short duration, just a few hundred picoseconds (trillionths of a second). This places the signal in the GHz microwave frequency range.

As the IBM Q Experience FAQ explains: "Quantum gates are performed by sending electromagnetic impulses at microwave frequencies to the qubits through coaxial cables. These electromagnetic pulses have a particular duration, frequency, and phase that determine the angle of rotation of the qubit state around a particular axis of the Bloch sphere."

But what is the "Bloch sphere" mentioned in that quote?

To understand the Bloch sphere representation, first let us again consider the representation of a qubit in Hilbert space, with the state vector representing some mix of the $|0\rangle$ and $|1\rangle$ states:

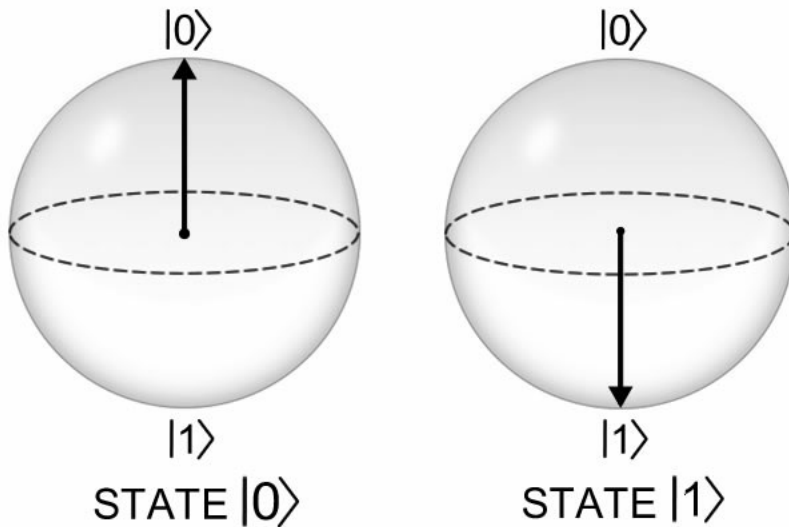

That is a nice, simple diagram to understand. However, just a little thought reveals that it cannot be a correct representation of the full picture. That is because — as was described in Chapter Five — coordinates in Hilbert space can be complex numbers. Therefore, any point in Hilbert space will have an associated phase angle. In particular, any quantum state vector will have a phase angle associated with it. However, there is no way for us to show the phase angle of the state vector on this diagram. The problem is that it is only a two-dimensional diagram, and to show an additional variable — the phase angle — associated with the vector would need us to add an extra dimension, and move to a three-dimensional diagram.

So that is what we have to do.

In order to make the move to a three-dimensional diagram, refer back to the previous diagram and imagine the horizontal $|1\rangle$ vector being pulled downwards so that it ends up pointing downwards as shown in the following diagram:

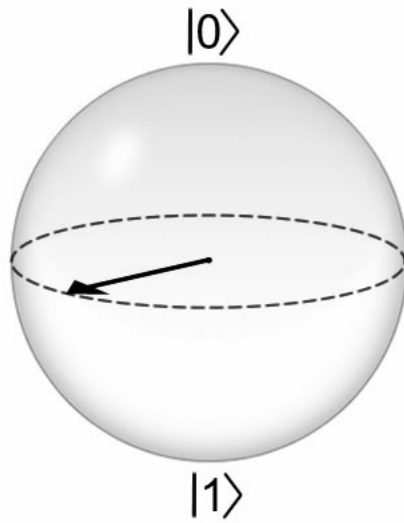

That now allows us to imagine the $|0\rangle$ vector as pointing to the top point on a sphere, and the $|1\rangle$ vector as pointing to the bottom point on a sphere, as shown in the following diagram:

As you can see in the previous diagram, with the state vector pointing to the top of the sphere, that represents state $|0\rangle$, and with the state vector pointing to the bottom of the sphere, that represents state $|1\rangle$.

This method of representing a qubit is called the *Bloch sphere*.

For a qubit in a superposition state — an equal proportion of $|0\rangle$ and $|1\rangle$ — the state vector will point to the equator line, halfway between the $|0\rangle$ and $|1\rangle$ states. The following diagram shows a qubit in a superposition state:

The big advantage of the Bloch sphere method comes when we consider the phase of the state vector. Because we are now working in three dimensions, the phase of the state vector can be represented by the rotation of the state vector around the vertical axis, as shown in the following diagram:

The previous diagram shows a qubit state vector — initially in a superposition state — rotating around the vertical axis to represent a change in the phase of the state vector from 0° to 90° . The qubit remains in a superposition state (the vector is still pointing to the equator, halfway between $|0\rangle$ and $|1\rangle$), the only difference is that the phase of the qubit has changed. Hence, the Bloch sphere method can show the phase of the state vector at any time: it is the amount of rotation of the vector around the vertical axis.

The Bloch sphere representation plays a central role in quantum computing. As we shall see in the next chapter, when you start programming a quantum computer you will be thinking in terms of rotating the state vector of a qubit around in the Bloch sphere.

Entanglement

Now we have come to the end of this chapter on the qubit, it seems like a good time to introduce the important concept of *quantum entanglement*.

In order to understand entanglement, we shall consider a qubit which is formed from the property of particle spin. Particles can have the property of spin, which has the units of angular momentum just like classical spin — the spin of a ball, for example.^[10] However, when we measure the quantum spin of a particle we find it can only have two values: either *spin-up*, or *spin-down*. As these are the only two states we will find after measurement, this makes particle spin ideal to be used as a qubit. As an example, we might interpret the $|0\rangle$ state of our qubit as being spin-up, and the $|1\rangle$ state as being spin-down.

If a pair of photons is released by a common source, then the properties of those two photons will be related. This is because of the conservation laws. For example, the law of conservation of momentum states that the momentum **before** the photons were emitted must be equal to the total momentum **after** the photons were emitted. As the momentum before the photons was zero (nothing was moving), the total momentum after the photons are emitted must also be zero. This requirement can be satisfied if the photons are emitted in precisely opposite directions, because momentum is a vector quantity (like an arrow) and if we add two arrows pointing in precisely opposite directions then we get zero.

The law of conservation of angular momentum imposes a similar constraint of the spin of the photons. As the angular momentum before the photons were emitted was zero (nothing was spinning), then the angular momentum after the spin of the two photons is measured must also be zero. This requirement can be satisfied if the spin of the two particles is opposite: one of the particles being spin-up, and the other particle being spin-down.

When the properties of two separate particles are correlated in this manner, the particles are said to be *entangled*.

When the two particles are emitted, however, they are both in a superposition state, an equal mix of state $|0\rangle$ (spin-up) and state $|1\rangle$ (spin-down). Let us imagine what happens when we measure the spin of one of the particles and find it to be in the spin-down state. That implies that the state vector of that particle has rotated from its superposition state (an equal mix of states) to point toward the spin-down state. At that point, we then know with 100% certainty that when the spin of the second particle is measured it will be found to be spin-up (it must have the opposite spin value). This implies that the state vector of the second particle has also rotated — to point to the spin-up state. When the spin of the second particle is then measured, it will be found to be spin-up with 100% certainty.

These two rotations of the two state vectors (from the superposition state to spin-down and spin-up) are shown in the following diagram:

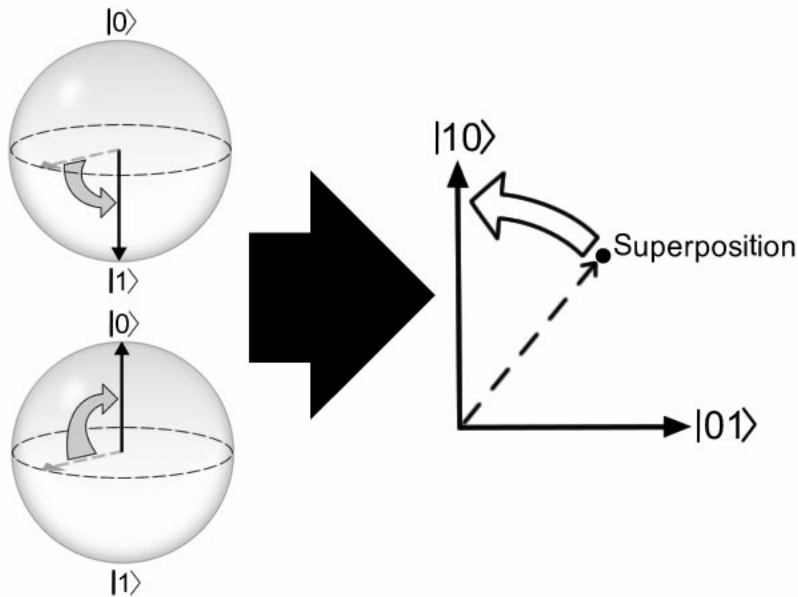

However, when Einstein heard of this behaviour predicted by quantum mechanics, he was horrified. This was because the two particles could, theoretically, be many thousands of miles apart when they are measured. Yet the rotation of the state vector of the second particle appears to happen instantaneously when the first particle is measured. Einstein's own theory of special relativity absolutely forbids this notion of an instantaneous effect being caused by a distant action. Special relativity states that nothing can travel faster than light, so there can be no instantaneous effects at distance. Einstein did not believe this prediction of quantum mechanics, and called it "spooky action at a distance".

The resolution of this mystery is quite simple — but it is fairly mind-bending.

The secret is that an entangled pair of particles can no longer be thought of as two independent systems — they must be considered as being a single system, a single object. As the Wikipedia page on quantum entanglement states: "A quantum state must be described for the system as a whole." And, because they now represent a single object, the two entangled particles are described by a single state vector.

Considering the previous example in which the two qubits had to be found in the opposite states when they were measured, that means the single state vector of the entangled system could only be measured in one of two possible states: either $|10\rangle$ or $|01\rangle$ (meaning if the first qubit was found to be in state $|1\rangle$, then the second qubit would have to be found to be in state $|0\rangle$, and vice versa).

The following diagram shows how the previous situation — with two state vectors — should be replaced by a single state vector for the single entangled system. Instead of two state vectors moving from superposition states to two well-defined (opposite) states, there is now a single state vector (for the entire system) moving from a superposition state to a single well-defined state:

And this model means that all of the old problems about faster-than light causality and "spooky action at a distance" disappear. We are now dealing with a single object, a single state vector. There is no longer a question of "which state vector causes the other state vector to move" because there is only one state vector. If you like, there is no longer a question of "spooky action at a distance" because if there is only one object then **there is effectively no distance!**

However, this neat resolution does imply that entangled particles separated by a great distance must be considered as being a single object. Admittedly, then, if there was one aspect of quantum mechanics that might be considered "weird", then it surely would be entanglement.

Later on in this book, we will be seeing that quantum entanglement plays a vital role in the functioning of quantum algorithms (programs) on a quantum computer.

This book has now covered the fundamentals of the theory of quantum mechanics. So all we need now is a real quantum computer ...

8

THE IBM Q EXPERIENCE

The main headquarters of IBM Research is located in the small wooded town of Yorktown Heights, about thirty miles north of New York City. The center is named after the founder of IBM, Thomas J. Watson.

Some of the breakthrough technologies invented at the center include dynamic random access memory (or DRAM — described in my previous book), and the FORTRAN programming language. Benoit Mandelbrot also discovered the famous Mandelbrot set while working for IBM at Yorktown Heights. IBM may have a reputation for grey corporatism, but that is far from the truth. The most innovative companies are judged on how many patents they are awarded. IBM has far more patents for its inventions than any other American company. In contrast, Apple do not make the top ten. You see, there's science — and there's fashion. Don't get them mixed up.

It is in the Yorktown Heights facility where IBM's quantum computer research is located. In a remarkable feat of generosity, IBM have launched the IBM Q Experience which makes their quantum computers available for use by businesses, universities, and even the general public. The quantum computers can be accessed over the internet ("cloud-based") from their website. The IBM Q Experience is free for all users, which means you can get an account at their website and start using a real quantum computer today.

According to Andrew Houck, Professor of Electrical Engineering at Princeton University: "Thanks to this incredible resource that IBM offers, I have students run actual quantum algorithms on a real quantum computer as part of their assignments! This drives home the point that this is a real technology, not just a pipe dream. What once seemed like an impossible future is now something they can use from their dorm rooms."

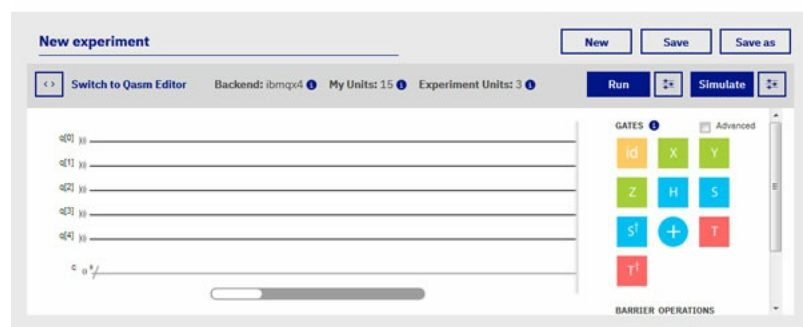

You can easily find the IBM Q Experience website by Googling it, or going to the site directly:

<http://quantumexperience.ng.bluemix.net>

You will need an account before you can start experimenting with the quantum computer. On the top menu bar, you can Sign In if you already have an account, or Sign Up if you do not have an account.

When you have your account, Sign In, which will then take you to the homepage of the IBM Q Experience. There are useful resources on this page, including an excellent Beginner's Guide, and the Full User Guide.

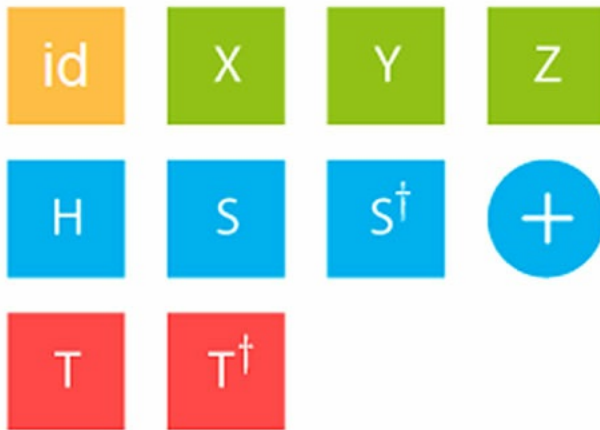

To start experimenting on the quantum computer, click on "Composer" on the top menu bar, which takes you to the Composer window:

In this Composer window, you can see the five horizontal lines, reminiscent of a piece of sheet music (hence the name "Composer").

Each of the five horizontal lines represents one qubit (because the quantum processor available to you currently has five qubits — see the photograph of the actual five-qubit IBM quantum processor in Chapter Seven). You can see on the left side of each of the lines that each qubit starts in state $|0\rangle$.

Individual processing units which modify the state of each qubit are called *quantum gates*. You can see the gates listed as coloured square boxes on the right-hand side of the Composer:

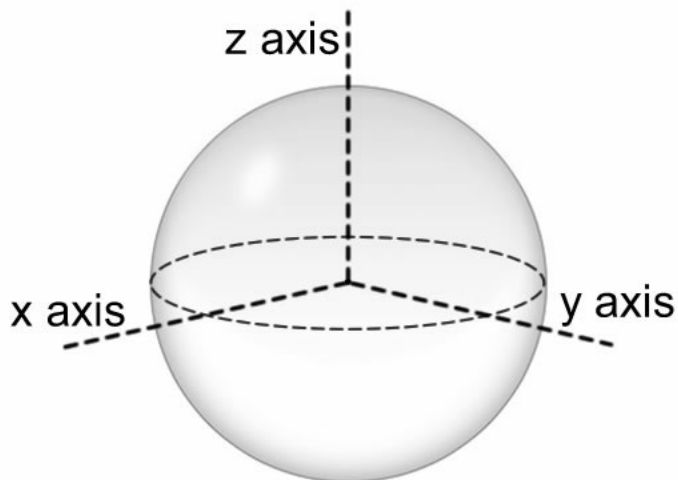

As the qubits pass along the horizontal lines from left to right, the qubits are processed by these gates. The final structure then forms what is known as a *quantum circuit*. The combination of gates provided for you by IBM form the standard set of gates with the whole package being known as the *standard circuit model*. Because of this, even if IBM one day discontinue the Q Experience, your experience of using it — and the standard circuit model described in this book — should remain relevant.

Let us now consider a few of these quantum gates, and show how they can be used to modify the state of a single qubit.

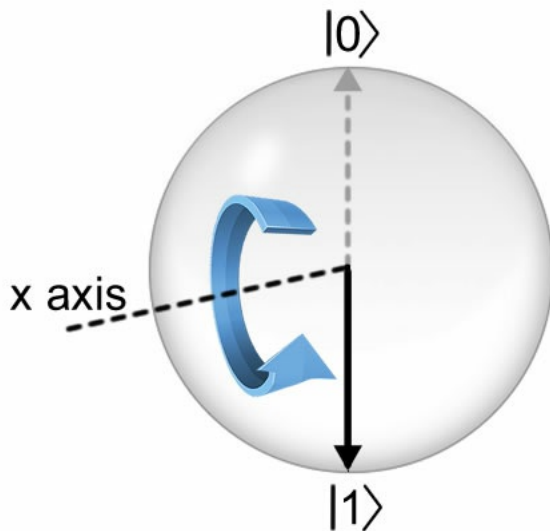

X: The bit-flip

The first quantum gate we will be considering is the X gate. The X gate is listed as one of the square boxes in the IBM Q Experience (see the previous diagram).

As stated earlier in this book, these quantum gates work by rotating the quantum state vector of a qubit. These rotations can be understood by considering the Bloch sphere as having three axes, as shown in the following diagram:

The X gate performs a rotation of 180° around the X-axis, as shown in the following diagram:

As you can see from the previous diagram, the effect of this rotation around the X-axis is to invert (or "flip") the state vector from $|0\rangle$ to $|1\rangle$ (or vice versa from $|1\rangle$ to $|0\rangle$).

The use of the X gate is shown in the following video which I recorded using the IBM Q Experience. You might want to sign-in to the Q Experience and perform the same experiment, or else you can just watch the video.

Here is a link to the video on YouTube:

<http://tinyurl.com/quantumxgate>

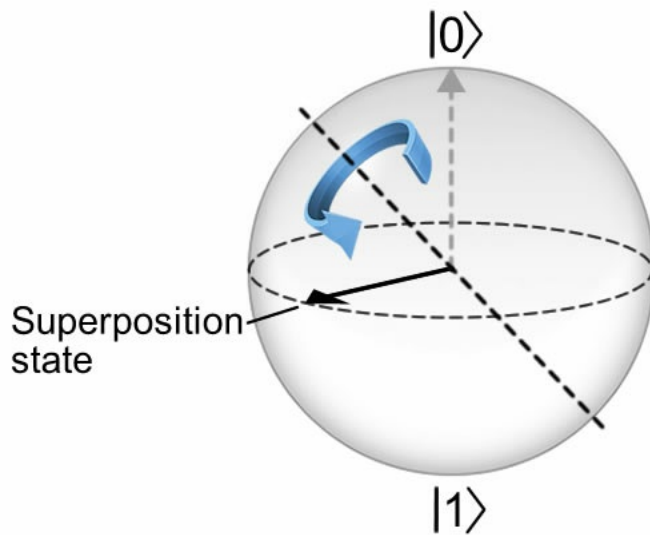

In the video, you will see that I actually use the simulator rather than the real quantum computer. You might find it more convenient to use the excellent simulator for development purposes. This is because a real quantum processor has qubits on a two-dimensional plane — the surface of the chip — so not every qubit can be connected to every other qubit (refer back to the photograph of the actual IBM processor in Chapter Seven). This places some limitations on which qubit can be connected to which other qubit, and you might find this rather frustrating when you are developing on the real quantum computer (it will sometimes not give you the option of connecting certain qubits to certain other qubits). In contrast, if you use the simulator, there are no restrictions on connectivity. Also, if you use the simulator, you get your results immediately, rather than having to wait for your experiment to be queued before it is run on the real quantum computer.

However, for our next experiment, we will be using the real quantum computer ...

H: The Hadamard gate

The Hadamard gate is one of the most useful quantum gates. It is the gate which is used for placing a qubit into a superposition state, an equal mix of state $|0\rangle$ and $|1\rangle$.

You can see the effect of the Hadamard gate in the following diagram of the Bloch sphere. The effect of the Hadamard gate is to rotate the state vector around the diagonal dashed line:

As you can see from the previous diagram, the effect of that rotation is to rotate a vector which is in state $|0\rangle$ (pointing to the North Pole) so that it points to the equator, a superposition state halfway between state $|0\rangle$ and $|1\rangle$.

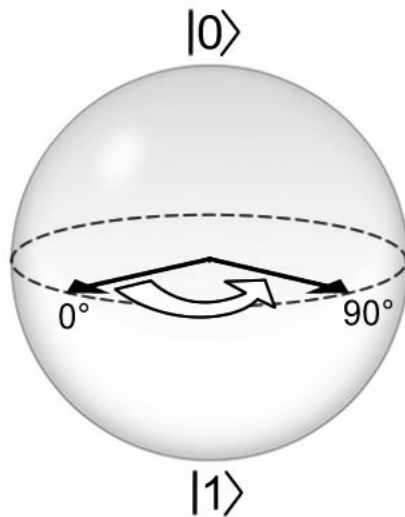

The use of the Hadamard gate is shown in the following video which I recorded using the IBM Q Experience, this time running on a real quantum computer.

Here is a link to the video on YouTube:

<http://tinyurl.com/gatevideo>

Gates which modify phase

All of these quantum gates represent rotations of the state vector in the Bloch sphere. The last set of these gates represent rotations around the vertical Z-axis. As was explained in the previous chapter, rotations around the Z-axis represent a change in the phase of the qubit:

The Z gate performs a rotation of 180° around the Z-axis (just as the X gate performs a rotation of 180° around the X-axis, and the Y gate performs a rotation of 180° around the Y-axis).

Additional quantum gates in the IBM Q Experience include the S gate (which performs a rotation of 90° around

the Z-axis — as shown in the previous diagram), and the T gate (which performs a rotation of 45° around the Z-axis).

So all three of these gates — Z, S, and T — act to change the phase of the qubit.

9

MULTIPLE-QUBIT QUANTUM GATES

In the previous chapter we considered the simple quantum gates which take a single qubit as input, and output a single qubit. However, in this chapter, we will see that if we want to do anything interesting with our quantum computer we will require more complex gates which can take two qubits as input, allowing us to compare and combine the values of those qubits.

These type of multiple-input gates are the simple logical units which form the basis of today's conventional classical computers. So let us start this chapter by examining those conventional logic gates.

Boolean logic

Since the time of Aristotle in 350 B.C., logical reasoning had been the preserve of the philosophers, with their reasoned arguments. For example:

*Socrates is a man.
All men are mortal.
Therefore, Socrates is mortal.*

In the case of this argument, logical reasoning is used to prove that the statement "Socrates is mortal" is a true statement.

In 1847, the British mathematician George Boole wrote a book entitled *Mathematical Analysis of Logic* which attempted to place logic on a firm mathematical footing. George Boole realised that he could create a mathematical system of logic by substituting the number 1 for TRUE and the number 0 for FALSE. These TRUE and FALSE numerical values could then be combined according to strict mathematical laws. The ambiguous arguments of the philosophers could then be replaced by clear, unarguable, mathematical operations.

George Boole's method is now called *Boolean logic*.

But what George Boole could never have anticipated was the role that his Boolean logic would play in digital computers (which, of course, were not around in the mid-19th century). At their core, digital computers are based on binary arithmetic, with data bits which can only take the values of 0 or 1. These values, therefore, were a perfect match for the TRUE and FALSE values of George Boole's logical system. When digital computers were invented, George Boole's system was seamlessly integrated. As a result, Boolean logic and Boolean logic gates now form the basis of today's digital computers. The logical thought processes of philosophers such as Aristotle could now be replicated by an automated process — with Boolean logic essentially forming the "thought processes" of the modern computer.

So let us now consider the range of available Boolean logic gates. A logic gate is a device which takes one or more inputs (which can be either 0 or 1), performs some logical operation on those inputs, and produces a single output (which will be either 0 or 1).

Firstly, there is the NOT gate. The NOT gate is unique among Boolean gates in that it only takes one input (which would be either 0 or 1). The output of the gate is then the inverse of the input (the output is 1 if the input is 0, and vice versa).

Here is the symbol for the NOT gate:

The behaviour of a Boolean gate can be described by a *truth table*, as shown in the following truth table for the NOT gate:

A	NOT A
0	1
1	0

You can see a truth table is divided into a left-hand side and a right-hand side. On the left-hand side, all the possible combinations of inputs are listed, and the right-hand side lists the output which will be produced by the gate when it receives those inputs. For the NOT gate, you can see that the output is simply the inverse of the input (the output is 1 if the input is 0, and vice versa).

All the other Boolean gates take two or more inputs. Let us consider the AND gate next.

The AND gate gives an output of 1 only if **both** of its inputs are equal to 1. Here is the symbol for the AND gate:

And here is the truth table for the AND gate. Note that the output is 1 only if both of its inputs are equal to 1:

A	B	A AND B
0	0	0
0	1	0
1	0	0
1	1	1

Now let us consider the OR gate. The OR gate gives an output of 1 if **either** input A **or** input B is equal to 1. Otherwise, the output of the OR gate is 0.

Here is the symbol for the OR gate:

And here is the truth table for the OR gate. Note that the output is 1 only if at least one of the inputs is equal to 1:

A	B	A OR B
0	0	0
0	1	1
1	0	1
1	1	1

Next, there are the NAND and NOR gates. The NAND gate is similar to the AND gate except its output is inverted (the opposite of the AND gate output). While the NOR gate is similar to the OR gate except its output is inverted (the opposite of the OR gate output).

Here is the symbol for the NAND gate:

And here is the truth table for the NAND gate. Note that the output is the opposite of the output of the AND gate:

A	B	A NAND B
0	0	1
0	1	1
1	0	1
1	1	0

Finally, here is the symbol for the NOR gate:

And here is the truth table for the NOR gate. Note that the output is the opposite of the output of the OR gate:

A	B	$A \text{ NOR } B$
0	0	1
0	1	0
1	0	0
1	1	0

The NAND and NOR gates are particularly important because they are *universal* gates. The term "universal" is used when an object can do anything, it can behave like any other object. A universal logic gate can behave like any other logic gate, and that makes it very useful and very powerful.

Let us consider examples of how a NAND gate or a NOR gate can act like a different gate. Firstly, if both of the inputs to a NAND or NOR gate are the same, then the gate will act like a NOT gate. You might like to check that this is the case by looking back to the truth table for the NAND or NOR gate and seeing that when both inputs are 1 then the output will be 0, and when both inputs are 0 then the output will be 1. Hence, the (inverting) behaviour is the same as a NOT gate. This is shown in the following diagram:

The previous diagram shows how a NAND gate with both its inputs tied together will behave like a NOT gate. This is one example of the universality of the NAND gate.

A more complex example of universality is presented in the following diagram. You might like to check from the truth tables that the following circuit of three NAND gates performs like an OR gate:

The previous diagram represents an example of how logic gates can be combined to create more complex circuits. We will be seeing that this is an essential skill for programming a quantum computer — using the quantum equivalent of Boolean logic gates. Fortunately, many IT professionals will already have experience of using Boolean logic gates, so that skill will be transferrable to quantum computing.

The final Boolean gate is the exclusive-OR gate, otherwise called the XOR gate (pronounced "ex-or"). The XOR gate behaviour is similar to the behaviour of the OR gate in that it gives an output of 1 if either input A or input B is equal to 1. However, its behaviour differs from the OR gate when **both** of the inputs are equal to 1. In that case, the output of the XOR gate is 0.

Here is the symbol for the XOR gate:

And here is the truth table for the XOR gate. Note that the output is the 0 when both of the inputs are equal to 1:

A	B	A XOR B
0	0	0
0	1	1
1	0	1
1	1	0

As we shall be seeing shortly, the XOR gate is of particular importance in quantum computing.

Unfortunately, the life of George Boole was to come to a rather tragic end. One rainy evening, Boole came in to his house with a very slight cold. His wife, unfortunately, had rather peculiar views about curing illnesses: she was convinced that the cure for an illness should resemble its cause. Because of this belief, she proceeded to continuously pour buckets of cold water over the poor man until he died from pneumonia at the age of just 49.

Reversible computing

Our next task is to implement these Boolean logic gates on a quantum computer. We would then have a guarantee that our quantum computer would be able to solve the problems which could be solved using a conventional classical computer. However, in this section we will see that implementing these Boolean gates on a quantum computer is rather tricky.

Let us first consider the AND gate. Here is the truth table for the AND gate which was presented earlier:

A	B	A AND B
0	0	0
0	1	0
1	0	0
1	1	1

As you can see from the previous table, the AND gate takes two inputs but has only one output. As a consequence, if you were only presented with the output of the gate, you would not be able to say what the inputs had been with complete certainty. As an example, you can see from the previous table that if you knew the output of an AND gate was 0, you would not be able to tell if the inputs had been 0 and 1, or both inputs had been 0. In both of those cases, the output of the AND gate would have been 0. In other words, some knowledge — some *information* — would have been lost through the application of the gate.

This type of two-input Boolean gate is therefore not reversible. If all we know is the output, we cannot "wind the gate back" and get the input values.

This might not seem like a very big deal for a conventional computer. After all, logic gates in a conventional computer only ever have to work in the forward direction. However, it represents a serious problem for a quantum computer.

The problem is due to the nature of the Schrödinger equation which we considered in Chapter Three. If you remember, the Schrödinger equation determines the behaviour of the quantum state vector over time, and the Schrödinger equation states that this motion is proportional to the total energy of the system (the Hamiltonian). As a result, the rotation of the state vector is linear: smooth and predictable. This is called *unitary evolution*. This also means that means the motion of the state vector is completely reversible: you could theoretically "wind back" the rotation of the state vector to an earlier state. Because of this reversibility of the Schrödinger equation, all quantum logic gates must be *reversible*.

However, as we have just seen in the AND gate example, if information is lost then the gate is **not** reversible (the inputs cannot be regenerated from the outputs). Therefore, we can deduce that **no information can be lost in unitary evolution.** [11]

This means that, because the AND gate loses information and is therefore not reversible, it would appear it is not possible to implement an AND gate as a quantum gate.

The CNOT gate

The important point we have just discovered is that information is lost in an AND gate — and the other Boolean gates — and so it appears it cannot be implemented as a quantum gate. Does that mean we cannot make a quantum computer? Let us not give up yet.

Instead, we will now see that there is a clever trick we can use to make an irreversible logic gate reversible. The trick requires carrying-over one of the inputs to the outputs. If both of the outputs are then examined, it is possible to uniquely determine what the inputs were. The gate therefore becomes reversible, and it can be implemented in a quantum computer.

Let us first start with a gate which we have just determined is irreversible — the AND gate — and let us see if this trick works. The following diagram shows an AND gate with one of the inputs carried-over to become one of the outputs:

Let us examine the truth table for this circuit, now with the two outputs:

INPUTS		OUTPUTS	
A	B	A	A AND B
0	0	0	0
0	1	0	0
1	0	1	0
1	1	1	1

Same outputs

We can see from the previous truth table that it is still not possible to uniquely identify the inputs from the outputs. For example, you can see that if the outputs of the circuit are 0 and 0, you would not be able to tell if the inputs had been 0 and 0, or 0 and 1. So **information has been lost** and that means that this AND circuit cannot be implemented as a quantum gate.

This is not only the case for the AND gate — you might like to check that this problem also applies to the OR gate, the NOR gate, and the NAND gate.

But let us now consider the exclusive-OR (XOR) gate which was described earlier in this chapter. The following diagram shows an XOR gate with one of the inputs carried over to the outputs:

Let us examine the truth table for this circuit, now with the two outputs:

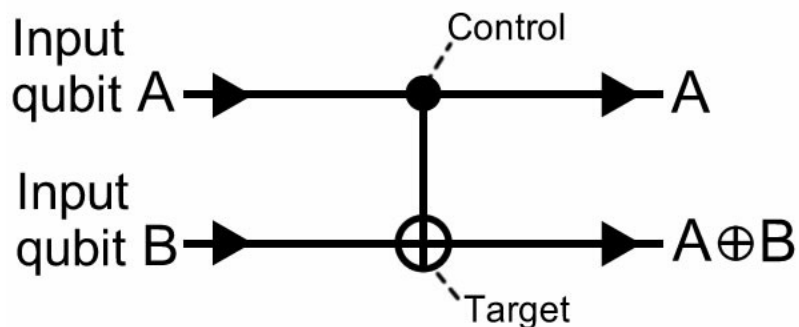

INPUTS		OUTPUTS	
A	B	A	$A \text{ XOR } B$
0	0	0	0
0	1	0	1
1	0	1	1
1	1	1	0

Each of the four output lines are different

In this case, you can see that the two outputs uniquely identify the two inputs. For example, if the output pair is 1 and 1 then we know that the input pair was definitely 1 and 0. So no information is lost, which means this gate is reversible (the inputs can be regenerated from the outputs).

So the XOR gate with one of the inputs carried-over can be implemented as a quantum gate. That means we have managed to discover a reversible two-input quantum gate we can use in our quantum computer! Hurrah!

Here is a diagram of this XOR gate circuit as drawn on a quantum circuit diagram. You will see I have replaced the written "XOR" gate symbol with the standard symbol for the XOR gate which is a circle with a cross in the middle:

You will also see that qubit A has been labelled as the "control" qubit, and qubit B has been labelled the "target" qubit. The reason for this will now be explained, and we shall see it is because of the way the behaviour of this gate is interpreted in quantum computing.

This quantum version of the XOR gate is not called an XOR gate in quantum computing terminology. To see why that is the case, let us examine the truth table for the XOR gate in this circuit, and see if we can interpret it in a different way:

A	B	$A \oplus B$
0	0	0
0	1	1
1	0	1
1	1	0

From the previous truth table, we can see that if qubit A is equal to 0, then the output is equal to the value of qubit B. But if qubit A is equal to 1, then the output is equal to the inverse of qubit B (the NOT operation applied to qubit B). In other words, the NOT operation is only applied if qubit A is equal to 1. Therefore, we could interpret the operation as a NOT operation which is controlled by qubit A.

And, indeed, this is how this XOR circuit is described in quantum computing: it is called the controlled-NOT gate, or CNOT gate. To recap, in a CNOT gate, the NOT operation is only applied on a qubit when the value of another qubit is equal to 1.

The qubit which controls the operation (qubit A in this case) is called the *control* qubit, and the qubit which is inverted (qubit B in this case) is called the *target* qubit (as shown on the earlier circuit diagram of the CNOT gate).

Here is a diagram of the CNOT gate as shown on a quantum circuit diagram:

So we have discovered that the CNOT gate is the only reversible two-input Boolean logic gate which can be implemented as a quantum gate. This explains the layout of the available gates in the IBM Q Experience:

The single-input qubit gates

You can see in the previous image that the range of gates available to you in the IBM Q Experience (the standard circuit model) include the full range of single-input quantum gates, plus the only possible two-input quantum gate: the CNOT gate.

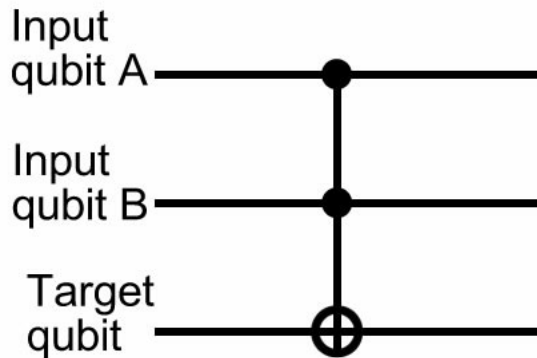

The Toffoli gate is your friend

However, this limited range of gates represents a problem. The problem is that we do not have any universal gates in our set of gates. As described in the earlier discussion on Boolean logic, a universal gate can be used to behave like any other gate. The CNOT gate is our only two-input quantum gate but it is not universal, which means it cannot be used to create all the other possible gates such as AND and NOR. If we want to be able to program anything on our quantum computer, we need to find some way of implementing those other Boolean gates.

A solution emerges when we consider expanding the CNOT gate to take an additional input. If you remember, the CNOT gate is a "controlled-NOT" gate, which means it is really a NOT gate which is controlled by another qubit. We can extend this picture by adding an extra level of "control" — we can control the controlled-NOT gate.

We can get a controlled-controlled-NOT (or CCNOT) gate by having an additional qubit control a controlled-NOT gate. Then, only if this additional qubit is in state $|1\rangle$ is the controlled NOT operation performed.

Here is the symbol for the CCNOT gate, which is more commonly known as the *Toffoli gate*:

In other words, both input qubits must be in state $|1\rangle$ for the NOT operation to be performed on the third (target) qubit. If the third qubit is initially in state $|0\rangle$ you can see that the Toffoli gate acts like an AND gate. That is because the third qubit will be inverted — changed to $|1\rangle$ — only if the other two qubits are both set to $|1\rangle$. And that is the characteristic behaviour of an AND gate (output equal to 1 when both inputs are 1).

What is more, it is easy to see that if the third qubit was initially in state $|1\rangle$ rather than state $|0\rangle$ then the Toffoli gate would act like a NAND gate rather than an AND gate. This is because if both input qubits were in state $|1\rangle$ then the target qubit would be flipped to be in state $|0\rangle$ — and that is the characteristic behaviour of a NAND gate (output equal to 0 when both inputs are 1).

That's great, because we know the NAND gate is universal, so we now have a universal set of quantum gates.

And what makes that such great news is that if we have a universal set of quantum gates then we have a guarantee that **we can calculate anything on our quantum computer which can be calculated on a classical computer!**

The Toffoli gate is not available as one of the gates within the IBM Composer. However, it is possible to program it using the available gates as shown in the following diagram: [\[12\]](#)

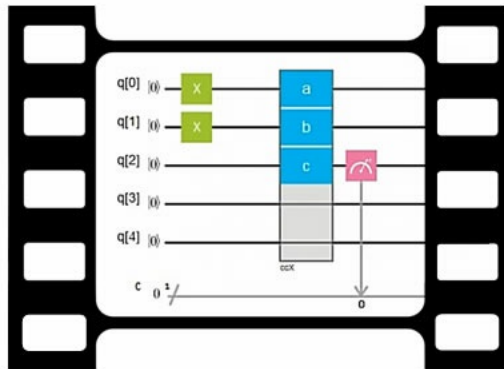

It is an interesting experiment to create the Toffoli gate as shown in the previous diagram inside the IBM Composer (I tried it, and you might like to try it too), but it clearly requires a lot of gates just to create the equivalent of a single Boolean AND gate. Fortunately, those thoughtful people at IBM have provided us with a simple form of the Toffoli gate for us to use. The developers at IBM have placed the previous arrangement of gates into a *subroutine* — a single gate which contains a series of many other gates — which means it is now a simple task to include the Toffoli gate on our circuit diagrams.

The use of the Toffoli gate subroutine is shown in the following video which I recorded using the IBM Q Experience. Here is a link to the video on YouTube:

<http://tinyurl.com/gatevideo3>

And here is a still from the video:

Now, to finish this chapter, the final two short sections will consider some of the useful side-products of the CNOT gate.

Copying a qubit

Sometimes while writing a quantum computer program you might find it useful to copy the value of a variable or qubit. You might imagine it would be easy to copy the value of a qubit in a quantum circuit diagram simply by using a T-junction:

However, that is not the case: T-junctions such as the one shown in the previous diagram cannot exist on quantum circuit diagrams. This is due to the *quantum no-cloning theorem* which states that a quantum state cannot simply be duplicated as shown in the previous diagram.

However, it is possible to use the CNOT gate to copy the value of a qubit to another qubit, and you will surely find that very useful when you come to writing your own quantum computing programs.

The qubit-copying process is simple. You need an additional qubit (the qubit to which the value is going to be copied). You then set the state of that qubit initially to be $|0\rangle$, and apply a CNOT gate — as shown in the following diagram:

You can see from the diagram that if the input qubit A is equal to $|0\rangle$, then the NOT operation will not be applied (because that is how the CNOT gate works), and so the output copy on the second qubit will remain at its initial state of $|0\rangle$. But if the input qubit A is equal to $|1\rangle$ then the state of the second qubit will be inverted by the CNOT gate to become $|1\rangle$. So, in both cases, the value of the input qubit is copied to the output qubit.

Entanglement and the CNOT gate

But the most important side-product of the CNOT gate is that it entangles the two input qubits.

If you remember, the definition of a CNOT gate is that it inverts the value of a qubit (applies the NOT operation) only if the state of a particular different qubit is $|1\rangle$. It is clear, then, that the use of the CNOT gate results in a dependency of the value of one qubit with the value of another qubit. This dependency is the very definition of entanglement, so the CNOT gate inevitably entangles its two input qubits. In fact, the CNOT gate is the method by which qubits are entangled in a quantum computer.

And this raises an interesting point ...

In the previous section we have just seen how the CNOT gate can be used to copy the value of a qubit, but it was also stated that the quantum no-cloning theorem prevents qubits from being copied. So what is going on? Is the no-cloning theorem being violated?

No, the no-cloning theorem is not being violated. To understand why that is the case, it must be realised that the no-cloning theorem states that it is impossible to copy the value of a qubit into two **unentangled** qubits. If the resultant qubits are entangled, then the no-cloning theorem does not apply. This is because, as was explained in Chapter Seven, when two objects are entangled then they represent a single object as far as quantum mechanics is concerned. So, as far as quantum mechanics is concerned, the two qubits have not been cloned at all — they are still one object!

QUANTUM ALGORITHMS

The experiments we have performed so far have not exploited the full power of the quantum computer. Indeed, in his *Lectures on Computation*, Richard Feynman covers the basics of quantum computing and reversible computing as we have covered so far in this book, but Feynman concludes: "What we have done is only to try to imitate as closely as possible the digital machine of conventional sequential architecture. What can be done, in these reversible quantum systems, to gain the speed available by concurrent operation has not been studied here."

The phrase "concurrent operation" is a reference to parallel processing. So Feynman is stating that in order to extract the maximum processing power from our quantum computer, we need to exploit the potential of the quantum superposition state to perform calculations in parallel — just as Feynman himself exploited the power of parallel processing with the IBM mechanical calculating machines back in Los Alamos.

If you remember, at Los Alamos, Feynman could have multiple data in his line of mechanical calculating machines by colour-coding the punched cards so he could keep track of the cards which were at different stages of the process. The principle behind a quantum computer is similar: multiple copies of the data can be held in the central processor at the same time, and those multiple copies of the data can be processed simultaneously. This enables the potentially vast increase in processing speed associated with parallel processing.

Let us explore this process in more detail.

From bits to qubits

At the core of a conventional computer lies the central processing unit (CPU) which, in most computers, takes the form of a microprocessor (a single integrated circuit). Within the microprocessor are a series of registers. A register is a line of bits, usually representing a single binary number. It is common for a single register to have maybe 8 bits, or 32 bits, but it is 64-bit registers which are usually found in modern computers ("64-bit processing").

The following diagram shows the decimal number 153 stored in an 8-bit register in a microprocessor in binary form (10011001). You can see each of the bits labelled from d_7 to d_0 :

The contents of a register represents the piece of data which the computer is currently processing. Various operations can be applied to the data in the register as the microprocessor steps through a computer program line-by-line. These operations would generally be Boolean logic operations such as AND and NOR which we considered in the previous chapter. In this way, even complicated computer programs are translated into very many simple Boolean operations which are then applied to the data stored in a register. In a modern computer, these operations can be applied in nanoseconds. That is incredibly quick, **but we are still dealing with only one piece of data at a time**. The only reason our computers are as fast as they are is because of their incredibly fast clock speed (speed at which a single operation is performed). Otherwise, conventional computers have a processing bottleneck, only being able to perform one instruction at a time.

However, a quantum computer promises to eliminate that processing bottleneck by holding multiple copies of its data in a superposition state. The inputs of a quantum computer are not composed of classical bits — they are composed of qubits. As an example, you will remember that the IBM Q Experience quantum processor we have been using so far in this book has five input qubits. If you look carefully in the composer window you will see that

these are labelled from q[0] to q[4], so we might interpret those qubits as making a five-qubit register.

And, of course, each of those qubits is capable of being in a superposition state which effectively means it is holding both the value zero and one **at the same time**. We now start to see how a quantum computer can overcome the processing bottleneck of a conventional computer.

To explain the advantage of a quantum computer, let us first consider an 8-bit classical register. With eight bits, the register is capable of holding 256 different binary numbers (2^8 equals 256). However, the register can only hold one of those 256 numbers at a time. In contrast, each of the qubits in a quantum computer can be both zero and one at the same time, and so a quantum register can consider all 256 different numbers at the same time.

As in a classical register, we would then apply logic gates to the qubits in order to process their values (stepping through each step of a computer program). But, of course, in a quantum computer we would apply our quantum gates (such as the X, H, and CNOT gates described in the previous two chapters) instead of the Boolean logic gates (AND, OR, and NOT) we would apply to a classical register. And those quantum gates would be being applied to multiple copies of the input data at the same time — you get so much more processing power for your buck.

And, because the number of possible input combinations rises exponentially (according to 2^N , where N is the number of qubits), a quantum computer gets very powerful very quickly. As just described, with eight input qubits there would be 2^8 different input combinations, which is equal to 256. And the quantum computer would be able to consider all of those 256 different input combinations at the same time. With sixteen qubits there would be 65,536 different input combinations. With 24 qubits there would be over 16 million different input combinations. And with just 300 qubits, a quantum computer would have more input combinations than there are atoms in the universe.

Let us now consider the problems we could solve using that tremendous quantum computing parallelism.

The inverse problem

What do we mean by a "problem"?

When we think of a typical problem, we probably think of a question which needs an answer. As a common example, I might ask: "Where have I left my reading glasses?". A different example from mathematics might be: "What is the answer when we multiply 47 by 31?"

So these represent the sort of problems we might encounter in everyday life: problems when we know the question and need to find the answer. However, there is a completely different type of problem. These are the problems when we know the answer, and we need to go back to determine the question. It might sound easy, but it's not.

Determining the question when we know the answer is called the *inverse problem*.

In general, to solve the inverse problem, we need to determine the reverse of the procedure which we would use to calculate the answer from the question. In that way, we calculate the *inverse transformation*. The inverse transformation would be the reverse of the forward transformation, with the forward transformation being the normal process which is used to calculate the answer from the question.

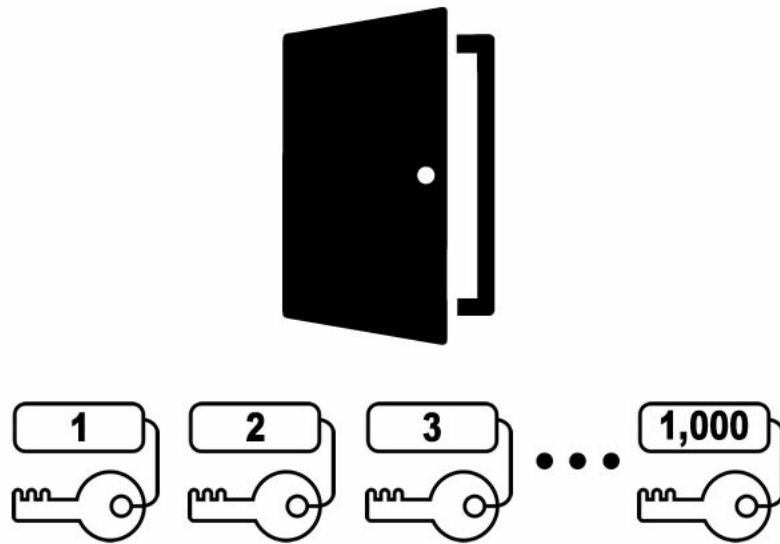

THE INVERSE PROBLEM

However, sometimes it might not be possible to calculate the inverse transformation, or it might be incredibly difficult. In other words, there is no way to directly link the answer with one particular question. Here is an example of such a problem.

You are faced with a locked door. On a table in front of you are a thousand different keys. Each key has a label

attached to it with a number from 1 to a 1,000, clearly identifying each individual key.

The "problem" in this case is how to open the door.

We can think of the number on a key as being the input to the problem. If we choose one number from 1 to 1,000 at random, and select the corresponding key, we can then attempt to open the door using that key. We can think of the act of "attempting to open the door using that key" as representing the "forward transformation" which uses the number of the key as its input. The output of the transformation would then be a Boolean value, either TRUE or FALSE depending on whether or not the door is opened by the key.

So the forward transformation in this case is straightforward. When you are asked "Does key number X open the door?", you select the key with that number (X), you insert the key into the lock on the door, and you see if the key opens the door. You get your answer to the question.

So we have a clear forward transformation working forwards from the question to the answer. But what is the reverse transformation, working backwards from the answer to the question? To be precise, if we are presented with the answer TRUE — that the door is open — is there any way we can work backwards from that answer (which is simply TRUE) to determine the number of the key which opened the door?

No, it is clear there is no inverse transformation. If we are presented with an open door, we cannot tell which key opened the door.

So, in the absence of an inverse transformation, do we give up, defeated?

No, of course we don't give up. We don't give up because we do at least have the forward transformation — we are able to test an individual key to see if it opens the door. We could then exhaustively test every one of those thousand keys to discover which key opens the door. Then, when we are presented with the inverse problem "Which key opened the door?" we will be able to provide an answer to that inverse problem.

That sounds straightforward: it appears that as long as we are in possession of the forward transformation we will be able to solve any inverse problem — it will just take a long time to test all the possible inputs. But what happens if there are more than a thousand keys? What happens if there are a million keys? What happens if there are a trillion keys? What happens if there are as many keys as there are atoms in the universe?

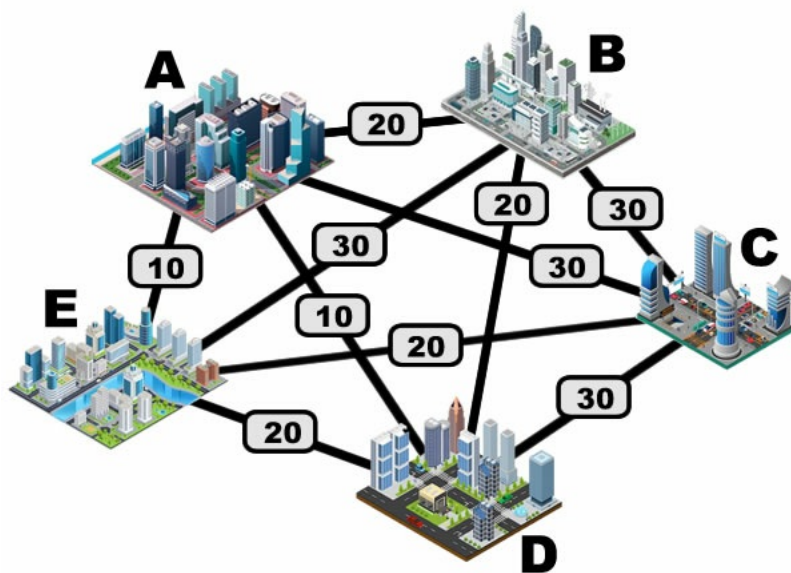

In those situations — with so many possible inputs — it appears we cannot use this method of exhaustively testing all possible inputs. **However, this method of considering all possible combinations of inputs is precisely the sort of thing that quantum computers do so well!** As we have seen, if the input qubits of a quantum computer are prepared in a superposition state, then **a quantum computer can check all possible combinations of inputs at the same time.** And, as was explained earlier in this chapter, with just 300 qubits in a superposition state, a quantum computer can check as many input combinations as there are atoms in the universe.

It would seem that a quantum computer is perfectly suited for tackling inverse problems.

As another example, let us consider the famous *travelling salesman problem*. Consider a salesman who is travelling around America. His schedule requires him to visit a certain number of specified cities, returning to the city he started from. However, the salesman has complete freedom as to the order in which he visits those cities. The salesman wants to save as much fuel as possible, so he selects to visit those cities in a certain order in an attempt to

minimise the total distance (obviously, zig zagging across America would be a bad idea as it would maximise the total distance).

The example in the following diagram shows the travelling salesman having to visit five cities. The cities have been given distinguishing letters, and the distance (in miles) for all the possible routes between the cities are displayed. Imagine that the salesman starts his journey in city A. Can you find the shortest route in which the salesman visits all five cities, before returning to his starting city? I will give the answer later.

It is clear that in this case we have a forward transformation: given a particular route as input, it is easy to calculate the total distance of the route. But the inverse transformation is extremely difficult: given a particular total length of a route, how do you calculate the route which taken? Or how do you calculate the minimum possible total distance, visiting all cities?

It turns out that there are a huge number of different possibilities. If there are n different cities, then the number of different routes is equal to the factorial of $(n-1)$. That means it is equal to all the positive integers equal to or less than $(n-1)$ multiplied together. As an example, if the salesman has to visit five cities then there are 24 different possible routes ($4 \times 3 \times 2 \times 1$). That might not sound too bad, but the factorial grows very rapidly as the number of cities increases. If the salesman had to visit just 52 cities, for example, there would be 10^{62} different routes (the number 1 followed by 62 zeroes)! In that case, how do you check all the possible routes?

Once again, this example of an inverse problem appears to be a perfect application for a quantum computer to tackle, because a quantum computer can evaluate all possible input combinations at the same time. Indeed, in the next section we will be seeing that the standard textbook on quantum computing explains how a quantum algorithm can solve the travelling salesman problem faster than any classical algorithm.

Another inverse problem which is rather similar to the travelling salesman problem arises when we consider the many possible arrangements of atoms as they combine to form molecules. Given a certain arrangement of atoms, it is possible to calculate the resultant energy of the molecule. We might consider that energy calculation as being the "forward transformation" of our inverse problem. A molecule will then tend to adopt the configuration of atoms which has the lowest energy: this is known as the ground state (we might think of it as the equivalent to the shortest route for the travelling salesman). But, given the ground state energy, is it then possible to work backwards to determine the arrangement of atoms? This then becomes an example of an *optimization problem* in which we have to try to find the best solution from a range of possible solutions (the travelling salesman problem is another example of an optimization problem in which the total distance has to be minimised). By determining the structure of molecules in this way, new life-saving drugs can be developed, and this is an area in which quantum computing is already showing great potential.

Shor's algorithm

But there is one particular inverse problem which has generated a great deal of attention and has made quantum computing a front page story. It is the inverse problem which involves finding the factors of a number.

It is a relatively simple process to multiply two integers (whole numbers) together, even very large numbers, to produce a larger number. We might think of the initial two numbers as representing the input to our process, and the act of multiplying the two numbers together as being the "forward transformation". It is clearly an easy task for a computer to multiply two large numbers together. However, the inverse problem then arises when we consider the resultant large number and want to work backward to determine the initial two numbers which were multiplied together. The initial two numbers are called the *factors* of the larger number, and the process of determining the two factors is called *factorization*.

It turns out that there is no quick and easy method to factorize a large number. In fact, it is incredibly hard and time-consuming — even for the most powerful classical computer. So, while the forward transformation is easy (multiplying two numbers together), we do not have access to a practical inverse transformation. And that should immediately make you think: "Aha! This sounds like an inverse problem which could be successfully tackled by a quantum computer!"

Indeed, in 1994, the mathematician Peter Shor developed a quantum algorithm for factoring large numbers. Shor's algorithm, utilising the power of quantum parallelism, was far faster than any existing classical algorithm.

For this reason, Shor's algorithm generated a lot of attention and newspaper column space because it threatened to crack the encryption technique — known as RSA encryption — used to secure internet communications. Every time you type "https:" into your internet browser address bar, you are using RSA encryption to encode your credit card details (the "s" in "https" stands for "secure"). If Shor's algorithm could crack RSA encryption, the consequences would be huge.

RSA encryption was first explained in a 1978 scientific paper which introduced us to two fictional characters named Alice and Bob. The names "Alice" and "Bob" (instead of just using A and B, as was usual up to that point) have since become the accepted names which are used in many thought experiments in physics.

To understand RSA encryption, imagine that Alice and Bob live a considerable distance apart. Now imagine Bob wants to send an encrypted message to Alice which only she can read. The conventional method of sending a coded message would require Alice and Bob to share a *key*, which is known only to themselves. Bob would use the key to encode his message, and Alice would then use the key to decode Bob's message. However, transmitting the key between Bob and Alice in advance of the message is inconvenient and a security risk.

Rather amazingly, RSA encryption does not require the secret sharing of a key in advance. To understand how RSA encryption works, first Alice picks two large prime numbers, say, p and q . These two numbers then represent Alice's *private key* which she keeps to herself. Alice then multiplies those two numbers together to form her *public key*. Alice must then publish her public key in a publicly-available directory — anyone can read it. However, Alice's private key still remains completely secure because of the difficulty of factoring large integers: no eavesdropping third party can work out what p and q are — Alice's private key — even if they have access to her public key. Even though the public key contains both p and q multiplied together!

When Bob wants to send a message to Alice, he encodes it using her public key, and then sends the message to Alice. This is entirely secure even if the message is intercepted because the resultant encoded message can only be decoded using Alice's private key. When Alice receives the message from Bob, she decodes it using her private key and reads the message. So encrypted messages using RSA encryption can be sent between Alice and Bob without the requirement for a secret key to be exchanged in advance.

It is clear that if Shor's algorithm could factor large numbers, it could reveal Alice's private key, and RSA encryption — the backbone of internet security — would no longer be secure.

Peter Shor's algorithm is clearly a tremendous achievement. However, it is specific to the problem of factoring numbers. The aim of this book, however, is to present general techniques which IT professionals might use for their own applications, and thereby take quantum computing into the mainstream. Though Peter Shor's algorithm is impressive, I suspect most IT professionals will not be interested in cracking internet security.

With that aim in mind, in the next chapter we will be examining a general technique for solving inverse problems which might be used in a wide range of applications.

The challenge of writing a quantum algorithm

So we have now gained an understanding of how a quantum algorithm works. Initially, we have a set of qubits which are initialised to be in either state $|0\rangle$ or state $|1\rangle$. Those qubits are placed in a superposition state by applying a Hadamard gate to each qubit. Because they are now in a superposition state, each qubit then becomes both "zero and

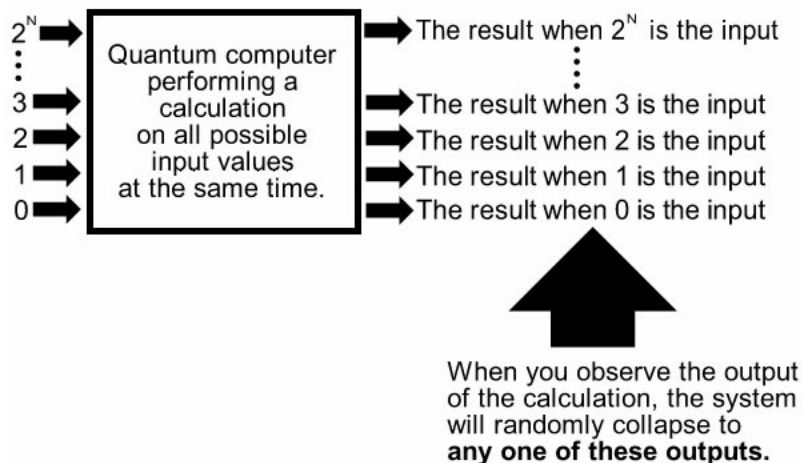

one at the same time". The qubits then pass through a series of quantum gates, and the values of the output qubits are generated. When those output qubits are measured, we obtain the result of our calculation.

However, the principle of massive parallelism which gives a quantum computer its power also makes a quantum algorithm very difficult to write. Because the qubits are in a superposition state, all possible values of the input data are presented to the quantum computer at the same time. But when we measure the output of the computer, at that moment there is the usual collapse of the quantum state, taking the quantum computer out of its superposition state. At this point, the quantum state collapses to a single well-defined value (as described in Chapter Four: "Observing a quantum system").

So, at that point, the output qubits collapse to a single value. If we then trace that output value back through the workings of our quantum computer, then that output value would represent just one particular input value. In other words, the input also suddenly becomes just one value. It is as if your entire quantum computer has suddenly collapsed to become a classical computer! To make matters worse, we have no control over which particular input value the qubits will collapse to — the collapse process is, of course, completely random.

This difficult situation is described by Eleanor Rieffel and Wolfgang Polak in their book *Quantum Computing: A Gentle Introduction*. As Rieffel and Polak say, the act of measuring will "project the final state onto **a single input/output pair, and a random one at that.**"

The problem is explained in the following image:

The previous diagram shows the numerous input/output pairings, with only one pairing being chosen at random to represent the output. Once again, this difficult situation is described by Rieffel and Polak: "**Only one result is obtained and, even worse still, we cannot even choose which result we get.**"

So how can we ensure that we get the correct value in the output qubits at the end of the calculation? There are so many possible input data values, and we have no control over which input value will eventually be randomly selected when we observe the output. In that case, how can we ensure that the output qubits collapse to the correct value of the calculation?

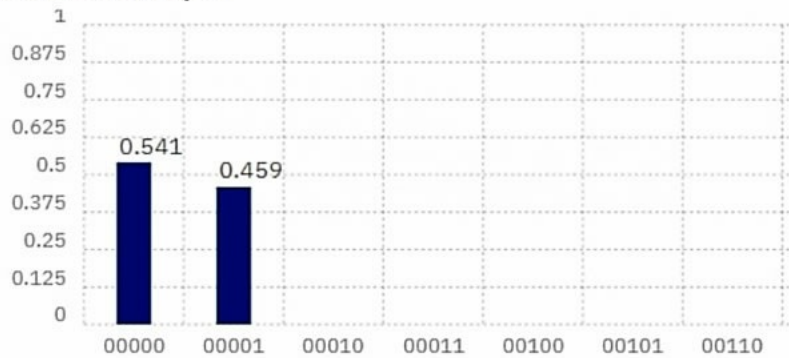

The situation sounds almost impossible! How on Earth can it be done?

Well, it turns out that it **is** virtually impossible: you can't write a quantum algorithm that gives you the correct answer every time.^[13] Instead, **you have to increase the probability of the correct answer being found on the output qubits**, and then rely on the probabilistic nature of quantum mechanics to do the rest. That is the best that you can do.

As an example, the IBM Q Experience will typically run your quantum algorithm 1024 times (this all happens in a fraction of a second) before delivering its results in histogram form showing how many times each possible result was measured. That way, as long as your quantum algorithm has ensured that the correct answer is the answer most likely to be measured, the correct answer will emerge from the histogram distribution with the highest number of hits.

Here is an example of the final histogram distribution in a screen capture from my earlier Hadamard gate video:

Device: ibmqx4

And this is where quantum entanglement plays a vital role. In the discussion of entanglement back in Chapter Seven, it was explained that when we are dealing with entangled qubits, you should no longer think of the qubits as independent units. Instead, you should think of the entangled qubits as representing a single quantum system, **described by a single state vector**. The task of your quantum algorithm is then to manipulate (rotate) that single state vector to align it more closely with the correct answer to ensure that the correct answer is more likely to be observed when the output of your quantum computer is finally measured.

If that sounds rather tricky, well, it is. Fortunately, I am not going to be suggesting that that is what you should attempt to do when you come to writing your own quantum algorithms. I am not going to be suggesting that you start from scratch, and have to devise some ingenious state vector rotation algorithm every time. Instead, in the next chapter — the final chapter of this book — a quantum algorithm will be presented which can be adapted to your own particular needs. In other words, the ingenious method of state vector rotation has been worked-out for you in advance, and you just have to modify one section of the algorithm to match your own particular problem.

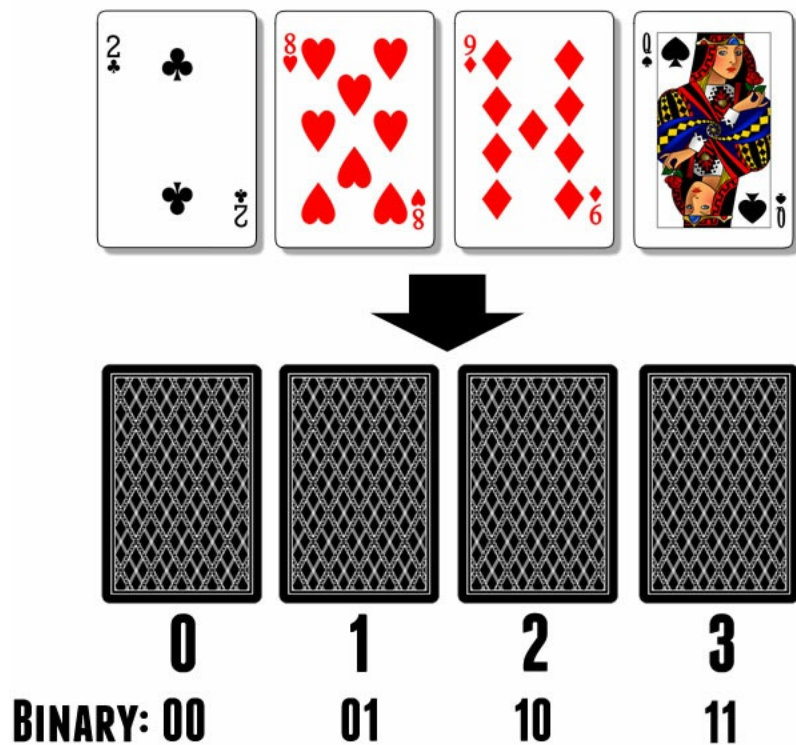

(By the way, I promised I would give you the answer to the travelling salesman puzzle presented earlier. If you visit the cities in the order ADBCEA — or the reverse order, of course — then you will travel a total distance of just 90 miles, which is the shortest possible distance.)

11

GROVER'S ALGORITHM

So what we really need is a general quantum algorithm for solving inverse problems. Quantum computing could then be adopted by IT professionals, and the potential of quantum computing could then be finally fulfilled. Fortunately, in 1996 the Indian-American computer scientist Lov Grover devised an algorithm which fits these requirements. The method is now known as *Grover's algorithm*. [14]

Grover's algorithm is often explained by an example using four playing cards. The following image shows four playing cards, one of which is the queen of spades. The cards are then turned face down, and randomly rearranged so that you no longer know which card is the queen. You will see in the diagram that each face-down card has been given an identifying number. Your task is to identify which card is the queen.

We can express this problem in a similar form to the other problems we have considered so far. We can consider the numbered position of the card (0, 1, 2, or 3) as being the input to a forward transformation. The nature of the forward transformation in this case is very simple: you take that numbered position of the card and you turn that particular card over to see what it is. The output of the forward transformation is then the Boolean value TRUE or FALSE depending on whether or not that particular card turned out to be the queen of spades.

So we have a simple forward transformation (from the question to the answer), but do we have an inverse transformation (from the answer to the question)? No we do not. If you are presented with the answer TRUE, meaning the queen of spades has been found, then from that answer can you determine which card at which numbered position was turned over? No, there is no way to do that (unless the cards were marked).

So, once again, we seem to have a problem with a simple forward transformation but no inverse transformation. And that should make you think, once again, that this is a representation of a problem which could be cracked by a quantum computer.

If the positions and values of the cards were represented by variables in a computer program, then the problem could be translated into a problem running on a computer. We could then use the forward transformation to turn

every card over in sequence until we find the queen. We know that process by another name: a *search*. So Grover's algorithm — which can be used to solve this problem of finding the queen — is an example of a *search algorithm*.

Let us now consider how long it would take us to find the queen by a manual search (or, equivalently, a search on a classical computer in which only one card at a time can be turned over).

The position of the queen is completely random, so, initially, the queen can be in any of the four numbered positions. Let us imagine our manual search always starts on the left-hand side. Then, if the queen is located on the extreme left position, we will find it on our first attempt, turning over just one card. Otherwise, if the queen is located in the second-from-left position, we will find it on our second attempt, turning over two cards. Otherwise, if the queen is located third-from-left we will find it on our third attempt, turning over three cards. And, in the worst case scenario, with the queen positioned at the extreme right, we will have to turn over all four cards before we find the queen.

With there being an equal chance that the queen was in any one of the four positions, the average number of cards we will have to turn over before we find the queen is:

$$\frac{1 + 2 + 3 + 4}{4} = 2.5$$

So, using a manual exhaustive search (or a search on a classical computer), we will have to turn over an average of 2.5 cards before we find the queen.

But Grover's search algorithm can find the queen by turning over just one card.

Grover's algorithm can speed up an exhaustive search by a factor proportional to the square root of the number of classical operations. In this example, with 2.5 classical operations having to be performed to find the queen, Grover's algorithm promises to find the queen using only the square root of 2.5 number of operations — which is a number close to 1.5. And this is what we find. In fact, Grover's algorithm in this particular case can always find the queen in only one operation, one attempt.

And Grover's algorithm can be applied to a huge range of different search operations. Michael Nielsen and Isaac Chuang have written the standard textbook on quantum computing entitled *Quantum Computation and Quantum Information*. They consider the travelling salesman problem in their book, and present Grover's algorithm as a potential solution: "Suppose you are given a map containing many cities, and wish to determine the shortest route passing through all cities on the map. A simple algorithm to find this route is to search all possible routes through the cities, keeping a running record of which route has the shortest length. On a classical computer, if there are N possible routes, it obviously takes a number of operations proportional to N to determine the shortest route using this method. Remarkably, there is a quantum search algorithm, sometimes known as Grover's algorithm, which enables this search method to be sped up substantially, requiring a number of operations only proportional to the square root of N . Moreover, the quantum search algorithm is **general** in the sense that it can be applied far beyond the route-finding example just described to speed up many (though not all) classical algorithms that use search."

Nielsen and Chuang also consider the potential of Grover's algorithm for searching for the factors of numbers, and thereby breaking codes. In order to find the factors of a number, an exhaustive search could progressively examine all the positive integers (whole numbers) smaller than that number, and see if they could be used to divide the larger number — leaving no remainder. If so, the smaller number is a factor of the larger number.

For factoring applications, Grover's algorithm is not as fast as Shor's algorithm, and so Grover's algorithm could not be used to break RSA encryption in a reasonable time.^[15] However, it is known that Grover's algorithm could be used to break the widely-used AES encryption scheme which does not use integer factorisation. Grover's algorithm could break the code in the square root of the time it would take a classical computer.

Solving a problem in the square root of the time might not sound impressive, but it can make a tremendous difference. An article on the Betanews technology website revealed the true implications of the "square root" speed-up achieved by Grover's algorithm: "If a classical computer needs to search 2^{56} possible keys to be guaranteed to crack DES encryption, a quantum computer running Grover's algorithm only needs to do 2^{28} searches. This is easier to understand when written in conventional notation: Classical computer: 2^{56} searches = 72,057,594,037,927,936, Quantum computer: 2^{28} searches = 268,435,456. When measured in terms of time, assuming both computers can search at the same speed: if it takes a classical computer one day to crack a particular 56-bit encryption, it would take the quantum computer just 0.322 milliseconds — or one thousandth the blink of an eye. And if it took a classical computer one year to crack 64-bit encryption, it would take a quantum computer 7.3 milliseconds." ^[16]

There is another benefit of Grover's algorithm. As described by Eleanor Rieffel and Wolfgang Polak in their book *Quantum Computing: A Gentle Introduction*: "Grover's algorithm is simpler and easier to grasp than Shor's, and has an elegant geometric interpretation."

It is clear, then, that Grover's algorithm represents a method of solving a wide variety of inverse problems. This is what we have been looking for.

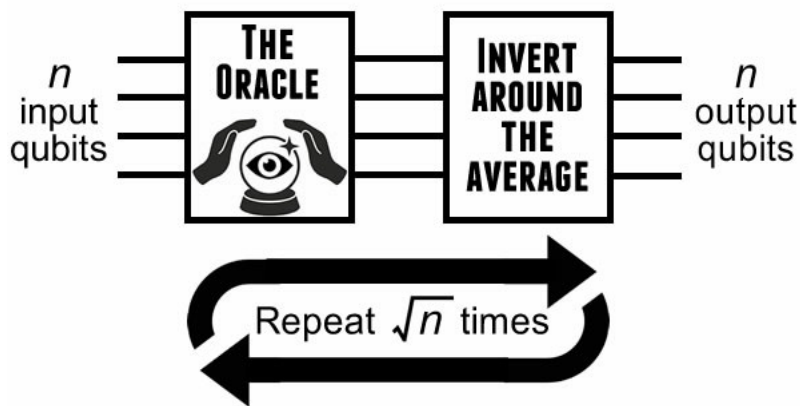

So let us now consider the structure of Grover's algorithm in full detail (although, you might be relieved to know that the bulk of the complicated detail has been moved to the two appendices at the back of this book). I suspect for many IT professionals and researchers looking to solve their own problems on a quantum computer, this will be the material they need to know.

As a reward, later in this chapter we will program an example of Grover's algorithm on the real IBM Q Experience quantum computer.

Yes, we'll be programming a real quantum algorithm on a real quantum computer!

The Oracle

The structure of Grover's algorithm can be split into two stages. Here is a block diagram of Grover's algorithm:

You can see from the previous diagram that Grover's algorithm is composed of two main blocks called "The Oracle" and "Invert around the average". I am going to jump slightly ahead at this point and show you how we will be coding these two blocks in the IBM Q Experience later in this chapter. The two blocks are going to look like this:

We are going to be using Grover's algorithm to find the position of the queen of spades in the previous playing cards example. As described earlier, this is a search operation — we have to search to find the queen.

There are four possible positions for the queen, with the positions numbered 0, 1, 2, or 3. The binary equivalent of those decimal numbers would be 00, 01, 10, and 11. So the binary numbers have two bits. Hence, our quantum algorithm is going to have two input qubits which will be capable of representing all possible positions of the queen (the previous block diagram of Grover's algorithm can be seen to be based on two qubits).

In this section we will consider the first part of Grover's algorithm, which, as you can see, is called the Oracle.

The first part of Grover's algorithm is a self-contained "black box" of code, a code block which — in computer science terminology — is often referred-to as an "oracle". The term "oracle" seems rather strange, but this is chosen because the unit is defined only in terms of what it does: its inputs, and its outputs. We are not particularly interested in the internal workings, how it derives those outputs from its inputs (this is why it is often called a "black box" — we do not care what happens inside it). Or, to be more specific, its internal workings are not defined, and it is left to the programmers to design how it works internally.

So this "black box" is rather similar to a human "oracle", a visionary or seer with a crystal ball, who you ask a question and who miraculously gives you the correct answer (I seem to remember one of the characters in the *Matrix* movie was called The Oracle — a lady who provided the answers for Keanu Reeves). You don't know how the oracle has done it, you don't know the internal workings — you are just glad it works.

So the first part of Grover's algorithm is an oracle. Let us now consider what the oracle has to do.

The oracle is presented with the n input qubits in a superposition state, which represents all possible input combinations (for two qubits, this would be the four possible states 00, 01, 10, and 11). The oracle then has to perform the following two tasks:

Oracle Task Number One

The first task for the oracle is that it has to consider the input value (00 or 01, etc.) and perform a calculation to see if that value satisfies the particular search problem. In this playing card example, the oracle has to decide if the number represents the correct position of the queen of spades. **So the key task of the oracle is that it has to recognise when a specific combination of input qubit values solves a problem.**

If you wanted to adapt Grover's algorithm to solve your own problems, you would have to adapt this oracle for your own problem. You would have to perform some calculation on the input value in order to test to see if the input value satisfies your search problem. Is it the number you are looking for? For example, is the number a factor of a larger number? Does it divide perfectly into the larger number? If so, you've cracked the code! And, of course, because you are being presented with your input qubits in a superposition state, your calculation will be working on all possible combinations at once. Like magic!

Oracle Task Number Two

The second task for the oracle is that when it finds the solution it is looking for, it has to "mark" the solution. According to Grover's algorithm, this marking is performed by inverting the phase of the state by rotating it by 180° . If you rotate anything by 180° , you are making it point in the opposite direction. So another way of interpreting this "marking" operation is that it puts a minus sign in front of the state vector.

Let us now consider how we can create a quantum oracle on the IBM Q Experience.

In our example of finding the queen of spades, we note that in our earlier diagram we placed the queen at the extreme right-hand position of the four cards. So we want to create our oracle to detect when this numbered position is input. You will notice on the earlier diagram of the playing cards that the right-hand position was given the number 3, which is equivalent to the binary number 11. So we want our quantum oracle to mark the input state when both input qubits are in state $|1\rangle$ — and not when the qubits are in any other state. In other words, we need to invert the phase only when both input qubits are in state $|1\rangle$.

It turns out that this phase inversion can be performed by a very simple circuit. It can, in fact, be done with a single CNOT gate and a couple of Hadamard gates. The following diagram is the actual circuit diagram for the Grover's algorithm oracle:

In the example shown in the previous diagram, both inputs are set to state $|1\rangle$. As just explained, this is the condition which we want to result in the phase inversion.

The details of how this oracle circuit was designed are fairly complicated, so they have been moved to Appendix One at the back of this book.

But we now have the design for our quantum oracle circuit, so we are getting closer to finding our queen ...

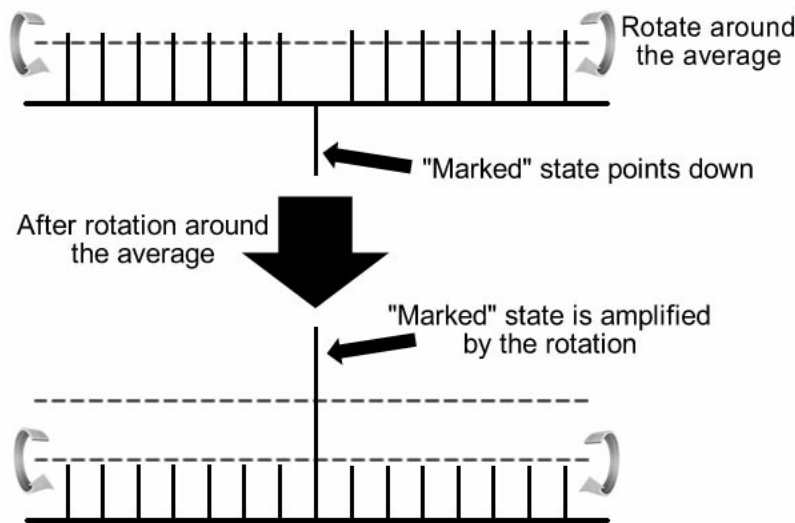

Inversion around the average

It is now time to move to the second stage of Grover's algorithm. And, as we shall see, it is quite ingenious.

To recap, the queen of spades has been found and the state representing the position of the queen (11) has been marked. But what do we do next with this marked state? How do we ensure that when we look at the output of our Grover's algorithm, the marked state will appear as the most likely solution with high probability? We need to find some way of amplifying the marked state.

Remember, we marked the state by inverting the phase of that state so it points in the opposite direction to the phases of all the other states. This situation is shown in the following diagram showing the phases of all the states. You can see that all the phases point up except for the single phase of the marked state which was inverted and therefore points down:

In the top part of the diagram you will also see a thin dashed line. This represents the **average** value of all the phases. Because almost all the phases are pointing upward, this average value is quite large, almost precisely aligned with the tips of all the lines which are pointed upward. The only thing which is dragging the average value down very slightly is the value of the single marked state which is pointed downward.

The next step is very clever. We rotate **all** the states by 180° around the average value, the dashed line. You can see the effect in the lower part of the previous diagram. Because the value of the upward-pointing states was very close to the average value, the effect of the rotation does not affect them very much. However, as you can see in the previous diagram, the tip of the downward-pointing state was very far away from the average value — approximately twice as far away as all the other upward-pointing states. So when we rotate all the states around the average value, the downward-pointing state now gets amplified to more than twice its original length, and now points upward — as shown in the lower part of the previous diagram.

Moving on to consider how to implement this rotation, it turns out that the final circuit for performing the "rotation around the average" takes the following form:

Once again, the details of how this circuit was designed are quite complicated and so they have been moved to Appendix Two at the back of this book.

And that is how the second part of Grover's algorithm works. The amplification boosts the marked state so that when the output of the quantum computer is observed, it is more likely to collapse to the correct state, revealing the position of the queen of spades. Usually several iterations have to be performed (the square root of n times) until the correct state receives sufficient amplification to ensure that it will be selected with high probability.

Programming a real quantum algorithm on a real quantum computer

So we have discovered the complete structure needed to implement Grover's algorithm. Now let us program this using the IBM Q Experience.

Here is the final complete block diagram:

This circuit diagram for implementing Grover's algorithm can be programmed directly into the IBM Q Experience. Give it a go and see if it works!

I am actually ahead of you because I have already tried it, and I have created a video of my efforts. Here is a link to the video:

<http://tinyurl.com/magicquantum>

And here is a still from the video:

The revealing of the queen of spades at the end of the video represents perhaps the most technologically-advanced magic trick in history.

Some final thoughts

I hope you have enjoyed the book.

When I wrote this book, I had three goals in mind.

Firstly, I was aware that there was a general lack of clear, easy-to-understand technical information about quantum computing. Therefore, I wanted to write an accessible book which would capture the essential concepts of quantum computing, hopefully simplifying a complicated subject.

Secondly, I wanted the book to appeal to software engineers and scientific researchers — anyone who might find quantum computing useful in their line of work. I wanted to explain the methods which they would most likely find useful to solve their particular problems. It does appear that Grover's algorithm is currently the most flexible method which might be applicable to a wide range of inverse problems.

Finally, I hoped to make the book entertaining and informative for people who have no intention of ever going near a quantum computer. If I have succeeded in that goal alone, then I will consider this book to have been a success.

APPENDIX ONE: THE ORACLE

This first appendix explains how the oracle circuit for the Grover's algorithm was designed. This is fairly complicated, so please only read it if you are interested in the gory details, and are maybe interested in extending it for your own applications.

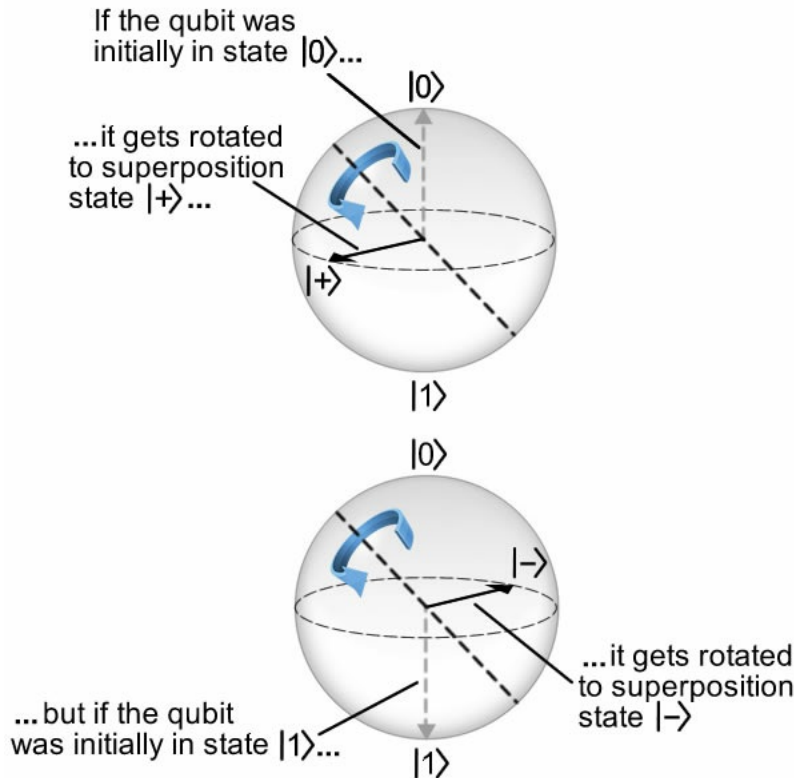

Otherwise, please skip it.

Let us remind ourselves of the oracle circuit diagram which was presented in the previous chapter:

Like all quantum circuit diagrams, we read the diagram from left to right.

You can see that the target qubit — the lower qubit — passes through the first Hadamard gate. The qubit state vector then gets rotated according to the usual behaviour of the Hadamard gate (see Chapter Eight for a reminder). So, as you can see in the following diagram, the qubit state vector gets rotated around the diagonal dashed line and thereby enters a superposition state:

But you can see from the previous diagram that the direction of the state vector in the superposition state is different depending on whether the initial state was $|0\rangle$ or $|1\rangle$. If the initial state was $|0\rangle$ (state vector pointing up), then the state vector gets rotated to a position pointing toward the left and to the front (see the previous diagram). This is called superposition state $|+\rangle$ (the "plus state"). However, if the initial state was $|1\rangle$ (state vector pointing

down), then the state vector gets rotated to a position pointing toward the right and to the back. This is called superposition state $|-\rangle$ (the "minus state").

In this playing cards example, we are passing a target qubit in state $|1\rangle$ to the Hadamard gate. So, in this case, the qubit enters the superposition state $|-\rangle$.

Expressed mathematically, the superposition state $|+\rangle$ is the usual equal mix of $|0\rangle$ and $|1\rangle$. However, the superposition state $|-\rangle$ is an equal mix of $|0\rangle$ and $-|1\rangle$ (the $|1\rangle$ now has a negative sign in front of it). That explains why this superposition state vector is pointing in the opposite direction to the usual direction.

For the next stage of the oracle, you can see that the CNOT gate is then applied to this qubit. Because the control qubit of the CNOT gate is also in state $|1\rangle$, the CNOT gate performs its usual "flipping" operation on the target qubit. This has the effect of flipping the values of the $|0\rangle$ and $|1\rangle$ terms of the state vector, changing $|0\rangle$ to $|1\rangle$, and vice versa. For a state vector in the superposition state $|+\rangle$, both of those terms are positive so flipping the terms has no effect. But for the superposition state $|-\rangle$ we have in this example, as mentioned earlier, the $|0\rangle$ term is positive but the $|1\rangle$ term has a negative sign in front of it. Therefore, flipping the two terms has the effect of placing a negative sign in front of the entire qubit state, as explained in the following diagram:

$$\begin{array}{c} \text{Initial state: } |0\rangle - |1\rangle \\ \text{Flip terms} \downarrow \\ |1\rangle - |0\rangle \\ \text{Which is the same as: } -(|0\rangle - |1\rangle) \\ \text{(i.e., the negative of the initial state)} \end{array}$$

And that is just what we have been looking for! If you remember, we wanted to find a way of inverting the state, which, as stated earlier, is the same as putting a negative sign in front of the state. And that is just what we have done with our CNOT gate.

So we have achieved the phase inversion we desired. And this phase inversion is caused when the following two conditions are true:

1. The lower of the two qubits in the circuit diagram must be in state $|1\rangle$ so that the qubit enters the superposition state $|-\rangle$.
2. The higher of the two qubits in the circuit diagram must also be in state $|1\rangle$ so that the CNOT gate does its "bit-flipping" operation.

So both input qubits must be in state $|1\rangle$ for the phase inversion to take place. And, if you remember, that is precisely how we wanted our quantum oracle to behave: we wanted our quantum oracle to perform a phase inversion ("marking" the state) when both of the input qubits are in state $|1\rangle$.

We have therefore found our quantum oracle!

APPENDIX TWO: ROTATION AROUND THE AVERAGE

This appendix describes how the "rotation around the average" quantum circuit in Grover's algorithm was designed. Once again, this is tricky stuff, so only read it if you need to.

We know how to do rotations, as we have just used the method in the quantum oracle. We will be reusing the same piece of code, and it will form the centrepiece of our new "rotation around the average". Here, once again, is the circuit diagram which performs the rotation:

Let us now extend this circuit diagram to perform the "rotation about the average".

You might think it would be a tricky calculation to find the average value of all the states, but it is actually extremely easy. An average might be considered as being halfway between two extreme values. Building on that idea, if we have two qubits, one in state $|0\rangle$ and the other in state $|1\rangle$, the half-way value would be the superposition state, halfway between state $|0\rangle$ and state $|1\rangle$. So the average, in this case, is defined by the superposition state. In fact, it can be shown that — no matter how many states you have — the average is always the equally-weighted superposition state.

So that makes things a lot easier: to perform the "inversion around the average" we need to rotate all the states around the superposition state $|+\rangle$. But there is an easier way of achieving that. Remember, if a Hadamard gate is applied to a superposition state $|+\rangle$, it gets rotated to state $|0\rangle$, as shown in the following diagram:

So we modify our circuit diagram by adding a Hadamard gate to each qubit, and then rotating every state around the state $|0\rangle$.

Actually, we don't have to rotate every state — there is an easier method. It is clear that we would get exactly the same result if we kept all the states the same, and just rotated the $|0\rangle$ state in the opposite direction. The final configuration of states would be exactly the same as if we had rotated everything around $|0\rangle$. So that is what we do: we just have to rotate the $|0\rangle$ state. [\[17\]](#)

We also need to add a couple of X gates (quantum NOT gates) because we know from our previous experience with the oracle that the circuit we used only performed the rotation when both qubits were in state $|1\rangle$, but we want the rotation to occur for state $|0\rangle$.

We end up with the following circuit to perform the "rotation around the average":

NOTES

[1] <http://tinyurl.com/ibmpunchedcard>

[2] This type of equation is called a *partial differential equation*. It means it considers the rate of change of a variable with respect to just one other, single variable — with all the other variables being held constant. In this case, it considers the rate of change of the wavefunction with respect to t .

[3] This provides the explanation for the *Born rule*, which states that the probability of finding a particle in a particular location is proportional to the **square** of the particle's wavefunction at that point.

[4] As James Cresser of Macquarie University has said: "It can also be argued that if, after performing a measurement that yields a particular result, we immediately repeat the measurement, it is reasonable to expect that there is a 100% chance that the same result be regained, which tells us that the system must have been in the associated eigenstate.", <http://tinyurl.com/jamescresser>

[10] The connection between classical spin and quantum spin was clearly revealed in an experiment by Richard Beth in 1936 in which polarised light was shone onto a pendulum — causing the pendulum to rotate.

[11] This is the principle behind one of the greatest mysteries in physics: the black hole information loss paradox. See my second book for more details.

[12] This diagram can be found in Chapter Four of the quantum computation textbook *Quantum Computation and Quantum Information* by Michael Nielsen and Isaac Chuang.

[13] That is not entirely true. There is an algorithm called *Deutsch's algorithm* which gives the correct result every time. Deutsch's algorithm was devised by David Deutsch in 1985 and was the very first quantum algorithm. Unfortunately, it does not do anything of practical use — it was merely devised to show that quantum algorithms can be faster than classical algorithms.

[14] Lov Grover, *A fast quantum mechanical algorithm for database search*, <http://tinyurl.com/lovgrover>

[15] Shor's algorithm is **exponentially** faster than the best known classical algorithm, for example 2^n , where n relates to the size of the number being factored, whereas Grover's algorithm only offers a **quadratic** speedup, for example, n squared. The squared term arises because, as stated in the text, Grover's algorithm only takes the square root of the time of a classical algorithm.

HIDDEN IN PLAIN SIGHT 11

The logic of consciousness

AVAILABLE NOW

The background of the entire image is a reproduction of Raphael's fresco 'The School of Athens'. It depicts various ancient Greek philosophers in a grand architectural setting. In the center, Plato (left) and Aristotle (right) are the focal points. Plato is shown with a white beard, wearing a red and purple robe, pointing his right index finger towards the sky. Aristotle is shown with a brown beard, wearing a blue and brown robe, gesturing with his right hand palm-down towards the earth. They are surrounded by other philosophers in various poses, some seated and some standing. The architecture features arches and classical columns.

HIDDEN IN PLAIN SIGHT 11

The logic of consciousness

This section shows the lower portion of the 'The School of Athens' fresco. On the left, a philosopher (likely Zeno or Chrysippus) is seated on the ground, leaning forward with his hand to his chin in a state of deep thought. On the right, Diogenes is reclining on the ground, wearing a blue tunic, holding a scroll. The floor is a checkered tile pattern.

APPENDIX

PREFACE

This is my eleventh book, and my second book dedicated to the subject of consciousness. My previous book on consciousness was my ninth book: *Hidden In Plain Sight 9*.

That previous book proved to be one of my most popular and best-received books. Obviously, many people are fascinated by this subject, and there is a hunger to know the answers — which is understandable.

I believe we are lucky to have been presented with a valuable tool which can help us in understanding consciousness and the workings of the mind. That tool is the computer. We are surrounded by these "thinking machines", and those machines are now starting to reach a level of complexity and sophistication which is comparable to the human brain.

When we are developing theories of consciousness, I believe we would be very unwise not to consider what we can learn from computers. Indeed, the main conclusion in this book derives not from philosophy or neuroscience, but from the research laboratory of IBM.

This book divides neatly into two completely distinct parts. The first part (spanning Chapter One to Chapter Five) attempts to understand the structure of the mind, especially the division between the conscious mind and the unconscious mind. The division seems so natural to us that we perhaps never question why our minds are divided in that manner, but surely there must be a reason.

The second half of this book — starting at Chapter Six — then takes a very different turn. The second half of this book takes the form of an epic historical saga, covering the history of logic, information, and consciousness over a 2,500 year period. And it comes to an incredibly simple conclusion about consciousness.

I hope you enjoy the journey.

THE MEDITATION CLASS

It is a glorious sunny Friday evening in late September, and instead of falling asleep drinking beer and watching the telly, I am going out for the night. I have signed-up for a ten-week course on meditation as part of my city's adult learning programme.

One reason for attending the meditation course was that I hoped it would provide a valuable new perspective for my research into consciousness. But another reason was that I had decided that I was becoming a boring old science nerd and I needed to open my mind to Eastern influences and get in touch with my inner chakra (no, I have absolutely no idea what a "chakra" is).

But I had another reason to attend the course. In retrospect, I was rather disappointed with one aspect of my previous book on consciousness. I felt I had written the book without giving a proper description or analysis of what consciousness actually is. I had blithely stated that consciousness was a "feeling", and that it was hard to define. In particular, I felt it was an omission to write an entire book on consciousness without seriously examining my **own** consciousness.

Hopefully, the meditation course was going to give me some answers — or, to be more precise, it was going to help me find the answers in myself.

And so I found myself on Friday night in a large room in a community centre in my home town. Most of the students had already arrived. I counted twelve women, the female instructor, and me — the only bloke. The room was full with tables which we had to move to the sides and then form a circle of chairs in the middle of the room. Another bloke arrived — what a relief.

The first ten minutes of the session were dynamic and highly productive — the tea was made. Once we all had a cup of tea, we settled down and the instructor began the class.

I was impressed by the instructor, who seemed very knowledgeable about the subject. She explained that meditation was invented in India as part of the Hindu religion, before being adopted by the Buddhists, but she was going to present a secular version. She described meditation as "a tool to investigate the mind", and provided a quote from Swami Rama, an influential Indian yogi: "From childhood onward, we have been educated only to examine and verify things in the external world. No one has taught us how to look within, to find within, and to verify within."

This sounded precisely what I wanted to do: I wanted to look inside myself in order to obtain insights into the nature of consciousness.

In other words, I wanted to perform *introspection*.

Introspection

"Introspection" is a word which we use in everyday conversation, but it is the correct term to describe a psychological research technique. Introspection is the method which involves "looking inside" at one's own conscious thoughts and feelings. In that way, it is possible to gain an understanding of the workings of the mind.

The first modern use of the term and technique took place at the end of the 19th century by the German psychologist Wilhelm Wundt, one of the founders of modern psychology.

Here is a photograph of Wilhelm Wundt:

Wundt's experiments involving introspection were performed under strict laboratory conditions. Wundt trained people to make accurate and objective observations of their conscious experience. However, Wundt's work was criticised on the basis that maybe the subjects of the experiments could not be trusted to accurately recount their own feelings.

Because of these difficulties, by the turn of the 20th century, introspection — and its preoccupation with "feelings" — was falling out of fashion: it was not considered to be scientific enough. In its place came *behaviourism*. Behaviourism considered human and animal behaviour, connecting that behaviour with states of the mind.

The most famous example of behaviourism is Ivan Pavlov's experiment with dogs in the early 20th century. Every time Pavlov rang a bell, a dog was given some food. This would be accompanied by the dog salivating, which was a reflex action. In time, the dog began to connect the stimulus (the ringing of the bell) with the reward (the provision of food). This connection was so strong that the dog salivated every time the bell was rung — even when no food appeared. Hence, Pavlov had revealed that a reflex action (the salivation) could be learnt.

Behaviourism suggests that all our behaviour is learnt behaviour. If we take a particular course of action, and that course of action turns out to be successful, or we get a reward, then we are more likely to take that same course of action in the future. In that way, behaviourism suggests that we are like robots — always taking the decisions which we believe will bring us the greatest reward. We are all under the impression that we have free will, but maybe we are just behaving like one of Pavlov's dogs!

For an example of behaviourism in action, see the episode of *The Big Bang Theory* entitled *The Gothowitz Deviation*. You can view the relevant extract from the episode on YouTube here: <http://tinyurl.com/sheldontraining>.

In the episode, Sheldon and Leonard are sitting on their sofa enjoying watching a Japanese animation entitled *Oshikuru: Demon Samurai*. Penny is unimpressed with the animation, and repeatedly annoys Sheldon with her jokes about her schoolfriend who had three nostrils. However, Sheldon is aware of behaviourism theory, and realises he can improve Penny's behaviour by using *positive reinforcement*, rewarding her with chocolate whenever she behaves correctly.

Apparently this *Big Bang Theory* episode is recommended viewing in some psychology classes.

At all times during the episode, Penny was under the impression that she had free will. However, that was clearly an illusion as her behaviour was deterministic: at all times she was following the path which led to the greatest reward.

One of the themes of this book will be that — although we feel as though our thoughts are completely free and unconstrained — many of our thought processes are actually following strict, predictable rules. And we can use that fact to our advantage when we attempt to detect consciousness.

As far as the psychologists were concerned, the obvious attraction of adopting behaviourism rather than introspection was that behaviour can be clearly measured, predicted, and objectively observed — whereas feelings cannot be measured by an external observer. Also, behaviourism could be used to study animals (try getting a chimpanzee to tell you how it feels and you will quickly discover the limitations of introspection). Suddenly,

psychology could be studied scientifically and no one wanted to talk about internal consciousness any more. Behaviourism became the dominant approach to psychology in the mid 20th century.

However, gradually, there emerged a disenchantment with behaviourism. It is a very limited and unsatisfactory approach just to consider the inputs and outputs of a system (the brain) without ever wondering about what goes on inside. We will be seeing in Chapter Five how introspection has made a recent comeback, and has proven to be an essential technique in the new science of consciousness.

But, for now, let us return to the meditation session ...

The stream of consciousness

Back in my meditation session, the instructor then started to explain the goals of meditation.

The main goal appeared to be to clear your mind of thoughts. The resultant clarity would then allow you to examine the true core of your being — without being distracted by the constant clamour of thoughts: "Did I leave the cooker on?", "What's the weather going to be like tomorrow?" Many of these thoughts deal with matters which are external to ourselves, and are often outside of our control. In other words, those type of thoughts are not a unique part of our individual minds: everyone worries if they have left the cooker on, everyone wonders what the weather will be like tomorrow. It would therefore appear to be essential to banish these general distracting thoughts during a meditation session.

So this seems like a good moment to examine in closer detail a question which seems very fundamental to consciousness. The question is: what is a "thought"?

In 1890, the American philosopher and psychologist William James wrote a book entitled *The Principles of Psychology*, which has been described as the most famous book in the history of psychology. In his book, James popularised the phrase "the stream of consciousness" to describe a thought process in the mind: "Consciousness, then, does not appear to itself chopped up in bits. Such words as 'chain' or 'train' do not describe it fitly as it presents itself in the first instance. It is nothing jointed; it flows. A 'river' or a 'stream' are the metaphors by which it is most naturally described. In talking of it hereafter let us call it the stream of thought, of consciousness."

However, when we talk about a "stream of consciousness" nowadays, we are more likely to be using the term when referring to a completely different field of interest. And that is because William James had a brother, the famous novelist Henry James.

Henry James had an experimental style, and attempted to describe the internal minds of his characters. James realised that our internal train-of-thought is usually formed out of conversational English. For example, in order to decide whether or not to make a shopping trip in the evening, we might literally think the phrase: "Should I go to the shops? Oh, the car's got no petrol." It is this type of highly-informal *inner monologue* that can be captured and written-down word-for-word in order to express the thoughts of characters in a novel. This is then known as a literary stream of consciousness.

This has now become a standard literary method, but it was a radical step when Henry James used it for the first time in his book *Portrait of a Lady* in 1881. However, the technique is most famously associated with the Irish novelist James Joyce's epic novel *Ulysses*. *Ulysses* was released in 1922 and is regarded as being a classic of modernist experimental fiction. The book tells the tale of one man, Leopold Bloom, as he travels around Dublin in a single day. Joyce accurately captures the inner thoughts of the characters in the book.

Here is an extract from *Ulysses* showing Molly's stream of consciousness as she tries to fall asleep at night. Note that it appears continuous and fractured, constantly switching between different lines of thought, an accurate representation of the stream of thoughts in our mind: "Let me see if I can doze off 1 2 3 4 5 what kind of flowers are those they invented like the stars the wallpaper in Lombard street was much nicer the apron he gave me was like that something only I only wore it twice better lower this lamp and try again so that I can get up early."

One thing we can notice from Molly's stream of consciousness is that it is continuous with no gaps — Joyce did not even include any full-stops. This characteristic feature of our thoughts was mentioned by my meditation instructor who described how our minds are occupied with a succession of thoughts: no sooner does one thought end, then another one starts. From the comments of the other attendees in the meditation course, I got the impression that most people there were trying to escape that clamour of continuous thoughts in their heads.

Ulysses is notorious for being a difficult read, but there is perhaps a simpler example of a stream of consciousness. In comic books, verbal communication between two characters is graphically represented by the usual speech bubble. However, the inner monologue of a character is represented by a *thought cloud*:

The thought cloud forms a perfect example of a stream of consciousness.

And this graphical use of a cloud to describe a thought is highly revealing. Intuitively, we have a feeling that our thoughts somehow inhabit a "higher realm" which is insulated from the physical world — just as a cloud exists at a higher level from the physical ground we inhabit.

If we close our eyes and meditate, we can travel anywhere in a fraction of a second. We can travel to the Moon and back faster than the speed of light. In our imagination, the laws of physics no longer apply. We are insulated from the rules and the confines of the physical world. The thought cloud in a comic book is therefore a perfect representation of how our consciousness feels.

And there is something else we can learn from this discussion about our stream of consciousness ...

If our internal stream of consciousness employs a language such as conversational English, then that has implications. Because languages have rules. The English language has strict rules of grammar. Those rules of grammar determine the structure of the sentences in our minds. Our internal monologues might be rather informal, and might sometimes not be much more than the fragments of sentences, but those sentence fragments would still follow the rules of grammar.

Considering the example presented earlier, we might think internally: "Should I go to the shops? Oh, the car's got no petrol." But we would never think to ourselves: "Should I **gone** to the shops? Oh, the car's got **none** petrol."

This is important because it reveals something profound about our thoughts. We like to think of our thoughts as being free, completely unconstrained. But this discussion has revealed that our thoughts follow rules, to some degree. And this will be a recurring theme in the later part of this book: our thoughts follow rules. And we will discover that those rules of thought follow a series of ancient principles which are even more fundamental and unbreakable than the rules of the English language.

The meditation session

Back in the meditation class, the meditation session was about to begin.

The instructor explained that meditation is normally performed by sitting on the floor in a cross-legged position. But, frankly, my knees aren't what they were, and we didn't fancy all that getting up-and-down, so we decided we would do it sitting on our chairs.

We were told to sit with our backs straight so that the "energy" could pass up and down our spine (was that potential energy or kinetic energy? I thought it wise not to ask). We then had to place our palms on our knees, and close our eyes.

It was explained that the purpose of meditation was to clear our thoughts, while still remaining aware. So, while our eyes were closed, we were still aware of our breathing, and our hands on our knees, and that extremely uncomfortable wooden chair which was pushing up into my bum. The chair had about a millimetre of foam padding on it. It's not easy trying to clear your thoughts when your bum is in agony.

But eventually I did relax.

The first thing I noticed as soon as I closed my eyes was that I was transported somewhere else. The act of closing my eyes had broken my tie with my current physical location, and — in my mind's eye — I now saw that I was in a local amusement park by the sea which I used to visit as a child. Of course, I knew I was not really there, but I experienced an internal mental image of the scene so that I felt I was there.

You might want to try this yourself. Sit down comfortably, close your eyes, and after a few seconds you forget where you are and you will probably experience a mental image of a different location. I suspect that the location will be somewhere you know very well, possibly somewhere you know from childhood. In other words, this is probably a pleasant location you have revisited in your mind many times, with the result that the visual scene has been burnt into your mental imagery — like the screensaver on a CRT screen.

What appears to be happening is that — in the absence of the continued sensory input from your eyes — your brain forgets about your current location and it retrieves a strong visual image from memory.

At this point, I still found I had thoughts racing through my mind. These resembled the random stream-of-consciousness of *Ulysses*. But meditation requires a mind free of such thoughts. The problem, though, is that it is very hard to not think of something. As the Russian novelist Fyodor Dostoevsky said in an essay in 1863: "Try to pose for yourself this task: not to think of a polar bear, and you will see that the cursed thing will come to mind every minute."

In 1987, David Wegner, a psychology professor at Harvard university, decided to test Dostoevsky's claim. Wegner's experiment was described in an article for the American Psychological Association: "He decided to test the quote's assumption with a simple experiment: he asked participants to verbalize their stream of consciousness for five minutes, while trying not to think of a white bear. If a white bear came to mind, he told them to ring a bell. Despite the explicit instructions to avoid it, the participants thought of a white bear more than once per minute, on average." [\[1\]](#)

So, trying to force thoughts out of your head does not work. Instead of trying to force the thoughts, you just have to ignore them and let them drift away. Susan Blackmore and Emily Troscianko have written a book entitled

Consciousness: An Introduction in which they devote a large section to meditation. They explain the required approach: "Unwanted thoughts may be held at bay temporarily, but then they come back with greater force, or change into other more persistent thoughts, or set up emotional states that keep reigniting them. The answer is not to fight against thoughts but to learn to let them go."

So that is what I tried to do. And then it happened ...

... I came to the realisation that I had not had any thoughts for the last five seconds.

My stream of consciousness — my inner dialogue — had briefly stopped. The only content of my conscious mind over that short period was that mental image of the amusement park. Other than that, my conscious mind contained no thoughts.

Also, interestingly — and perhaps significantly — I was no longer conscious of my sore bum.

However, even in that state of a clear conscious mind, we are still able to respond to external stimuli. For example, when the instructor started to talk, I immediately snapped-back to the present time and place.

We were then told to rub our eyes, and slowly open them. At that point, I was no longer in the amusement park — I was back on my chair in the circle with my fellow students.

And, once again, my bum was sore.

2

THE CONSCIOUS MIND AND THE UNCONSCIOUS MIND

I found my time at the meditation class to be a very valuable experience. At the end of the course, I thanked the instructor, and said goodbye to some lovely people. I am sure that they — like me — had discovered some new truths about themselves.

But then I was faced with the task of making sense of my experiences at the class. What had I learnt about myself, and how my mind works? Had introspection proven to be a good method for uncovering the secrets of consciousness?

Well, considering the meditation session, firstly it was clear that we have a conscious mind — fairly obviously. This is the part of the mind which we consider our "self", the part of the mind which hosts our conscious thoughts. This stream of thoughts takes the form of an inner monologue — our "stream of consciousness" as described in *Ulysses* and in the previous chapter.

However, even though our conscious mind hosts that stream of thoughts, it was also clear from the meditation session that it is possible — though difficult — to relax and to clear our conscious mind of that stream of thoughts for a short period of time.

But even though it is possible to clear the conscious mind of thoughts, that does not mean the mind as a whole is inactive. Far from it. Even though I had my eyes shut and my conscious mind was clear, when the meditation tutor started talking again I was immediately made aware of the talking and it snapped me back to reality. It was clear that a part of my mind must have been constantly scanning all sensory inputs (sound, vision, etc.) for any important signals.

But there were other sounds in the room as well. The clock was ticking. There was road traffic outside. But these unimportant signals did not gain access to my conscious mind. Also, my bum was sore from the hard chair, but when my conscious mind relaxed and cleared, I was no longer conscious of the hard chair. You might argue that the sound of the clock ticking and the sound of the road traffic were not sufficiently strong stimuli to enter my conscious mind, but I can assure you that my sore bum was producing a sufficiently strong stimulus.

So why did some sensory signals enter my conscious mind, while some strong signals got filtered-out? What part of my mind was doing the filtering?

It was clear that it was not my conscious mind that was doing that continuous scanning — I was not consciously thinking "Don't listen to the clock, forget about the hard chair". So what part of my mind was active?

It is now widely accepted that these tasks — which do not involve the conscious mind — are performed by the *unconscious mind*. Even if your conscious mind is clear, your unconscious mind does not rest. It is your unconscious mind which is constantly filtering the multitude of input sensory signals to detect any important signals, and only passing those signals to the conscious mind. Your unconscious mind is also responsible for intuition, and generating flashes of inspiration and creativity, passing those ideas up to the conscious mind for conscious evaluation.

Further evidence for the existence of the unconscious mind comes from hypnosis. In order to place a person into a hypnotic trance, the person must be in a carefully-controlled calm environment in which the conscious mind can be completely relaxed. For example, the hypnotist might say soothing words, or capture attention by spinning a pocket watch. Perhaps you have noticed that you have entered a similar trance-like state when driving a long distance on a straight road. That is another example of the conscious mind becoming completely relaxed, with the unconscious mind taking over control.

Once the subject's conscious mind is relaxed, and the subject is in a trance, the hypnotist can then communicate directly with the subject's unconscious mind. A suggestion can then be placed into the unconscious mind. For example, the subject might be instructed to perform a dance when the hypnotist clicks his or her fingers. When the hypnotist later clicks their fingers, the subject will, indeed, start to dance — although the subject will have no conscious understanding of why they are dancing. In this case, the suggestion from the unconscious mind overwhelms the control of the conscious mind.

The conscious mind is responsible for controlling the urges and instincts which rise up from the unconscious mind. This explains why subjects in a hypnotic trance can behave in a uninhibited and playful manner, with

behaviour no longer being filtered by the conscious mind. When the unconscious mind is given free rein, the subject can feel liberated and more creative.

Hypnotherapy is a form of psychological therapy in which fears, negative thoughts, and phobias can be eliminated by using hypnosis. As many of these problems arise from the unconscious mind, hypnosis can be used to reprogram the unconscious mind and eliminate the problem.

The unconscious mind is also the storehouse for all our long-term memories. By accessing the unconscious mind during hypnosis, it is possible to revisit past events that the subject might have forgotten. It is then possible to resolve long-term psychological problems.

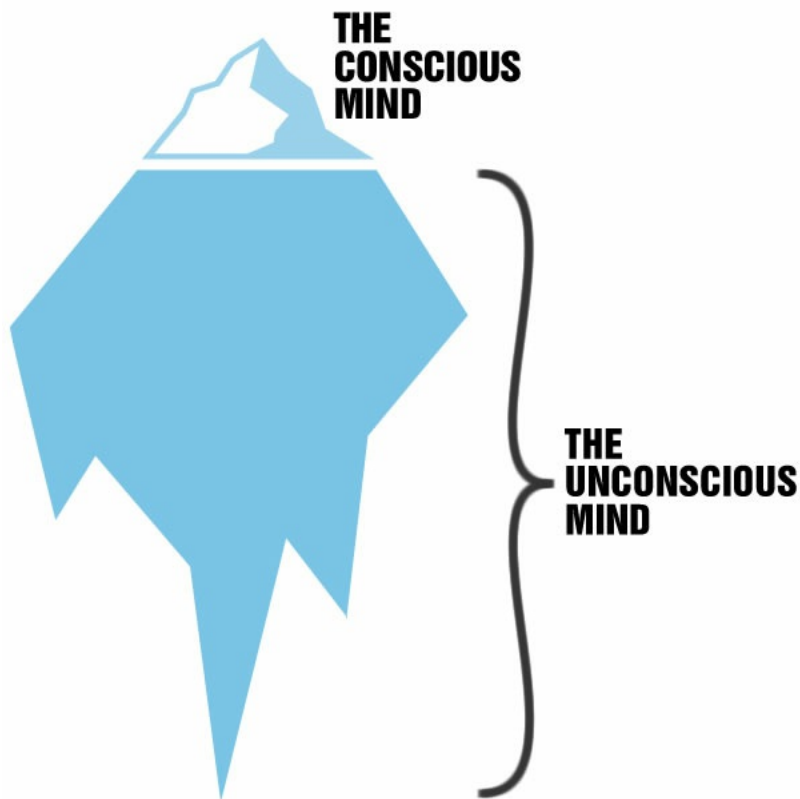

Another example of the power of the unconscious mind is provided by *subliminal images*. You may already be aware of subliminal images because of their controversial use in advertising. Subliminal images are images which are flashed very briefly before disappearing. The period of visibility is so brief (less than 80 milliseconds) that these images or words do not register with the conscious mind — the subject undergoing the experiment denies having seen the words. However, the words have been processed by the unconscious mind, and that is enough to modify behaviour — maybe even persuading the viewer to buy a particular product. For this reason, subliminal advertising has been illegal in the USA and the UK since 1958.

In psychology, this technique of modifying behaviour by presenting a subliminal image is called *priming*. Studies of priming are valuable for determining the extent of the influence of the unconscious mind. It is clear that, although we like to think that our decisions are wholly made by our conscious mind, the truth is that our decisions are often based on suggestions from our unconscious mind.

We shall return to consider subliminal images and priming in the next chapter.

It is clear that the unconscious mind is extremely powerful, and that its power is generally underestimated. It was Sigmund Freud who popularised the notion of the unconscious mind. Freud described the great power of the unconscious mind by using a metaphor. Freud compared the conscious mind to the "tip of an iceberg", with the conscious mind being the small, visible portion of the mind with the far larger unconscious mind lying unseen beneath the water. According to Freud: "The mind is like an iceberg: it floats with one-seventh of its bulk above water".

The following diagram shows Freud's iceberg metaphor, with the conscious mind represented as the "tip of the iceberg":

"Access" and the conscious mind

We might ask, what is the distinguishing feature of the conscious mind? In other words, what is it that distinguishes the conscious mind from the unconscious mind?

Well, in psychology, philosophy, and in consciousness research, conscious thoughts are described by the term "access". If we are able to use a particular concept or information in our conscious train-of-thought then it is said that we have "access" to that concept. In other words, we are able to use that object in our conscious reasoning processes.

For example, you have access to the thoughts that represent your car, or the printed letters on this page, or your intended holiday destination. You have access to any thought or information which you can bring to the foreground of your mind for conscious processing.

And you have access to each step of any conscious thought process. That means you have complete visibility of each step, how you proceeded from some initial knowledge, through a step-by-step reasoning process, toward a conclusion. In your conscious mind, you have complete access — complete visibility — of each step.

The term "access" might appear to be rather a peculiar term to describe the conscious mind (well, I find it rather peculiar). But its use perhaps becomes clearer when we move on to consider the unconscious mind. That is because the unconscious mind is very clearly defined by its **lack** of access.

Our conscious mind continually receives ideas and intuitions from the unconscious mind. But those ideas arrive fully-formed, carrying no information about how those ideas were generated. For that reason, it is often said that ideas arrive "out of the blue". What this means is that we possess no access — no visibility — on how the unconscious mind has generated those ideas. While we have access to each step of our conscious thought processes, we have absolutely no access to each step of our unconscious thought processes — we only receive the results of those processes.

Returning to consider Freud's iceberg metaphor, the unconscious mind lies under the surface of the ocean in the murky depths — we cannot see its workings. However, ideas constantly bubble-up to the surface, from the unconscious mind to the conscious mind. When we say an idea arrives "out of the blue", we might well mean "out of the blue unconscious ocean".

The unconscious mind is therefore defined as that part of the mind which the conscious mind cannot access.

As a brief detour, I would like to introduce a couple of concepts and some terminology which is in common usage in philosophy and consciousness research.

In an influential 1995 paper, the philosopher Ned Block suggested that our conscious experiences could be classified into two groups.^[2] Firstly, Block suggested the existence of one class of conscious experience called *access consciousness*. As just described in this section, access consciousness is the thought processes we can access in our rational thinking. Access consciousness would therefore represent the near-constant stream of thoughts which flow through our minds.

Secondly, Ned Block suggested the existence of a second classification of conscious experience which he called *phenomenal consciousness*. Phenomenal consciousness is our general awareness of feelings and sensations.

In the meditation session, when I successfully eliminated my stream of conscious thoughts (my "access consciousness"), what was left was my phenomenal consciousness — my general awareness of sensations.

These two terms — access consciousness and phenomenal consciousness — seem to have received fairly wide acceptance in consciousness circles, though the idea remains controversial.

Thinking, fast and slow

In 2011, Daniel Kahneman released his book *Thinking, Fast and Slow*. Kahneman is a professor of psychology at Princeton University and has been described as being the world's leading psychologist. In 2002, Kahneman was awarded the Nobel Prize for Economics (yes, economics is basically psychology).

Thinking, Fast and Slow became a publishing sensation, and has sold over one-and-a-half million copies. The

book was that rarest of things: a bestselling and entertaining book aimed at the general public, but it is also a book which is considered to be a major contribution to its field. That combination of achievements represents the Holy Grail of science writing.

Thinking, Fast and Slow proposes that there are two different types of thought process which Kahneman calls System 1 thinking and System 2 thinking. System 2 thinking is slow, deliberate, and accurate, and is used for making decisions, solving problems, and planning. In contrast, System 1 thinking is fast and intuitive, but not as reliable.

What makes Kahneman's proposal so interesting from the point-of-view of this book is that he associates the slow and deliberate System 2 thinking with the conscious mind, while he associates the intuitive System 1 thinking with the unconscious mind.

Kahneman makes the connection between System 2 thinking and consciousness explicit when he states: "When we think of ourselves, we identify with System 2, the conscious reasoning self that has beliefs, makes choices, and decides what to think about and what to do."

Kahneman then associates System 1 thinking with the unconscious mind when he says: "System 1 runs automatically. System 1 continuously generates suggestions for System 2: impressions, intuitions, intentions, and feelings."

Also, Kahneman associates System 1 thinking with lack of access, which is what we would expect from the unconscious mind: "Phenomena arise in System 1, and you have **no conscious access** to them."

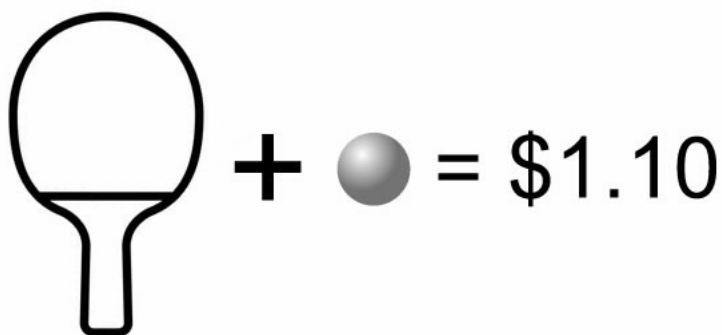

Kahneman's theory is one example of what are known as *dual-process theories*. Dual-process theories split our thought processes into two categories, and these can be associated with the conscious mind and the unconscious mind. In their book *Consciousness: An Introduction*, Blackmore and Troscianko describe this association: "These theories can come in many forms, applying to memory, learning, or decision-making, but most suggest that one process is fast, automatic, inflexible, effortless, and dependent on context, while the other is slow, effortful, controlled, flexible, requires working memory, and is independent of context. **The two kinds of process map easily onto a distinction between unconscious and conscious processes.**"

Kahneman explains that, in general, we rely on System 1 thinking (unconscious thinking) to get us through the day. Even though System 1 thinking is not as sophisticated as System 2 thinking, it is sufficient for most tasks we encounter: "When all goes smoothly, which is most of the time, System 2 adopts the suggestions of System 1 with little or no modification. You generally believe your impressions and act on your desires, and that is fine — usually."

One of the big advantages of System 1 thinking is that it is fast — faster than System 2 thinking (hence the title of the book: *Thinking, Fast and Slow*). As a result, System 1 thinking can respond quicker to external events, with no need to invoke the laborious and time-consuming problem-solving capabilities of System 2 thinking. However, as Kahneman reveals using entertaining examples, the lack of sophistication of System 1 thinking can introduce problems which include inaccurate and misleading assessments, bias, and a tendency to stereotype.

An example of these two modes of thought comes from considering the following example of simple arithmetic, considering the prices of a table tennis bat and a ball. Try and respond to the question quickly:

A bat and a ball together cost \$1.10. The bat costs \$1 more than the ball. How much does the ball cost?

You have might have quickly responded that the bat costs a dollar and the ball costs ten cents. But if you had taken a bit more time then you would have realised that could not possibly be the correct answer: if the ball costs ten cents, and the bat costs a dollar more than the ball, then the bat costs \$1.10. In which case, the total cost of the bat and ball would be \$1.20, which is the wrong total amount.

If you were given more time to consider the example in detail, you could then employ your conscious skills in

mental arithmetic and calculate the correct answer, which is that the ball costs just five cents and the bat costs \$1.05. Kahneman describes the puzzle: "The distinctive mark of this easy puzzle is that it evokes an answer that is intuitive, appealing, and wrong."

If you responded quickly and you gave the wrong answer, do not be too worried. More than half of the students from Harvard, MIT, and Princeton who attempted the problem gave the wrong answer initially.

According to Kahneman, our initial incorrect calculation was performed by our intuitive System 1, which did not engage our conscious thought processes. Remember, System 1 is faster and more instinctive. According to Kahneman, it was only when we engaged our System 2 conscious thought processes — our mental arithmetic abilities — that we were able to calculate the correct answer. System 2 is not "always on", but it is available for use when required.

As another example, consider the following optical illusion and make a quick decision as to which horizontal line is longest. Is the top horizontal line longer, or is the bottom horizontal line longer:

If you said that the bottom line is longer — well done. The bottom line is, indeed, 5% longer than the top line. However, I suspect you might have been fooled by the phrase "optical illusion" into thinking that the lines were actually the same length — as in the case of the well-known optical illusion.^[3] If so, then your System 1 thinking would have been responsible for fooling you. If you had been able to spend more time inspecting the problem, and had engaged your slower and more analytical System 2 thinking, I suspect you would have realised that the lines were different lengths (use a ruler to measure the two lines if you do not believe me).

In this chapter we have discovered that the mind appears to be split in two: a conscious mind, and an unconscious mind. But why is there this split? The structure of our mind seems so natural to us that we perhaps never consider why our minds have this divided structure. Perhaps it is hard to comprehend that a mind might be structured differently.

But surely there must be a reason for this structure. Let us ask the difficult question: Why is our mind divided into two parts, a conscious mind and an unconscious mind?

Surely Kahneman's description of System 1 thinking and System 2 thinking provides us with a valuable insight into the different structures of the conscious mind and the unconscious mind. In particular, why should the conscious mind be slow? And why should the unconscious mind be fast? In other words, why is there *Thinking, fast and slow*?

In the next chapter, we will be considering a possible solution to this mystery ...

... and the answer comes from computing.

3

THE BRAIN AS A COMPUTER

At the start of this book, it was explained how behaviourism became the dominant approach to psychology in the mid 20th century. The appeal of behaviourism was that behaviour can be clearly measured, predicted, and observed. It therefore turned psychology into an objective science — something that you could measure, together with experiments that provided quantitative results.

It is therefore easy to understand the appeal of behaviourism. But these attractive features of behaviourism also became its weaknesses. Behaviourism treated the mind as a "black box", only considering its inputs and outputs. The example was presented earlier of Pavlov's dogs: ring the bell, and note the salivation of the dog. The inputs and outputs can be clearly measured. However, if the mind is being treated like a black box, then that implies that you are no longer attempting to discover the internal workings of the mind. And it is that limitation of behaviourism which started the decline in its popularity.

There is an old joke which is intended to reveal the weakness of behaviourism. The joke concerns a behaviourist who observes the behaviour of other people, but refuses to use introspection to investigate his own mind. As a result, after having sex, the behaviourist says: "That was great for you, how was it for me?"

And so it was, in the 1960s and 1970s, a new method of understanding the internal workings of the mind emerged. The catalyst for this new approach was the emergence of the computer.

Computers process information, taking information as input, processing that information in some way, maybe storing some information in its memory, and then producing modified information as output. It was realised that the brain works in exactly the same way, obtaining information through our eyes and ears, processing that information, maybe storing some of that information to memory, and then producing an output in the form of our actions or speech.

The new approach to understanding the mind was therefore based on treating the mind as an information processor. Just as we have an understanding of the individual processes which occur inside a computer, so it became possible to speculate about the processes which exist inside the mind.

This approach which treats the mind as an information processor is called *cognitive psychology*. This major change of direction in psychology which took place in the 1960s and 1970s has been called the "cognitive revolution". You may have heard of "cognitive behavioural therapy" (CBT) which is an attempt to remedy irrational thought processes by developing new information-processing skills. In essence, CBT attempts to "reprogram" the mind in the same way as you would reprogram a computer.

Let us now consider how information is processed in the mind — by comparing the way information can be processed in a computer.

Serial processing

In computing, there are two fundamentally different methods of information processing. Firstly, there is *serial processing*. A serial processing approach to computing involves each instruction of an *algorithm* being performed one after another in sequence. An algorithm is a description of the step-by-step process needed to solve a problem. This is how we intuitively think of a computer program, and if you have done any computer programming yourself then you will have used this method of serial processing.

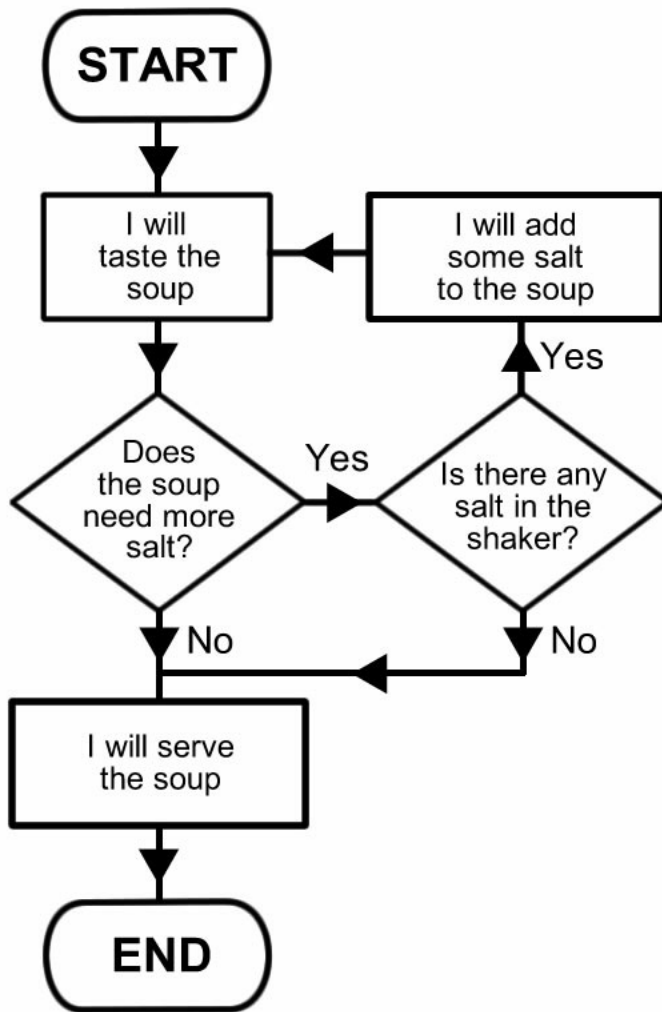

The following block diagram shows a serial processing operation composed of three tasks performed one after the other:

Note that there is a single stream of processing. In computing terminology, it would be said that there is a single *thread* of execution.

Serial processing has to be used to solve any problem in which the execution of each task depends on the execution of a previous task. This requirement forces the tasks to be performed in a certain order, and prohibits the possibility of running more than one task at once.

However, that restriction does not necessarily mean that the tasks have to be performed in a strictly linear order (as shown on the previous diagram). There can be branches and decisions, the outcome of those decisions changing the direction of processing. This can be seen by considering a computer *flowchart*. The following flowchart represents the steps which might be taken by a cook who is adding salt to soup. Note that the flowchart includes two decision boxes which take the form of diamond-shaped boxes:

It is clear from this particular example that a flowchart can be used to represent a conscious thought process — a stream-of-consciousness. This particular flowchart would represent the stream-of-consciousness of a cook who is adding salt: "Does the soup taste like it needs more salt? Oh yes, it does. I better add some more salt. Oh dear, there's no more salt in the shaker! Never mind, I'll serve it as it is."

We each have one, single train of thought. And just as we have a single stream-of-consciousness (we never talk of the plural: **streams** of consciousness) so there is only ever one thread of execution in serial processing.

The need for this single thread of execution in our mind arises because real-world problems generally require a step-by-step solution in which tasks must be performed in a particular order. For example, trying to build a house (the walls must be constructed before the roof), or any attempt to solve a complex puzzle. Considering purely mental examples, solving a problem of mental arithmetic, or any form of logical reasoning also requires a step-by-step process. And all of these step-by-step processes represent examples of serial processing.

This suggests that **our conscious thought process is a form of serial processing**. Put simply, we can only think of one thing at once, which inevitably represents serial processing.

In his book *Consciousness and the Brain*, Stanislas Dehaene makes a direct connection between our conscious thoughts and serial processing, and uses an example from mental arithmetic to illustrate the connection: "In humans at least, consciousness gives us the power of a sophisticated **serial computer**. For instance, try to compute 12 times 13 in your head. Did you feel each of the arithmetic operations churning in your brain, one after the other? Can you faithfully report the successive steps that you took, and the intermediate results that they returned? The answer is usually yes; we are aware of the **serial** strategies that we deploy to multiply."

And, as we shall now see, this serial processing conscious train-of-thought is even more remarkable in that it is not representative of how the majority of the brain operates ...

The parallel processing of the unconscious mind

There is an alternative to serial processing. If the execution of a task does not rely on the execution of a previous task, then it becomes possible to process each of the individual tasks **at the same time**. This approach is called *parallel processing*. The great advantage of parallel processing is that it is faster than serial processing. Obviously, performing many tasks simultaneously is going to be faster than performing those tasks one at a time.

The following block diagram shows parallel processing:

So let us recap what we have discovered so far.

Serial processing is relatively slow, but it has to be used for processing in which the execution of one stage relies on the execution of a previous stage. There has been a suggestion that our conscious thought processes use serial processing. Parallel processing is an alternative which is very much faster if the problem can be divided into independent tasks.

So there are two types of processing in computing: one type fast, one type slow. What does that remind you of? I hope it reminds you of the title of Daniel Kahneman's book *Thinking, Fast and Slow*. Bearing that in mind, could we associate slow serial processing with Kahneman's conscious System 2 thinking, and associate fast parallel processing with Kahneman's unconscious System 1 thinking?

Is that the case? I believe to a large extent, yes, that is correct. And in this section reasons will be presented — apart from the processing speed argument already presented — for why that appears to be true.

In the previous section, it was explained how our conscious mind could be associated with serial processing. If that is the case, then why should we associate our unconscious mind — the majority of the brain — with parallel processing?

Let us examine the evidence.

The first evidence comes from examining the hardware of the brain. Put simply, the brain by its very nature is a huge parallel processing machine. Multiple patterns of activated neurons occur simultaneously across the brain. It is this vast parallelism which is the source of the power of the brain. Put simply, the brain can process many things at once.

This, then, fits the "iceberg" metaphor: the unconscious mind forms the majority of the brain (the bulk of the iceberg, under the ocean), and the majority of the brain is parallel.

In a paper entitled *In the Theater of Consciousness*, Bernard Baars refers to this parallel processing of the brain and the "largely unconscious" nature of that parallel processing: "The brain is massively parallel — many things are happening at the same time — largely unconscious in its details." [\[4\]](#)

More evidence for making this connection comes from considering how clever ideas and solutions are generated and enter our conscious mind. We receive ideas and solutions from our unconscious mind all the time. Those unconscious thoughts which bubble-up can often be ingenious solutions to problems, solutions which surely could only have been produced by the unconscious mind considering a wide range of alternative solutions. And sometimes the unconscious mind can come up with creative ideas, strange connections between apparently completely different concepts which could only have arisen by the unconscious mind considering a wide range of alternative connections. In other words, in all these cases of ideas and solutions, we find an unconscious mind which is constantly doing many things at once, considering many ideas or many solutions **at the same time**.

We are all aware of the great power of our unconscious mind, and that power surely comes from parallel processing.

The psychologist Saul McLeod has presented an example of a human typist using thought processes based on parallel processing: "Parallel processing is probably more frequent when someone is highly skilled; for example, a

skilled typist thinks several letters ahead." [5]

This is an example which links parallel processing and the unconscious mind. The typist thinks several letters ahead, which, as the quote states, represents a form of parallel processing. But, at the same time, the typist is unaware of that forward thinking — it is an unconscious process.

Another example of the parallel processing of the unconscious mind was provided by a paper published in 1980 by the English psychologist Anthony Marcel.[6] Marcel's work used subliminal images. As described in the previous chapter, subliminal messages are words which are flashed so briefly that they do not register in the conscious mind. But even though the conscious mind is completely unaware of the messaging, it can still influence behaviour. As mentioned in the previous chapter, this technique is called "priming".

In his paper, Marcel presented a series of subliminal words to a subject. The words were specially chosen to have multiple meanings. For example, the word "palm" might mean a part of a hand, or it might mean a type of tree. In that case, Marcel discovered that the unconscious mind primed for **both** meanings of the word. This meant that the later behaviour of the subject showed favourable bias both towards hands **and** towards trees. This showed the unconscious mind working in parallel, processing two meanings at the same time. In fact, in his paper, Marcel proposed that all possible meanings were processed simultaneously by the unconscious mind: "apparently both meanings were accessed, irrespective of context. It is argued that unconscious perception ... is of **unlimited capacity** and precedes conscious perception."

Yes, in that quotation Marcel even suggests that unconscious perception is of "unlimited capacity" so could potentially process **all** meanings of words — no matter how many meanings a particular word might have. This reveals the remarkable parallel processing capacity of the unconscious mind. Stanislas Dehaene also considers this result in his book *Consciousness and the Brain*, emphasising the parallel processing capability of the unconscious mind: "Thus our unconscious mind is clever enough to store and retrieve, **in parallel**, all the possible semantic associations of a word."

Parallel processing is also ideal for the unconscious filtering of sensory input. We can imagine how this might have arisen via evolution. Imagine ancient man roaming the African savannah many millennia ago. As he leisurely walks a great distance, he is relaxed, and his conscious stream-of-thought is disengaged — his mind is clear of thoughts. However, his unconscious mind never rests, constantly monitoring his surroundings, scanning the savannah and monitoring the large number of different possible sources of sensory input data (ears and eyes). This would all be necessarily performed simultaneously by parallel processing. The advantage of parallel processing is that it can process multiple streams of input data at the same time.

Suddenly, a lion appears on the horizon. One of the parallel processing threads — a pattern matching operation capable of visually detecting lions — responds with a high level of activation. That single signal gets sent up to the conscious mind.

At that point, the conscious thought process is alerted and takes over. As described earlier, this is based on serial processing. This is Kahneman's System 2 thinking, able to analyse the problem and determine the best course of action. How far away is the lion? How fast can I run? Is there a tree nearby? System 2 logically selects the eventual action. In other words, System 2 has overall control — the conscious mind has overall control.

The man decides to climb a tree, and is saved.

The structure of the mind

To sum up, our mind seems to be mainly composed of a parallel processing part, which represents the unconscious mind, while the smaller conscious part (the tip of the iceberg) uses serial processing. This model was suggested by the cognitive psychologist Philip Johnson-Laird in his 1988 book *The Computer and the Mind*: "The brain, unlike the conventional digital computer, is not a device with a single processor. Many processes occur in parallel, though the stream of conscious experience seems to be serial."

And this arrangement can potentially explain the reason why our minds are divided into two parts, a conscious mind and an unconscious mind.

In this chapter it has been explained that there are two fundamentally different methods of processing information: serial processing and parallel processing. Each method of information processing — serial processing and parallel processing — has its own relative advantages and disadvantages. Parallel processing can perform simple evaluation of multiple scenarios simultaneously, sending the most promising ideas up to the conscious mind. Parallel processing is also required for monitoring multiple sensory inputs, and would therefore be used for unconscious scanning of the environment, and filtering of important signals.

However, high-level conscious tasks such as problem solving and decision-making require serial processing: a

single train-of-thought. Serial processing is, by its nature, slower than parallel processing. We therefore end up with a brain with two systems, with each system able to process information at very different speeds — hence Kahneman's *Thinking, Fast and Slow*.

It is therefore suggested here that the true fundamental reason for this division of the mind into two parts — a conscious mind and an unconscious mind — is because there are two fundamentally different ways to process information in any computing device: parallel processing and serial processing.

The divided structure of the mind is not arbitrary, it arises because information processing itself has a natural divide into parallel and serial processing. Each of the two methods has its own relative advantages and disadvantages. Nature would surely exploit the relative advantages of each method, and so the eventual dual structure of the brain would reflect that natural divide.

And we might even take this idea one step further. This structure might potentially explain why the serial processing part of the mind would view the parallel processing part as being "unconscious". It would purely be because the serial processing part of the mind (the conscious mind) would not be able to process data at the same rate as the parallel processing part of the mind (multiple threads can process more data than a single thread). Inevitably, some data could not be passed up from the unconscious mind to the conscious mind. As a result, the conscious mind would not have "access" to all the intermediate processing of the unconscious mind.

There is another way of thinking about this. Imagine if all the details of the parallel processing system were passed up to the conscious mind. Your conscious mind would be simply overloaded with data — you would not be able to think straight! For this reason, only the end result of the parallel processing system would be passed to the conscious mind.

This idea is explained by Philip Johnson-Laird in his book *The Computer and the Mind*. Johnson-Laird suggests that the conscious mind: "would have no access to the processes on which it is based. There are good evolutionary reasons for this arrangement: if you could scrutinize the whole process of perception, it would have to be much slower since it could not depend on parallel processes."

Results passed-up from the parallel system would just appear to the serial system as if those results had been magicked out of thin air, with no way of knowing how those results had been derived. If our conscious mind is just the tip of the iceberg, then that tip of the iceberg would be unable to see the rest of the huge iceberg below the surface of the water. Ideas would appear "out of the blue".

This lack of transparency would result in the parallel processing system appearing to be a dark, mute, black box. As a result of this lack of access, the serial processing system would interpret the parallel processing system as being "unconscious".

To sum up, as soon as we realise that there are two distinct methods of processing information in any computing device — serial processing and parallel processing — then the dual conscious/unconscious structure of the mind emerges quite naturally.

4

THE FAME OF PHINEAS GAGE

Phineas P. Gage was born in Grafton County, New Hampshire in 1823. He was the first of five children, and received little in the way of education, rendering him illiterate. However, Gage was mightily strong and healthy, outgoing and popular.

When he was twenty five years old, Gage obtained a job as a blasting foreman working on the construction of the Hudson River Railroad. Gage's job required him to use explosives to blast large cuttings through rock so that the railroad track could be laid. The job required Gage to place explosive into holes which had been drilled into the rock. After the explosive was inserted, sand or clay had to be inserted above the explosive to pack it down so that the explosion would spread outward into the rock. A large iron rod — called a tamping iron — was used to pack the sand and clay firmly onto the explosive charge.

Here is a daguerreotype (a very early type of photograph) of Gage holding his tamping iron. The iron was four foot long, and one-and-a-quarter inches in diameter, and weighed over thirteen pounds:

On September 13th, 1848, Gage was working on the railroad south of the town of Cavendish, Vermont. In order to clear a path for the railroad, a hole had been drilled deep into rock. Blasting powder and a fuse had been added, and it was then Gage's job to compress the explosive mixture using his tamping iron.

As Gage was packing the explosive using his iron, his attention drifted toward some men talking behind him. He turned his head to look, and opened his mouth to speak. At that moment, the tamping iron hit the rock. A spark was generated.

The resultant explosion blasted the tamping iron out of the hole as if it was a rocket. It smashed into the lower left side of Gage's face, sliced through the front of his brain behind his left eye, and exited through the top of his head.

The tamping iron landed like a javelin in the ground eighty feet away.

The following diagram — drawn by the doctor John Harlow after Gage's death — shows the path of the iron as it passed through Gage's brain and rocketed out through the top of his skull:

But Phineas Gage did not die. Not even close.

After a few minutes, Gage sat up and was able to walk to the cart which would take him home. Later that day, when he was sitting on the porch outside his house, a doctor happened to pass by. Gage shouted with remarkable understatement: "Doctor, here is business enough for you!"

The doctor initially found it hard to believe Gage's story. However, after examining Gage — and clearing away a few loose bits of broken skull — the hole in his brain was clearly visible. The doctor covered the wound with bandages and a head cap. Gage specifically requested that his friends were not to visit him. After all, said Gage, he'd be back in work in a few days anyway.

Gage's recovery took rather longer than that, but he was soon walking around his house, and helping with the ploughing on a nearby farm. His mother noticed that his memory seemed impaired, but otherwise there was no obvious sign of mental damage. It appeared that Gage had miraculously made a complete recovery.

And then Phineas Gage became famous.

Henry Bigelow, the Professor of Surgery at Harvard Medical School, heard of Gage's remarkable story and arranged for him to travel to Boston. Gage was presented at meetings and medical school class.

The famous showman P.T. Barnum became aware of Gage's amazing story, and decided that he would make an excellent addition to Barnum's American Museum, which was a combination of a zoo, museum, waxworks, and freak show. Gage was presented as a kind of living museum exhibit, alongside the "Fiji Mermaid" (a mummified monkey's body with a fish's tail), and a loom powered by a dog.

Phineas Gage — always holding his tamping iron — had finally become a sensation:

**THE WORLD'S
WONDER**

PHINEAS P. GAGE,
A native of LEBANON, N. H., would announce to the citizens of CON. that on
Tuesday Evening,
AT
RUMFORD HALL,
He will exhibit to view, in his own person, one of the
Greatest Wonders of the World!
Nothing less than a Man who has had a
Huge Iron Bar, which he will Exhibit,
Forced through his Head from chin to crown; has had, in fact,
HIS BRAINS BLOWN OUT!
Partially, and who is still living, breathing, and in full possession of his health and faculties. It is a case unparalleled in the annals of Surgery, and has excited the astonishment of the most eminent members of the Medical Faculty in the country. On the 13th of September 1848. M.

It was then that things started going badly wrong.

People who knew Gage from before the accident — when he was, by all accounts, a charming man — agreed that he had changed. Bigelow's report on Gage's behaviour now described him as "fitful, irreverent, indulging at times in the grossest profanity and manifesting little deference for his fellows." Gage lost all his social inhibitions. He took to womanising, partying, and was a perpetual drunk. He had lost all restraints on his behaviour.

As his behaviour became more unpredictable, Gage's theatrical work dried up. He moved to Chile and got a job as a stagecoach driver. However, his health started to fail and — twelve years after his injury — Gage died from an epileptic seizure.

No autopsy was performed after Gage's death, but his body was exhumed seven years later and his brother-in-law donated his skull and his tamping iron for medical examination. Today they are both housed in Harvard's Warren Anatomical Museum.

But the story of Phineas Gage did not end there. It was clear that there was a relationship between the part of the brain which had been damaged and the change in Gage's behaviour. To this day, discovering the relationship between brain injuries to specific parts of the brain and changes in behaviour remains one of the most useful tools in understanding the functioning of the brain. This forms the basis of *neuropsychology*.

In this chapter, we will be considering the central role of the part of the brain which was injured in Phineas Gage's accident, and discovering why injury to that part of the brain led to the dramatic change in Gage's personality.

The boss of the brain

The structure of the brain is really quite surprising.

Our conscious thinking appears to be confined to the extremely thin outer layer of the brain. This thin layer is called the *cortex*. The cortex is only about two millimetres thick, but the neurons (brain cells) within it are so tightly-packed that this thin layer represents 40% of the total brain mass. The cortex appears grey in colour, and so the cortex is often called the *grey matter* of the brain.

Inside the cortex we find the main volume of the brain which is white in colour and is therefore called the *white matter*. This white matter is mainly composed of "wires" which connect the various parts of the cortex together, and allow different regions of the cortex to communicate with each other. In contrast to the cortex, the white matter is

not believed to be conscious.

The following diagram shows the conscious thin outer cortex of the brain, and the inner white matter:

The thin cortex
outer layer
is **conscious**

The white matter of the brain has been described by psychology professor Frank Amthor: "Most of the volume of the brain is wiring, not cells".^[7] So why is it that the "wire" composition of the white matter should result in it not being conscious? Are wires not conscious? These questions shall be considered (and hopefully answered) in the final chapter of this book, but for now we shall concentrate on the conscious cortex.

The part of the cortex which was injured in Phineas Gage's accident was the very front part of the cortex, which is called the *prefrontal cortex*. We will be seeing that the prefrontal cortex plays a central role in the operation of the brain.

The following diagram shows the location of the prefrontal cortex (coloured grey) at the front of the brain:

**Prefrontal
cortex**

The prefrontal cortex is the centre of our planning, problem-solving, and decision making. These tasks are known as *executive functions*. The use of the word "executive" makes the decision-making of the prefrontal cortex sound like a human executive making decisions affecting a large company composed of many divisions. In that respect, we might think of the prefrontal cortex as being the "boss of the brain".

The prefrontal cortex was the last part of the brain to evolve, but once it had evolved it was its planning and problem-solving ability that provided humans with the capability to make tools and weapons, and build farms, and domesticate other animals. The following diagram shows the size of the frontal lobe (of which the prefrontal cortex is one part) in the human brain as compared to other animals: ^[8]

SQUIRREL MONKEY

DOG

CHIMPANZEE

HUMAN

It can be seen from the previous image that the prefrontal cortex is proportionately far larger in humans than in any other animal. It is this size of our prefrontal cortex — and, therefore, our unique ability to plan and make tools and weapons — which allows us to completely dominate a natural world inhabited by animals with much more obvious physical advantages, such as those animals which are faster or stronger, or those with terrifying sharp teeth and claws.

To show how important the prefrontal cortex is in decision making, David Eagleman considers the example of a woman with a damaged prefrontal cortex in his book *The Brain*. We are introduced to Tammy Myers who was injured in a motorcycle accident. The part of Tammy's prefrontal cortex which was injured was the orbitofrontal cortex, which is the region just above the sockets of the eyes.

According to David Eagleman, Tammy encounters severe problems when she has to make decisions: "Tammy doesn't look like someone who has suffered a traumatic brain injury. But if you were to spend even five minutes with her, you would be able to detect that there's a problem with her ability to handle life's daily decisions. Although she can describe all the pros and cons of a choice in front of her, even the simplest situations leave her mired in indecision. Without decision making, little gets done; Tammy reports she often spends all day on the sofa."

In 1991, an experiment was conducted at University College London, which clearly showed the role of the prefrontal cortex in making willed decisions.^[9] In the experiment, people had to move a finger — either by their own free will, or by being told to move a finger. Only in the first case was the person employing their own free will. During the experiment, the brains of the subjects were monitored by a PET scan. Increased blood flow to the prefrontal cortex was only detected during the free choice task.

On that basis, it might appear that the prefrontal cortex is the location of our "free will".

But not only does it appear that our prefrontal cortex is the location of our free will — it also appears that it is the location of our **willpower**. Todd Hare, an associate professor at the University of Zurich, has identified two regions in the prefrontal cortex which show high levels of activity when strong willpower is required.^[10] The first region became active when researchers gave subjects a choice between receiving a small amount of money now, or a larger amount of money later. A second region became active when subjects showed strong willpower by choosing a healthy food option over a tasty but unhealthy option. It is clear that the prefrontal cortex takes into account all the factors of a situation — both short-term and long-term considerations — when making a decision.

The prefrontal cortex is also in charge of suppressing urges that would be socially unacceptable, such as stripping off your clothes and running naked through a shopping centre. Unfortunately, the prefrontal cortex is one of the last regions of the brain to be fully developed, with the brain continuing to develop until the age of twenty five. This explains why teenagers are drawn to risky activities. According to David Eagleman in his book *The Brain*, this behaviour is due to the late development of the prefrontal cortex: "Activity in the orbitofrontal cortex — involved in executive decision making, attention, and simulating future consequences — is still about the same in teens as it is in children. A mature pleasure-seeking system coupled with an immature orbitofrontal cortex means that teens are not

only emotionally hypersensitive, but also less able to control their emotions than adults."

In this chapter, we have seen that the prefrontal cortex plays the crucial role in our decisions and planning. In that respect, our prefrontal cortex seems to lie at the heart of our identity, defining how we act and who we are. This was clearly evident in the case of Phineas Gage who changed as a person after his accident.

So, with the prefrontal cortex playing such a central role in our thinking processes and personality, might it be the case that the prefrontal cortex is the centre of our consciousness?

Well, as we shall now see, it is rather more complicated than that ...

5

THE EMERGENCE OF CONSCIOUSNESS

So, as we have seen in the case of Phineas Gage, we can deduce which areas of the brain are responsible for which aspects of behaviour. In the case of Phineas Gage, it was damage to his prefrontal cortex which resulted in his unpredictable, unreliable, anti-social behaviour. It was then possible to deduce that the prefrontal cortex is responsible for controlling our behaviour.

We might then suppose that a similar technique might be used to determine which parts of the brain are responsible for consciousness. If we have a patient with a brain injury who has an impairment of consciousness, we could then deduce that the part of the brain which was injured plays a role in consciousness. And, conversely, if the patient's consciousness is not affected, we could then deduce that the part of the brain which was injured did **not** play a role in consciousness.

As an example, the *cerebellum* is a relatively large part of the brain, packed with neurons, which lies at the back and bottom of the brain. The cerebellum is shown in grey in the following diagram:

The cerebellum is responsible for governing learnt motor functions, such as walking, or playing tennis, or playing the piano. As these are the functions which can be performed unconsciously (when we are walking, we do not consciously think "Move left leg, move right leg") we might imagine that the cerebellum does not play a role in consciousness. And, indeed, this is what has been discovered. If the cerebellum is damaged, the patient might have difficulties walking or speaking, yet it appears that the conscious mind of the patient is unaffected. Hence, we can deduce that the cerebellum — a large part of the brain containing 69 billion neurons — does not play a role in consciousness.

By considering patients with other brain injuries, it has been possible to deduce that the region in the brain responsible for consciousness is the cortex — that thin and wrinkled sheet of neurons which covers the top part of the brain. If you were able to remove the cortex and spread it flat, it would be about the size of a small tablecloth. But the cortex is divided into different regions which perform different functions. How can we tell which regions are responsible for consciousness?

In order to answer that question, in the early 1990s, an ingenious solution was proposed by Francis Crick (the joint discoverer of DNA, who later in his career developed an interest in consciousness) and the neuroscientist Christof Koch. The goal of Crick and Koch was to identify the parts of the brain which play the essential roles in generating consciousness.

Crick and Koch's method relied on functional brain imaging techniques, with the word "functional" meaning the examination of the brain in real-time as the brain is thinking. Functional imaging techniques include the electroencephalogram (EEG) which records neural activity as voltages on the scalp, and functional magnetic

resonance imaging (fMRI) which detects changes in blood flow to the various regions of the brain.

The method of Crick and Koch is based on contrasting two images taken of neural activity in the brain. The first image is of a brain during consciousness, and the second image is of an unconscious brain. By subtracting the neural activity patterns captured in the two images, it is then possible to identify which parts of the brain play the essential roles in generating consciousness. Those parts are then said to be the *neural correlates of consciousness*.

One particularly ingenious use of Crick and Koch's method comes from its use with optical illusions. As an example of that principle, let us consider the following famous optical illusion created by the Danish psychologist Edgar Rubin. Does the image show a vase — or two faces?

The image seen by your conscious mind will alternate: sometimes you might see a vase, and then the image will switch and you will see two faces. The alternation is continuous, but you will never see both the vase and the two faces at once — you will only ever see one or the other. This is an example of *bi-stable perception*.

The strategy of Crick and Koch involves showing an illusion such as this to a person who, at the same time, is undergoing brain imaging. What happens inside the brain when the conscious experience changes, sometimes conscious of the vase, sometimes not conscious of the vase?

As the actual image does not alter, the only thing which changes is the pattern of activity in the brain. Therefore, by imaging the brain when the mind is conscious of the vase, and comparing that to the image of the brain when the mind is not conscious of the vase, it is possible to identify the region of the cortex which is responsible for the conscious awareness of the vase.

Crick and Koch's method is clearly ingenious. For the first time it allowed the connection to be made between measurable scientific phenomena (the pattern of neural activity across the brain) and the internal experience of consciousness. For that reason, it has been said that the technique launched the modern science of consciousness.

However, the technique is clearly reliant on introspection, dependent on the subject to accurately signal when they are conscious of the image, and when they are no longer conscious of the image. For this reason, introspection has made a comeback as a key technique in the new science of consciousness.

Another example of Crick and Koch's method comes from *binocular rivalry*. Binocular rivalry occurs in an experiment in which one image is shown to one eye of a subject, and a completely different image is shown to the other eye. You might imagine that the two images would somehow merge into a single image, with the subject being consciously aware of that single merged image. However, that is not what happens. Instead, the subject is only ever aware of one of the images at a time. In a situation very much resembling the previous "vase" illusion, the image which is in the conscious mind tends to alternate between the two images. Therefore, by imaging the active brain, it should be possible to identify which regions of the cortex are responsible for bringing a particular image into conscious awareness.

So where in the brain does an image enter consciousness? Let us consider the visual system:

The previous image shows the eye at the front of the brain. The image is focussed onto the retina of the eye, and then the data passes along the optic nerve to an area of the cortex at the back of the brain called the *primary visual cortex* (coloured grey on the previous image).

The spatial arrangement of the image is retained on the primary visual cortex, with the relative positions of the "pixels" in the image being unchanged. Hence, the primary visual cortex could be thought of as a "cinema screen" on the back of the brain, with the image being projected onto it from the eye.

The fact that the primary visual cortex contains purely raw data has implications for its role in consciousness. If we consider the vase illusion, or binocular rivalry, in both of those cases the images being observed did not alter with time — they were fixed images. Therefore, the raw data on the primary visual cortex would also not alter with time. But over that period of time, the conscious experience of the subject would be altering — sometimes consciously perceiving the vase, sometimes not consciously perceiving the vase. But if we compare brain images of the two scenarios, the activity of the primary visual cortex would be unchanged. We can therefore deduce that consciousness is not to be found in the primary visual cortex.

That is quite a conclusion! And I hope it gives you an impression of the power of Crick and Koch's idea.

Space, time, and consciousness

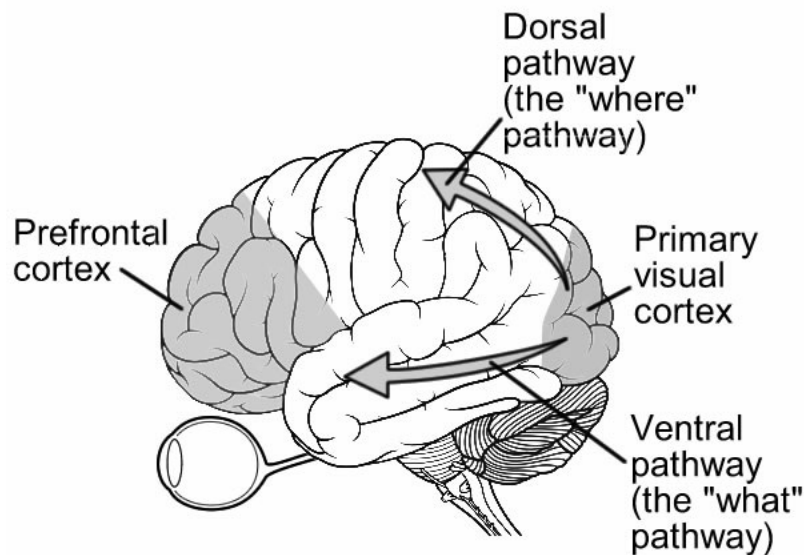

From this discussion of the techniques proposed by Francis Crick and Christof Koch, you might have gained the impression that it will someday be possible to precisely locate the position of consciousness in the brain, as if consciousness is produced by the action of a single neuron somewhere, or maybe by the action of a small network of neurons. However, this is most certainly not the case. It is widely accepted that consciousness emerges through the interactions of billions of neurons as information is passed across the brain. Indeed, Christof Koch makes this point in his book *Consciousness*: "These are early days. We cannot yet pinpoint which regions of the brain underlie consciousness. But this is barking up the wrong tree — we must resist the hypnotic appeal of hot spots in brain scans with their naive phrenological interpretation: the perception of faces is computed over here, pain over there, and consciousness just yonder. **Consciousness does not arise from regions but from highly networked neurons within and across regions.**"

Consciousness cannot be "localised" in the brain, which means it does not reside at one particular point. Consciousness arises as information passes across the entire brain. And progress has been made in understanding how that happens.

Firstly, in the previous section it was explained that the raw visual data held in the primary visual cortex does not represent the final processed image which enters your conscious mind. As one example, the image must be "stitched together" to remove the blind spot which is found on the retina at the point where the optic nerve leaves the retina. As raw visual data is heavily-processed in this manner before it enters conscious awareness, it has even been said that "You don't see with your eyes".

The raw visual data is processed as the data moves along streams from the back of the brain (primary visual

cortex) to the front of the brain (prefrontal cortex), as shown in the following diagram:

Remember the primary visual cortex can be thought of as a "cinema screen" on the back of the brain. For that reason, Crick and Koch described the brain's visual system as if "the front of the brain is 'looking' at the sensory systems, most of which are at the back of the brain", which I think is a very neat way of thinking about it. [\[11\]](#)

Two separate data streams for visual data have been identified, and these are shown on the previous diagram. There is a *dorsal pathway* across the top of the cortex which considers the spatial locations of objects in the scene. This is sometimes called the "where" pathway. And there is a *ventral pathway* along the bottom of the cortex for identifying objects in the scene. This is sometimes called the "what" pathway.

A characteristic of consciousness is that millions of neurons tend to synchronise to form waves of activity which reverberate across the brain. The reason for this synchronisation is not yet known, but it is possible to imagine that the motion of these waves represents the emergence of consciousness over a brief period of time, the development of an internal picture of the world.

Let us speculate on one hypothetical possibility of how that might happen ...

Consider the brain's visual system trying to make sense of the items lying on my desk. There might be a pencil, and a book, and a ruler on my desk. That scene would be observed by the eyes, and the data would be passed along the optic nerve to the primary visual cortex. From there, that raw data would be passed through the higher-level processing regions of the brain toward the prefrontal cortex. This flow of information represents *bottom-up* processing, as the data passes from simple low-level processing to sophisticated high-level processing.

But this is not the first time that the brain has seen rulers and pencils. High-level processing regions have access to long-term memory, and idealised models of what pencils and rulers look like. They would try to match the received raw data with its internal models. If a match is found, the high-level processing might want to zoom-in closer, to confirm that the object is actually a pencil or a ruler. A signal would then be sent back down from the high-level region to the low-level region. High-level regions are also capable of making predictions based on incomplete sensory information ("filling in the gaps" of an image), and would request confirmation from the sensory regions that the interpretation was correct. These scenarios — in which high-level processing directs low-level processing — are called *top down* processing.

And so a dialogue occurs between high-level regions of the brain and low-level regions of the brain as a internal conscious model of the world emerges. Christof Koch has described this dialogue by saying "a reverberatory feedback loop is established and can maintain itself".

As a result, a continuous oscillation occurs, a brain in constant surging activity. These waves of neuronal activity are called *brain waves*. These brain waves oscillate across the brain at frequencies from 0.5 hertz to 150 hertz. The waves are categorized into groups which are labelled by the Greek letters delta, theta, alpha, beta, and gamma. Gamma waves in particular appear to represent a signature of consciousness:

Brain wave name	Frequency range
Delta waves	0.5 to 4 hertz
Theta waves	4 to 8 hertz
Alpha waves	8 to 12 hertz
Beta waves	12 to 40 hertz
Gamma waves	> 40 hertz

But a deeper and more fundamental message about consciousness emerges from this discussion. And that is that consciousness is a **process**, emerging over a period of time. Consciousness does not just appear in a flash, and then disappear in a flash. No, just as consciousness cannot be localised at one point in space (no single neuron in the brain), so consciousness cannot be localised at any one point in time (no single point in time).

This principle is described by Paul Nunez in his book *The New Science of Consciousness*: "Consciousness is not an object occupying a fixed location or instant in time; rather it is an ongoing process **distributed over both time and space within the brain.**"

Perhaps we should not be surprised about this similarity in the behaviour of consciousness over time as well as over space. As Einstein revealed, time should be considered as being a dimension — just like space. Space and time are components of a four-dimensional spacetime. So consciousness is spread over time just as it is spread over space (spread over the brain).

This fact that consciousness is a **process** spread across time will be one of the main conclusions of the second half of this book.

For we have now come to the end of the first half of this book. The second half of this book has a different theme and a different style.

Allow me to take you on an epic journey ...

6

THE LOGIC OF CONSCIOUSNESS

This chapter takes the form of an epic historical saga. It is the longest and most ambitious chapter I have ever written.

It is a story of the golden ages of great civilisations and the achievements of their citizens. It is a story of personal triumph and personal tragedy. In many ways, it represents the story of human knowledge, from the ancient Greeks to the present day. It is also a journey through space as well as time, from the Parthenon of Athens to the research labs of IBM in New York.

In this chapter, we will be using ancient knowledge — discovered over 2,000 years old — to develop a theory related to consciousness. Using that theory, we will discover an incredibly simple rule to detect consciousness (or, more accurately, the **absence** of consciousness) in a variety of objects.

So, let us begin our journey ...

The start of our journey

Let us travel back in time 2,500 years to ancient Greece.

At that time, Greece was not a united country. Instead, it was divided into many self-governing city-states. The reason for this was largely due to geography: many areas in Greece are cut-off from each other. Some regions are separated by sea, and there are many islands, while many of the mainland regions are separated by mountain ranges.

The two most powerful city-states at that time were Athens and Sparta. The other city-states included Corinth, Thebes, and Argos. The following map shows some of the Greek city-states:

The most populous of the city-states was Athens. The citizens of Athens were young, wealthy, and artistic. The Athenians placed great emphasis on the importance of knowledge, believing that obtaining knowledge brought them closer to the gods.

The contrast between Athens and Sparta was striking. While the Athenians placed their trust in knowledge, the Spartans placed their trust in military might. At the age of seven, all Spartan boys were removed from their parents and conscripted into military training. The study of poetry, music, art, and science was discouraged by the militaristic regime.

If you have seen the recent action movie *300* you will know about the heroic final battle of three hundred Spartan soldiers led by their king Leonidas against a Persian army of 100,000 men. The battle took place in 480 BC, with the Spartans defending the narrow coastal pass of Thermopylae, with only 100 metres separating the sea on one side from high mountains on the other side. In the narrow pass, the Persians could not capitalise on their numerical advantage, and the Spartans were more skilled at the brutal, hand-to-hand fighting. The Spartans inflicted heavy casualties on the Persians before being finally betrayed and encircled.

Spartans were unquestionably fearsome warriors, but if you gained the impression from the movie that the Spartans were a noble tribe, fighting for justice, then nothing could be further from the truth. The Spartans were cruel, brutal, and ruthless. Whenever the resources of Sparta ran low, the Spartans would simply invade a neighbouring region, force its citizens into slavery, and steal their property and land.

And so it was that, in the 6th century BC, the Spartans turned their envious eyes to the riches of Athens.

Aware of the danger, and determined that Athens should not become another Spartan colony, the Athenian aristocrat Cleisthenes proposed a radical solution. Cleisthenes proposed that every Athenian citizen should have an equal say in political power. This was nothing less than a revolution, and the first time that such a system had been proposed in world history.

The world would never be the same again.

The Athenians had invented democracy.

Classical Greece

The adoption of democracy unleashed the talents of the Athenian people. The citizens felt they had become shareholders in their own country, and, as a result, they became determined to save it from the Spartan invasion. Indeed, the huge Spartan three-pronged invasion was repelled, and the Athenians rejoiced in their new democratic freedoms.

The introduction of democracy in Athens in 508 BC launched a Golden Age. The period from 500 BC to 300 BC in Athens was one of the most remarkable eras in human history. There was an explosion of talent in literature, architecture, sculpture, mathematics, and philosophy, the influence of which went around the world and is still being felt today. This period from 500 BC to 300 BC is now known as Classical Greece, or the Classical Age.

Classical Greek culture formed the foundation for modern Western culture, and Classical Greece is commonly known as the "cradle of Western civilisation". It has been suggested that the knowledge gained during the 200 years of Classical Greece in art, mathematics, philosophy, and science is unmatched by any other period in human history (except, perhaps, for the last 200 years — the 19th and 20th centuries). As an example of the influence of Classical Greece on the modern world, sixty-five percent of the countries in the world today have adopted the Athenian innovation of democracy.

At the centre of Athens, a forbidding citadel known as the Acropolis was built. The walls of the citadel were as much as six metres thick, as shown in this 1882 engraving by the German artist Jacob von Falke which imagined the Acropolis at the height of its glory:

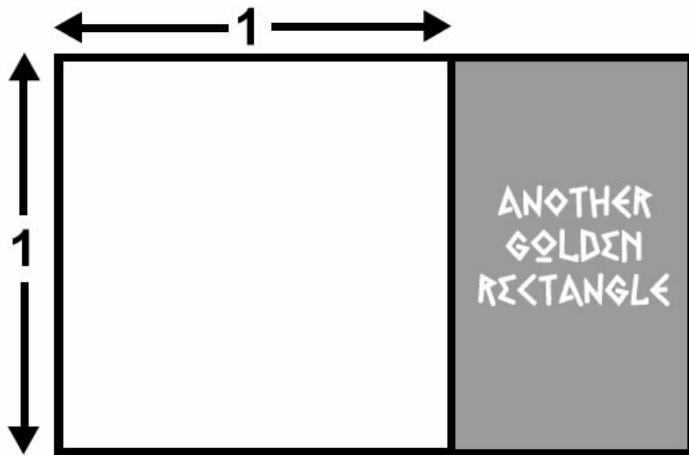

The Acropolis was dominated by the building at its very top, the building which has now become the most famous symbol of the glory of Classical Greece: the Parthenon. It has been said that the Parthenon is the symbol for civilisation itself.

It has also been said that the Parthenon is the most beautiful building in the world. It is indeed beautiful and graceful, with seemingly perfect balance and sense of proportion. But what is the underlying reason for the beauty of the Parthenon? To understand that, we need to understand the huge advances in mathematics that were being made in Classical Greece.

As an example of the progress in geometry, it was the Greek mathematician Euclid who discovered the remarkable properties of the number which we now call the *Golden Ratio*. The Golden Ratio is a number which is approximately equal to 1.6180. The ancient Greek mathematicians realised that this number has special properties, and we can understand those properties if we consider a rectangle in which the ratio between the lengths of its larger and smaller sides is equal to the Golden Ratio. Such a rectangle is called a *Golden Rectangle*, and an example of a Golden Rectangle is shown in the following diagram:

To understand why a Golden Rectangle is special, we should consider cutting a square out of a Golden Rectangle. Considering the measurements of the previous diagram, this would involve removing a square which had each of its sides equal to a length of 1 unit:

As you can see on the right-hand side of the previous diagram, the effect of removing the square has been to leave us with another Golden Rectangle. This time, though, you can see that the rectangle is smaller and is oriented vertically.

And, of course, as we now have generated a second Golden Rectangle, we can again extract a square from that new rectangle — and that will leave us with a third Golden Rectangle. And this process can continue to infinity, generating an endless string of squares — as shown in the following diagram:

So there is clearly something special about the Golden Ratio — and a Golden Rectangle. And it is remarkable that the mathematicians of Classical Greece were the first to recognise that specialness.

The shape of the Golden Rectangle was recognised by ancient Greek artists as possessing a particular balance and sense of proportion which was pleasing to the eye. As a result, many aspects of the Parthenon design incorporate the Golden Ratio, both in its façade and in the spacing of its columns. It has been suggested that this is the reason why the Parthenon is often described as "the most beautiful building in the world".

The following image shows how the façade of the Parthenon is based on the Golden Rectangle: [\[12\]](#)

The Golden Ratio continues to be used by designers in the modern world, notably in the layout of webpages. And the design of the Parthenon — especially its grand columns — has influenced the design of thousands of modern public buildings such as town halls, museums, and art galleries (we will be returning to consider the psychological appeal of the Golden Ratio later).

The logic of Aristotle

The citizens of Athens loved knowledge, and believed it brought them closer to the Gods. So, when Athens entered its Golden Age in the 5th century BC, it is not surprising that it also brought a new wave of discovery.

A new breed of thinkers appeared, and those thinkers believed we could make sense of the world by understanding the natural laws. Today, we call those thinkers the first philosophers. In his book *Ancient Greece*, Thomas Martin considers the methods of those philosophers: "These thinkers were proposing a dramatic new way of understanding reality. They were arguing that human beings could investigate and explain the ways in which the universe works because the phenomena of nature were neither random nor arbitrary. This insistence that natural laws governed how reality operated was a crucially significant development for later philosophical and scientific thought. The thinkers who conceived this view believed it necessary to give reasons for their conclusions and to be able to persuade others by arguments based on evidence. In other words, they believed in **logic** (a word derived from the Greek term 'logos', meaning 'a reasoned explanation')."

The most famous Greek philosopher to emerge in the 5th century was Socrates. Socrates believed the way to understand the universe was by asking questions of it. He would often get involved in heated discussions with his fellow citizens of Athens, asking them questions and challenging their assumptions. Unfortunately, challenging the conventions of the status quo is not without its dangers. When Socrates criticized the Athenian government and leaders, he was charged with undermining the state. Socrates was found guilty, and was executed by being forced to drink a cup of poisonous hemlock.

Socrates was a talker — not a writer — and he never wrote anything down. Fortunately, we have Socrates' pupil Plato to thank for his written accounts of Socrates' thoughts. In 387 BC, Plato established his famous Academy in Athens as a centre for learning. Plato's Academy has been called the first European university. However, the Academy was not a college in the modern sense. Instead it was more of a centre for informal discussion about philosophy — with Plato being the central figure. The sign above the entrance of the Academy said: "Let no one ignorant of geometry enter here".

Plato is perhaps best known today for discovering the five regular symmetrical three-dimensional shapes known as the *Platonic solids* (which were considered in my sixth book).

Plato's most brilliant pupil at the Academy was Aristotle, who lived from 384-322 BC and is considered to be the father of modern Western philosophy. Aristotle's influence was vast, covering areas such as biology, botany,

physics, and psychology. The teachings of Aristotle continued to be considered as the state-of-the-art well into the 19th century, and his writings are still influential today.

The following image shows a small extract from Italian painter Raphael's fresco *The School of Athens* (which is located in the Vatican). Raphael was one of the great artists of the Italian renaissance, a period from the 14th century to the 17th century during which Italy enjoyed its own golden age. During the Italian renaissance, there was renewed interest in the achievements of classical Greece, and the discoveries of the great Greek thinkers.

The School of Athens is considered to be Raphael's masterpiece. In this extract from the fresco, the two central figures are Plato and Aristotle, with the older figure of Plato on the left and his pupil Aristotle on the right:

(Raphael substituted the likeness of Leonardo da Vinci for Plato).

Aristotle produced several works explaining the principles behind logical arguments. These are grouped into a collection of six books known as the *Organon*, or "tool of thought". It was in the *Organon* that Aristotle founded the field of logic.

According to Thomas Martin in his book *Ancient Greece*, Aristotle developed his sophisticated system of logic to allow "precise argumentation": "Creating a careful system to identify the forms of valid arguments, Aristotle established grounds for distinguishing a logically sound case from a merely persuasive one."

Aristotle's method of logic was based firstly on stating some initial assumptions, called *premises*. From those initial premises, a step-by-step method of *inference* is then applied (logical reasoning) by which a conclusion is eventually produced.

According to Aristotle, the basic unit of logic is the *syllogism*. A syllogism consists of three lines: two premises, and one conclusion. Here is a famous example of one of Aristotle's syllogisms:

Socrates is a man.
All men are mortal.
Therefore, Socrates is mortal.

It is clear that it is easy to follow the reasoning of a syllogism. In fact, it may seem so obvious that it might be wondered why we even need to bother with logic as an independent science at all. But the truth is that this method of inference only seems obvious because we are participating in logical thinking in our own minds during every minute of the day — and have done so since an early age. Something which comes so naturally to us is, of course, going to appear obvious.

Logic — like mathematics — is timeless, so we might try creating a different example of logical inference, this time referring to modern life:

The battery of my iPhone is running low.

*If an iPhone is placed in its charger, its battery will be charged.
Therefore, I will place my iPhone in its charger.*

It is clear that this sort of logical thinking is used in our thought processes throughout the day, from the time we wake up to the time we go to bed — without realising we are using techniques first described by Aristotle over two thousand years ago.

We might also think of our thought processes as being unconstrained, without being subject to any rules or laws. Indeed, this seems to be the basis of the current emphasis on our apparent free will. But from this discussion on logic, it is clear that there **are** rules and laws which govern our thoughts throughout the day — the rules of logical inference — but we are just not aware that we are applying those rules.

As an example, you would be unlikely to think:

*The battery of my iPhone is running low.
If an iPhone is placed in its charger, its battery will be charged.
Therefore, I will throw my iPhone in the river.*

In this case, the conclusion of the inference process does not follow logically from the premises. Yes, you could think illogically like that, but you would not get very far in life — and you would find it very expensive continuously throwing your iPhone in the river. Indeed, if you persisted in thinking illogically — and thereby acting illogically — at every occasion, you would probably not live very long: you would quickly find yourself under the wheels of a passing bus, or with your head in the mouth of a lion.

This makes it clear that the ability for logical thinking would evolve as an evolutionary necessity in the brain. You are unable to think logically? Then you won't survive for long.

On a Wichita State University website, I found an article by Alayna Cobb on the geometry of Euclid which bemoaned the lack of geometry teaching in school: "I have noticed that in many high schools today, very little geometry is taught, if any at all. This disturbs me because math teaches logic. Geometry is like a big puzzle. You find the pieces, and put them where they go. Geometry also teaches understanding. How do you know if something is true or right? You don't until you prove it. **Not only do you need logic for geometry class, you also need logic to survive in the world.**" [\[13\]](#)

I have emphasised the phrase "You also need logic to survive in the world". This could be taken as a reference to the evolutionary advantage — the necessity — for logical thinking. Fortunately, I would reassure Alayna Cobb that surely basic logical thinking does not need to be taught — it is an evolutionary necessity, and, as we shall soon see, for that reason it appears to be hard-wired into our brains.

Put simply, if you want to do anything useful, you need to use logic. Our conscious mind is ruled by logic.

So, although we might perceive our thought processes to be a free series of independent thoughts, unrestricted by any rules or laws, the reality is very different. Our stream-of-consciousness is not composed of a succession of random, unconnected thoughts. No, our stream-of-consciousness is actually a string of logically-connected thoughts.

If we want to detect consciousness, then, it appears we only need to detect the presence of logical thinking. This is a valuable insight which will play a central role in this long chapter.

The vanishing middle term

Aristotle's work on logic was regarded as definitive for over two thousand years. Let us now consider a characteristic feature of Aristotle's syllogisms.

Let us remind ourselves of the syllogism which is most often presented as an example of Aristotle's logic:

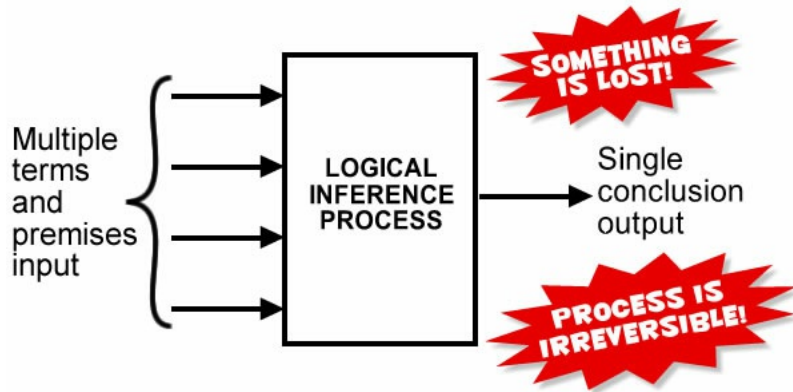

*Socrates is a man.
All men are mortal.
Therefore, Socrates is mortal.*

In any logical expression such as this, we can identify the *terms*. The terms are the objects in the expression, which in this example would be "Socrates", "man", and "mortal". A feature of this type of syllogism is that there is always a term which appears in the first two lines — both premises — but which does not appear in the conclusion. This is called the *middle term*. In this example, we can see that the middle term is the "man". You can see that the "man" term (or "men") appears in the first two lines, but does not appear in the conclusion.

What are the implications of this "vanishing middle term"?

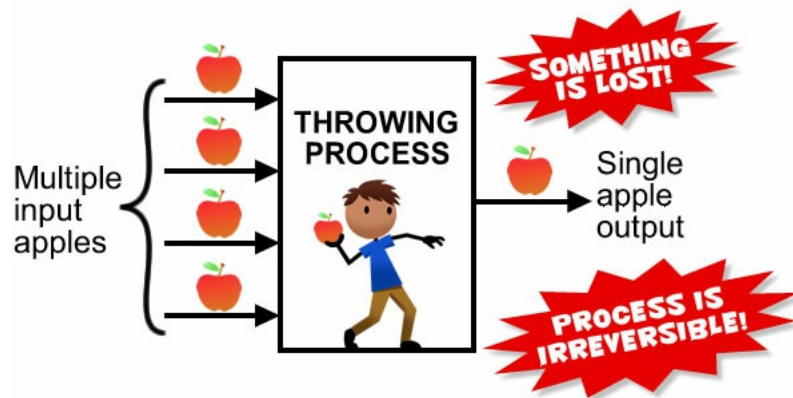

Well, to understand the implications, we see that in a logical syllogism, we always start with a number of terms and premises. Then — as we have seen — we always lose a middle term (or maybe multiple terms) as we arrive at a single conclusion. So we have multiple lines of input which are reduced in number to produce a single line of output.

This type of process is therefore known as a MISO process (multiple input, single output). Here is Aristotle's logical inference process drawn as a MISO process:

As shown on the previous diagram, any MISO process such as this has two side effects. Firstly, "something is lost" — and we have just seen that the middle term of a syllogism is lost. Secondly, the process becomes irreversible.

It is easy to see why a process should become irreversible when "something is lost". Imagine you are standing in a garden, and you have four apples in your basket. You decide to throw three of your four apples over a wall, leaving just one apple in your basket. Your act of throwing the apples then might be interpreted as a MISO process as you initially had multiple apples, but the end result of the process was just a single apple:

And because three apples have been lost in this process — and are now inaccessible on the other side of the wall — the process is irreversible as you are unable to return to the previous situation when you had four apples in your basket. [14]

As we shall now see, the syllogisms of Aristotle — and examples of logical inference in general — are indeed irreversible. This irreversibility of logical inference has been described by Prof. Simon Colton of Imperial College, London. [15]

Simon Colton, once again, examined the famous syllogism involving the mortality of Socrates:

Socrates is a man.
All men are mortal.
Therefore, Socrates is mortal.

Simon Colton then states the following: "We see that we have deduced the fact that Socrates is mortal from the two true facts that all men are mortal and Socrates was a man. So, because we know that the rule about men being mortal and the classification of Socrates as a man are true, we can infer with certainty that Socrates is going to die — which, of course, he did. **Of course, it doesn't make sense to go backwards as we would deduce that Socrates being mortal implies that he was a man and that all men are mortal!**"

You can see that Simon Colton has stepped backwards through the syllogism and shown that it makes no sense when considered in the backwards direction. Here is the syllogism written backwards:

*Socrates is mortal.
Therefore, all men are mortal,
And Socrates is a man.*

Indeed, this makes no sense at all. If all you know is the conclusion of the syllogism — that "Socrates is mortal" — then you cannot work your way backward to regenerate the premises. For example, if all you know is that "Socrates is mortal", you cannot tell whether or not Socrates is a man or a woman (no, you are not allowed to assume the gender of Socrates just from his name). A logical syllogism — and the logical inference process in general — is irreversible.

We shall be encountering more examples of MISO processes later in this chapter. But we now have to leave classical Athens, and travel forward in time where we will find another empire enjoying its Golden Age ...

The Victorian era

Just as Athens enjoyed a golden period in its history in the 5th century BC, so Britain enjoyed its Golden Age in the Victorian era of the 19th century. This was a period of great national confidence and achievement. It was also a period of relative peace and prosperity.

The Industrial Revolution — which began in Britain — had established Britain as the world's leading commercial nation. Just as in classical Athens, the Victorians valued knowledge and science. The spirit of the age was epitomised by the engineer Isambard Kingdom Brunel who changed the face of Britain with his extensive network of railways and bridges, many of which are still in use today.

Here is a photograph of Isambard Kingdom Brunel standing by the chains of his steamship the *SS Great Eastern*, which was the largest ship in the world at that time:

Every great civilisation has its defining monument. For classical Greece, it was the Parthenon, the "most beautiful building ever built". But what was Victorian England's equivalent of the beautiful Parthenon?

Well, it was surely the sewage system of London. The population of London had doubled in fifty years, but its infrastructure had not kept pace. The Thames was an open sewer, and cholera was rife. After the so-called "Great Stink" of 1858, it was none other than Michael Faraday who decided to spring into action.

Michael Faraday is now known as one of the greatest experimental physicists of all time, but it was to be one of Faraday's lesser-known experiments which revealed the scale of the sewage problem. Faraday dropped pieces of white paper into the Thames to "test the degree of opacity". Faraday was disgusted at what he found, and he wrote a letter to the Times newspaper demanding that something had to be done to improve the dire situation.

The engineer Joseph Bazalgette was placed in charge of designing and building a new sewage system for London. The final system was the greatest engineering construction of its time, featuring 82 miles of sewers which were the size of boulevards, eleven feet tall. The infrastructure was put in place for London to become the first modern metropolis. Bazalgette's sewers still form the core of the sewage system of modern London.

But I wasn't joking when I said we should compare Bazalgette's system with the beautiful Parthenon of classical Athens. The following photograph shows the interior of Bazalgette's astonishing sewage pumping station at Crossness, the centre of which is known as the Octagon. It has been described as a "Victorian cathedral of ironwork", and it is currently open for public visits.

It was truly the Parthenon of its age:

What lessons should we learn from these "Golden Ages" of human civilisations, and the great achievements of their citizens? Surely the message is that individual achievements should not be considered in isolation, but are, instead, inspired by the surrounding environment and the general spirit of the age. Just as in Plato's Academy, scientists and engineers talk and collaborate, and there emerges a "collective consciousness" with the whole being greater than the sum of the parts.

Perhaps that is a topic which should be considered in a later book. But for now, let us return to Victorian England ...

The laws of thought

George Boole was born in Lincoln, England in 1815. The son of a shoemaker, he received little formal education. He was almost entirely self-taught in mathematics, a subject at which he was to excel.

Boole started teaching mathematics at the age of sixteen in order to support his family, and he opened his own school in Lincoln at the age of just twenty. Boole started writing his own original papers on mathematics, and in 1844 he was awarded the British Royal Society's gold medal for one of his papers. However, it was when Boole turned his attention to logic that he made his greatest impact on the world.

It is fitting (and maybe predictable) that Boole emerged in another "Golden Age", because Boole might well be considered as being the natural heir to Aristotle.

Here is a drawing of George Boole:

Before Boole had his breakthrough, logic had always been expressed only in words. As an example:

*If the kettle is plugged in,
and the button on the kettle is pressed,
then the water will boil.*

We have already seen that this type of logic was proposed by Aristotle more than 2,000 years earlier. Boole admired Aristotle's writings on logic. However, Boole was less impressed by the idea of writing logical statements in conversational English. A logical statement written in an imprecise language such as English is always going to be prone to misinterpretation.

As a result, Boole believed logic should be a part of mathematics (up to that point, logic had been considered to be part of philosophy). By bringing logic under the remit of rigorous mathematics — and replacing words with mathematical symbols — the meaning of logic would then become precise and unambiguous.

But how could logical statements written in English be processed mathematically? That was Boole's challenge.

To understand Boole's solution, we need to realise that logical statements (or *propositions*) can take one of only two values: either "true" or "false". For example, in the previous example of boiling the kettle, we have two propositions. The first proposition is:

The kettle is plugged in.

This statement can be either true or false: the kettle might be plugged in (in which case, the statement is true) or the kettle might not be plugged in (in which case, the statement is false).

The second proposition is:

The button on the kettle is pressed.

Again, this proposition can be either true or false: the button on the kettle might be pressed (in which case, the statement is true), or the button on the kettle might not be pressed (in which case, the statement is false).

So, if we want to convert logic to mathematics, we have a series of statements which can take only one of two values: either true or false. A mathematical system of logic should then be based around variables which can take only two possible values. In making the conversion to a mathematical system, Boole substituted the value "true" with the number 1, and substituted the value "false" with the number 0. This then allowed mathematical operations to be performed on logical statements.

We might first try applying conventional arithmetic to these new values. For example, we might try combining two values using conventional addition. In that case, let us imagine the kettle is plugged in (the statement has the value "1" because the statement is true), and the button on the kettle is pressed (this second statement also has the

value "1" because the statement is true). In that case, when we add the values we get the answer 2. **But that answer is no good in our system of mathematical logic, because we only have two possible values in our system: 0 or 1.** Therefore, we cannot allow the value 2 as an answer.

So Boole had to find a new method of combining values in his method of mathematical logic, a method which could only ever give the answer 0 or 1 (representing true or false). The method Boole developed is now called *Boolean logic* or *Boolean algebra*.

Boolean logic was covered in detail in my previous book on quantum computing, but here is a brief description of just one of the possible Boolean operations.

The Boolean operation we will consider is known as the AND operation. The AND operator considers two Boolean input values — which we will call A and B — and only gives an output of 1 if both A **and** B are equal to 1. So we can capture the functionality of the AND operator in the following *truth table*:

A	B	A AND B
0	0	0
0	1	0
1	0	0
1	1	1

You can see that a truth table is divided into a left-hand side and a right-hand side. On the left-hand side, all the possible combinations of inputs are listed, while the right-hand side lists the output which will be produced by the operator when it receives those inputs. For the AND operator, you can see that the output is 1 only if inputs A and B are both equal to 1 (the output is zero otherwise).

You can see that the output of the AND operator is only ever equal to 0 or 1 — it can never be any other value such as 2. So, by discovering the Boolean operators such as the AND operator, George Boole had satisfied the requirement of Boolean algebra that only the values 0 or 1 could ever appear within the system.

But what George Boole could never have anticipated was the role that his Boolean logic would play in modern digital computers. Digital computers are based on binary arithmetic, using data bits which can only take the values of 0 or 1. Therefore, Boolean algebra was perfect for processing these binary values. When digital computers were invented, George Boole's system was seamlessly integrated. As a result, Boolean logic now forms the basis of today's digital computers.

In a digital computer, Boolean logic operations are implemented via *Boolean logic gates*. These take the form of miniaturised transistor circuits which perform the particular logical operation. Here is the symbol for the AND gate which performs the AND operation which was shown in the previous truth table:

Other Boolean logic gates include the OR gate, which gives an output of 1 if either A **or** B is equal to 1. Here is the symbol for the OR gate:

Have you ever wondered what goes on inside an electronic integrated circuit (silicon chip)? Well, some integrated circuits — such as microprocessors — can be extremely complicated, it is true. But other integrated circuits merely implement Boolean logic gates, and these type of chips are extremely common in electronics.

As an example, the following diagram shows how the logic gates are arranged inside a particular integrated circuit. The integrated circuit shown is a very common logic chip called the 7432, which is one of the popular and widespread 7400 series of integrated circuits which have been used to build computers for decades. You can see it has a total of 14 pins (legs), and the schematic diagram shows that it contains a total of four logical OR gates. You can see how the inputs and outputs of the OR gates are connected to individual pins (with two pins being reserved for the power supply to the chip):

So maybe digital electronics is not as complicated as you might imagine.

But, through all this talk of electronics, we must be careful not to forget that at the heart of all this high-technology lies logic. It is the logic of George Boole, which Boole based on the logic of Aristotle. Yes, the underlying principles of that 7432 integrated circuit are based on the writings of Aristotle 2,500 years ago.

So let us now try to explicitly connect the functioning of Boolean logic gates with the logic of Aristotle.

Remember the previous example of Aristotelian logic which involved the boiling of a kettle. If you remember, there were two propositions. The first proposition was:

The kettle is plugged in.

And the second proposition was:

The button on the kettle is pressed.

Either of these two propositions can be either true or false (it might be true that the kettle is plugged in, or it might be false). Hence, making the transition to Boolean logic, we can assign the value 0 or 1 to both of these propositions, and they can then be used as inputs to a Boolean AND gate:

As you can see in the previous diagram, the AND gate then performs the correct logical inference. Because both of its inputs are equal to 1, the output of the AND gate will then also be equal to 1 (the standard behaviour of an AND gate). If we then associate the output of the AND gate with the final proposition "The kettle will boil" then we

can see that the AND gate is stating that the proposition is true (its output value is 1). Yes, the AND gate has correctly concluded, the kettle will boil.

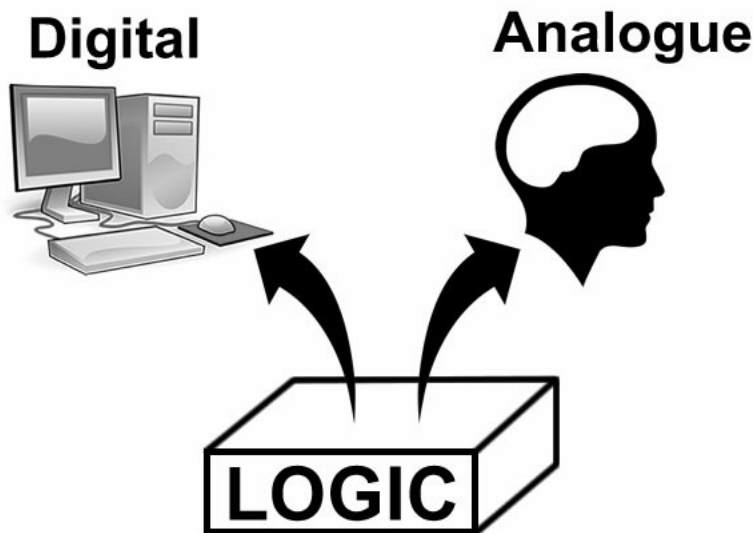

The AND gate has therefore performed the correct logical inference. In other words, the AND gate has come to the same logical conclusion as a human. It might therefore be said that the AND gate has followed the same "thought process" as a human, given the initial premises.

This represents the simplest form of "thinking", and reveals how an electronic digital device can "think" like a human who is trying to make a cup of tea.

George Boole presented his new algebra in 1854 in a book entitled *The Laws of Thought*. The title of the book now seems almost provocative. We like to imagine our thought processes as being free and unconstrained, but the title of Boole's book suggested that there are rules and laws which constrain our thoughts.

And those rules are the laws of logic.

So when people compare human brains with computers, and say that they are not the same because one is based on analogue hardware, and one is based on digital hardware, the wrong comparison is being made — too much emphasis is being placed on the hardware. The particular hardware is irrelevant. At a deeper level, both of these forms of "thought process" have logic at their base. It is logic which provides the commonality of operation. Brains and computers are both basically doing the same thing: processing logic.

So far we have only considered the functioning of logic in computer hardware. But now let us move to consider the functioning of logic in the hardware of the brain.

Because things are about to get very interesting.

We are about to enter the 20th century ...

The wild-bearded poet

As our tale enters the 20th century, our attention turns to another country about to enter its own Golden Age. This was the century in which America emerged as a superpower, the most influential and powerful country in history. It was in the 20th century that America also became the world's leading centre of scientific research, taking the crown from the Old World centres of Britain and Germany (a process which was hastened by the exodus of Jewish scientists escaping Nazi Germany for America).

Warren McCulloch was born at the start of the 20th century in Orange, New Jersey. The McCulloch family was

wealthy, and upper middle class. Warren was educated at a private school, and revealed himself to have "an eager and inquiring mind that went way beyond his assigned studies". McCulloch was described as having an insatiable curiosity.

When McCulloch was a student in Pennsylvania in 1917, one of his teachers asked him what his ambitions were in life. McCulloch said his aim in life was to be able to answer the following question, and gave a famous, poetic quote: "What is a number, that a man may know it, and a man, that he may know a number?"

As far as McCulloch was concerned, the first part of the question had been satisfactorily answered by mathematicians: "What is a number, that a man may know it?" McCulloch said that his goal in life was to answer the second part of the question: "What is a man, that he may know a number?" In other words, McCulloch wanted to know how a brain worked.

McCulloch started his career as an undergraduate at Yale in 1918, studying philosophy and psychology. For his undergraduate thesis, McCulloch chose to consider the psychological appeal of the Golden Ratio and the Golden Rectangle, which was considered earlier in this chapter. This was a particularly hot topic during the 1920s in America because of the rise of a new subject: the psychology of advertising. McCulloch decided to determine whether or not it was true that consumers might have an aesthetic preference for the Golden Rectangle design.

For his experiment, McCulloch presented various images — some based on the Golden Rectangle design, some not — to twenty-four of his fellow Yale students. After evaluating the results, McCulloch concluded that it was, indeed, true that designs based on the Golden Ratio would be preferred by consumers.

Following his Golden Ratio experiment, McCulloch was impressed by this example of geometry and mathematics for revealing truths about the mind. McCulloch found himself increasingly convinced that only a multi-disciplinary approach would be capable of unlocking the secrets of the mind.

McCulloch's approach required the incorporation of ideas from neuroscience, physics, mathematics, engineering, and philosophy. However, following such a multi-disciplinary approach is not easy in academia. Academia tends to require specialisation in a single discipline, be it physics, or mathematics, or biology, or any other science. There is also tremendous pressure to publish papers regularly — leaving little time to obtain a wider range of knowledge about unrelated disciplines. As a result, an academic researcher's knowledge about a subject can sometimes be rather narrow, with a lack of awareness of other research fields. However, to gain a true understanding of the brain — and consciousness — requires a true multi-disciplinary approach and a broad range of knowledge over many different scientific fields. [\[16\]](#)

Due to his belief in a multi-disciplinary approach, McCulloch's work often ran counter to academic conventions, and the boundaries of individual disciplines. Because of this, when Tara Abraham wrote a biography of Warren McCulloch, she chose to call her book *Rebel Genius* — which seems a fitting term to describe McCulloch.

The rebellious nature of McCulloch was also described in a *Nautilus* article by Amanda Gefter in which McCulloch is described as a "confident, gray-eyed, wild-bearded, chain-smoking philosopher-poet who lived on whiskey and ice cream and never went to bed before 4 a.m."

What a man!

Here is a photograph of Warren McCulloch taken in 1967:

McCulloch started reading the *Principia Mathematica*, the monumental work written by the mathematical logicians Bertrand Russell and Alfred Whitehead. As stated in *Rebel Genius*, Russell believed that "the laws of logic are the laws of thought". This had a great influence on McCulloch. According to Stanislas Dehaene in his book *The Number Sense*, McCulloch started to hold a strong personal conviction that the brain should be considered as being a "logical machine".

However, as Tara Abraham states in *Rebel Genius*: "McCulloch's interest in the logic of the nervous system would not become explicit until the early 1940s".

That was because, in the 1940s, McCulloch met the perfect collaborator, a man with whom McCulloch would present a new theory of how the hardware of the brain processes logic ...

The unhappy childhood of Walter Pitts

Walter Pitts was born in Detroit in 1923. He had a tough upbringing, surrounded by poverty, and with a boiler-maker father who was not afraid of dishing-out physical punishment to his young son. Walter was also regularly bullied by boys in the neighbourhood. But on one occasion in 1935, when Walter was being chased by the boys through the streets, he sought sanctuary by making a sharp turn into a local library — and, at that point, his life changed forever.

Walter hid in the library until it closed for the night. When he emerged from his hiding place later that evening, he had nothing else to do but read the books. Walter discovered the three-volume *Principia Mathematica* written by Bertrand Russell and Alfred Whitehead (it has just been mentioned that this was a book which Warren McCulloch

also read). The *Principia Mathematica* is a huge and impenetrable work on mathematical logic (it was described in my fourth book). This did not deter Walter, who stayed in the library for three days and read each volume in its entirety.

It is easy to understand why Walter wanted to immerse himself in the world of mathematics. Surely the logic and rationality of mathematics represented an escape from the chaos of his traumatic reality.

Walter discovered he had a talent for mathematics, and he wrote to Bertrand Russell to inform him that he believed he had found a few mistakes in the *Principia Mathematica*. Remarkably, not only did Russell reply, but he invited Walter — at just twelve years of age — to come and visit him in Cambridge University. Walter was too young to travel, but three years later, when Bertrand Russell came to visit the University of Chicago, Walter ran away from home hoping to meet Russell.

Walter Pitts never went home again.

The McCulloch-Pitts artificial neuron

In Chicago, Walter managed to sneak into one of Russell's lectures, and finally managed to meet his idol. Even though Pitts was not registered as a student, he started attending lectures. And so it was that young Walter Pitts was introduced to the wild-bearded Warren McCulloch.

Here is a photograph of Walter Pitts taken in 1950:

McCulloch instantly recognised that he had shared interests with Pitts, and the two became collaborators. McCulloch was convinced that the brain could be modelled as a logical machine. Pitts, with his background in logic

and mathematics, developed a similar conviction.

McCulloch's multi-disciplinary approach meant that he was aware of the structure of neurons. As can be seen in the following diagram, a neuron is composed of a cell body with an internal nucleus. Many branches come out of the cell body, and these are called *dendrites*. These branches receive input signals from previous neurons in the network. There may be in the region of a hundred dendrites on a single neuron. There is a single long output branch from the neuron, and this is called the *axon*. The signal along the axon is always in one direction — away from the cell body:

The neuron receives multiple input signals on its dendrites. These input signals take the form of electrically-charged particles. If these input signals result in raising the internal electric charge of the neuron sufficiently, then the neuron is said to "fire", which means that an electrically-charged pulse (an *action potential*) is sent down the neuron's axon to the next neuron in the network.

Axon terminals at the end of the axon connect to the dendrites of the next neurons in the network. However, it is not a direct physical connection: there is a narrow gap between the axon terminal and the dendrite of the next neuron, and this gap is called a *synapse*. As one synapse represents the connection between a neuron and the next neuron in the network, we might consider each synapse as representing an input to a neuron. Crucially, therefore, neurons have **multiple logical inputs** — each of which can be either 0 or 1 — but **only one logical output** (a single value, either 0 or 1).

McCulloch was also aware of the "all-or-none" principle which meant that a neuron would only fire when the total value of that neuron's inputs exceeded a certain value. This meant that a neuron behaved like a Boolean logic gate, with only two possible outputs: 1 (when the neuron was firing), or 0 (when the neuron was not firing).

The science writer Amanda Geffer has written a superb article about Pitts and McCulloch for the *Nautilus* website.^[17] In that article, McCulloch's insight was described: "Neurons seemed to work like logic gates, taking in multiple inputs and producing a single output. By varying a neuron's firing threshold, it could be made to perform AND, OR, and NOT functions."

Walter Pitts immediately understood McCulloch's idea, and together they worked to create a model of a neuron which worked in a similar fashion to a logic gate. Tara Abraham describes the theory of the neuron which was developed by McCulloch and Pitts as: "a theory that transcended the divides between science, philosophy, and experimental medicine. McCulloch and Pitts were not interested in the mechanism of transmission of the nerve impulse but rather in the **relation** between stimulus and response, which they ultimately translated into a **logical** relation."

The following diagram shows the design of the *McCulloch-Pitts neuron model*. The model represented the first artificial neuron.

In the model, there are multiple inputs, with each input representing a dendrite of the neuron. Each input has a value which, in the case of this simple model, can only take one of the binary values: 0 or 1. Each input is then multiplied by a weight, as shown on the following diagram:

The total of all the inputs is then summed internally by the artificial neuron, and a thresholding function is applied. The thresholding represents the implementation of the "all-or-none" principle in actual neurons: the artificial neuron will only fire if the total value of its weighted inputs is greater than some threshold value. The output of the artificial neuron then becomes the equivalent of the single axon output of an actual neuron. Because of the thresholding function, the output of the artificial neuron can only be 0 or 1, and that output value then becomes one of the input values of the next neuron in the network. In this way, highly complex networks of artificial neurons can be constructed.

In her book *Rebel Genius*, Tara Abraham considers the goal of McCulloch and Pitts: "McCulloch and Pitts's goal was to represent the functional relationships between neurons in terms of Boolean logic: **to embody reasoning in the physiology of the brain.**"

That phrase "to embody reasoning in the physiology of the brain" means that **logic is hard-wired into the structure of our brains.** It might be imagined that neurons have the structure that they have — with multiple inputs and a single output — simply because of a vague notion that the design allows for a large number of connections. But, no, that is not the reason for the specific design of neurons. Neurons are designed specifically to perform logical operations. As a result, neurons have multiple inputs and a single output, just as Aristotle's logic had multiple input premises and a single conclusion, or a Boolean logic gate has multiple inputs and a single output. **Neurons have the structure they have because they are the living embodiment of Aristotle's logic (or, its more modern equivalent, Boolean logic).**

Logic is hard-wired into the structure of our brains. Logic is so fundamental to our thought processes that the structure of logic defines the structure of every neuron in our brain, which is why neurons resemble Boolean logic gates.

Unfortunately, Walter Pitts' story did not have a happy end. He sank into depression, and began drinking heavily — he had never recovered from his traumatic childhood experiences. He burnt his unpublished doctoral dissertation, and all of his private documents and papers. Amanda Gefter described this self-destructive act as "priceless information reduced to entropy and ash".

It has been said that Walter Pitts spent the last years of his life trying to erase his very existence. However, that did not happen, as the influence of Walter Pitts lives on. That is because today we are surrounded by the descendants of the McCulloch-Pitts artificial neurons. Their design represented the first form of *neural network*. Neural networks now form the foundation for the current revolution in artificial intelligence (see my previous book on consciousness for more details). So the work of the wild-bearded poet Warren McCulloch and the tragic genius of Walter Pitts lives on in the artificial intelligence which lies at the heart of much of our modern technology.

Thermodynamics and the brain

At this point in our historical saga, we need to take a slight detour from our story of the history of logic. Before we can proceed further, the science of *thermodynamics* needs to be introduced. Thermodynamics is going to be a central theme of the rest of this book. This might seem like a slightly puzzling detour, but I can assure you that we shall soon see the close connection between thermodynamics and our logical thought processes.

Thermodynamics is the science of heat ("thermo") and motion ("dynamics"). The science of thermodynamics was developed in the 19th century in order to obtain a better understanding of the workings of steam engines. However, in the 20th century it was realised that thermodynamics is relevant to a much wider range of applications. Indeed, Stephen Hawking's most famous work was related to the thermodynamics of black holes.

So why does thermodynamics have such a wide range of applications?

Well, first let us consider the traditional model of physics. Physics can be used for making accurate predictions about the behaviour of particles and forces. In the classical physics of Newton, for example, we might consider a single object, such as a billiard ball. We might have precise information about the position and motion of that single ball. If that ball is then struck by a second moving ball, we can use the physics of Newton to accurately calculate the velocities of both balls after the collision. It is all very precise.

But what if we do not have complete information about the balls? For example, what happens if we have a large sack full of billiard balls, and we start shaking the sack. The balls start moving and colliding in a random fashion. We do not possess accurate information about the positions or velocities of any of the individual balls. Does that mean we can no longer use physics to describe the motions of the balls? Can we no longer use Newton's laws of physics to describe the balls? Do the laws of physics no longer apply?

No, of course the laws of physics still apply, but instead of using Newton's laws of classical mechanics, we now have to use *statistical mechanics*. Statistical mechanics describes the aggregate behaviour of a very large number of individual particles. We can use statistical mechanics to consider the **aggregate** behaviour of **all the balls** in the sack. For example, we might calculate the **average** velocity of **all** the balls in the sack.

When it is used to analyse the motion of atoms and molecules, statistical mechanics gives rise to thermodynamics. To see how that happens, let us replace the random motions of billiard balls with the random motions of trillions of atoms (or molecules) of gas in a sealed container. Those atoms will be moving and colliding randomly — just like the billiard balls in the sack. As a result, we clearly cannot possess accurate information about the motion of any of the individual atoms. However, that random motion of the atoms will result in heat (heat is the random motion of atoms or molecules), and we can measure the temperature of the gas. Even though we do not possess information about the motion of any of the individual atoms, we can still characterise the overall motion of the all the atoms by using an aggregate measure: the temperature of the gas.

And that is the basis of thermodynamics. Even if we do not have complete information about all the individual elements of a system, we can still generate aggregate measures and then use the laws of thermodynamics to describe the behaviour of the system.

And that is why thermodynamics is a branch of physics which is so well-suited for describing the behaviour of the brain. The brain is composed of approximately 86 billion neurons. At any particular moment, we do not possess complete information about the behaviour of the individual neurons — just as we do not possess information about the behaviour of individual atoms in a gas. However, we can still use aggregate measures and the laws of thermodynamics to describe the total behaviour of **all** the neurons in the brain.

The science which considers the thermodynamics of the brain is still in its relative infancy.[\[18\]](#) However, the remainder of this book will be concentrated on considering the thermodynamic behaviour of the brain, and the relationship to the logical behaviour of neurons.

But, first, let us consider the most famous thought experiment in thermodynamics.

Maxwell's Demon revisited

The thought experiment which is now known as *Maxwell's Demon* was devised by the great Scottish physicist James Clerk Maxwell in 1867 (another product of the Victorian golden age). The details of the thought experiment were described in the first chapter of my previous book on consciousness, but the experiment will be described again here because this time we will be taking the experiment further, to reveal new insights and new implications for information processing.

The experiment considers a gremlin-type character (known as the "demon") who operates a trap door which separates two compartments. The two compartments are both filled with the same gas, which is initially at the same temperature in both compartments.

The demon has superpowers, which include incredibly good eyesight which allows him to see each individual gas molecule, incredibly high information processing power in his brain which allows him to calculate the speed and trajectory of each gas molecule, and incredibly quick reflexes which allows him to quickly open the trap door to allow selected individual molecules to pass between the two compartments.

The following diagram shows the demon in action. You can see him opening the trap door to allow a fast-moving gas molecule to pass from the right-hand compartment to the left-hand compartment:

Let us imagine the demon continues with this strategy, allowing faster-moving molecules to pass to the left-hand compartment, and allowing slower-moving molecules to pass to the right-hand compartment. Over time, this will result in the gas in the left-hand compartment becoming warmer, and the gas in the right-hand compartment becoming cooler (because heat is nothing more than the motion of molecules).

As a result of his actions, we can say that the demon is lowering the *entropy* of the system. We can consider the entropy of a system as being the amount of disorder or randomness in that system. Initially, the gas was equally divided between the two compartments, with both compartments being at the same temperature. There is no organization to this situation: the molecules have not been ordered in any way, they have been distributed randomly between the two compartments. We therefore say that this is a situation of high entropy. In that situation, the entire system can be completely described by just one piece of information: the temperature of the entire body of gas. So high entropy is connected with low information content.

But when the demon performs his sorting operation — ordering the molecules according to speed, and assigning them to separate compartments on that basis — the demon is organizing the system. He is introducing a structure to the arrangement of the gas molecules. We would therefore say that the demon is lowering the entropy of the system.

The organized system then contains two pieces of information: the temperature of the left-hand compartment, and the different temperature of the right-hand compartment. Hence, the information content has increased as the entropy has decreased.

To recap our findings:

High entropy is connected with low information.

Low entropy is connected with high information.

In other words, there is an inverse relationship between information and entropy. [\[19\]](#)

As another example of the relationship between information and entropy, let us return to consider the actions of the tragic Walter Pitts as he burnt his doctoral dissertation and research notes. As Amanda Gefter described earlier in this chapter, this act represented "priceless information reduced to entropy and ash". That is perhaps the clearest example of how a reduction in information (the loss of his papers) leads to an increase in entropy (the random and

featureless ash).

However, the action of the demon introduces a mystery. This result of the demon's actions appears to be in conflict with the second law of thermodynamics, one of the cornerstone laws of physics. The second law of thermodynamics states that heat will always tend to move from a warmer region to a cooler region, thus eventually equalising the temperatures. The entire compartment would then eventually be at the same temperature. We have just seen that this single-temperature gas represents a situation with maximum entropy. So the second law states that the entropy of a system will always increase (a system will always tend to become more disordered).

But if the demon is lowering the entropy by organizing the gas molecules, then that would appear to contravene the unbreakable second law of thermodynamics.

So, what is going on?

A solution was urgently required ...

The solution of Leo Szilard

The mystery of the apparent breaking of the second law of thermodynamics in the Maxwell's Demon thought experiment remained a mystery for several decades after James Clerk Maxwell first proposed the experiment. However, in 1929, an apparent solution was found by the physicist Leo Szilard.

We met Leo Szilard in my eighth book which explained how to make an atomic bomb. Szilard played a central role in the story of the bomb development. He was the first person to conceive of the nuclear chain reaction, and he persuaded Einstein to write his letter to President Roosevelt urging the United States to start its own nuclear program.

But Szilard was not only a physicist — he was also an entrepreneur who knew a business opportunity when he saw one. In one of the more bizarre episodes in the history of physics, between 1926 and 1930, Leo Szilard persuaded his friend Albert Einstein to work with him to develop a new type of refrigerator. We should remember that Einstein was at the peak of his fame and powers at the time. Presumably Einstein saw building a new fridge as a logical next step after developing the equations of general relativity. Or maybe it speaks volumes about the persuasive abilities of Leo Szilard. Whatever his motivation, it represented an opportunity for Einstein to use the technical knowledge he had gained during his time as a humble patent clerk.

The "Einstein refrigerator" was patented in 1930, but it was never put into commercial production.

Here is a photograph of Leo Szilard:

It was during this period that Szilard was working with Einstein on the refrigerator that Szilard thought he would attempt to find a solution to the mystery of Maxwell's Demon. After all, the operation of a refrigerator is based on thermodynamics, and Maxwell's Demon was a thought experiment about thermodynamics, so Szilard's fridge skills would have been directly transferable.

If you remember, the mystery of Maxwell's Demon is how can the demon manage to lower the entropy of the gas

— seemingly in contravention of the second law of thermodynamics. Szilard realised that the solution was to not only consider the change in entropy of the gas, but to consider the change in entropy of the entire system — including the demon. But where was this increase in the entropy of the demon coming from?

If we consider the idealized version of the thought experiment, in which the trap door is completely frictionless, then the only possible source of the increased entropy of the demon would be from the measurements and calculations in the demon's mind. Remember, the demon is having to perform a truly superhuman mental feat, calculating the velocities of every single individual molecule of gas. Szilard realised that the increased entropy generated by the superhuman mental processes of the demon could hold the key to the mystery.

For every molecule of gas, Szilard realized that the demon had to make a binary decision: whether or not to open the trapdoor. Hence, if the demon could calculate a single bit of information for every molecule of gas in the box, then the entropy of the gas **could** be reduced (a *bit* is a unit of information which can only take the binary values of 0 or 1).

The amount of entropy associated with a bit of information is well-known and is given by the *Boltzmann entropy formula* as:

$$k \ln(2)$$

where k is Boltzmann's constant, "ln" is the natural logarithm, and the "2" arises because a bit has two possible values.

If you calculate this value, you find that the amount of entropy associated with a single bit of information is equal to the microscopic amount of 9.57×10^{-24} joules/kelvin.

This value representing the increase in the entropy of the demon is such a small amount that it might be wondered how it could ever be large enough to exceed the reduction of the entropy of the gas. However, it must be realised that this value just represents the increase of entropy due to a **single** molecule of the gas. With a truly astronomical amount of molecules in the gas, the increase of the entropy of the demon would exceed the reduction of the entropy of the gas.

As a result, the total amount of entropy in the entire system — including the demon — would have increased, and so the second law of thermodynamics would not have been broken.

Szilard published his solution to Maxwell's Demon in 1929. He gave it the title *On Entropy Reduction in a Thermodynamic System by Interference by Intelligent Subjects*.

The use of the word "intelligent" in the paper's title is revealing. Remember, Szilard was a physicist. Up to that point, physicists had only talked about fundamental things, such as atoms and forces, things which could be easily measured. In contrast, the messy, complex, emergent concept of "intelligence" was not considered to be something which physicists should study, or mention in their published papers.

But now, for the first time, Szilard was connecting the concept of "intelligence" with the laws of physics. Szilard's approach was described in a paper by Maruyama *et al.*: "Szilard treated the demon's intelligence as information, and linked it with physics ... Szilard's work was epoch-making in the sense that he explicitly pointed out, for the first time, the significance of information in physics." [20]

Physicists had always avoided the concept of "intelligence" because it was something internal to the human mind — it was not something that could be measured. After all, we cannot see inside a mind.

But Leo Szilard had managed to see inside the mind of the demon.

The man from IBM

Our saga now moves on to the 1960s in the USA.

Turn on, tune in, drop out ...

This was a decade in which young people rebelled against traditional values, instead placing an emphasis on peace, love, and personal freedom. This atmosphere of liberation also included sexual freedom, and the freedom to take drugs, with the drug of choice being lysergic acid diethylamide, or LSD.

But the 1960s was also one of the most turbulent decades in the history of the United States. As the Vietnam War raged, it was a decade of assassinations and riots. The reality of America was far from the ideals of the hippies — it was a deeply divided country.

These divisions were even visible in the heart of corporate America, in the IBM Research Center in Yorktown, New York. One of the leading researchers, the information theory pioneer Rolf Landauer, was remembered by his fellow computing legend Charles Bennett: "Rolf was an old IBM type who did things on the straight and narrow. I was a scruffy hippie."

Here is a photograph of Rolf Landauer taken in the 1960s, looking very dapper:

Landauer was well aware of Leo Szilard's solution to the mystery of Maxwell's Demon, which was generally believed to have solved the problem. But Landauer was not convinced that Szilard's solution told the whole story.

If you remember, Leo Szilard proposed that the measurement and calculations being performed in the demon's

head would necessarily generate more entropy than the reduction in entropy of the gas. As a result, the total entropy of the system would increase — in accordance with the second law of thermodynamics. But Rolf Landauer wasn't satisfied: he wanted to know the details of the internal processes of the demon's brain. Why was entropy increasing?

To understand Landauer's approach, let us consider the internal workings of the demon's brain.

As was described toward the start of this long chapter, we like to consider our thoughts as being free and unconstrained. However, perhaps we do not realise that there are rules and laws which govern our thoughts, and those rules are the rules of logic. Certainly, to be capable of ordering molecules according to their measured and calculated velocities, and thereby making a decision to open a trap door, the demon would need to possess a mind capable of logical thought. As we shall be seeing later, if you want to do anything useful with information, you have to use logic.

And that logical ability would surely be hard-wired into the demon's brain in the form of neurons which resemble our own neurons. In other words, just as McCulloch and Pitts suggested, the demon's brain would be composed of neurons which resembled logic gates.

Just as Amanda Gefter described the work of McCulloch and Pitts earlier: "Neurons seemed to work like logic gates, taking in multiple inputs and producing a single output. By varying a neuron's firing threshold, it could be made to perform AND, OR, and NOT functions."

So let us consider a particular neuron which operates like an AND gate:

The structure certainly resembles a neuron with multiple inputs and a single output. Logic gates such as the AND gate can also have many more than just two inputs, which make them appear even more like neurons. In the case of the AND gate, that would mean that the output would only be equal to 1 if **all** of its multiple inputs were equal to 1.

Here is the truth table for the AND gate which was presented in the earlier discussion on Boolean logic:

A	B	A AND B
0	0	0
0	1	0
1	0	0
1	1	1

We might think of this truth table as describing a neuron which only "fires" (output equal to 1) when all of its inputs are equal to 1. This is common behaviour for a neuron.

What Rolf Landauer did was consider the relationships between the inputs and the outputs in the previous truth table. He realised that if the output was equal to 1, then you would be certain that both of the inputs had to be equal to 1 (as you can see from the previous truth table). However, that certainty vanished if the output was equal to 0. As you can see from the following truth table, if the output was equal to 0 then you could not tell if the inputs had both been equal to 0, or if one of the inputs had been equal to 0 while the other input had been equal to 1. In all three of these cases, the output would have been equal to 0:

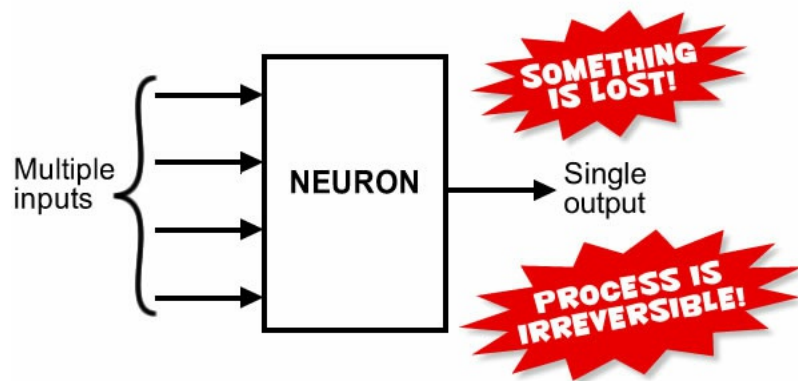

A	B	A AND B
0	0	0
0	1	0
1	0	0
1	1	1

} Same outputs

As a consequence, if you were only presented with the output of the gate, you would not be able to say what that the inputs had been with complete certainty. Before the operation of the logic gate, you knew the value of both of the inputs, but after the operation of the logic gate, you no longer knew the value of both of the inputs. In other words, some knowledge — some *information* — would have been lost through the operation of the gate.

This type of Boolean gate is therefore not reversible. If all we know is the output, we cannot "wind the gate back" and get the input values. As Rolf Landauer said in his original landmark paper: "We shall call a device *logically irreversible* if the output of a device does not uniquely define the inputs". [21]

We cannot return to our previous situation because we have lost information. And this, therefore, reminds us of a MISO process in which something is "lost" and, as a result, the process becomes irreversible:

What we can see in both the AND gate and in the MISO process is that the root cause of the irreversibility is that we have multiple bits of information coming into the gate, but the output is only a single bit of information. As a result, information is bound to be lost. Some of those input bits of information are bound to be lost.

And that is also the root cause of the increase in entropy in the mind of the demon. As we saw in the earlier discussion of Maxwell's Demon, there is an inverse relationship between information and entropy: that means if information increases then entropy decreases, but if information decreases (as is the case here, with information being lost) then entropy increases. And therefore the entropy in the demon's mind is bound to increase as information is lost in the neurons of the demon's brain.

On the basis of the reasoning presented here, Landauer then stated his conclusion: **entropy will increase when bits of information are lost, or deleted, or erased.** This represents one of the most important principles in information theory, and it is called *Landauer's principle*.

Landauer's principle is now accepted as the true reason why Maxwell's Demon cannot violate the second law of thermodynamics.

Remember, Rolf Landauer worked for IBM Research, and his research interest was not brains — it was computers. In particular, the aim of this theorising of Landauer was to make more efficient computers. That involved reducing the energy requirement of computers, and reducing their heat output. There is a direct connection between entropy and heat as entropy is randomness, and heat is nothing more than the random motion of atoms and molecules. So Landauer decided to use his new principle to calculate how much heat would be produced by the

erasure of a single bit of information.

To convert entropy to energy (heat energy in this case) you have to multiply the entropy by the temperature. So Landauer took Szilard's formula for the entropy of a single bit of information (which was presented in the previous section) and simply multiplied it by the temperature. As a result, according to Landauer, the erasure or deletion of a single bit of information in a computer would produce an amount of heat equal to:

$$kT \ln(2)$$

where T is the ambient temperature. You will note that this is just Leo Szilard's formula multiplied by T .

This represents an extremely small amount of heat. Therefore, does Landauer's principle have any relevance to the functioning of the brain, and the heat output of the brain? We will discover the answer shortly.

The incredible power of Landauer's principle

At this point, I want to devote this section to emphasising the most important and powerful feature of Landauer's principle. The most important feature is this: Landauer's principle allows us to calculate the **absolute minimum** amount of heat which must be produced when a bit of information is deleted. You will note that the emphasis in the previous statement is on "absolute minimum". When something represents a minimum amount that means it can never be reduced to something smaller. Never. Under no circumstance whatsoever. It is physically impossible to reduce the amount of heat produced below the Landauer limit.

I am sure that this is not generally appreciated. As has just been explained, wherever there is logical information processing — either in Boolean logic gates in a computer, or in the neurons of a human brain — then bits of information will inevitably be lost. Landauer's principle can then be used to determine how much heat will be produced due to that lost information. But the key point is **that amount of heat will be the absolute minimum amount, and can never be reduced below that amount.**

As an example of this incredible consequence of Landauer's principle, let us imagine a PC on your desk performing an intensive calculation, maybe encoding a video. The fan on your computer might well start to spin to cool the processor to stop it overheating. We might think of that heat being produced in some vague way as being an unwanted nuisance, just an annoying side-effect of the processor working hard. We might imagine that if we had better technology in our PC (maybe copper wires?), or maybe a better processor design then that heat could be eliminated. But if we thought that, we would be wrong.

Landauer's principle reveals that the heat is not an annoying by-product — it is an intrinsic feature of logical information processing. The amount of heat could possibly be reduced, but it cannot be eliminated. Even if we replaced all the wires in our computer with zero-resistance superconductors so that heat is not produced by the electrical current flowing through the wires, that minimum amount of heat would still be produced by the logic gates. The heat can never be completely eliminated.

Rolf Landauer refers to this dissipation of heat in his original paper: "The relevant point, however, is that the dissipation has a real function and is not just an unnecessary nuisance".

This represents a new way of looking at the heat produced by your computer. The heat is not an "unnecessary nuisance" — it is an intrinsic part of logical information processing.

But it is not all bad news. This inevitable production of heat is definitely a bad thing if you are interested in designing computers for IBM, but — as we shall soon see — it represents a powerful signature if you are interested in detecting consciousness.

Landauer's principle and the brain

Rolf Landauer developed his principle to predict heat production in computers. But what does it tell us about the brain?

Since ancient times, it has been known that the brain produces an extraordinary amount of heat. It was Aristotle who first became fascinated by the heat production of the brain. Aristotle decided — on the basis of the sheer amount of heat being produced — that the sole function of the brain must be to cool the blood (Aristotle believed that consciousness resided in the heart). [\[22\]](#)

The statistics are striking. The average power consumption of a human at rest is 100 watts (imagine a 100 watt light bulb as a comparison — it is hot). The brain has a power consumption of approximately 20 watts, which means that a fifth of the entire power consumption of a human is being used by the brain. It is the most energy-hungry organ. In comparison, the heart pumps 2,000 gallons of blood every day, but it still only requires 13 watts of power. So the brain — which has no moving parts — has a power consumption which is considerably greater than your continually-beating heart which pumps the equivalent of sixty baths full of water around your body every day.

What is going on? Can Landauer's principle explain this, just as Landauer's principle explained the true reason for the entropy increase (and, therefore, the heat production) of the brain in Maxwell's Demon?

To answer this question, I decided to use Landauer's principle to calculate the total heat output of the brain. The calculation was based on the MISO model of the neuron, with a neuron having multiple inputs, but only a single output. Each input which is not carried-over to the output represents a deleted bit of information.

As described earlier, the amount of heat produced by the deletion of a single bit of information is extremely small. However, there are approximately 150 trillion synapses in the adult human brain. If you remember, a synapse is the narrow gap representing an input to a neuron. Each of those synapses represents a single bit of information from a previous neuron, a bit of information which can be lost. Multiply a small amount of heat by 150 trillion synapses and the result will be a very significant amount of heat.

The calculation is presented in the appendix at the back of this book. The result of the calculation was that Landauer's principle predicts the total heat output of the brain to be 16.5 watts, which compares very well with the actual value of 20 watts.

What the calculation reveals is that the analysis in this book is correct. The heat production of the brain arises because of the fundamental design of neurons. Information is lost in neurons because inputs are not carried-over to outputs. Landauer's principle then allows us to calculate the total heat output.

But that neuron design is aimed at allowing a neuron to process information in a logical manner. Logic is hard-wired into the design of neurons. In other words, **the brain is so hot because it is a logical information processor.**

Aristotle would surely have been fascinated to learn that the true reason why the brain is so hot is because of the system of logic which he invented — and is nothing to do with cooling the blood.

If it's cold, it's not conscious

So the Landauer's principle calculation has revealed that any large-scale information processing — such as in a brain — must inevitably produce a detectable amount of heat. The heat production is utterly unavoidable.^[23] The heat produced by logical computation or thinking will always have a minimum limit — the Landauer limit — which means that the heat produced by thinking can never be reduced to zero.

In effect, we have found a "heat signature" of logical thought. This represents a very powerful tool for us as it represents a simple way to detect logical thought in objects.

In his book, *The Singularity is Near*, Ray Kurzweil asked the question "How smart is a rock?": "Consider the computation that takes place in an ordinary rock. Although it may appear that nothing much is going on inside a rock, the approximately 10^{25} (ten trillion trillion) atoms in a kilogram of matter are actually extremely active. Despite the apparent solidity of the object, the atoms are all in motion, sharing electrons back and forth, changing particle spins, and generating rapidly moving electromagnetic fields. All of this activity represents computation, even if not very well meaningfully organized. In terms of computation, and just considering the electromagnetic interactions, there are at least 10^{15} changes in state per bit per second going on inside a 2.2-pound rock, which effectively represents about 10^{42} (a million trillion trillion trillion) calculations per second. **Yet the rock requires no energy input and generates no appreciable heat.**"

But there is a very good reason why the rock is generating "no appreciable heat". Firstly, we should consider if the rock is really performing "computation" as Ray Kurzweil suggests. For a definition of "computation" and a "computer" we need to consider the archetypal form of computer which is the *Turing machine*.

The Turing machine was invented by the English mathematician Alan Turing in 1936. It is a simple device which can perform a sequence of logical operations — encoded as symbols — which are written on a long strip of tape. Those symbols written on the tape formed the basis of the modern computer program. Indeed, the Turing machine forms the blueprint for all modern computers (the Turing machine was considered in detail in my previous book on consciousness).

But is a rock doing anything like this? Of course it is not. To suggest, as Ray Kurzweil suggests, that a rock is "computing" is to stretch the definition of "computing" so thin that it breaks.

In the more general sense, "computation" involves **logical** information processing, performing a series of logical steps to achieve some useful goal, such as solving some problem, or performing a calculation.

If you want to do anything useful by processing information, you have to use logic. The reason why computers are so useful is because they have logic at their core. The reason why computer programs are so useful is because they are the written embodiment of a logical sequence of operations. This need for logical information processing is the reason why a computer — or a brain — is composed of billions of logic gates (or neurons).

And this is why Ray Kurzweil's rock is cold: **the rock is not performing any logical information processing.** As we have just seen, if the rock was performing any type of logical information processing then it would inevitably produce heat — as predicted by Landauer's principle.

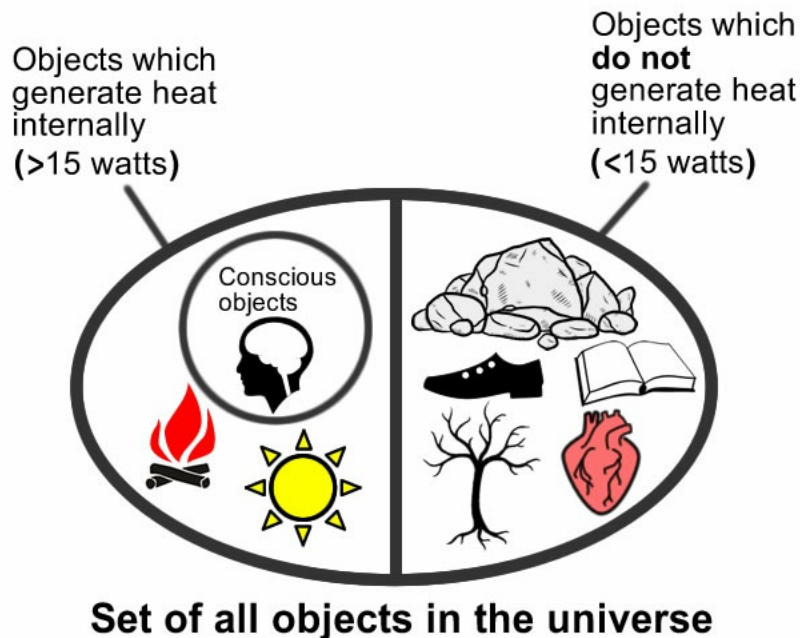

Real computing produces heat. If an object is not computing anything, it will be cold. Hence the phrase "stone cold". The rock is cold because it is not "thinking" anything.

And we can then invert this argument to consider objects which are warm because they **are** logical information processors.

One of the themes of this chapter has been that our thoughts are not as free as we imagine them to be. Our stream of consciousness follows a series of logical steps, performing logical information processing. Indeed, if our conscious mind is to do anything useful, or achieve any goal, it has to perform logical information processing. Therefore, if we can use Landauer's principle to detect the presence of logical information processing, then that could be used as a signature for the detection of consciousness.

On the basis of Landauer's principle, we might say, then, that any conscious object **has** to generate internal heat. From the calculation in the appendix of this book, it would appear that any high-level consciousness at a similar level to human consciousness would have to produce an absolute minimum of approximately 20 microwatts of heat. However, once the inefficiency of neurons is taken into account, that value rises to approximately 15 watts of heat.

The following diagram shows the set of all the objects in the universe. The set is divided into two groups. On the left-hand side is the group of objects which generate internal heat, of magnitude greater than 15 watts. As shown on the diagram, this group would include a fire (a campfire is shown) and the Sun (and all stars). As this analysis has concluded that all recognisable consciousnesses would have to produce heat greater than 15 watts, the left-hand set also contains a subset (drawn as a circle labelled "Conscious objects") which contains all known conscious objects (a human brain is drawn inside the circle):

On the right-hand side of the diagram we find all the objects which either generate no heat, or they generate less than 15 watts of heat. It can be seen on the diagram that these objects include rocks, shoes, books, trees (or any plants), and even the human heart. Yes, the simple classification rule correctly predicts that the human heart is not conscious (remember, the power consumption of the human heart is only 13 watts). Aristotle would be disappointed.

So, have we discovered a simple method to detect conscious objects? Can we just say "If an object generates over

15 watts of internal heat, then it is a conscious object?" Well, that would be nice, but, of course, we can't say that. As indicated on the previous diagram, the group of warm objects would also include objects which generate internal heat via chemical reactions (such as campfires), or via nuclear reactions (stars). These are clearly not conscious objects.

However, the right-hand side of the diagram then becomes more interesting. The right-hand side represents all the objects which are either stone cold, or which generate less than 15 watts of internal heat. Because the group of all conscious objects is contained within the circle on the left-hand side of the diagram, we can say with confidence that all the objects on the right-hand side of the diagram are not conscious.

The all-important right-hand side of the diagram is shown in grey in the following image:

So this allows us to create a very simple and memorable rule:

"If it's cold, it's not conscious".

It is such a simple rule that it is possible to determine if an object is not conscious in seconds — just by touching it and measuring its temperature. If the object is cold — or not generating heat — it is surely not conscious.

Here is a photograph of me applying the simple classification rule to determine that a bust of Aristotle is not conscious — merely by touching it and finding it to be stone cold. It is such a simple test that you might like to try it on various objects around your house:

It would be very tempting to extend this principle to treat the amount of heat produced by logical information processing as some kind of measure of consciousness in a system. That would be a wonderfully simple solution to the problem of detecting consciousness! It would lead you to conclude that a more powerful, hotter computer was "more conscious" than a less powerful, cooler computer.

Unfortunately, you cannot do that. It is very easy to detect the **absence** of consciousness because you merely have to detect that **nothing** is being computed: "If it's cold, it's not conscious". However, to detect the **presence** of consciousness would not only require you to detect that **something** was being computed, but it would also require you to consider **what** was being computed. You would have to examine the system in great detail to make sure it possessed structured "thoughts", and had a rational stream of consciousness. For example, if you had a highly-powerful, hot computer but all it was doing was calculating random numbers — or was even just trapped in a loop producing random nonsense — then it would surely not be conscious in any recognisable sense of the word.

And having to consider the system in great detail to consider **what** is being computed makes the problem of detecting the **presence** of consciousness a far more difficult task. For a network with high-connectivity and high-complexity, containing billions of neurons or logic gates, the analysis of all the possible states would be almost unimaginably complicated.

One theory which is attempting this ambitious goal of detecting the presence of consciousness in a complex network is *Integrated Information Theory* (IIT). IIT was proposed by the neuroscientist Giulio Tononi in 2004, and has been continuously extended since then. The theory is now very large — and very complicated! IIT was briefly considered in my previous book on consciousness.

IIT attempts to consider all the possible arrangements of active neurons in a complex network. This involves splitting a system into all possible arrangements, and characterising the complexity and connectivity of the system by a single value, Φ (the Greek letter "phi"). However, like any theory attempting to detect the positive **presence** of consciousness, the problem arises from the sheer number of different possible states of the network.

In his book *Consciousness*, Christof Koch considers the computational requirement of calculating Φ : "Computing Φ is rather demanding because all possible ways the system can be divided have to be considered — that is, every way to cut the network into two parts, all ways to cut it into three parts, and so on until one arrives at the atomic partition, where all units that make up the network are considered in isolation. In combinatorial mathematics, the number of all such partitions is Bell's number. It is large. For the 302 neurons that make up the nervous system of *C. elegans* (a type of roundworm), the number of ways that this network can be cut into parts is the hyperastronomical 10 followed by 467 zeroes. Computing Φ for any nervous system, therefore, is fiendishly difficult and requires heuristics, shortcuts, and approximations."

So computing the **positive presence** of consciousness in a network with high complexity would inevitably be an incredibly computationally-intensive task, maybe beyond our capabilities for decades. But if computing the positive presence of consciousness is incredibly difficult, it would appear from this discussion that computing the **negative absence** of consciousness is really incredibly simple. All that is necessary to test for the absence of consciousness is to test for the absence of a property which would inevitably be produced by any conscious system:

"If it's cold, it's not conscious".

The end of the saga

At so that brings us to the end of this epic tale, the longest and most ambitious chapter I have ever written. We have traversed the full length of scientific history and recorded human knowledge, from the very first scientists of ancient Greece to the present day.

Bringing the saga right up to date, in a 2012 *Nature* article, a team of physicists announced that they had measured the microscopic amount of heat which is produced when a single bit of information is erased.[\[24\]](#) Landauer's principle had been experimentally confirmed for the first time.

This chapter has proceeded in a logical manner from the insights of Aristotle, to George Boole, to McCulloch and Pitts, to Leo Szilard, to Rolf Landauer. Each step builds on the previous step. The final conclusion can be traced back to the very first discoveries of Aristotle, 2,500 years ago. This emphasizes how mathematics and logic are timeless: a theory which was proven true 2,500 years ago remains true forever.

We have a tendency in current society to only value young things, or transient fashion. We would be wise to remember that the most important concepts in the universe are eternal.

IMPLICATIONS OF THE RULE

This is the final chapter of this book.

In this chapter, we will be considering the implications of the simple classification rule: "If it's cold, it's not conscious". We will be seeing how the rule can be used to provide valuable insights into the nature of consciousness.

Later in this chapter, we shall be applying the principle in three fairly mind-bending thought experiments. But first let us return to consider a part of the cortex of the brain which is not believed to be conscious ...

The primary visual cortex revisited

If you remember, back in Chapter Five it was explained how Francis Crick and Christof Koch developed an ingenious technique to determine which parts of the brain were responsible for consciousness. And, conversely, it was explained how the technique can be used to determine if consciousness is **not** to be found in a particular part of the brain.

Bearing that in mind, in Chapter Five it was explained how the technique of Crick and Koch revealed that consciousness is not to be found in the primary visual cortex which lies at the back of the brain. It was explained how visual data is copied from the retina, along the optic nerve, to the primary visual cortex at the back of the brain. The raw data is copied precisely onto the primary visual cortex, which acts like a "cinema screen" on the back of the brain. As this is purely a precise information-copying operation, no information will be lost. It is very easy to see why no information is lost by considering the truth table of the information-copying logic gate:

A	B	
0	0	}
1	1	

Output uniquely identifies input.
No information lost.

In the previous truth table, you can see that the input value (A) is simply copied to the output value of the gate (B). Therefore, as you can see from the truth table, there is a unique relationship between the output of the logic gate and its input. That means that if we know the output of the gate, we can therefore "wind back" the gate to find its input. This means that no information has been lost due to the operation of the gate: the gate is reversible.

No information being lost means that there is no logical information processing occurring, and no information being lost also means that there will be no heat produced. We should therefore not be surprised that consciousness is not to be found in the primary visual cortex. Consciousness is associated with logical information processing, information loss, and the production of heat.

This phenomenon can be clearly seen in the following thermal images of a head (*thermographic* imaging). You will see that the back of the head is the cold portion of the brain (denoted by a dark colour on the images). As explained in Chapter Five, this is the location of the primary visual cortex. According to the classification rule, this coldness indicates a lack of consciousness in that area:

This result represents convincing evidence that the classification rule — applied to the primary visual cortex — is correct: "If it's cold, it's not conscious".

Is a wire conscious?

If we consider the microprocessor at the heart of a computer — the computer's "brain" — we would find several billion miniaturised transistors. Those transistors are linked together to form electronic logic gates, and those logic gates allow the computer to perform logical operations.

The linkages between the transistors are thin, metal connections — which, for the purposes of this discussion, we might think of as "wires". Hence, the billions of transistors are wired together. Similarly, in the brain, the billions of neurons are linked together by biological "wires". In Chapter Four it was explained that neurons in the cortex are linked together by the "wires" which comprise the white matter of the bulk of the brain, which lies beneath the cortex. Psychology professor Frank Amthor has described this white matter by saying: "Most of the volume of the brain is wiring, not cells".

So, assuming it might be possible to one day construct a conscious computer, we might wonder if that consciousness would be found either in the logic gates, or in the wiring which connects those logic gates? Similarly, is the consciousness of the brain to be found in the neurons or in the wiring which connects those neurons?

To answer these questions, we need to realise that a wire actually performs a kind of logical operation. Bits of information (zeroes and ones) are input at one end of the wire, and those bits of information are output at the other end of the wire:

The previous diagram shows a wire, with information entering the wire at one end (Point A), the information flowing down the wire, and the information being output at the other end of the wire at Point B. The logical operation is then clearly a simple copying operation, with the data being precisely copied from A to B. We can therefore describe the operation using the same truth table we used in the previous section to describe the primary visual cortex:

A	B
0	0
1	1

}

Output uniquely identifies input.
No information lost.

Once again, as with the primary visual cortex, no information is lost. Indeed, if the wire in our computer was composed of a superconducting material, it could perform this operation without producing any heat (zero electrical resistance). According to the classification rule, we should therefore consider the wire as not being conscious. Remember: consciousness is associated with information loss and the production of heat.

This, then, explains why consciousness is not found in the white matter of the brain. As was explained in Chapter Four, it is known that consciousness is only found in the thin cortex — the covering of the brain. This is known as the grey matter of the brain. In contrast, consciousness is not found in the white matter of the brain, which makes up the brain's inner volume. This arrangement is shown in the following diagram, which shows the conscious outer cortex, and the unconscious inner white matter:

The thin cortex outer layer is **conscious**

On the basis of the discussion which has just been presented, we should not be surprised that the white matter is not conscious. The white matter is composed of the wiring which connects the neurons of the cortex, and, as has just been explained, wires are not conscious (also, presumably, the temperature of the white matter would be considerably lower than the temperature of the cortex).

So far in this chapter, the simple classification rule — and the techniques described in this book — have been used to explain that the primary visual cortex and the brain's white matter are not conscious. The fact that it is generally accepted that these regions of the brain are, indeed, not conscious provides a great deal of confirmation that the techniques described in this book are correct.

In the following three sections we will now apply the classification rule to everyday objects. We will be considering three mind-bending thought experiments to see if we can decide whether or not those objects are conscious.

Food rearranged

In a TED talk in 2014 entitled *Consciousness is a Mathematical Pattern* (available on YouTube), the physicist Max Tegmark asked a deep question wondering when does a particular configuration of atoms become conscious: "From my physics perspective, a conscious person is simply food ... rearranged. So why is one arrangement conscious, and not the other? Moreover, from my physics perspective, food is just a bunch of quarks and electrons arranged in a certain way. So why is one arrangement — like your brain — conscious, while another arrangement — like a bunch of carrots — not conscious?"

In his talk, Max Tegmark illustrated this point with a slide which resembled the following diagram:

As you can see in the previous diagram, Max Tegmark's physics experience means he is forced to consider a conscious human being (shown on the left) to be nothing more than the equivalent of "rearranged food" (shown on the right). This is because any human at the fundamental level is just a rearrangement of the food that he or she has eaten over their lifetime. So, at the level of fundamental physics, Max Tegmark is surely correct.

But, on that basis, Tegmark then asks "Why is one arrangement — like your brain — conscious, while another arrangement — like a bunch of carrots — not conscious?"

To attempt to answer Tegmark's question, let us consider the items of food which compose that elegantly-presented meal shown in the previous diagram. The face is made of a thin slice of cheese, with watercress hair, cucumber slices and raisins for eyes, slices of green peppers for ears, a tomato for a nose, and a slice of red pepper for a mouth. And, finally, the whole monstrosity is placed on a slice of bread.

Let us now consider each of those food items and place them inside the diagram which was presented earlier:

As before, all classification is performed on the basis of whether or not the object is generating significant internal heat. Obviously, none of these food items generate heat internally (hence the phrase "cool as a cucumber"), so all of the food items are classified as belonging to the right-hand side of the diagram — the side that represents "not conscious" (remember, "if it's cold, it's not conscious").

So here, then, is an answer to Max Tegmark's question. In order for "rearranged food" to become conscious, it needs to cross from the right-hand side of the diagram to the left-hand side. Therefore, the rearrangement of atoms must be quite specific, in order to produce an object capable of logical information processing. The inevitable production of heat from that logical processing will mean that the object will be then be reclassified into the left-hand grouping.

When the food becomes a conscious brain, it also becomes a warm object. [25]

Who would have thought that carrots, tomatoes, and cucumbers could be used to gain insights into the nature of consciousness? It would also appear that this vegetable-oriented example also has implications for the theory of consciousness which is known as *panpsychism*.

Panpsychism is the theory that everything — even elementary particles — contains a "little bit of consciousness". The philosopher David Chalmers described panpsychism during his 2014 TED talk entitled *How do you explain consciousness?* (available on YouTube): "I think that we may need one or two ideas that initially seem crazy before we can come to grips with consciousness scientifically. There are a few candidates for what those crazy ideas might be. One crazy idea is that consciousness might be universal: every system might have some degree of consciousness. This view is sometimes called panpsychism. Every system is conscious — not just humans, dogs, mice, flies, but even microbes, elementary particles. Even a photon has some degree of consciousness. This panpsychist view has the potential to transfigure our relationship to Nature, and it may have some serious social and ethical consequences. **I used to think I shouldn't eat anything which is conscious, so therefore I should be vegetarian. Now, if you are a panpsychist, and you take that view, you're going to go very hungry.**

It sounds like a humorous conclusion: we should not eat vegetables if panpsychism is correct. David Chalmers' panpsychist views would make him feel uneasy about eating a cucumber or a tomato because of the belief that vegetables can be conscious. Although it sounds like a crazy, humorous conclusion, it is the inevitable conclusion of panpsychism. Read into that what you will.

However, if the conclusion of this book about Max Tegmark's "Food Rearranged" thought experiment is correct, then David Chalmers can tuck-in with confidence.

As has just been discussed, a cucumber or a tomato does not generate internal heat, and we should remember: "if it's cold, it's not conscious". These objects — like Ray Kurzweil's rock — are not performing logical information processing. They are not performing any recognisable computation, and are therefore surely not conscious.

For this reason, I do not believe panpsychism is correct. I believe it is a mistake to believe all objects contain "a

little bit of consciousness" which is always present in all circumstances. Instead, as we shall be seeing in the next few sections, consciousness is not "contained" within anything, and consciousness is not "made of" anything. Instead, consciousness appears to be an emergent effect which only emerges in very particular circumstances.

Let us continue to the next thought experiment ...

The frozen head of Walt Disney

Nowadays, the name of Walt Disney is probably exclusively associated with animated movies: Mickey Mouse and Donald Duck. What is perhaps not so well known is Walt Disney's fascination with science and technology, his drive to promote science to the public, and his pursuit of technological solutions to the world's problems.

If you read my eighth book about building an atomic bomb, you will know that Walt Disney had a fascination with the potential of nuclear power, featuring a nuclear submarine in the live-action movie *Twenty Thousand Leagues Under The Sea*, and even building Disney's own "Atomic Energy Lab". In the 1960s, Walt Disney started planning for the Experimental Prototype Community of Tomorrow (EPCOT), a futuristic town which he hoped would provide a blueprint for urban planning. The EPCOT Center educational theme park opened in 1982.

Here is a photograph of Spaceship Earth — a geodesic sphere which lies at the heart of EPCOT:

It might be said that Walt Disney was the Elon Musk of his day.

So, considering Walt Disney's love of technological solutions, it is perhaps not surprising that a bizarre rumour started circulating when Walt Disney died in 1966.

A popular 1964 book by Robert Ettinger called *The Prospect of Immortality* had raised the possibility of a seemingly bizarre new technology. Ettinger suggested the possibility of freezing a dead human body at extremely low temperature, in the hope that sometime in the future there would be sufficient technological advances that the body could be taken out of refrigeration and revived. Ettinger is now considered to be the godfather of the science of *cryonics*. The first documented cryonic freezing of a dead body took place in 1967.

It is likely that Walt Disney read Ettinger's book, and the possibility of technology overcoming mortality would surely have appealed to Disney. According to Robert Mosley's 1986 biography of Disney: "Disney's growing preoccupation with his own mortality also led him to explore the science of cryonics, the freezing of an aging or ill person until such time as the human body can be revived and restored to health. Disney often mused to Roy about the notion of perhaps having himself frozen, an idea which received indulgent nods from his brother."

When Walt Disney died of lung cancer in 1966, a rumour started circulating that he had arranged for his dead body to be frozen in liquid nitrogen. The rumour spread, and the rumour mutated. The latest version of the rumour is that the metal tank containing Walt Disney's frozen body is buried in Disneyland in Anaheim, California — in the precise location currently being occupied by the *Pirates of the Caribbean* thrill ride.

So ... is the king of animation waiting to be reanimated?

Well, it's a great story — but it's not true. Walt Disney was cremated and buried at the Forest Lawn Memorial

Park in Glendale, California. The truth — as far as we will ever know — appears to be that Disney wanted to be frozen, but his family refused to go along with it.

The cryonics industry is currently thriving in America, with several companies offering the service for a fee of around a hundred thousand dollars. There are currently approximately 250 bodies in cryopreservation in the United States. Following his death in 2004, Baseball legend Ted Williams became the highest-profile celebrity to be placed in cryostasis.

Contrary to popular belief, the freezing process would not cause cells to burst due to the formation of ice, and we already possess the technology to freeze a dead body indefinitely with no deterioration. So the freezing technology is not so crazy: cells, tissues, and small organs have all been successfully cryopreserved and returned to working order. The big problem would be curing the person from the disease which caused them to die in the first place.

But that "big problem" is not going to be a big problem for our purposes. Firstly, it is not going to be a problem because we are performing a thought experiment, and thought experiments can deal with idealised hypothetical situations — with no regard for practical limitations. And secondly, the "big problem" of curing the deadly disease is not going to be a problem for us because we are not going to be using a dead body. Instead, we are going to imagine placing a healthy, conscious person into cryostasis. In science fiction movies such as *Alien* and *Interstellar*, this is the technique used to place healthy astronauts into cryostasis for decades-long space journeys.

The questions that arise are, firstly, would the person be conscious during the period while they were in a state of cryostasis? And, secondly, what would the person feel after being thawed-out? Would the person have a recollection of the period during which they were frozen?

The answer to the first question is surely rather clear: a person in cryostasis would surely not be conscious — it would be like the deepest sleep imaginable. And, just like being in deep sleep, the person would surely have no recollection of the time during which they were in cryostasis. In fact, if our idealised cryonic procedure was truly perfect, we might imagine a person being instantly frozen, and then waking up twenty years later feeling as though no time had passed. It would be as if they had instantly jumped twenty years forward in time.

This all might sound intuitively obvious, but I would suggest that it reveals some deep fundamental truths about the nature of consciousness. For our hypothetical and idealised thought experiment, let us imagine a technologically-advanced truly perfect process of cryostasis which perfectly preserves every aspect of the brain. In this science-fiction example of cryostasis, every atom and every molecule in every neuron in the brain is preserved in exactly the same position as it was before freezing. The only effect of cryostasis would be to make those atoms and molecules motionless — it would be as if the brain was frozen in time.

If that was the case, then it is clear that the information contained within the brain in cryostasis would be exactly identical to the information before the brain was placed in cryostasis — the information in the brain would not be altered in any way. However, before the brain was frozen, the person was conscious, and after the brain is frozen the person is unconscious. This seems obvious. But if consciousness is purely due to the arrangement of information in the brain, how can it be the case that the same arrangement of information can lead to both consciousness and unconsciousness? The arrangement of information in the brain is identical after freezing as it was before freezing, and yet consciousness has been lost.

So it appears that the connection between the arrangement of information and consciousness is rather more complex than might have been assumed. The effect of cryostasis is simply to make all atoms and molecules in the brain motionless. The brain is effectively frozen in time, and the result is that the information contained within the brain no longer leads to consciousness. It is therefore clear that **static information does not lead to consciousness**, no matter how that information is arranged in the brain. Organization of information is not sufficient to produce consciousness — there has to be time-based processing of information for consciousness to emerge.

On the basis of this discussion, I feel this principle is fairly inarguable, so that is surely an important conclusion.

It is another reason why a cucumber, or a tomato is not conscious. These objects contain information, yes, but that information is static — it is not being processed. As in the case of Ray Kurzweil's rock, nothing is being computed in these objects.

And if no information is being processed, then no heat will be generated. Remember, "If it's cold, it's not conscious".

A similar scenario would arise with a conscious computer (if such a device could ever exist). It is possible to place a computer in *sleep mode* in order to save power. Sleep mode acts to pause the computer: the processor clock stops, so the processor stops executing instructions. It is as if time has been eliminated. However, the entire state of the computer remains unchanged — the contents held in RAM remain unchanged. So the arrangement of information within the computer is unaltered.

As the processor stops the logical processing of information, there is no inevitable heat generation and the computer goes cold (remember: "If it's cold, it's not conscious"). Surely the conscious computer would not be

conscious for the period it was in sleep mode. However, when the computer is brought out of sleep mode, processing would start again from the precise moment when it entered sleep mode. The conscious computer would feel as though it had jumped forward in time.

As the arrangement of the information of the computer is unchanged during sleep mode (the information stored in RAM is unchanged), this represents another example of how static information does not lead to consciousness.

Now let us consider the third and final mind-bending thought experiment ...

A conversation with Einstein's brain

Douglas Hofstadter is the author of the dazzling book about computing and the mind entitled *Gödel, Escher, Bach*, which was considered in my previous book on consciousness. In 1981, Hofstadter presented a thought experiment which he called *A Conversation with Einstein's Brain*.^[26] In that thought experiment, Hofstadter imagined a huge book which contained a complete detailed description of the state of Albert Einstein's brain which was captured just a fraction of a second after he died.

Hofstadter describes the book of Einstein's brain: "Each page of this book — and there are around a hundred billion numbered pages in it — corresponds to one neuron and contains numbers recording such aspects relevant to that neuron such as what other neurons its axons lead to, what its threshold current is for firing, and so on."

If you had a question which you wanted to ask Einstein, you could leaf through the book and follow the instructions on each page. Eventually, you would receive a calculated response which would be exactly the same answer as the real Einstein would have given. Hofstadter then suggests that, as the book is performing the same sequence of instructions as the brain of Einstein would perform, then surely the book is completely equivalent to the mind of Einstein — though the book's "thought processes" would be considerably slowed-down.

Imagine, then, if we told the book that it (Einstein) had just died, and that his thought processes had been captured in a book. Surely the book would have responded in horror: "Oh no, I'm dead!" In other words, it appears that the book "felt" horrified. But can a book can have feelings?

The physicist Roger Penrose considered this thought experiment in his book *The Emperor's New Mind*. Penrose was not impressed by the conclusion that the book has feelings, and he also considered some additional complications: "But now a new difficulty presents itself. The book might never be opened, or it might be continually pored over by innumerable students and searchers after truth. How would the book 'know' the difference? Perhaps the book would not need to be opened, its information being retrieved by means of X-ray tomography, or some other technological wizardry. Would Einstein's awareness be enacted only when the book is being so examined? Would he be aware twice over if two people chose to ask the book the same question at two completely different times? Would the book remain completely self-aware even if it were never examined or disturbed by anyone or anything?"

The book contains a list of instructions, and therefore represents an algorithm. According to Penrose, the crux of the matter is "What does it mean to **activate** an algorithm?"

Can the simple classification rule — "If it's cold, it's not conscious" — cast a light on this problem?

Let us consider the first classification diagram which was presented earlier. On that diagram, you can see that a book does not generate heat and so was classified as belonging to the right-hand side of the diagram, which is the non-conscious side. We therefore conclude that the book — being left by itself, sitting on a shelf — is not conscious. As explained by the previous Disney thought experiment, static information — such as information contained within a book — is not conscious. At this stage, Roger Penrose would say that the algorithm has not been "activated":

So the classification rule provides an answer to Roger Penrose's question: "Would the book remain completely self-aware even if it were never examined?" No, on its own, it would not be conscious.

Now let us imagine that the book is opened and is being read. This represents an act of information-copying: the information contained within the book is precisely copied into the brain of the reader. The classification rule now clearly distinguishes the two situations. When the information is in the book, the book is cold, and is therefore not conscious. However, when the same information is copied into the brain of the reader and processed, it is subjected to logical information processing: each instruction in the book describes the operation of a neuron, and calculating the output of a neuron is a logical operation requiring logical information processing. It does not even have to be a human reader: a computer could perform the same logical information processing.

According to Landauer's principle, the inevitable result of this logical information processing is that heat will be produced. The composite object — book plus brain, or book plus computer — would therefore no longer be classified into the right-hand side of the diagram, the non-conscious side. Instead, the book would move to the left-hand side of the diagram: the algorithm has been activated.

Does this mean that Einstein has become conscious? Can Einstein now think and feel? The classification rule does not specify if that is the case: not all of the objects on the left-hand side of the diagram are necessarily conscious. Remember, it is a far more difficult task to detect the presence of consciousness than it is to detect the absence of consciousness. But there is now at least the possibility that Einstein has become conscious — which was not the case before the book was read.

Conclusion

In this final chapter, we have considered three mind-bending thought experiments, and used those thought experiments to try to identify the implications of the classification rule "If it's cold, it's not conscious".

The three thought experiments which have been considered were:

- Max Tegmark's *Food Rearranged*.
- A brain in cryostasis.
- Douglas Hofstadter's *Conversation with Einstein's Brain*.

These three thought experiments have a lot in common. All three cases deal with objects that are not performing internal logical information processing. In Max Tegmark's experiment, we considered carrots and tomatoes. In the example of the brain in cryostasis, we considered a brain in which the particles had been rendered motionless. And in *A Conversation with Einstein's Brain* we considered the static information in a book. Because none of these objects were performing internal logical information processing, none of the three objects produced any heat. It was therefore a simple matter to use the simple classification rule "if it's cold, it's not conscious" to classify them as not conscious.

However, when the carrots and tomatoes were rearranged into a brain, the material contained within those vegetables was transformed into a logical information processing device — which started to generate heat. Likewise the brain in cryostasis if it was thawed, or the book describing the neurons in Einstein's brain if that book was read and processed by a human or computer. In all three cases, the transition was observed when a cold, unconscious

object becomes a warm, conscious object.

In my previous book on consciousness, I emphasised the importance of information in consciousness, and suggested that information might be considered as being the "stuff" — the raw material — of consciousness. On the basis of this latest book, however, I now believe that viewpoint needs modification.

At the end of Chapter Five, the chapter at the end of the first part of this book which described the emergence of consciousness, it was explained how consciousness emerges over space just as it emerges over time. It was therefore explained that consciousness should be viewed as a **process**. With that in mind, it appears that consciousness is not "made" of anything. Yes, information plays a central role, but consciousness is not "made" of information. Instead, consciousness emerges from the processing of information. It is the **processing** of information over time that results in consciousness. If that processing stops, consciousness disappears.

And the type of information processing is also crucial. In order for an object to be conscious — in order for any useful goal to be achieved — it must be performing **logical** information processing. In other words, it must be performing **computation**. And, as Rolf Landauer showed, all computation inevitably involves the production of heat. A conscious object can therefore be identified as an object which is performing logical information processing which must necessarily produce a significant amount of heat: a minimum of 15 watts of heat for a human-level consciousness.

To sum up, we cannot yet tell if a computer is conscious, but we can be fairly certain that a banana is not.

Appendix: Using Landauer's Principle to calculate the total heat output of the brain

In Chapter Six of this book, an attempt was made to use Landauer's principle to calculate the total heat output of the brain. The rather complex details of that calculation are presented here.

The calculation requires the values for two properties of the brain. The first required value is the total number of synapses in the brain. If you remember, a synapse is the connection between a neuron and a previous neuron: it is one of the inputs to a neuron. So, comparing it with a Boolean logic gate, each synapse represents one bit of information which will inevitably be lost during the operation of the neuron (as the neuron only has one bit of output).

The number of synapses in the adult human brain is well-documented and freely available. A common range for the number is between 100 trillion to 500 trillion synapses — a truly astronomical number. A published figure is 150 trillion, and it is that value which will be used in the calculation. [\[27\]](#)

The second required value is the rate of neuron firing. Every time a neuron fires, that represents the completion of a logical operation, and so information is lost. Once again, a range of values is given in the literature, with neurons in the cortex supposedly firing between one time and 100 times a second. A published paper by Laughlin *et al.* gives a value of 55 firings of a neuron per second, and that value will be used in the calculation. [\[28\]](#)

That is all the information which is needed. As described in Chapter Six, according to Landauer's principle the minimum amount of heat produced by the loss of a single bit of information is equal to:

$$kT \ln(2)$$

Therefore, the total minimum heat output of the brain in a single second is the amount of heat produced by the loss of a single bit, multiplied by the number of synapses, multiplied by the number of neurons firing in a single second. The calculation which has to be performed is therefore:

$$kT \ln(2) \times (150 \times 10^{12}) \times 55$$

Assuming room temperature (20°C, or 293.15K), you might want to perform the previous calculation yourself to find that Landauer's principle predicts a minimum heat output of the brain of 23 microwatts.

This is clearly a very small amount of heat. However, this value assumes perfect efficiency of each of the neurons, which is unrealistic. So how efficient are neurons?

In 1998, an experiment was performed by Laughlin *et al.* (described in the previously-referenced paper) to calculate the energy requirement of a single synapse in a blowfly:

Inside every neuron, there are ion pumps whose job it is to restore the electrochemical balance inside a neuron after it has fired (effectively attempting to reverse the effects of an irreversible process). These ion pumps require the largest proportion of the neuron's energy budget. The pumps are powered by the breakdown of molecules of adenosine triphosphate (ATP). ATP is the universal fuel which is used by all cells in the body to power their activities.

According to Laughlin *et al.*, it takes the breakdown of between 2×10^4 and 6×10^4 molecules of ATP to transmit a single bit of information at a chemical synapse, and the breakdown of a single molecule of ATP releases $25kT$ joules of energy. Multiplying 2×10^4 and 25 together means that the transmission of a single bit at a synapse has an energy cost of $5 \times 10^5 kT$ joules.

In comparison, we know that the Landauer limit says that $kT\ln(2)$ joules of energy are required to delete a single bit. The natural logarithm of 2 is 0.69. This means that a real neuron needs 7.2×10^5 more energy to delete a bit of information than the minimum amount of energy predicted by Landauer's principle. This is a similar level of efficiency to a Boolean logic gate in a modern computer. [\[29\]](#)

So let us take this efficiency figure into account. We calculated earlier that Landauer's principle predicts a minimum heat output of the brain of 23 microwatts. If the inefficiency of neurons raises that amount by a factor of 7.2×10^5 then that means the total heat output of the brain is predicted to be 16.5 watts, which compares very well to the actual heat output of the brain of 20 watts.

The origin of the brain's remarkable heat output is therefore clear: it arises from the astronomical number of synapses contained within the brain. As each synapse represents the loss of a single bit of information, Landauer's principle reveals we should not be surprised at the amount of heat produced: the production of a significant amount of heat is inevitable.

The brain is so hot because it is a logical information processor, with information being lost in each neuron.

- [14] In physics, the famous *black hole information loss paradox* presents the clearest example of this connection between "something being lost" and "irreversibility". According to quantum mechanics, all quantum operations must be reversible, with the result that no information about a particle can ever be lost. However, when a particle enters a black hole, the current theory of general relativity states that all information about that particle is lost for ever. This represents a paradox. See my second book for more details — and a potential solution.

- [19] Sometimes you might read that "information is the same as entropy" — not inversely related. This is because of confusing terminology introduced by information theory pioneer Claude Shannon. Shannon took what we generally think of as information and called it "information entropy", a term which is only used in information theory — not physics. Apparently people told Shannon he should never have called it entropy because entropy is disorganization, but he did not seem to care.

PREFACE

In the *Hidden in Plain Sight* series of books, this is my third book dedicated to the subject of consciousness.

In my first book on the subject, it was explained how information is likely to play a central role in the emergence of consciousness. Then, in my second book on the subject, it was suggested that the physics of thermodynamics might hold the key to unlocking the problem. This third book on the subject of consciousness builds on the conclusions of those previous two books (information and thermodynamics).

This book represents the culmination of my three years working on this problem. I am pleased to say that in this third book I now feel confident to present an original, scientific theory of consciousness. The theory is being presented in this book for the first time.

As you will see, the theory is very simple. It attempts to describe the basic principles of consciousness, explaining why some devices are capable of generating consciousness, whereas other devices do not possess that special quality. Unusually for this subject, the theory is firmly based in mainstream, orthodox physics.

I believe the theory is correct.

Of course, I am totally biased in favour of my own theory! But by the time you finish this book, I hope you will agree with me.

“Four Laws that Drive the Universe”

1

THE INDUSTRIAL REVOLUTION

The eighty-year period from 1760 to 1840 was a time of great change in Britain. It was a period of rapid technological innovation, and the emergence — for the first time in human history — of a modern industrial economy. In this chapter we will be examining how a small, rain-soaked island in the North Atlantic became the world's dominant industrial power, and the richest nation on Earth. It is the story of the Industrial Revolution.

The Industrial Revolution was based on a series of inventions. The inventors tended to be based in the North of England rather than the more genteel South. These men were not scientists: hardly any of them had received a university education. They had no interest in knowledge for knowledge's sake. No, they were practical men, often with an engineering background, who could recognise problems which urgently required solutions. Usually, their motivation for inventing was purely financial.

Roger Osborne considered the impact of these inventors in his book about the Industrial Revolution, *Iron, Steam & Money*: "The Industrial Revolution came about because of inventors and their innovations. So, having survived a few decades in the wings of history, the great inventors — Watt, Newcomen, Hargreaves, Arkwright, Trevithick — are once again centre stage as the great movers in this historical drama. It was a single generation of British artisans who made possible Britain's transition to industrialisation and transformed the prospects of humanity."

Let us start by considering the invention which Roger Osborne called "one of the greatest inventions in human history". It is also the invention which — as we shall see later in this book — potentially holds the key to unlocking the mystery of consciousness.

It is the invention of the steam engine.

James Watt and the cooking pot

Every British schoolchild knows the legend of how James Watt invented the steam engine. Indeed, it was the story I was taught in my history lessons in school. If you do not already know the story, allow me to tell you the legend of James Watt and the cooking pot.

The various forms of the legend revolve around a young James Watt watching a cooking pot which belonged to his mother. As the water in the pot boiled, it turned into steam. The only way the water could escape from the pot was by lifting the metal lid which was on top of the pot. As we can imagine, the escaping steam caused the lid of the pot to rapidly jump up and down. According to legend, it was at this moment that James realised that there was "power in steam".

The following drawing shows an older James Watt watching the moving lid of the legendary cooking pot (from an original engraving by Jacob Abbott, 1854):

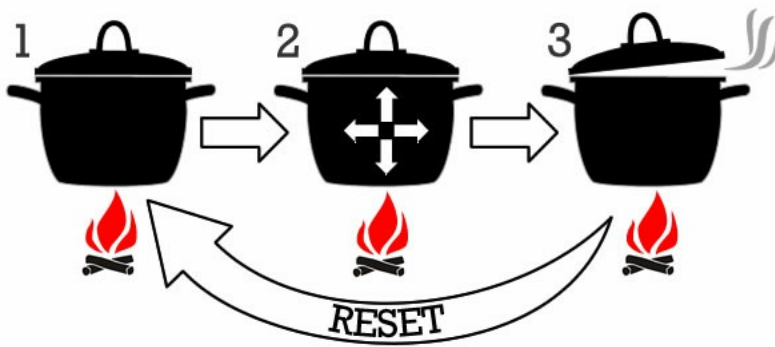

We will now examine the "jumping" of the cooking pot lid in more detail. In doing so, we will discover how it is possible to convert the intermittent lifting of the cooking pot lid into a continuous form of motion. The method will involve a linked sequence of steps, a sequence which lies at the heart of all steam engines.

The sequence is known as a *cycle*.

The cycle

Let us consider the jumping of the cooking pot lid in more detail. The three steps are shown in the following diagram:

Step One of the previous diagram shows the cooking pot above the fire, with the lid lying on top of the pot. At this stage, the pressure of the steam in the pot is the same as the atmospheric pressure outside the pot.

Step Two shows pressure building inside the pot as the water is heated, creating steam.

Step Three shows the cooking pot lid flying up off the pot. This is caused by the pressure of the steam inside the pot becoming sufficiently large to lift the lid. However, once the lid lifts off the pot, the pressure inside the pot is equalised with the atmospheric pressure outside the pot, so the lid drops down again. The system is therefore returned to its initial state.

This last step is vital. It acts as a "reset" operation (drawn as a curved arrow on the diagram). The result of the reset operation is to perfectly restore the state of the system back to its initial state (in this case, equalising the pressure inside the pot with the atmospheric pressure). Because of the reset operation, and the restoration of the system back to its initial state, it is possible for the entire sequence of steps to immediately repeat.

The sequence of steps then returns to Step One again, and the sequence repeats with pressure building inside the pot again. This sequence of steps therefore forms a cycle. A cycle is defined as being a sequence of steps performed by a system before the system returns to its initial state. The cycle then repeats continuously, creating continuous motion.

A repeated cycle plays a central role in the operation of a steam engine, with the motion of a piston moving in and out of a cylinder representing one cycle. As we shall see, one particular cycle will play an important role towards the end of this book when we come to consider human consciousness.

The story of James Watt and the cooking pot is a great story, but it is just a legend. James Watt made tremendous contributions to the development of the steam engine, but he was not responsible for its invention. So let us now consider the true story of the invention of the steam engine.

The first steam engine

Britain in the 1700s found itself in the midst of an energy crisis, a crisis which threatened to stop the Industrial Revolution before it had even begun. The problem was that, up to that point, vast forests had provided a plentiful supply of wood which could be burnt as fuel. With the expanding population, however, the demand for wood had increased to such an extent that Britain had become largely deforested. The country was rich in coal, which could potentially be used as an alternative source of energy. However, to extract coal from deeper underground involved digging mines which rapidly filled with water. Some method had to be found for pumping the water out of deep mines.

The solution was found by Thomas Newcomen. Newcomen lived in Cornwall, which is a mineral-rich county in the far south west of England. It was Newcomen who invented the world's first steam engine, and it was used to pump water out of mines in Cornwall.

In the previous section, it was considered how pressurised steam might be used to power a steam engine. The idea seems intuitively obvious, so it is surprising that Newcomen's first steam engine was powered by a completely

different principle. In fact, it might be said that Newcomen's engine worked by the reverse principle, exploiting the power of low pressure (a partial vacuum) rather than using pressurised steam.

The three stages in the cycle of a Newcomen steam engine are shown in the following diagram:

The previous diagram shows a round boiler containing water being heated by burning coal. In Stage One of the cycle, it can be seen that the load is allowed to drop, and this lifts a piston which is in a cylinder. As the piston rises, it draws steam from the boiler into the cylinder. Note that the steam engine is not performing work at this stage of the cycle as the load is being allowed to drop (i.e., the engine is not lifting the load).

In Stage Two of the cycle, it can be seen that cold water is injected into the cylinder. This causes the steam to condense into water (just as your breath condenses into water on a cold pane of glass). When steam condenses and turns into water, the volume of water created is 1,800 times smaller than the volume of the steam. Therefore, a partial vacuum is created in the cylinder.

In Stage Three of the cycle, the exterior atmospheric pressure plays the central role. Air has weight, and the pressure pushing the piston down into the vacuum generates a tremendous force (indeed, in Newcomen's first experiment the force was so great that the piston broke the chain it was attached to and crushed the bottom of the cylinder). **Crucially, it is only on this powerful downward stroke that the Newcomen steam engine performs work.** As you can see in Stage Three of the previous diagram, it is this powerful downward stroke that lifts the heavy load (such as lifting a load of coal out of a mine, or operating a water pump to raise water from the bottom of a deep mine).

Steam engines such as this which only perform work on either the up or down stroke — but not both — are called *single-acting* engines. The internal combustion engine in your car or motorcycle is another example of a single-acting engine, with a piston only performing work on the down-stroke when the spark plug above the piston fires.

The three-stage cycle of the Newcomen engine then repeats. However, unlike James Watt's jumping cooking pot lid, this was most certainly not a rapid repeat: a Newcomen steam engine could only perform about twelve strokes per minute.

So that is how the world's first steam engine operated. Roger Osborne describes Thomas Newcomen's achievement in his book *Iron, Steam & Money*: "It deserves a place among the greatest inventions in human history.

This was the first machine that replaced human, animal, and water power; its effect on the world could hardly have been greater."

The fiery monster

Before the invention of the steam engine, the power for factories was mainly produced by waterwheels. One advantage of a steam engine as compared to a waterwheel is that a steam engine is mobile. It was realised that it might be possible to take advantage of the mobility of a steam engine to put a steam engine on wheels — thereby creating a steam locomotive. A big problem, however, was the huge size and weight of the Newcomen engine. If steam engines were to be used for locomotion, they had to be made smaller and lighter.

As explained in the previous section, the Newcomen engine used a vacuum and atmospheric pressure to produce power. Because of its use of a vacuum, it might be called a low pressure engine. However, it was realised that steam at high pressure could also be used to move a piston (in the same way that steam moved the lid of James Watt's legendary cooking pot).

James Watt was, by now, a successful inventor who had made significant improvements to Newcomen's engine. However, Watt was reluctant to make the change to using high pressure steam because of safety concerns: there had been several cases in which the boilers of high-pressure engines had exploded, causing several fatalities.

James Watt's assistant was an enterprising young engineer named William Murdoch. Ignoring Watt's concerns about its safety, Murdoch became interested in the possibilities of high pressure steam. To test its feasibility, Murdoch built a small working model of a steam locomotive. The resultant model had three wheels, and was about a foot in height. The model has survived to this day, and is shown in the following photograph:

Murdoch was living in Redruth in Cornwall at the time, and he found the perfect track on which to test his vehicle. The path which led from the church had steep banks on either side, which would act to keep his vehicle on track. Murdoch started the engine, and ran alongside it as it powered its way towards the church. In his book *Energy and the Unexpected*, Keith Laidler described what happened next: "When he made his first trial, at night, the engine moved so fast that it out-distanced him and almost ran down the rector of the church who happened to be walking along the road. As he ran away in terror, the rector assumed the fiery monster to be the embodiment of the devil."

All initial experiments with steam-powered locomotion proved unsuccessful due to the poor quality of the roads, and William Murdoch did not pursue the idea. However, Murdoch had a neighbour in Redruth named Richard Trevithick who was also an engineer. Murdoch showed his working model to Trevithick who was intrigued, and Trevithick decided to build his own steam locomotive.

Trevithick realised that a solution to the problem of rough road surfaces would be to put the locomotive on the metal rails which were being used in the coal and iron industry. As a result, on 21st February 1804, Trevithick

demonstrated the first steam locomotive running on the rails of the Penydarren Ironworks in Merthyr Tydfil in South Wales. It travelled a distance of 9.75 miles carrying ten tons of iron and seventy people, travelling at an average speed of 2.4 miles per hour. As to why the average speed was so slow, Trevithick himself described the journey: "We carry'd ten tons of iron, five waggons, and 70 men riding on them the whole of the journey. It's above nine miles which we perform'd in 4 hours and 5 mins, but we had to cut down some trees and remove some large rocks out of the road. The engine, while working, went nearly 5 miles per hour."

At this point, I must declare a personal interest as Merthyr Tydfil is the town in which I grew up. It is a remarkable town, with a rich industrial heritage. The achievement of Richard Trevithick has not been forgotten and a monument was erected in the town centre. A model of Trevithick's locomotive sits proudly atop the monument:

The inscription on the monument reads: "Richard Trevithick, 1771-1833. Pioneer of high pressure steam built the first steam locomotive to run on rails. On February 21st 1804 it traversed the spot on which this monument stands on its way to Abercynon."

I no longer live in Merthyr, having moved to the town of Swansea which is thirty miles from Merthyr. However, in the National Waterfront Museum in Swansea, a full-size completely operational replica of Trevithick's locomotive has been built. In the following video taken by Matt Slade, you can see the locomotive in action, running on the rails outside the museum in Swansea:

<http://tinyurl.com/steamtrainvideo>

That first journey of Trevithick's locomotive was a truly monumental event, not just for Britain but for the world. According to Roger Osborne in *Iron, Steam & Money*: "The Penydarren locomotive had most of the essential features of steam locomotives that would transform the world over the next 150 years."

From a physics viewpoint, Trevithick's locomotive showed it was possible to convert heat into motion, the heat in the boiler being converted into the motion of the locomotive. Therefore, in the 1800s, what was needed was a new science which was able to describe the connection between heat and motion. That science was the science of *thermodynamics*. It is that new science of thermodynamics which we shall consider in the next chapter.

2

THE MOTIVE POWER OF FIRE

Our attention now turns across the English Channel to Britain's neighbour, France.

During the period of the Industrial Revolution, Britain was involved in a series of lengthy wars with France. The leader of France at that time was the ambitious and charismatic Napoleon Bonaparte. Napoleon was a brilliant military commander who developed novel military strategies which laid the foundations of modern warfare. Instead of the traditional head-on approach to battle, Napoleon's armies were fast and mobile, capable of outflanking the opposing forces.

Napoleon was famously a man of short stature, and it has been suggested that he overcompensated for his lack of height by presenting himself as a figure of great grandeur (in psychology, this has even been given the term the *Napoleon complex*). Indeed, by 1804, Napoleon had awarded himself the title of first Emperor of France. The following painting by Jacques-Louis David titled *Napoleon Crossing the Alps* shows Napoleon in a typically grandiose pose (Napoleon actually crossed the Alps seated on a mule):

Napoleon enjoyed astounding military success in a series of famous battles, most notably the defeat of the much larger Russian and Austrian armies at the Battle of Austerlitz in 1805. At its height, the French Empire under Napoleon extended from Portugal to Moscow.

Napoleon's progress across Europe appeared unstoppable. However, on the 18th June 1815 in the fields of

Belgium, the forces of Napoleon met the forces of his greatest enemy, the British army led by the Duke of Wellington. The battle is now known by the name of a nearby village: Waterloo.

The night before the battle saw a thunderstorm of biblical proportions. The torrential rain made the ground soft and boggy. As a result, the French forces were unable to get their cannons into position until late in the morning. Also, because of the soft ground, the recoil from the cannons caused them bury themselves into the ground after firing. A huge effort then had to be made to haul the cannons back into position, which greatly reduced the rate of firing. Unable to rely on his artillery to devastate the British forces from a distance, Napoleon's forces had to engage the British infantry in close quarters fighting. After a brutal day of hand-to-hand fighting, Napoleon's forces were narrowly defeated by the British army.

The Battle of Waterloo was to be Napoleon's final defeat. He was deposed as Emperor, and exiled to the small, damp island of St. Helena in the South Atlantic — one of the most remote islands in the world — where he could pose no more threat. Napoleon died on St. Helena six years later, supposedly from boredom.

The humiliation of Sadi Carnot

In 1800, soon after rising to power in France, Napoleon appointed Lazare Carnot to be his Minister of War. Carnot was trained as a military engineer, and was known for his analytical mind. Throughout his leadership of France, Napoleon came to rely on the strategic advice of Carnot. It was Carnot who developed the modern principles of lightning pace combined with an outflanking strategy (*pincer movement*) which Napoleon employed with great success.

Perhaps we should not be surprised that Carnot had such a strategic and technical mind as he was also a highly-talented physicist. When he was not involved in military activities, Carnot continued to develop his ideas about physics, and he published several books about physics in his spare time.

Lazare Carnot had a son whose name was Sadi. Carnot had often taken the young Sadi to meet Napoleon. It is recorded that a four-year-old Sadi once ran up to Napoleon shaking his fist and reprimanding the continent-conquering Emperor for his rude treatment of women. Luckily, Napoleon roared with laughter.

When the time came to choose a college for Sadi, with his family background in physics and the military, there was an obvious choice. An establishment had been created precisely for the purpose of fostering the scientific talents of young French men. The French had realised that British military superiority had been founded on their technological superiority gained during the Industrial Revolution. It was therefore decided that French engineers and scientists needed the best training. As a result, in 1794, Lazare Carnot co-founded the École Polytechnique in the Latin Quarter of Paris as the premier training school for young scientists.

Here is a painting of Sadi Carnot in 1813 at the age of seventeen, wearing the traditional uniform of a student at the École Polytechnique (painting by Léopold Boilly):

The École Polytechnique became the first great scientific school of the modern world. The roll call of those associated with the school now reads like a list of the early giants of mathematical physics, including Fourier, Lagrange, Laplace, and Ampère. The terms "Fourier analysis", "Lagrangian", and "Laplace transform" are now well known to every physics student.

The name of Sadi Carnot was added to that illustrious list of names when he enrolled at the École Polytechnique in 1812 at the age of sixteen. However, by the time Sadi had finished his studies in 1814, Napoleon was in full retreat and Paris was besieged. The students of the college — including Sadi Carnot — fought bravely to defend the outskirts of the city, but were forced to retreat under sustained artillery fire.

The final defeat of France by the British at Waterloo in 1815 had a devastating impact on Sadi Carnot. Remember, Sadi Carnot's father had been Napoleon's Minister of War, and he had become one of Napoleon's finest generals. Sadi Carnot became determined to avenge the defeat of his father — and his country.

The revenge of Sadi Carnot

When Sadi Carnot saw a steam engine for the first time, he became obsessed with the question of understanding how it worked. The problem was that the operation of a steam engine was not fully understood. Isaac Newton had presented his laws of mechanics a century earlier, but Newton had no understanding of energy, or heat. With no theory to guide them, steam engine designers had proceeded on the basis of trial-and-error: build a different engine design, and see if it produced more power. A theory of steam engines was therefore desperately needed.

In 2012, the BBC made a two-part documentary series about thermodynamics called *Order and Disorder*. The series was written and presented by Prof. Jim Al-Khalili. Here is a link to a video of episode one on YouTube:

<http://tinyurl.com/videoheat>

The video is excellent and is well worth watching.

At the 12-minute mark of the video, Jim Al-Khalili considers Sadi Carnot's reaction to the French military defeat: "The humiliation he felt personally would drive him and motivate him to uncover a profound insight into how all engines work. Carnot came from a highly-respected military family. After the French defeat, he became determined to reclaim French pride."

Jim Al-Khalili then proceeds to describe how Sadi Carnot realised the true basis for the British military advantage: "What really bothered Carnot was the technological superiority that France's enemies seemed to possess. And Britain, in particular, had this huge advantage both militarily and economically because of its mastery of steam power. So Carnot vowed to try and understand how steam engines work, and use that knowledge for the benefit of France."

In the video, Prof. Simon Schaffer then describes how Sadi Carnot realised a method to gain revenge over Britain: "He says absolutely explicitly that if you could take away steam engines from Britain then the British Empire would collapse."

Sadi Carnot became determined to exact revenge on Britain, and the way he would do it would be to design a better steam engine ... for France.

Historic theories of heat

The problem faced by Sadi Carnot was that the operation of a steam engine was based on heat, and nobody actually knew what heat was. The ancient Greeks believed that everything was composed of four fundamental elements: earth, air, fire, and water. Fire was thus thought of as a substance.

This model of the elements survived through the Middle Ages and into the Renaissance. However, in 1678, the German alchemist Johann Becher proposed a new theory called the *phlogiston* theory. According to Becher, all inflammable substances contained the material known as phlogiston. When the material burnt, the phlogiston was released, which gave the appearance of a flame. The material which was left (the ash) was then considered to be "dephlogisticated". Hence, the ash was considered to be the true essence of the material. Growing plants then absorbed the phlogiston from the air, which explained why they burned so well.

The phlogiston theory was generally accepted for 100 years, but flaws in the theory started to emerge. Firstly, the theory predicted that materials should lose weight as they burned and the phlogiston was released. However, some metals actually increased in weight when they burned (we now understand that this is due to the metal combining with oxygen from the air). Secondly, the theory had no explanation of why heat should flow in only one direction: from a hot object to a cold object. An improved theory was required.

As a result, in 1783 the great French chemist Antoine Lavoisier introduced the *caloric* theory of heat. The theory proposed that heat consisted of a weightless substance called caloric. According to the theory, caloric was a material substance (a fluid) and the amount of caloric in the universe was constant: caloric could be neither created nor destroyed. It was also proposed that caloric was self-repellent. The self-repellent nature of caloric provided an explanation as to why heat travels only from hot objects to cold objects: caloric would naturally move from regions in which it was highly concentrated (hot) to regions in which it was more sparsely concentrated (cold).

Although we now know the caloric theory to be incorrect, it gave Sadi Carnot the idea he needed to be able to analyse steam engines, as we shall now see ...

The waterwheel of heat

Sadi Carnot wondered if there was a limit to the amount of power which could be produced by a steam engine. Assuming that there was a limit to the efficiency of a steam engine, then what was the formula for that efficiency?

Carnot's analysis of steam engine efficiency was heavily influenced by waterwheels. Before the widespread adoption of the steam engine, factories had generated their power from waterwheels. Waterwheels provided a constant, smooth rotary action, ideal for driving the mill machinery used for spinning cotton in the Industrial Revolution. The use of waterwheels might sound primitive, but we still use waterwheels today — though we call them hydroelectric plants. Hydroelectricity currently provides sixteen percent of the world's electricity, and the world's largest power plants are hydroelectric plants.

Let us analyse how power can be produced by a waterwheel. The following diagram shows how water flows from a height, h , with the flow of water powering the wheel:

You may remember from physics lessons in school that an object which is at a height contains *potential energy* due to that height. That means that the water at the top of the waterwheel will have more energy than the water when it drops to the bottom of the waterwheel. But, according to the law of conservation of energy, energy cannot just vanish — it must have gone somewhere. So if the energy of the water is less at the bottom of the waterwheel than it was at the top, then where has the energy gone?

To answer that question, we need to consider what we mean by "work". "Work" has a very specific meaning in physics. In physics, work means the application of a force to move an object. So, for instance, if a pump lifts water out of a deep mine, then that pump has performed work.

Now let us consider the definition of energy. What is energy? Energy is defined as the ability of a system to do work. If a system has more energy, it can do more work. Exactly the same principle applies to human beings: if you are feeling more energetic, you can do more work. If you have more energy, you can do the gardening, or lift some heavy rocks.

So, as the energy of the water is less at the bottom of the waterwheel than it was at the top, we can now understand where the missing energy has gone. The missing energy from the waterwheel is used to perform work inside the factory. That work might involve moving machinery such as a cotton weaving loom, for example.

At this point, Sadi Carnot realised that this model of a waterwheel could also be applied to analyse steam engines. The breakthrough came when he used the caloric model of heat. If you remember, the caloric theory said that heat was a substance (a fluid), which always moved in one direction: from high temperature to low temperature. Carnot realised that the behaviour of water in a waterwheel was identical: water was a substance which always moved from a high level to a low level. Therefore, the passage of heat through a steam engine was the same in principle as the passage of water through a waterwheel.

Carnot realised he could describe any steam engine in abstract form as a form of "waterwheel" with the caloric fluid of heat "falling" from a high temperature to a cold temperature. The high temperature would be the temperature of the hot boiler, and the low temperature would be the temperature of the external environment.

How, then, could Carnot use this model to analyse the efficiency of a particular steam engine? Well, as has just been described, the potential energy of a waterwheel is dependent on the height difference of the water in the two reservoirs. Carnot applied similar logic to his analysis of the steam engine. In the case of the steam engine, the available energy would be dependent on the difference in temperatures.

In that case, Carnot realised that the available energy which could be produced by the steam engine would depend on the difference in temperatures:

$$T_H - T_L$$

where T_H is the high input temperature, and T_L is the lower output temperature. This formula might be considered

as representing the height of the "waterwheel of heat".

Does this value then represent the efficiency of the steam engine? Not quite. To get to the final form of the formula, let us consider what we mean by "efficiency". Efficiency is the proportion of the energy which is input to the system which is converted into work. We have just seen that the energy which is converted into work is proportional to $T_H - T_L$, so to get the efficiency we have to divide that value by the amount of energy which was input to the system which would be the total height of the waterfall, T_H . The final formula for the efficiency of a steam engine is then:

$$\frac{T_H - T_L}{T_H}$$

Even though Carnot was using the caloric model of heat — which we now know is incorrect — it is amazing that this formula remains the correct formula for the efficiency of a steam engine.

In 1824, Sadi Carnot published his results about the efficiency of steam engines in a book titled *Reflections on the Motive Power of Fire*. This classic book is now considered to have created the science of thermodynamics, the science of heat ("thermo") and motion ("dynamics").

Here is the cover of Sadi Carnot's legendary book. You can see that Carnot described himself as an "Ancien élève de l'École Polytechnique", which translates to "Former pupil of the École Polytechnique":

Heat engines

What does Carnot's formula tell us about how to improve the efficiency of a steam engine? First, allow me to remind you of Carnot's formula:

$$\frac{T_H - T_L}{T_H}$$

Now let us put some numbers into the formula. Let us imagine a steam engine which has a boiler full of boiling water (which is 100 degrees Celsius, equal to 373 degrees Kelvin). Let us also imagine that the external temperature is freezing (which is 0 degrees Celsius, equal to 273 degrees Kelvin). Putting those numbers into the formula gives a value for the efficiency of that steam engine:

$$\frac{373 - 273}{373} = 0.27$$

So the efficiency of that steam engine is 0.27, or 27%. If you think that sounds inefficient, well, you would be correct. But, considering the formula, how could the efficiency be improved? Before Carnot's result, it had been thought that engine efficiency could be improved by using different materials, such as boiling alcohol instead of water. However, Carnot's formula revealed that the important factor was the working temperature — not the materials used. In order to improve the efficiency of this steam engine, we need to increase its working temperature, T_H .

Prof. Jim Al-Khalili considers this strategy at the 17-minute mark of the excellent BBC thermodynamics video (a link was provided earlier in this chapter). According to Jim Al-Khalili: "Carnot's crucial insight was to show that to make any heat engine more efficient, all you had to do was to increase the difference in temperature between the heat source and the cooler surroundings. Ultimately, a car engine is more efficient than a steam engine because it runs at a much hotter temperature."

Note the use of the term "heat engine" in the previous quote by Jim Al-Khalili. The term "heat engine" is the generic term for any engine which exploits the passage of heat from hot to cold, with the difference in heat energy being used to perform mechanical work:

A heat engine is powered by the movement of heat from hot to cold. For example, in a steam engine that would be the movement of heat from a hot boiler, through the steam engine, and then expelled as exhaust steam.

A steam engine is just one example of a heat engine. Many other types of heat engine exist, all working on the same principle. For this book, I have created an entertaining video showing some other types of heat engine (you

may be surprised!).

Here is a link to the video:

I hope you enjoy the video!

3

REVERSIBILITY

In his 1687 masterwork, the *Principia*, Isaac Newton had presented his laws of mechanics. These were the laws of masses, forces, and accelerations. Newtonian mechanics provided the theoretical tools needed by the engineers who created the Industrial Revolution. Just as importantly, Newton's discoveries generated a new excitement in the general population about the possibilities of science, and this encouraged engineers and entrepreneurs such as James Watt and Richard Trevithick to devise their world-changing inventions. It was largely because of Isaac Newton that Britain became the world's leading technological nation.

As a result, Newton became an almost godlike figure in Britain. The insights of Newton, which had been captured in the *Principia*, were treated with almost the same reverence as the Bible.

When Newton died, the English poet Alexander Pope wrote the following famous epitaph which reflected the almost divine status of Newton: "Nature, and nature's laws lay hid in night; God said 'Let Newton be' and all was light."

The esteem in which Newton was held is clearly displayed in his magnificent tomb at Westminster Abbey:

On the tomb, you can see the reclining Newton resting on four of his books, including the *Principia*. At the top of

the tomb can be seen the celestial globe onto which is drawn the path of Newton's Comet of 1680.

It was Newton who had shown that the same force which holds the planets in their orbits was also responsible for pulling an apple down from a tree. Previously, these two phenomena were considered to be completely unrelated. By showing that they were two different aspects of the same force of gravity, Newton had achieved one of the first *unifications* in physics.

Beneath the sculpture of Newton on his tomb, the heliocentric model of the Solar System is drawn showing the Sun at its centre and the known planets orbiting around the Sun — according to Newton's law of gravitation. By unlocking the mystery of the motion of the planets and the heavenly bodies, it finally seemed as though mankind had completely unlocked the secrets of the universe.

So when the steam engine appeared in the 1800s, it might have been expected that it would be no problem for Newton's laws to explain the behaviour of the steam engine. After all, the laws which described the motion of planets and comets could surely explain the operation of a lump of iron filled with water and heated by coal.

What is more, in the previous chapter we have seen how the operation of a steam engine is really quite simple. Like all heat engines, it is based of the one-way flow of heat energy, always from hot to cold, and never in the opposite direction.

But there was only one problem. The laws of Isaac Newton were not one-way at all.

The laws of Isaac Newton were completely reversible.

Reversibility in the movies

Newton's three laws of motion form the basis of Newtonian mechanics (*classical mechanics*). The three laws are as follows:

1) An object remains at rest or continues at constant velocity unless it is acted on by a force. This is sometimes called the *law of inertia*.

2) A force will cause an acceleration of an object. The acceleration will be proportional to the magnitude of the force, and inversely proportional to the mass of the object.

3) Every action (force) will produce an equal and opposite reaction.

The three laws are clearly very simple, but they govern the motion of all objects. Part of the simplicity of the laws arises because they include no mention of any particular direction of time. The laws do not specify that they only apply in the forward time direction. In other words, there is nothing in the laws to indicate that they would not apply in a system in which all the objects suddenly reversed their direction of motion and started running backwards — as if time had been reversed. It is therefore said that Newton's laws are *time-reversal invariant*.

There is one simple way to demonstrate the reversibility of Newton's laws, and that is because it is possible for us to generate an artificial form of "time reversal". And the way we can achieve that time reversal is by making a movie.

The British movie director Christopher Nolan has gained a reputation for making innovative, unconventional movies which consider deep themes about the nature of time, space, and reality. His movies often incorporate ideas from science, particularly physics. Nolan's desire for scientific accuracy was most clearly demonstrated in his movie *Interstellar* which relied on technical advice from the Nobel prize-winning theoretical physicist Kip Thorne.

Nolan first showed an interest in the phenomenon of time reversibility in his movie *Memento*. This brilliant movie told the story of a man with amnesia trying to find the murderer of his wife. But what made the movie so remarkable is that the screenplay unfolded in reverse, starting with the final scene, and ending with the first scene. In other words, the events in the movie unfolded in time-reversed order (though Nolan still manages to surprise us at the end of the movie — or should I say the start?).

But it was in a later movie that Christopher Nolan's interest in time reversal was to play a central role. That movie was *Tenet*, released in the late summer of 2020.

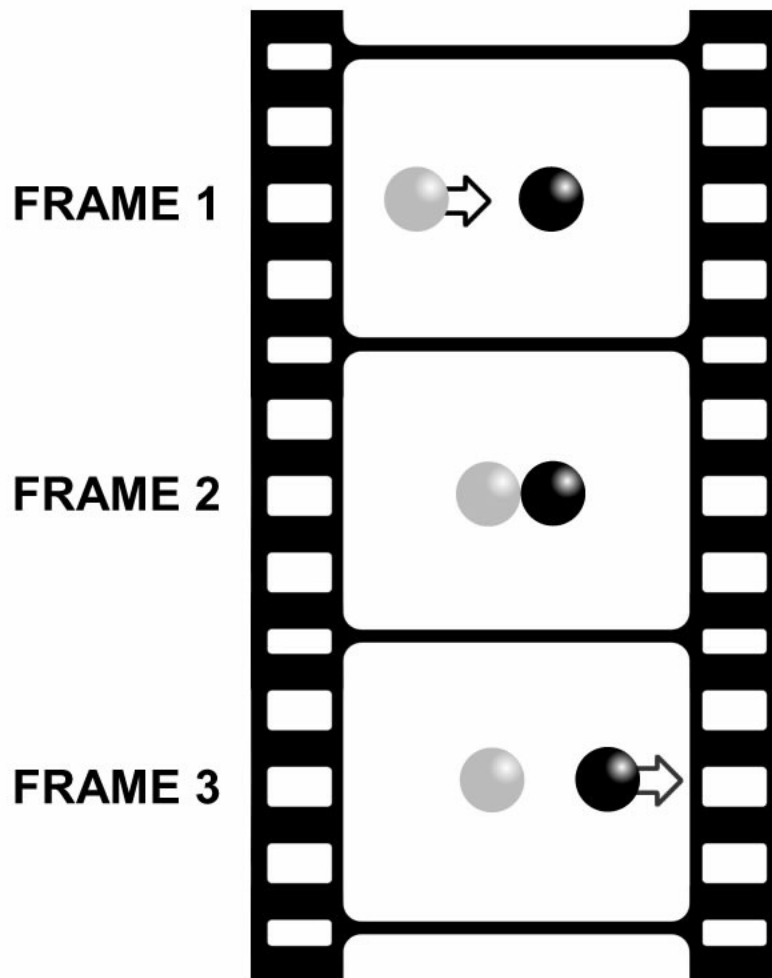

Unfortunately, the coronavirus pandemic, and the resultant closure of cinemas, meant that the release date of *Tenet* was delayed several times. However, the movie was finally released in the UK at the end of August. And so it was that I found myself in a virtually empty cinema with just four other socially-distanced people.

The central premise of *Tenet* is that there exists a technologically-advanced device (called a "turnstile") which can reverse the direction of the flow of time for objects. This idea resulted in some spectacular and inventive time-

reversed scenes. As was stated earlier in this section, time reversal would involve objects in a system reversing their direction of motion. Hence, as an example, one time-reversed scene in *Tenet* shows bullets leaving a target and following a reversed trajectory back into the barrel of a gun.

These time-reversed motions shown in movies such as *Tenet* are the best way to demonstrate the reversibility of Newton's laws. All we need to do is make a movie of the movements and interactions between a group of objects, and then play that movie backwards. If it can be seen that Newton's laws still apply to the reversed sequence of events, then that means that Newton's laws are reversible in time. As the physicist Paul Davies says in his book *The Physics of Time Asymmetry*: "Time reversal may be imagined as taking a movie film of the original motion, and then playing it backwards."

The following diagram shows three frames of a short movie. The movie is of a game of snooker (or pool). The first frame shows a stationary black ball in the middle of the frame, and a moving white ball coming in from the left of the frame. The second frame shows the white ball colliding with the black ball. The third frame shows the result of the collision: the white ball becomes stationary, while the black ball moves off at speed:

Simple motions of balls, and collisions (forces) between those balls, are described by Newton's laws of motion. So let us reverse this short movie and see if it still makes sense, i.e., do Newton's laws still apply to the time-reversed motions?

To answer that question, let us consider the sequence of frames in the reverse order, so that the last frame becomes the first frame, and the first frame becomes the last frame.

Here is the new sequence of frames, now numbered from Frame 3 to Frame 1:

As you can see, the first frame now shows the white ball stationary in the middle of the frame, and the black ball moving in from the right of the frame. The second frame shows the collision between the two balls. And the new final frame (the old first frame) shows the black ball stationary in the middle of the frame, while the white ball moves out of the frame to the left.

So this new time-reversed sequence of events seems reasonable, perfectly in accordance with Newton's laws of motion. This tells us that Newton's laws are reversible in time.

However, the situation would have been different if our movie had involved the passage of heat, rather than the motions of snooker balls. Imagine a movie of a hot object in a cold room. As the movie is filmed, heat leaves the object, and passes into the colder environment. Now let us imagine we play that movie in reverse. In reverse, we would see heat passing from the cold environment to heat the warmer object, thereby raising its temperature. This behaviour is something we would never encounter in reality: heat only ever travels from a hot object to a cold object — never from a cold object to a hot object. So this tells us that the laws of physics which govern the behaviour of heat cannot be time-reversible. It also tells us that Newton's laws cannot describe the behaviour of heat, because — as we have just seen — Newton's laws are time-reversible.

As described earlier, Isaac Newton was perceived as almost a divine being in Britain during the Industrial Revolution. So it must have been a shock to discover that Newton's supposedly infallible laws — the laws which were treated with almost the same reverence as the Bible — were incapable of describing the behaviour of the new steam engines which were having such a great impact at that time.

The failure of Newton's laws to describe the behaviour of heat explains why there was such urgency in the early 1800s to develop a new science which was capable of describing the functioning of steam engines.

So let us now rejoin our story in France ...

Reversibility and efficiency

Let us now return to consider the story of Sadi Carnot. If you remember, Carnot was obsessed with a desire to overcome the English technological superiority. To achieve his goal, Carnot aimed to improve the efficiency of French steam engines.

When we last left Carnot in the year 1824, Carnot had just published his book *Reflections on the Motive Power of Fire*. As described in the previous chapter, this was the book which launched the new science of thermodynamics — the science of heat and motion. And thermodynamics — unlike the laws of Newton — was the branch of physics which **was** capable of describing the behaviour of steam engines.

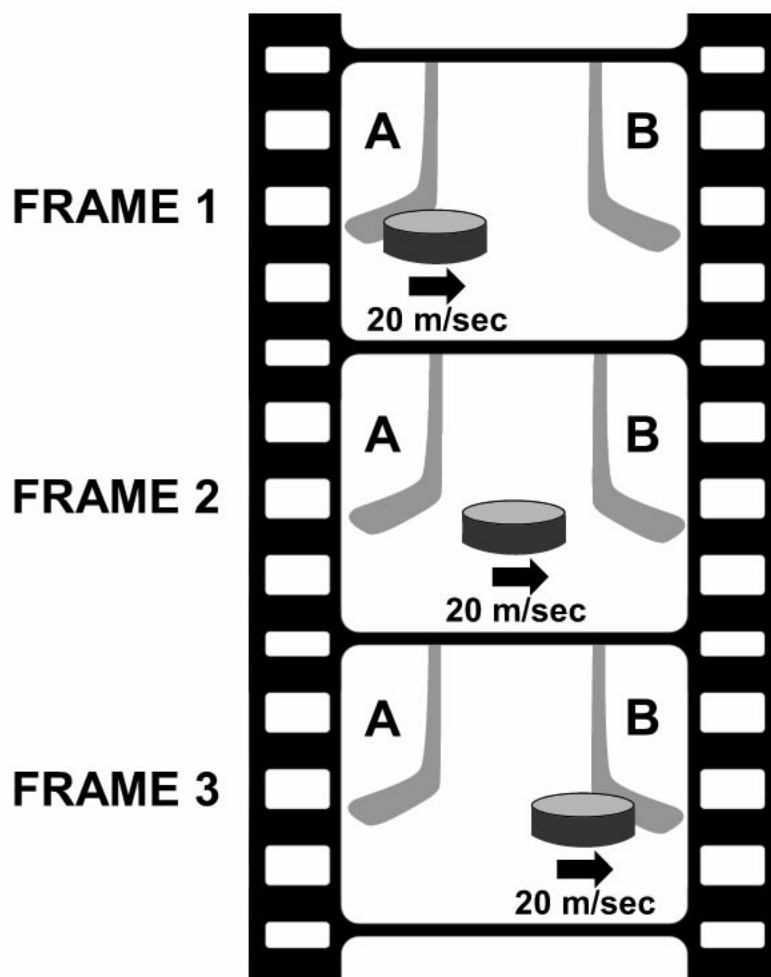

Also in his book, Carnot described how the principle of *reversibility* played a central role in determining the efficiency of a steam engine — or any machine. Why should reversibility be so important?

To understand why this is the case, consider the following thought experiment. Two ice hockey players are on a perfectly smooth surface of ice. As you can see in the following diagram, the player on the left (Player A) is hitting the puck to the player on the right (Player B):

Let us imagine that Player A strikes the puck at a speed of 20 metres/sec towards player B. Let us also imagine that the ice is perfectly smooth and frictionless, so that the puck loses no speed on its journey. As a result, the puck arrives at Player B travelling at the same speed of 20 metres/sec.

Now let us imagine we make a movie of the sequence of events, just as we earlier made a movie of the snooker ball collisions. Here are three frames of the short movie which just shows the movement of the puck:

In the first frame of the movie, you can see the puck being struck by the hockey stick of Player A on the left, which results in the puck moving at a speed of 20 m/sec. Because the ice is perfectly smooth and frictionless, there is no reduction in the speed of the puck in the second frame as it continues its journey across the ice. Finally, in the third frame, we see the puck hit the hockey stick of Player B — still travelling at a constant speed of 20 m/sec.

It is easy to see that if this movie was reversed, this sequence of events would still make sense. All that would change is that the direction of motion of the puck would be reversed, so the movie would show the puck moving in the opposite direction — at the same constant speed of 20 m/sec. For that reason, it is clear that this is a time-reversible situation.

Now let us consider the situation in which the playing surface of perfectly smooth ice is changed to be a surface of rough sandpaper. This would introduce the effect of friction on the motion of the puck. This would act to slow the puck on its journey across the ice. Although the puck would start its journey at the same speed of 20 m/sec, it might now slow down to a speed of just 5 m/sec by the time it reaches player B.

Here is the movie of this new situation. It can be seen that the puck loses speed as it moves across the sandpaper:

What has happened is that the puck has lost energy as it has passed across the ice. The energy associated with moving objects is *kinetic energy*, so the puck has lost kinetic energy as it moves across the sandpaper, due to the effect of friction.

Now let us imagine watching this new movie in reverse. In this new time-reversed movie, we would see the puck initially travelling at a speed of 5 m/sec as it leaves Player B, but speeding up as it moves across the sandpaper until it reaches a speed of 20 m/sec at Player A. This would, of course, never happen in reality: objects do not speed up as they travel across rough surfaces — they lose energy and slow down. So, because this time-reversed situation could never happen in reality, we can say that this has become an irreversible system.

So why has the previously reversible system now become an irreversible system? The cause of this irreversibility is the puck losing kinetic energy due to friction as it moved across the sandpaper. But the law of conservation of energy says that energy cannot be created or destroyed — it can only change its form. So the energy must have gone somewhere. But where did it go?

The answer is revealed when we realise that friction produces heat, a feeling we experience when we rub our hands together and feel them getting warm. Heat is a form of energy, so the kinetic energy lost by the puck is converted into heat energy by friction from the rough sandpaper. And that heat energy then transfers from the puck into the general cooler environment.

So the root cause of the irreversibility comes from the heat released by friction. Any friction in a system will introduce irreversibility.

This connection between irreversibility and the production of heat will play a central role later in this book when we come to consider consciousness.

The Carnot cycle

Sadi Carnot realised that any system which was losing energy due to friction would exhibit irreversible behaviour. And that energy loss would have the effect of reducing the efficiency of an engine. Therefore, in his book, *Reflections on the Motive Power of Fire*, Sadi Carnot explained that an engine with the greatest possible efficiency would be perfectly reversible. We now call this perfectly reversible engine a *Carnot engine*.

In order to achieve maximum efficiency, each individual step in the cycle performed by the engine must also be reversible. The complete sequence of reversible steps which is performed by the engine is called the *Carnot cycle*. In theory, the cycle could be interrupted at any point and the engine could then be operated in reverse.

So Sadi Carnot had finally achieved his goal of specifying how a perfect steam engine could be made: it should be reversible, or as near reversible as possible.

However, in reality, it can never be possible to make a perfectly reversible engine as it can never be possible to remove all loss-making factors such as friction. But, even for modern engineers, the goal of perfect reversibility is used to guide the process of efficient engine design.

A musical interlude

We have now come to the end of this chapter on reversibility. In the later chapters of this book, we will be returning to consider irreversibility. It will be seen that irreversibility potentially plays a key role in the emergence of consciousness.

However, right now, I think you deserve a reward. So I have specially written and recorded a song and music video based on the theme of this chapter.

The song is called *Turn Back Time*, and it is about irreversibility. The music video includes several examples of irreversibility including a collapsing house of cards, a breaking wine glass, and me getting wet (or, more accurately, me getting dry). Here is a link to the music video:

<http://tinyurl.com/irreversibility>

The song and video were influenced by the time-reversal movie *Tenet*.

Hopefully the song will have the effect of emphasizing the central role which irreversibility will be playing in this book.

I hope you enjoy the video!

4

HEAT, TEMPERATURE, AND ATOMS

As we have just seen, Sadi Carnot made great advances in understanding the behaviour of steam engines. However, Sadi Carnot still did not understand the true nature of heat. As explained in Chapter Two, Carnot still believed in the caloric theory of heat which proposed that heat was an actual substance. Carnot was fortunate that this mistaken theory of heat did not prevent his progress in understanding the steam engine. As Ingo Müller says in his book *A History of Thermodynamics*: "It was quite irrelevant whether he knew what heat was — and he didn't!"

A deeper understanding of heat was desperately required. In this chapter, we will see how that accurate, deeper understanding of heat was obtained. We will see how an entirely new theory had to be developed, a theory which relied on a completely new model of reality at its smallest scales.

At the end of this chapter we will also see that the theory of heat has implications for a theory of consciousness.

The rings of Saturn

The planet Saturn is the second-largest of the eight planets in the Solar System, almost a hundred times larger than Earth. The planet is mostly made of hydrogen and helium, with a total density less than water. But, of course, Saturn is most famous for its spectacular system of rings:

The rings around Saturn were first observed by Galileo Galilei in 1610 using his telescope. However, because of the low magnification of Galileo's telescope, the internal structure of the rings was unobservable. The true nature of the rings remained unknown. Were they connected to the planet, or separate? Were they solid, or made of small rocks, or even a fluid?

In 1857, in the hope of finally solving the problem, St. John's College in Cambridge announced a competition. A prize would be awarded to anyone who could solve the problem of the composition of the rings. The competition attracted the attention of 25-year-old James Clerk Maxwell, a highly-skilled mathematician who was a professor at Aberdeen University.

In 1859, after studying the problem for two years, Maxwell proposed his solution. In his essay *On the Stability of the Motion of Saturn's Rings*, Maxwell was able to show that if the rings were completely solid then the internal stresses would break the rings into smaller pieces as they orbited the planet. The same result would occur if the rings were made from a fluid: tidal waves would be created of such a monstrous size that the rings would eventually be torn apart.

Maxwell announced that the rings must be composed of a swarm of smaller objects, such as small rocks or lumps

of ice. Occasionally, Maxwell realised, those rocks would collide with each other. This prediction was eventually confirmed by the images sent back from the Voyager spacecraft in 1980. The images showed that the rings are made of lumps of ice ranging in size from a radius of one centimetre to ten metres.

The Astronomer Royal described Maxwell's work as "One of the most remarkable applications of mathematics to physics that I have ever seen." James Clerk Maxwell won the £130 prize, and the physics community became aware of his name as a new rising star in the field.

Maxwell realised that his work on the rings of Saturn had wider applicability. Maxwell was one of a growing number of physicists who believed that all materials were made of smaller particles which were called atoms. Just as Maxwell had shown that the rings of Saturn were made from a huge number of smaller lumps colliding with each other, could he now use similar techniques to explain the properties of gases made of trillions of microscopic swarming atoms?

The kinetic theory of gases

If a gas really was made of trillions of atoms, then the challenge was to explain how the large-scale properties of a gas — such as its temperature and pressure — could be explained in terms of the interactions of the microscopic atoms in that gas. The solution was developed by Maxwell, together with the German physicist Rudolf Clausius and the Austrian physicist Ludwig Boltzmann. Together, those three giants of 19th century physics created what we now know as the *kinetic theory of gases*.

The kinetic theory of gases models the atoms of a gas as microscopically small balls. Those balls move at high speeds, and, because of the vast number of atoms in a gas, collisions are extremely frequent. When these balls collide, the kinetic theory proposes that the balls bounce off each other perfectly elastically. As a result of these collisions, the motion of the atoms is completely random.

To provide some actual numerical values, the theory can be used to calculate that one molecule of oxygen in a room full of oxygen gas will be moving on average at the astonishingly high speed of 461 metres per second. When this result was announced, it raised some objections to the theory. As an example, consider the situation in which you are standing at one end of a room and someone wearing heavy perfume enters the other end of the room. With gas molecules predicted by the theory to travel at several hundred metres per second, it might be imagined that you would smell the perfume as soon as you see the person. But this is obviously not what happens — it takes several seconds for the scent to drift across the room.

The answer to this objection is that the atoms of the scent do not fly in straight lines. Instead, those atoms collide with other gas atoms as they zigzag across the room — just as the lumps of ice in the rings of Saturn collide with each other as they orbit the planet. This is the reason why the smell of the perfume takes several seconds to cross the room.

The kinetic theory of gases reveals that these collisions are occurring with extraordinary frequency. At room temperature, one oxygen molecule can travel an average distance of only 67 nanometres before it collides with another oxygen molecule, a distance which is 1,500 times smaller than the width of a human hair. Remembering that molecules are travelling at great speed, that means that a molecule will collide with another molecule 6.8 billion times per second. It is clear that the microscopic world is a world of extreme dynamism and constant, violent collisions.

The kinetic theory of gases provides an explanation of how large scale, measurable properties of a gas are produced by the interactions of the microscopic atoms in the gases. One such example is an explanation of how the pressure of a gas results from the forces applied by its atoms.

To see how this occurs, we might consider a sample of gas which is trapped in a cylinder, as shown in the following diagram. The atoms of the gas are drawn as small balls, bouncing off each other at high speed. The motions of the atoms are indicated by the small arrows. It can be seen that the cylinder contains a piston which is pushing down on the gas:

As has just been explained, the atoms of the gas are travelling at tremendous speed. Those atoms would strike the piston extremely fast, and this would result in a force being applied to the piston — like tennis balls striking a tennis racket. Because there are so many atoms in the gas, and they strike the piston with such high frequency, this would have the effect of exerting a constant outward force onto the piston. We would interpret this force as the pressure of the gas, and we could measure that pressure using a gauge (as shown in the previous diagram).

Hence it can be seen how the kinetic theory of gases can explain how a large scale, measurable property of the gas (such as pressure) can arise from the interactions of the microscopic atoms within that gas. The field of physics which considers how measurable properties arise from the interactions of microscopic particles is called *statistical mechanics*.

Heat

We might wonder how the kinetic theory of gases can explain the heat and temperature of a gas. Heat and temperature are closely related, but they are different properties. Let us consider heat first.

It was explained in Chapter Two that it was originally believed that heat was a substance, named either "phlogiston" or "caloric". It was suggested that caloric was a fluid, and caloric could be neither created nor destroyed. However, the main flaw in this theory is fairly obvious: if you create heat by friction — by rubbing two surfaces together — then you can create an endless source of heat. It was clear that heat could not be a substance which was limited in amount.

In his 1857 paper *On the Nature of the Motion which we call Heat*, Rudolf Clausius rejected the caloric theory of heat. Instead, Clausius suggested that heat was motion: the motion of atoms in an object. This makes a lot of sense, after all, when you rub your hands together they get hot. In that case, the motion of your hands is causing the atoms of your hands to move, which generates heat.

Clausius realised that each of those moving atoms would possess an amount of kinetic energy, the energy

associated with movement. Let us consider how atoms and molecules can move. In a gas, three types of molecular motion are possible, as shown in the following diagram:

As the previous diagram shows, the three possible types of molecular motion are translation (movement in a straight line), rotation, and vibration. Each different way in which the molecule can move is called a *degree of freedom*. There is some kinetic energy — the energy of motion — associated with each degree of freedom. In other words, each different way in which the molecule can move adds an amount of energy to the total energy of the molecule. If we then add up the total energy of all the molecules we get the total thermal energy (the heat) of the gas.

Heat, therefore, is the energy associated with the random motion of atoms and molecules in an object.

Temperature

So the total amount of thermal energy in an object is the heat in that object. Let us now move on to consider temperature — which is different from heat.

We can measure temperature using a thermometer — or even our bare hands. In terms of physics, the temperature is the **average** kinetic energy of the atoms in an object. The word "average" is crucial here. A very large object might contain a great amount of heat energy in total, but — because of the size of the object — the average temperature might be surprisingly low. An example of this is the temperature of the sea. The sea contains a huge amount of heat energy in total, but, because of its size, the temperature of the sea when we put our hand in the water — the **average** amount of energy in a small sample — can be chilly!

The ocean has absorbed more than 90% of the heat caused by human activity. John Abraham, a professor of thermal sciences at the University of St. Thomas in Minnesota has explained how much heat energy is absorbed by the ocean: "It's about five Hiroshima bombs of heat, every second, day and night, 365 days a year". This reveals the vital role of the oceans in absorbing heat in the battle against global warming.

So the heat energy contained within the ocean is huge — but if you dip your toe into the sea, the water will feel cold! This is an example of the difference between temperature and heat.

The bridge between the human world and the atomic world

Let us now consider in more detail the connection between temperature and the properties of individual atoms.

The kinetic theory of gases can be used to calculate the amount of kinetic energy of a single molecule of a gas. That kinetic energy can be found from the following formula:

$$\text{Kinetic energy of molecule} = \frac{3}{2} kT$$

where T is the temperature of the gas and k is a constant value known as *Boltzmann's constant*.

But where does the $3/2$ factor come from? Well, as explained earlier in this chapter, gas molecules have various degrees of freedom, which means they have various directions in which they are free to move. Each degree of

freedom adds an amount of kinetic energy to the molecule which is equal to:

$$\frac{1}{2}kT$$

With three dimensions of space in which the molecule is free to move (three degrees of freedom), that means that this amount of energy gets added three times to the total energy of the molecule, thereby resulting in the 3/2 factor shown earlier.

Now let us consider how we measure temperature. If I want to measure temperature, I would use a thermometer. A thermometer is a fairly large instrument which I can hold in my hand. A thermometer is definitely part of the human-scale world. Because of its size, we would say that a thermometer is a *macroscopic* object (a human-scale object).

In contrast, I cannot see an atom because of its incredibly small size: it is unobservable. I cannot hold a single atom in my hand, or use a single atom as a tool. An atom is not part of my human world. Because of its small size, we would say that an atom is a *microscopic* object (as opposed to macroscopic).

But the analysis which has just been described managed to connect temperature with the kinetic energy of an individual molecule. How was that magic achieved? Let us again consider the previous formula for the kinetic energy of a molecule:

$$\text{Kinetic energy of molecule} = \frac{3}{2}kT$$

We can see that the factor which links temperature of a gas with the energy of one of its molecules is Boltzmann's constant, k . For this reason, it is often stated that Boltzmann's constant represents "the bridge between the microscopic and macroscopic world". For an example, see the following page on the Boltzmann.com website:

<http://tinyurl.com/boltzmannconstant>

As that webpage states: "Boltzmann's constant bridges macroscopic physics (temperature, entropy) with microscopic physics (average energy of particles/atoms/molecules)."

Consciousness is part of the human experience, part of the human world. So consciousness is a *macroscopic* phenomenon. Whereas the motion of particles in our brains — out of which consciousness emerges — is a *microscopic* phenomenon.

This point was made by the physicist Carlo Rovelli in a recent YouTube video (<http://tinyurl.com/rovellivideo>). In the video, Rovelli attempts to understand consciousness within the known laws of physics, and emphasises the macroscopic nature of consciousness. According to Rovelli: "Consciousness is a macroscopic phenomenon. Subjective experience ... is a macroscopic phenomenon."

The challenge for physicists is to explain how consciousness emerges from the trillions of interacting particles in our brains. How can we link microscopic activity to a macroscopic phenomenon? For this reason, I would suggest that Boltzmann's constant will likely play a central role in any final theory of consciousness. The theory of consciousness presented later in this book will have a central role for Boltzmann's constant.

Consciousness and physics

This line of reasoning, I would suggest, provides us with the first indication of why thermodynamics is the branch of physics which is best suited for studying the phenomenon of consciousness.

When we consider a brain, we observe a staggeringly complex swarming of microscopic particles. Somehow, our consciousness emerges as a macroscopic phenomenon from the interactions of these particles in the same way that the temperature or pressure of a gas arises from interactions between the atoms of that gas. Consciousness is,

therefore, a phenomenon which needs explaining in terms of the activity of its microscopic constituents, in the same way that explanations were found for temperature and pressure in terms of microscopic atoms — as this chapter has explained.

Although, historically, there has been little interest in consciousness from physicists, several high-profile physicists now appear to be taking the problem seriously. And, I am pleased to say, I detect a general focus on thermodynamics as a likely solution.

This trend towards considering thermodynamics as a solution was clearly shown in the 15th February 2020 cover story of *New Scientist* magazine. The article was called *Finding Our Place in the Universe* and was written by Richard Webb. In the article, Webb interviewed several prominent physicists including Sean Carroll and Carlo Rovelli. In the following extended extract from the article, the possible explanation for consciousness in terms of thermodynamics is explored, with particular reference to the kinetic theory of gases: "For Carroll and many others, the answer lies not in mysticism, but in emergence. This is the idea that behaviours and properties that are inscrutable when you look at single components of a complex system pop into existence when you view things as a whole. There are plenty of precedents. The temperature or density of a gas, for example, doesn't mean much at the level of single molecules. Look at all the molecules of the gas together, however, and they are measurable quantities that explain physical change: how temperature differences cause heat flows, for example, or how a gas pushes a piston when compressed. The catch is that human brains are phenomenally complex. A fully grown one contains nearly 100 billion interconnected neurons, and we are still far from establishing how they produce the felt states of our conscious world, let alone how those states interface with the wider world: "It's one thing to say I can explain the temperature and density of the air by hypothesising that it is made of molecules bumping into one another" says Carroll. "It seems quite a more dramatic project to say I can explain mind and choices and consciousness as emerging out of atoms and molecules bumping into one another."

For physicists, the challenge is clear. An explanation of the macroscopic phenomenon of consciousness in terms of microscopic atoms is required — just as explanations were found for temperature and pressure.

With that in mind, let us continue our story ...

5

ENTROPY

When we last left Sadi Carnot it was the year 1824, and Carnot had just published *Reflections on the Motive Power of Fire*. The principles which Carnot described in that book still influence engineers to this day. Unfortunately, Carnot did not live to see the widespread adoption of his ideas as he tragically died in Paris during a cholera epidemic in 1832 at the age of just 36.

Carnot's work remained largely unnoticed for almost twenty years after his death before it was rediscovered by a few notable scientists. That small group included the German physicist and mathematician Rudolf Clausius.

It was Clausius who, in the 1850s and 1860s, analysed the work of Carnot and placed it on a stronger theoretical foundation. Clausius proceeded to make a series of theoretical breakthroughs, in the process becoming one of the key founders of the science of thermodynamics.

Despite Carnot's advances, one great mystery remained about the behaviour of heat. That mystery was the tendency of heat to travel in only one direction: from hot to cold. As explained in Chapter Three, this was a mystery because Newton's laws — and the fundamental laws of physics in general — are all reversible in time. It was Clausius who provided the breakthrough in solving the problem when he introduced the concept of *entropy*.

In developing the concept of entropy, Clausius carefully analysed the writings of Sadi Carnot about steam engine efficiency. Clausius considered a system which had heat energy added to it. Clausius then defined the increase in the entropy of that system as follows:

$$\text{Entropy change} = \frac{\text{Heat}}{\text{Temperature}}$$

Crucially, Clausius also combined this definition of entropy with a rule to describe its behaviour:

The entropy of a closed system always increases in time.

This rule is called the *second law of thermodynamics*, and it is considered to be one of the most important and unbreakable rules in physics.

It can immediately be seen that there is a crucial difference between this law and the laws of Newton. While the laws of Newton do not specify any particular direction of time, it can be seen that the second law of thermodynamics says that entropy always increases in the forward direction of time — never in the reverse direction of time. So, unlike the laws of Newton, **a direction of time is explicitly stated within this law**. It is clear that we are moving away from the laws of Newton and into a new world of physics.

An example calculation of entropy

Let us now consider an example calculation of entropy, according to Clausius's definition. The following example is from the excellent free online physics textbook provided by OpenStax. Here is a link to the relevant page in the book:

<http://tinyurl.com/entropybook>

The example described in the book considers the following scenario. Imagine a metal bar. The left half of the bar is at a very high temperature of 600 Kelvin (327 degrees Celsius), while the right half of the bar is at a low temperature of 250 Kelvin (-23 degrees Celsius). This arrangement is shown in the following diagram, with one half of the metal bar being hot, and the other half being cold:

If we leave the bar for a period of time, we will find that heat energy naturally flows from the hot end of the bar to the cold end of the bar (heat naturally flows from hot to cold). Let us consider the situation in which 4000 Joules of heat energy flows from hot to cold (shown by the arrow in the previous diagram). We then ask the question: what is the overall change in the entropy of the entire system?

Firstly, let us remind ourselves of Clausius's definition of the change in entropy:

$$\text{Entropy change} = \frac{\text{Heat}}{\text{Temperature}}$$

Now let us calculate the entropy change in the hot, left half of the metal rod:

$$\begin{aligned} \text{Entropy change} &= \frac{-4000}{600} \\ &= -6.67 \text{ J/K} \end{aligned}$$

Note that this is a negative value, representing a decrease in entropy. But that is strange as it was just explained that entropy always increases. So what is going on?

All becomes clear when we consider the cold, right half of the metal rod:

$$\text{Entropy change} = \frac{4000}{250} = 16 \text{ J/K}$$

This time the result is positive, representing a large increase in entropy. If we then consider the total entropy change in both halves of the metal rod, we get the following value:

$$\text{Total entropy change} = \\ 16 \text{ J/K} - 6.67 \text{ J/K} = 9.33 \text{ J/K}$$

which is a positive value. So the total change in entropy of the rod is a positive value. In other words, the total entropy has increased — in agreement with the second law of thermodynamics.

This calculation has revealed how the second law of thermodynamics — the rule that entropy always increases — can describe the flow of heat from hot to cold.

However, for many years after Clausius's discovery, no one actually knew what entropy was. Why should there be this strange property which was always increasing?

The answer was provided by an Austrian physicist, and it was an answer which changed our view of reality ...

The atoms of Ludwig Boltzmann

Ludwig Boltzmann was born in Vienna in 1844. In 1866 he obtained his doctorate from the University of Vienna, and by 1869 he had become a professor of mathematical physics at the University of Graz.

It was when he was a student at the University of Vienna that Boltzmann performed his first important work. That work was on the kinetic theory of gases, which was considered in the previous chapter. If you remember, the kinetic theory of gases revealed how the temperature of a gas represented the average kinetic energy of a single molecule of that gas. It was explained how the factor which links the overall temperature of the gas to the energy of a single molecule is now called Boltzmann's constant, named in recognition of Ludwig Boltzmann's pioneering work.

Here is a photograph of Ludwig Boltzmann:

It was clear, then, that Ludwig Boltzmann believed in the reality of atoms, that a gas was composed of trillions of atoms moving around with considerable kinetic energy. What is more, Boltzmann realised that if a gas was, indeed, made of atoms then a simple explanation for entropy emerged. Remember, the second law of thermodynamics stated that entropy had to always increase. Boltzmann realised that this made sense if entropy represented the amount of

disorder of the atoms in a gas. If that was the case, then entropy would naturally tend to increase — in the same way that a set of playing cards would tend to become more disordered when it was shuffled.

It really is quite a simple idea. But, as we shall now see, this simple idea was capable of explaining the flow of heat from hot to cold.

Let us imagine the metal rod which was described in the previous section. The left half of the rod is hot, while the right half of the rod is cold. We might consider this arrangement as representing a type of "ordering" of the atoms in the rod: the faster-moving atoms (hotter) have been ordered so that they are in the left half of the rod, while the slower-moving atoms (colder) have been ordered so that they are in the right half of the rod.

Over time, as the atoms in the two halves of the rod interact with each other, this ordering would tend to disappear. As the atoms in the two halves randomly collide with each other, some of the atoms in the left half of the rod would slow down, while some of the atoms in the right half of the rod would speed up.

Eventually, an equilibrium position would be reached in which the atoms in both halves of the rod have the same average velocity. At this point, the entire rod is at the same temperature. All of the initial ordering of the atoms would have disappeared. This would be the point of maximum disorder: maximum entropy.

But how would we interpret this increase of disorder? We would observe the cold half of the rod getting warmer, while the hot half of the rod becomes colder. So we would interpret the increase of entropy as a flow of heat from hot to cold. This atomic model of Boltzmann could therefore explain how an increase in entropy would lead to a flow of heat from hot to cold — but never in the reverse direction.

We now know that Boltzmann's theory was correct, and his explanation of entropy is accepted as one of the great achievements of 19th century physics. However, the theory received a great deal of opposition at the time. All of Boltzmann's work depended on the existence of atoms. However, when Boltzmann proposed his theory, the existence of atoms was by no means certain. Indeed, many German scientists believed that atoms did not exist, and they were openly critical of Boltzmann's idea. Influential critics such as the Austrian physicist Ernst Mach subscribed to the positivist school of thought which believed that physics should only consider things which can be directly observed — and atoms are, of course, too small to be directly observed.

Throughout his life, Ludwig Boltzmann had suffered from manic depression. This continued rejection of his ideas contributed to the slow decline in Boltzmann's mental state.

In September 1906, Boltzmann took a vacation to the coastal village of Duino, near Trieste, with his wife and daughter. The trip was specifically intended to improve his state of mind. Indeed, by the end of the holiday his health seemed much improved. About six o'clock in the evening of September 5th, Boltzmann's wife and daughter went to the beach for a swim, and Boltzmann assured them he would join them shortly. But Boltzmann never arrived. Tragically, Ludwig Boltzmann had hanged himself from a window in his hotel room.

Order and disorder

The interpretation of entropy as a form of disorder provides an intuitive notion of the nature of entropy. However, it also introduces a problem. Just saying that one arrangement of particles is "ordered" while a different arrangement is "disordered" appears to be a matter of personal taste. Who gets to decide what is an ordered state and what is a disordered state?

As an example, if we look into the bedroom of a teenager, it might look to be in a disordered state — a complete mess. Take a look at the following image, for example. You might think it looks completely disordered. But maybe the teenager would insist that all of the items are positioned just where he or she wants those items to be, and so, according to the teenager, the room is perfectly ordered.

So what is the answer? Does the following image show an ordered room or a disordered room? Hence, is it low in entropy or high in entropy?

Ordered or disordered?

It is clear that if we want to use the model of entropy as disorder then we need to find an unambiguous definition of the difference between order and disorder. In order to solve that problem, we first need to introduce the concepts of *microstates* and *macrostates*.

Firstly, remember from the discussion in the previous chapter that the prefix "micro" refers to very small objects, usually atoms, while the prefix "macro" refers to the large human-scale world. So the term "microstate" refers to the state of a system at the smallest level: the positions and velocities of its atoms. However, humans cannot see atoms, so the term "macrostate" refers to the state of a system as recognisable by a human.

A classic example of a macrostate is the temperature of a system. Temperature is a macrostate as it can be measured by a human-scale device: a thermometer. If an object is at a certain temperature, that means that the atoms of the object are moving randomly, possessing a certain kinetic energy. If the atoms then move to different positions, that would mean that the system is then in a different microstate as the microscopic positions of the atoms would have changed. However, the temperature of the system might well be the same as before. So the temperature macrostate of an object is associated with a large number of different microstates (different arrangements of atoms).

Let us consider the example of the teenager's room again. If the room is in a state of "order", then there are not many associated microstates. The reason why that is the case is described by Peter Hoffman in his book *Life's Ratchet*: "There are only a few arrangements (microstates) compatible with a tidy room: clothes in the closet, grouped by long-sleeve shirts, short-sleeve shirts, slacks, jeans, and so on; books on the shelves, sorted alphabetically by author; and so forth."

So when a room is in an ordered state, there are not many different possible arrangements of the objects in that room — not many microstates. However, when a room is in a disordered state, there are a vast number of possible different arrangements. As Peter Hoffman again describes: "There are almost unlimited ways the room could be messy: jeans on top of the computer, books on the floor, shirts strewn over the bed."

So this provides us with a way of distinguishing between ordered and disordered states. A disordered state will have many more microstates associated with it than an ordered state will have. A disordered room has many more ways that it can be disordered. This allows us to categorically state — for the reason described by Peter Hoffman — that the teenager's room in the previous diagram is in a state of disorder!

And, as entropy is defined as being the amount of disorder in a system, this allows us to create a formula for the amount of entropy in a system. The amount of entropy of a system will be proportional to the number of microstates associated with the current macrostate of that system: more microstates means more entropy. This allowed Ludwig Boltzmann to develop a formula for the entropy of a system.

Here is Boltzmann's formula:

$$\text{Entropy} = k \ln W$$

where W represents the number of microstates associated with the current macrostate of the system, k represents Boltzmann's constant (introduced in the previous chapter), and "ln" represents the natural logarithm function. The units of entropy are joules per kelvin.

Put simply, we see that the formula tells us that the greater the number of microstates associated with the current macrostate, the greater will be the entropy of that macrostate.

Boltzmann's formula for entropy was such a tremendous achievement that you can see the formula engraved near the top of Boltzmann's magnificent tombstone in Vienna:

6

MAXWELL'S DEMON

James Clerk Maxwell was born in Edinburgh, Scotland, in 1831. Maxwell was born into a wealthy and eccentric family. As an example of the adventurous and eccentric nature of the family, Maxwell's Scottish grandfather, James Clerk, was a captain in the East India Navy. Unfortunately, his ship was wrecked in the River Ganges. James Clerk managed to avoid drowning by floating to shore on his inflated bagpipes. When he reached the shore, he played the bagpipes to scare away some predatory tigers.

James Clerk Maxwell inherited his grandfather's adventurous and curious nature. As a young boy, he would often ask questions about the operation of the devices he found in the house. In his Scottish accent he would ask: "What's the go o' that?". If he did not find the answer to his question to be satisfactory, he would then ask: "But what's the *particular* go o' that?"

Maxwell's talents as a superb mathematician became clear when he studied as an undergraduate at the University of Edinburgh and Cambridge University. It was while he was in Cambridge that he started his work on analysing the composition of Saturn's rings. As described in Chapter Four of this book, Maxwell realised that the rings had to be composed of many smaller rocks which would frequently collide with each other. Also as described in Chapter Four, this work on the interactions of rocks in the rings of Saturn would lead to James Clerk Maxwell becoming one of the most important contributors to the kinetic theory of gases.

However, Maxwell's work on the kinetic theory of gases is not the work for which James Clerk Maxwell is most famous. After securing a professorship at Kings College in London, Maxwell started to analyse the connection between the electric force and the magnetic force. In his 1865 paper *A Dynamical Theory of the Electromagnetic Field*, Maxwell unified electricity and magnetism, showing that they were two aspects of a single electromagnetic force. As a result of that unification, Maxwell had the historic insight that light must be an electromagnetic wave.

Mainly for his achievement in electromagnetism, Maxwell is now regarded as one of the most important physicists of all time. When *Physics World* magazine conducted a poll of 100 leading physicists to discover who was considered to be the greatest physicist of all time, James Clerk Maxwell came third, only behind Albert Einstein and Isaac Newton.

Here is a drawing of James Clerk Maxwell:

Maxwell enjoyed a lifelong correspondence with his good friend Peter Tait. Tait was an outstanding Scottish physicist and an expert on thermodynamics. They would send letters to each other, often containing humorous stories, or observations about science.

In December 1867, Maxwell had an idea which he found deeply puzzling, so he described the idea in a letter to Tait. The idea contained in Maxwell's letter was so startling that it is still having ramifications to this day. Let us consider Maxwell's remarkable idea.

As has been described, Maxwell was a major contributor to the kinetic theory of gases, and he was well aware of the latest developments in thermodynamics. In his letter to Tait, Maxwell described a thought experiment which apparently broke the "unbreakable" second law of thermodynamics.

If you remember from the previous chapter, the second law of thermodynamics states that the entropy of a closed system will always increase over time. If we consider entropy to be the amount of disorder in a system, then this makes intuitive sense: ordered systems tend to become more disordered over time.

However, in his letter to Peter Tait, James Clerk Maxwell described the following scenario. Imagine a sealed box which contains a gas. The box is divided into two compartments by a solid partition in the middle of the box. The gas is initially at the same temperature in both compartments.

There is a small trapdoor in the partition which can be opened and closed to allow individual atoms of the gas to pass from one compartment to the other.

Maxwell then asked us to imagine a so-called "demon" who was in charge of opening and closing the trapdoor. The demon is in charge of performing the following operation. If the demon sees a fast-moving atom of gas approaching the trapdoor from the right-hand compartment, the demon opens the trapdoor to allow the atom to cross to the left-hand compartment. And, vice versa, if the demon sees a slow-moving atom of gas approaching the door from the left-hand compartment, the demon opens the trapdoor to allow the atom to cross to the right-hand compartment.

The following diagram shows the demon opening the trapdoor to allow a fast-moving atom of gas to cross from the right-hand compartment to the left-hand compartment:

We see that, over time, the effect of the demon's actions will be that the left-hand compartment contains faster-moving atoms than the right-hand compartment. As heat is nothing more than the movement of atoms, that means that the left-hand compartment will become hotter than the right-hand compartment.

And so this is where the puzzle emerges. As described in Chapter Two of this book, a heat engine operates on the basis of a temperature difference: a "waterfall of heat". So we could connect a heat engine in between the two compartments and use that temperature difference to perform work. In theory, this could continue forever as the demon continues to order the gas atoms according to their speed. It appears we have found a form of perpetual motion machine, which is, of course, impossible.

But the puzzle which really concerned James Clerk Maxwell is that the demon appears to have broken the second law of thermodynamics. The second law states that entropy — disorder — of a system will always tend to increase. But the demon has ordered the gas molecules according to their speed, so the demon has ordered the atoms. As an ordered system has lower entropy, this has had the effect of reducing the entropy of the system. It would appear that the second law of thermodynamics has been broken.

This mystifying thought experiment is now called *Maxwell's Demon*.

In 2012, the BBC made an excellent two-part documentary series about thermodynamics called *Order and Disorder*, presented by Prof. Jim Al-Khalili. A link to the first episode was presented earlier in Chapter Two of this book. The second episode considered Maxwell's Demon. Here is a link to the second episode on YouTube:

<http://tinyurl.com/videomaxwell>

The whole video is excellent. The discussion of Maxwell's Demon is at the 23-minute mark of the video.

The physicist Paul Davies has recently written a book about information in biological systems. The book is titled *The Demon in the Machine*, and it contains a chapter on Maxwell's Demon. In that chapter, Paul Davies explains that the problem of how Maxwell's Demon could seemingly break the second law of thermodynamics remained unsolved for over sixty years. According to Paul Davies: "For many decades, it lay like an inconvenient truth at the core of physics, an ugly paradox that most scientists chose to ignore."

To find the solution, physicists had to look in a very dark and surprising place ...

Inside the mind of the demon

In 1929, the Hungarian physicist Leo Szilard believed he had found a solution to Maxwell's Demon. Szilard considered the second law of thermodynamics, which says that the entropy of a system will always tend to increase. Szilard realised that, in the case of Maxwell's Demon, **the whole system also included the demon** — not just the gas in the box. If the entropy of the demon was increasing by a greater amount than the entropy of the gas in the box was decreasing, then the entropy of the system **as a whole** would be increasing. In that case, the second law of thermodynamics would not be violated after all.

But this posed a second mystery. Why should the entropy of the demon be increasing? At first glance, it appeared the demon was not doing very much at all — just opening and shutting the trapdoor. That surely did not require much expenditure of energy. It was even possible to imagine that the trapdoor was completely frictionless — in which case the demon would be performing no physical work at all!

But, of course, the demon was actually exerting a huge amount of effort — but it was not physical work. No, all the work was in the demon's mind. The demon was having to perform a superhuman feat in his mind, measuring the velocity of every single atom of the gas, and then calculating whether or not the trapdoor should be opened. When the vast number of atoms in the gas is considered, Szilard realised that the increased entropy generated by the superhuman mental processes of the demon could hold the key to solving the mystery.

In 1929, Szilard published this proposed solution to Maxwell's Demon in his paper *On Entropy Reduction in a Thermodynamic System by Interference by Intelligent Subjects*.

The use of the word "intelligent" in the paper's title is remarkable. Up to that point, physicists had only talked about simple, clear properties such as velocities and forces, properties which could be easily measured. But now, for the first time, Szilard was bringing "intelligence" within the domain of the laws of physics.

Physicists had always avoided the concept of intelligence because it was something internal to the human mind — it was not something that could be measured, or studied objectively. After all, we cannot see inside a mind.

But Leo Szilard had managed to see inside the mind of the demon.

Information, entropy, and bits

In the remainder of this chapter, let us consider Leo Szilard's solution of Maxwell's Demon in more detail, based on the argument which Szilard presented in his original paper.

The first step taken by Szilard was to simplify the problem. In order to do that, he considered a box which was filled with very little gas. In fact, he considered a box containing just a single atom of gas.

Initially, before the demon has had a chance to do his ordering job, we would consider the gas (at least, the single atom of the gas) to be in a "disordered" state. At that point, the single atom of the gas is flying around the entire box randomly, and at any particular moment in time it could be in one of two positions: either in the left-hand side of the box, or in the right-hand side of the box. The task of the demon is then to "order" the gas, which means using the trapdoor to trap the single atom in either the left-hand compartment or the right-hand compartment — depending on the speed of the atom.

So, in which side of the box should the demon trap the atom? In order to calculate that, the demon must first observe the atom, and measure its velocity. The demon must then use its mind to perform a simple comparison operation to determine if the particle is either slow or fast. On the basis of the result of that operation, the demon then either opens the trapdoor, or leaves the trapdoor closed.

We can therefore see that the end result of all the processing in the demon's mind (observing, measuring, calculating) is to produce just a single piece of **information**, and that single piece of information can take one of only two values: "slow" or "fast". The following diagram shows Leo Szilard's demon, with only a single atom of gas in the box, and the demon having to use its mind to calculate if the atom is "slow" or "fast":

A piece of information which can only take one of two possible values (in this case, "slow" or "fast") is called a *bit*. "Bit" is short for "binary digit". By convention, a bit can only take the value 0 or 1. We might therefore represent a slow atom by a bit with the value 0, and represent a fast atom by a bit with the value 1. The task which the demon must perform in its mind then becomes clearer:

With one atom in the box, the demon must generate one bit of information.

Of course, the demon does not have to calculate the information himself in his own mind. Instead, the calculation could be performed elsewhere by some third party, and then that information could be transmitted to the demon who could then use that information to decrease the entropy of the gas. This situation is shown in the following diagram. In this case, all the atoms of the gas are now in the box. The demon therefore needs a large number of bits of information — one bit per atom of gas. This information is calculated elsewhere, and is then transmitted to the demon as a long string of bits:

You can see in the previous diagram that the demon is now holding a smartphone. The demon receives the transmitted string of bits (zeroes and ones) on his smartphone, and then by reading the information one bit at a time he knows whether to open the trapdoor or leave it closed. Hence, the demon can use the transmitted information to lower the entropy of the entire gas.

So here we have revealed a very important principle: information is the inverse of entropy. If relevant information is available, then that information can be used to lower the entropy of a system. As Paul Davies states in his book *The Demon in the Machine*: "Information is, in some sense, the opposite of entropy."

And, vice versa, if information is lost, then the entropy of the system will increase. We will see that this second point will have major implications later in this book: if information is lost, then entropy will increase.

Back inside the mind of the demon

Let us now return to consider the situation in which the demon processes the information in his own mind. It is in this case that Leo Szilard had his moment of brilliant inspiration. As described earlier, Szilard realised that if the demon reduced the entropy of the gas, then the second law of thermodynamics would then require the entropy inside the demon's brain to increase by at least an equivalent amount.

This was a remarkable discovery. The brain is an incredibly complicated system, containing approximately 86 billion neurons, wired in an almost inconceivably complex manner. Similarly, the range of various thoughts which might be passing through the demon's mind might appear to be uncountably huge in number: "Do I open the trapdoor? Yes or no? It is a fast-moving particle so, yes, I will open the trapdoor."

It might appear impossible that our current knowledge of physics could ever be used to analyse such a complicated system. But, via an indirect technique using the second law of thermodynamics, Szilard had shown how it could be done — at least in the Maxwell's Demon example. Szilard had shown that if we use our minds to process information and make a decision about whether or not to open the trapdoor, the entropy of our brain has to increase by a certain, fixed amount. In this example at least, Leo Szilard had brought the human brain and the workings of the human mind into the domain of exact physics.

So by how much, exactly, would the entropy of the brain have to increase? To answer that question, we have to use the formula of Ludwig Boltzmann which was described at the end of the previous chapter. If you remember, Boltzmann's formula for the entropy of a system was given as:

$$\text{Entropy} = k \ln W$$

where W represents the number of microstates associated with the current macrostate of the system, and k is Boltzmann's constant.

With that in mind, let us once again consider the situation in which there is only a single atom of gas in the box. In this situation, before the demon has performed his ordering operation, we might consider the gas to be in a "disordered" macrostate. The atom is flying around the entire box randomly, and at any particular moment in time it could be in one of two positions: either in the left-hand side of the box, or in the right-hand side of the box. Hence, this "disordered" macrostate is associated with two microstates (remember: microstates deal with the positions of individual particles, individual atoms).

If we then substitute the value of W equal to 2 in the previous equation, we then get the value for the entropy of the initial disordered system as:

$$\text{Entropy} = k \ln(2)$$

And this is therefore the amount by which the entropy of the gas is reduced when the demon performs his ordering operation on the single atom of the gas.

So, even though the brain is an inconceivably complex structure, we have arrived at a very precise result. The entropy of the demon's brain would have to increase by an amount equal to $k \ln 2$. Leo Szilard really had brought the operation of the brain and mind into the domain of exact physics.

But this result raises another question. What is the underlying reason for this precise value of entropy increase in the brain? Where does this value of $k \ln 2$ originate in the processing of information in the brain? In the next two chapters, we will discover the solution to that question.

And we will see that the explanation is entirely logical ...

7

LOGIC

The development of logic dates back to antiquity. In ancient Greece, philosophers such as Aristotle and Plato would often spend their days having arguments about mathematics and philosophy. These arguments would sometimes extend for many days, or remain permanently unresolved. Aristotle believed that it should be possible to develop a clear method for resolving these arguments. How could the truth or falsity of an argument be unambiguously established?

The methods of logic were developed for precisely this reason of settling arguments. It was Aristotle who suggested the first method for determining whether a claim or statement made by one of his fellow philosophers was true or false. With a clear method in place, the philosophers on both sides of the argument would be forced to accept the conclusion.

To understand the basis of Aristotle's approach, it must first be explained that at the core of logic lies statements — or claims — which can be either true or false. No other value is possible. These statements are called *propositions*.

As an example, "The cat is on the mat" is a proposition as it is a statement which can be either true or false. The following image shows how the proposition "The cat is on the mat" could be evaluated to one of two different values:

At this point, you might recognise the similarity between a proposition and a "bit" of information (considered in the previous chapter), as a bit is also restricted to taking only one of two possible values: 0 or 1. We will shortly be returning to consider this similarity.

Aristotle's method of logic was based on stating some initial assumptions, called *premises*. Those premises would be simple propositions which everybody could agree were true. For example, "Socrates is a man" is an example of a premise — a simple statement which everyone can agree is true.

In order to create a convincing *argument*, those initial premises would then be connected to produce a single *conclusion*. Here is a famous example of one of Aristotle's arguments which consists of two premises (the first two lines) and a single conclusion (the last line):

Socrates is a man.
All men are mortal.
Therefore, Socrates is mortal.

It can be seen in this example that the conclusion ("Socrates is mortal") logically follows from the two premises (the previous two lines).

It is important to note that there may be a large number of premises, but **there is only ever one single conclusion**. This crucial point is emphasized by Dr. Siu-Fan Lee in his book *Logic: A Complete Introduction*: "An argument contains one and only one conclusion. If we want to make more than one conclusion, then there must be more than one argument."

Truth tables

The example of Aristotle's argument included two premises ("Socrates is a man" and "All men are mortal"). However, there is no upper limit on the number of premises. Multiple premises can be connected by using *logical operators*.

Logical operators such as AND and OR operate in a similar manner to how they operate in the English language. The following example shows two premises connected by the AND operator:

IF
I have a knife
AND
I have a fork
THEN
I can eat the meal

In this example, the conclusion ("I can eat the meal") is only true if both the first premise **AND** the second premise are true, and is false otherwise. The premises are therefore connected by the AND logical operator. The use of logical operators plays a central role in *Boolean logic*.

Boolean logic is a branch of logic which resembles mathematical arithmetic. In Boolean logic, the logical value TRUE is replaced by the number 1, and the logical value FALSE is replaced by the number 0. In that case, if a premise is true then it is given the value 1, and if it is false then it is given the value 0.

In arithmetic, numbers are connected using operators such as addition and multiplication. A similar principle applies in Boolean logic, except the operators are the logical operators such as AND and OR.

The functioning of those logical operators can then be illustrated by the use of a *truth table*. As an example, the truth table for the AND operator in Boolean logic is:

A	B	A AND B
0	0	0
0	1	0
1	0	0
1	1	1

In the previous truth table, the two inputs, A and B, are listed in the two left-hand columns. The output of the AND operation is listed in the right-hand column. As you can see, the result of this operation is only equal to 1 when **both** of the inputs, A **and** B, are equal to 1.

Similarly, the truth table for the OR operator in Boolean logic is:

A	B	A OR B
0	0	0
0	1	1
1	0	1
1	1	1

As you can see, the result of this operation is equal to 1 when **either** of the inputs, A **or** B, is equal to 1.

The simplest Boolean operation is the NOT operator. This simply acts to invert the input value, as shown in the following truth table:

A	NOT A
0	1
1	0

As you can see from the previous truth table, the result of a NOT operation will be 1 if the input is 0, and it will be 0 if the input is equal to 1.

The electrical circuits of Claude Shannon

Boolean logic, developed in the mid-1800s, might well have vanished as nothing more than a footnote in history had it not been resurrected in America in 1938 by the mathematician Claude Shannon. At the time, Shannon was a 21-year-old master's degree student at MIT, studying electrical engineering.

To understand Shannon's breakthrough, it must be realised that Shannon — as a student of electrical engineering — was well-acquainted with electromechanical *relays*. A relay is a type of switch. We all know how a switch works, just like the switch that turns the light on and off in your room. A switch is a mechanical device which you can move with your finger to open or close an electrical circuit. When a switch is *open*, there is no direct path for current to flow through the switch, but when the switch is *closed*, current can flow between the two terminals:

A relay operates in the same way as a mechanical switch, except that the mechanical movement to open and close the switch is caused by an electromagnet attracting a piece of metal. In this way, an electric current can cause the switch to be closed — instead of your finger doing the job.

The following diagram shows how an electromagnetic relay is a form of switch:

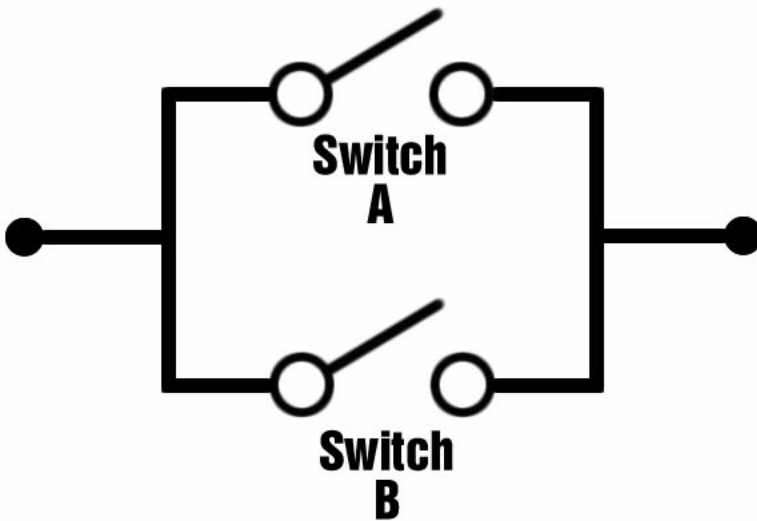

Note that the mechanical switch on the right-hand side of the diagram has been labelled with the two values 0 and 1. This immediately reveals that a switch is a perfect device for processing Boolean logic. In the mechanical switch, the value 1 is being used to signify a closed circuit (current can flow, so the device would be turned on), and the value 0 is being used to signify an open circuit (no current can flow, so the device would be turned off).

Even though Claude Shannon was studying electrical engineering, he had studied Boolean logic in an undergraduate philosophy course, and this is where his breadth of knowledge proved invaluable (Shannon said later "It just happened that no one else was familiar with both fields at the same time"). Shannon realised that it would be possible to create Boolean logic operations using these relay switches. The idea was simple — brilliantly simple. As an example, Shannon realised that it would be possible to implement an AND operation simply by connecting two switches in *serial* ("serial" means connected in sequence, on the same wire):

As you can see on the previous diagram, when two relay switches are connected in serial, then there will only be a connection along the total length of the wire when **both** switch A **and** switch B are closed. Therefore, this forms a simple implementation of a Boolean AND operation.

Similarly, two switches connected in *parallel* ("parallel" means they are connected side-by-side) would implement a Boolean OR operation:

As you can see on the previous diagram, when two relay switches are connected in parallel, then there will be a connection along the total length of the wire when **either** switch A **or** switch B is closed. Therefore, this forms a Boolean OR operation.

The biographer Walter Isaacson has written a book about the pioneers of computing titled *The Innovators*. In *The Innovators*, Isaacson describes how Shannon brought Boolean logic to electrical circuit design: "Shannon figured out that electrical circuits could execute these logical operations using an arrangement of on-off switches. To perform a AND function, for example, two switches could be put in sequence, so that both had to be on for electricity to flow. To perform an OR function, the switches could be in parallel so that electricity would flow if either of them was on. In other words, you could design a circuit containing a lot of relays that could perform, step-by-step, a sequence of logical tasks."

Shannon had shown how electrical circuits could be designed to perform any logical function. According to the computer scientist Herman Goldstine, Shannon's work "helped to change digital circuit design from an art to a science". In his book *The Innovators*, Walter Isaacson describes Shannon's 1938 master's thesis as "the most influential master's thesis of all time". (Do not confuse this work of Shannon with his later groundbreaking work on information theory, which was described in my ninth book. The two different achievements are completely separate.)

As Walter Isaacson states at the end of his previous quote, Shannon had shown how to "design a circuit containing a lot of relays that could perform, step-by-step, a sequence of logical tasks". A device which can perform, step-by-step, a sequence of logical tasks is a computer. So Shannon had shown how a computer could be constructed using mechanical relays. Indeed, in 1941, the German engineer Konrad Zuse used 2,600 relays to build the Z3 computer. The Z3 was the world's first programmable digital computer (just to be clear, the Colossus computer which was made in Britain in 1944 — and was featured in my seventh book — was the world's first programmable **electronic** computer).

Here is a photograph of a replica of the Z3 computer on display at the Deutsches Museum in Munich. You can see the relays in the cabinet:

But the Z3 had a problem, a problem shared by all electromechanical computers. The root of the problem is that mechanical relays have moving parts, and moving parts are slow. As a result, the Z3 could only perform five to ten logical operations per second. We might compare this to a modern digital computer which can perform several billion instructions per second.

So where did the massive increase in speed come from? It came from a miniature device which was invented in 1947, as we shall now see ...

Electronic logic gates

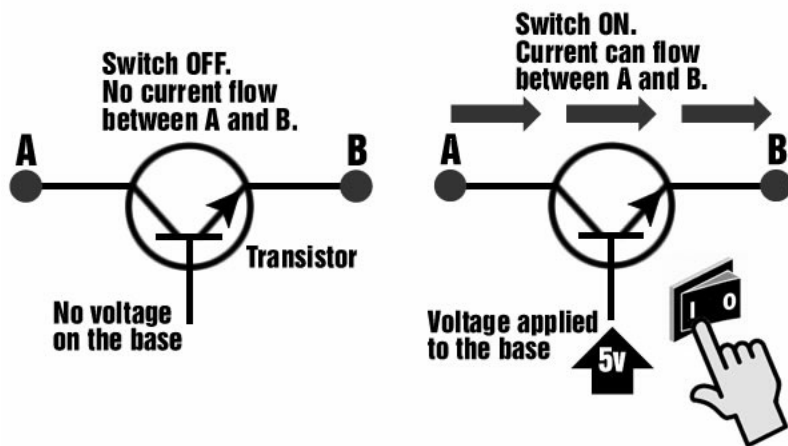

As has just been explained, mechanical relays could perform logical operations, but they were slow. The problem was that mechanical devices have moving parts. If a fast, practical computer was ever going to be developed, it needed a device which could perform logical operations without involving moving parts.

The solution arrived with the invention of the *transistor* in 1947. A transistor is a switch — just like a relay — but a transistor has no moving parts. Instead of the switching being achieved by the movement of a mechanical switch (by your finger, for example), a transistor is switched on and off by the application of a voltage to one of its three legs (the leg which is known as the *base*).

Here is a photo of a transistor (its actual size would be only about two centimetres long in total). Note the three legs:

The following diagram shows a transistor being switched on and off by the application of a voltage (effectively equivalent to a mechanical switch being switched on and off by a finger). The large black circle with the three black wires coming out of it is the standard representation of a transistor in circuit diagrams:

Just as Claude Shannon had shown it was possible to use mechanical switches to perform Boolean logical operations, so it was possible to use transistors as switches and arrange them into electronic circuits which could perform Boolean logic. Extremely fast computers could then be constructed.

These simple electronic circuits which can perform logical operations are called *logic gates*. The following diagram shows an actual circuit diagram which uses two transistors to implement an AND logic gate:

Remember from the previous section on Claude Shannon's electrical circuits that an AND logic function can be implemented by two switches in series. Well, that is precisely what we see in the previous diagram. You can see in the diagram that the two transistors are connected in series along the vertical wire. That immediately tells us that this is an AND gate. Let us now consider how this logic gate works.

If either input A or input B are at zero volts, then one or other of the transistors (switches) will be turned off, breaking the circuit along the vertical wire. In that case, you can see that the output will only be connected to the zero volt line (i.e., the output will be zero). This is the behaviour we would expect from an AND gate: if either one of the inputs is 0, then the output will be 0. However, if both of the inputs are 1, then both of the transistors (switches) will be turned on, and the output will be directly connected to the five volt line (i.e., the output will be 1). Again, this is the behaviour we would expect from an AND gate: if both of the inputs are 1, then the output should also be equal to 1.

In circuit diagrams, an AND gate is denoted by the following symbol:

However, there is no reason why a logic gate should be restricted to having just two inputs. An AND gate with multiple inputs would look like this:

In the multiple input AND gate shown in the previous diagram, the output would be 1 only when **all** of the inputs are equal to 1, and would be 0 otherwise.

Note that — although there is no upper limit on the number of inputs to a logic gate — there is only ever one single output from a logic gate. The structure of a logic gate therefore mirrors the structure of an argument in logic. As described earlier, there is no upper limit on the number of premises in a logical argument, **but there is only ever one conclusion**. This principle is shown in the following argument which connects multiple premises using a multiple input AND operator. Note there is only a single conclusion:

IF
 I have a knife
AND
 I have a fork
AND
 I have a plate
AND
 I have some food
THEN
 I can eat the meal

And when we start to consider this structure of a multiple input logic gate, we find an uncanny similarity with the structure of another type of information processing unit ...

The structure of a neuron

The brain is composed of an incredibly complex network of approximately 86 billion cells which are called *neurons*. In that sense, we might think of neurons as the "building blocks" of the brain. It is these neurons which transmit information throughout the brain, and allow information processing to take place. Somehow, it is the processing of information by these neurons which gives rise to consciousness.

The following diagram shows the structure of a neuron. As with all cells, a neuron has a cell body which contains a nucleus at its centre. Information enters the neuron via *dendrites*, which are branches which emerge from the cell body (shown on the following diagram). These dendrites receive input signals from previous neurons in the network. There may be in the region of a hundred dendrites on a single neuron. However, a neuron only ever has a single output, which is called an *axon*. Here is a simplified diagram of a neuron, only showing the features which are essential for this discussion:

Inside the brain, the length of a neuron's axon might be as little as a millimetre. However, the axon which transmits information from a motor neuron in the spinal cord to the foot (telling a foot to move) can be a metre in length. This makes it clear that what we call "nerves" are, in fact, the axons of neurons (which are themselves "nerve cells"). To put it simply, all information in the body is transmitted by neurons.

Information is transmitted along an axon by a series of rapid spikes of electrical charge. These spikes can travel at a speed of over 100 metres per second. The mechanism which produces these spikes will be considered later in this

book.

So, to sum up the structure of a neuron:

- Dendrites (inputs) bring information to the neuron, and there can be many dendrites on a single neuron.
- The axon (output) carries information out of the neuron, and **there is only ever one axon (output) on a neuron.**

The similarity with the logical structures we have considered so far in this chapter is clear. Truth tables, arguments in logic, and multi-input logic gates all have multiple inputs (no upper limit on their number) **but only one conclusion (output)**. This is precisely the structure we see in neurons, with a large number of dendrites (inputs) but only ever one axon (output). It is as if logic is inscribed into the structure of each and every neuron.

But why should the structure of neurons necessarily take this logical form? It is because if you want to do anything useful with information processing, to solve some problem or puzzle, or to achieve some goal, or to come to some conclusion, then **you have to use logic**.

To illustrate this point, we might consider an example in which an early ancestor of *homo sapiens* might have been walking across the African savannah many millennia ago. Suddenly, he spots a lion on the horizon. He has to think of a way to escape from the hungry lion. In that case, he would have to use logic in order to devise a suitable escape strategy. His logical thought process might then be as follows:

IF

I can reach the lake before the lion

AND

I can swim faster than the lion

THEN

I will escape from the lion.

So logic is required for any form of mental activity in which reasoning is required in order to do something useful, such as solve a puzzle, or build a house, or grow crops successfully, or escape a hungry lion. So, as an evolutionary necessity, **the human brain emerged as a device for processing logic**.

The reason for the logical structure of neurons then becomes clear.

Many great names in the history of science — including Alan Turing, George Boole, and Gottfried Leibniz — have believed that an understanding of logic is the key to understanding the working of the human mind. In the book *Introducing Logic*, we find the thoughts of the great German mathematician Gottfried Leibniz: "Logic is no longer a tool for convincing arguments but rather a system of rules of thought, so that even God's thought is necessarily logical. Even He could not create a world where a contradiction is true."

In this chapter, we have seen how the human mind (and the mind of God) would necessarily have to follow the laws of logic. Presumably, even a demon would have to use the laws of logic. Might this, then, provide the clue we need to finally unlocking the mystery of Maxwell's Demon ...

8

LANDAUER'S PRINCIPLE

The green and leafy town of Yorktown Heights is located in upstate New York, about forty five miles from New York City. The peaceful nature of the town — coupled with its proximity to New York — has made it a desirable location for commuters, being just a fifty minute train ride from Grand Central Station.

Yorktown Heights is also where the research division of the giant computer corporation IBM has been located since 1961. Named after IBM's founder, the Thomas J. Watson Research Center has been responsible for some of the most important breakthroughs in computing, including the invention of dynamic random access memory (DRAM), the FORTRAN programming language, and the discovery of fractals (by Benoit Mandelbrot, while he was working for IBM at Yorktown Heights).

The period of the early 1960s was the start of the computer revolution. The research center at Yorktown Heights had been established with the aim of discovering the fundamental laws of computing.

One of the research scientists in the IBM facility was Rolf Landauer. As part of the programme to determine the limits of computing, Landauer was charged with exploring ways of reducing the amount of heat produced by a computer.

Here is a photograph of Rolf Landauer during his time at IBM:

Landauer successfully analysed the reason underlying the heat production of a computer. But his work also revealed a surprising side effect. It was to be that side effect which finally solved the problem of Maxwell's Demon. And, as we shall now see, Landauer's solution had logic at its very core ...

The irreversibility of logic

In order to analyse the production of heat by computers, Landauer considered how computers process information

using logical operators. As we have seen in the previous chapter, electronic logic gates such as AND and OR form the core of information processing in a computer. Landauer noted something interesting about all of these logic gates. To understand what Landauer noticed, let us once again consider the truth table of an AND gate:

A	B	A AND B
0	0	0
0	1	0
1	0	0
1	1	1

} Same outputs

Landauer realised that this truth table is irreversible. It is irreversible in the sense that once the logic gate has processed its inputs to calculate the output, you cannot then operate the logic gate in reverse to regenerate the inputs. We can see why this is the case from the previous truth table for the AND gate. If the output of the gate is 0, you can see that we cannot be certain if the input pairing had been 0 and 0, or 0 and 1, or 1 and 0 (on the previous truth table, you can see that those three conditions are grouped under the label "Same outputs"). So the logic gate cannot be operated in reverse as it is simply impossible to know what the inputs had been if you only know the output.

In his landmark 1961 paper, Landauer referred to this type of irreversibility as *logical irreversibility*. As Landauer said in his paper: "We shall call a device logically irreversible if the output of a device does not uniquely define the inputs. We believe that devices exhibiting logical irreversibility are essential to computing." [1]

In this quote, Landauer is defining logical irreversibility as the situation in which "the output of a device does not uniquely define the inputs". This is precisely the situation we have been considering with the AND gate in which knowledge of the output does not allow you to determine the particular values of the inputs.

The second part of Landauer's quote is also interesting. By saying that "We believe that devices exhibiting logical irreversibility are essential to computing" he is essentially making the same point which was made in the previous chapter of this book. In that chapter, it was explained that if you want to do anything useful with information processing, then **you have to use logic**. In his belief that logical irreversibility is "essential to computing", Landauer is making the same point that logic is essential to computing.

In computing, you simply cannot avoid logic, and you therefore cannot avoid irreversibility.

The inevitable production of heat

In his attempt to reduce the heat output of computers, Rolf Landauer realised that there would be a remarkable side effect of this logical irreversibility. To understand what Landauer realised, we need to return to consider Maxwell's Demon.

If you remember, the demon was able to reduce the entropy of the gas if he obtained **information** about the position and velocity of the atoms in the gas. Hence, it was explained that there is an inverse relationship between information and entropy. If information increases, then entropy decreases. And, vice versa, as stated in Chapter Six, "if information is lost, then entropy will increase".

So when Rolf Landauer examined these irreversible logic truth tables, he realised that information was, indeed, being lost in a logic gate. For example, a two-input AND gate takes two bits as input, and produces a single output bit. If you only have access to that output bit, you cannot then tell with certainty what the two inputs of the gate had been. This is due to the logical irreversibility of the gate. Before the operation of the logic gate, you knew the value of both of the inputs, but after the operation of the logic gate, you no longer know the value of both of the inputs. Hence, you do not know as much after the application of the gate as you did before the application of the gate. So some information would have been lost.

Another simple way of understanding that information must be lost in a logic gate is due to a logic gate having, for example, two input bits but only ever one output bit. Hence, one bit of information is lost. It is as simple as that.

This point was made by Francis Crick in his book about consciousness titled *The Astonishing Hypothesis*. In the following quote from that book, Francis Crick compares the operation of neurons to logic gates, and realises that information must be lost: "One characteristic of a neuron is already fairly clear. A single neuron can fire at different rates and, to some extent, in different styles. Even so, in any period of time it can only send out limited information. Yet during that time the potential information coming into it, through its many synapses, is very large. In this process — going from its input to its output — **there must be a loss of information.**"

As a result of this information loss, Landauer realised that entropy would increase (due to the inverse relationship between information and entropy). What form would this increase of entropy take? Well, it was explained in Chapter Five how Rudolf Clausius discovered the close connection between entropy and heat. Entropy is a measure of disorder, and disorder at the atomic scale is heat. So the increase of entropy would take the form of the production of an amount of heat.

How much heat would be produced? To answer that question we need to return to the result of Rudolf Clausius in Chapter Five. If you remember, Clausius defined the increase in the entropy of a system as:

$$\text{Entropy change} = \frac{\text{Heat}}{\text{Temperature}}$$

By reorganising this equation we get:

$$\text{Heat} = \text{Entropy change} \times \text{temperature}$$

So, to calculate the amount of heat produced, we simply need to multiply the increase of entropy by the ambient temperature. In Chapter Six it was explained that the amount of entropy associated with a single bit is $k \ln 2$. So, for every single bit of information lost in a logic gate, Landauer realised that $kT \ln 2$ joules of heat would be produced (where T is the ambient temperature).

This was a remarkable discovery, and it is called *Landauer's principle*. Computing pioneer Charles Bennett has said that Landauer's principle is "often regarded as the basic principle of the thermodynamics of information processing". [\[2\]](#)

I am convinced that the implications of Landauer's principle are not generally realised. Landauer had shown that any attempt to completely eliminate the heat produced by a computer would be doomed to failure — it is completely impossible. We might listen to the cooling fan spinning on our laptop computer and imagine that — given better technology or better design — the heat produced by the computer could be completely eliminated and so the fan would be unnecessary. However, that is not the case. Landauer had shown that whenever you have the logical processing of information, **heat must be produced.**

Rolf Landauer refers to this fact in his original 1961 paper, referring to the dissipation of heat in a computer: "The relevant point, however, is that the dissipation has a real function, and is not just an unnecessary nuisance."

So heat must be produced by a computer. In fact, heat must be produced by any system which processes information in a logical manner, be it an iPad, or a digital watch — or a brain. In a nutshell, **logical information processing must produce heat.**

This production of heat is very noticeable in the human brain. The average power consumption of a human at rest is 100 watts. The brain has a power consumption of approximately 20 watts, which means that a fifth of the entire power consumption of a human is being used by the brain — and almost all of the energy used by the brain is converted into heat. Twenty watts represents a lot of heat (compare to a sixty watts incandescent light bulb — it is very hot).

In fact, if you were not aware of the true function of the brain, the production of heat would be its outstanding feature, and you might well imagine that was its main purpose. As an example, the philosopher Aristotle believed that the main function of the brain was for cooling the blood, with the brain acting as a radiator.

And this discussion about Landauer's principle and its implications (such as the production of heat) represents the final answer to the mystery of Maxwell's Demon. The entropy of the demon increases because of the processing of information in the demon's brain. The entropy increase would manifest itself as the production of heat from the brain of the demon. The entropy (disorder and randomness) of the heat produced by the brain of the demon would be more

than enough to outweigh the reduction of entropy caused by the demon ordering the atoms of the gas.

The second episode of the excellent BBC documentary series *Order and Disorder* presented by Prof. Jim Al Khalili considers Landauer's principle as a solution to Maxwell's Demon. Here is a link to a video on YouTube:

<http://tinyurl.com/videmaxwell>

The discussion of Maxwell's Demon and Landauer's principle is at the 52-minute mark.

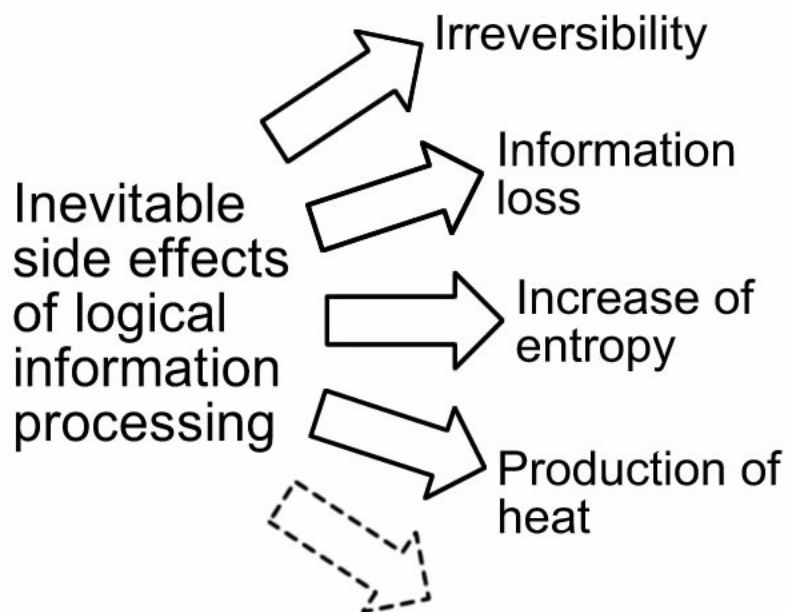

The video considers the slightly different situation in which the information is not immediately lost in the logic gates. Instead, the demon stores that information in memory rather than deleting it. But, as the video explains, eventually the demon runs out of memory and has to delete the information after all — so the end result is the same.

Side effects

This discussion of Landauer's principle has revealed that there are four side effects associated with the logical processing of information.

Firstly, when we studied the truth tables of logical operators, we found that they were irreversible. Secondly, we have seen that this logical irreversibility leads to the loss of information across the gate. Thirdly, because of the inverse relationship between information and entropy, the loss of information leads to an increase of entropy. Finally, that increase of entropy would manifest itself as the production of heat from the gate.

The following diagram shows these four inevitable side effects of logical information processing:

Note that a blank position has been included at the end of the diagram. Might there be a fifth side effect of logical information processing?

We will find out in the next chapter ...

9

THE MAKING OF A THEORY OF CONSCIOUSNESS

What do we mean by a "theory"?

Firstly, a scientific theory should be able to predict the outcome of experiments and observations with accuracy. As an example, one of the central theories in physics is the theory of general relativity, which is a theory of gravity. The theory can be used to predict the motions of the planets around the Sun with great accuracy. So a theory makes predictions.

This introduces another important property of a scientific theory: it can be falsified. For example, if I was to suggest a different theory of gravity, but my theory failed to correctly predict the motion of the planets (which general relativity predicts with great accuracy), then my theory would have been falsified. In that case, general relativity would have successfully repelled the challenge from my theory.

These aspects of a theory would apply to any potential theory of consciousness. The theory would need to make predictions about whether or not a system is conscious. That system might be a biological system (a brain) or an electronic or mechanical system.

But a theory should be more than just a generator of predictions. A theory should also provide an *explanation*. An explanation requires a deep understanding of **why** a particular phenomena occurs.

This point is made by the physicist David Deutsch in his book *The Fabric of Reality*. The first chapter of that book is devoted to describing why a theory is an explanation. According to Deutsch: "Our best theories embody deep explanations as well as accurate predictions."

I would also suggest that, to be an explanation which would satisfy a physicist, the explanation would ideally be phrased in terms of the behaviour of low-level, fundamental entities, such as particles, or fields, or space or time. A scientific explanation needs to be deep, referring to some low-level of reality.

Bearing all of this in mind, in the remaining chapters of this book, an original theory of consciousness will be presented. It will be based on the material we have covered so far in this book, in other words, it will have a firm basis in mainstream, orthodox physics. It will attempt to connect to reality at a deep level (the atomic level). It will be seen that the theory largely agrees with our intuitive notions about consciousness.

Perhaps, best of all, it is a simple theory.

OK, let's go ...

An imaginary survey of physicists

I think it would be fascinating to organise a survey.

This survey would require the assistance of 100 of the leading theoretical physicists in the world today. Each physicist would be asked for his or her opinion as to what is the most likely solution to the mystery of consciousness. Theoretical physicists are a bright bunch of people, so you would think that they would know the answer, or at least the likeliest answer.

As far as I am aware, no such survey has ever been conducted, so we will have to use our imagination. Fortunately, I think I have a fair idea of the outcome.

Firstly, I suspect a large proportion of the physicists would refuse to answer the question, stating that they regard the subject of consciousness to be subjective and unscientific.

Secondly, I suspect a small percentage of the physicists would state that they agree with the controversial theory of consciousness presented by the physicist Sir Roger Penrose. Penrose's theory was first presented in his book *The Emperor's New Mind* in 1989. In his book, Penrose suggested that quantum mechanics plays the central role in generating consciousness (see my ninth book for details). Everybody loves Roger Penrose, but, unfortunately, I think it is fair to say that very few physicists agree with his idea. The small percentage who might agree with it in the survey would probably only be saying that because Sir Roger's theory is the only theory of consciousness that they know.

So, regarding my survey, up to this point it seems to be a case of "so far, so bad". The physicists do not seem to agree, and candidate theories — those theories which would be known by physicists — are few and far between, and suspected to be wrong.

But all is not lost.

Out of the physicists who provide an answer, who are prepared to suggest a likely solution, I am convinced one solution would have a huge lead in popularity over all the other proposed solutions. And it would simply be this:

Consciousness is an emergent phenomenon which arises from information processing.

You will notice the two key points in this sentence being the words "emergent" and "information processing". The word "emergent" simply refers to the idea that consciousness is a macroscopic effect — a human-scale effect arising from the interaction of trillions of microscopic particles. This was covered back in Chapter Four, so let us concentrate on the idea that consciousness arises from information processing.

Let us consider some of the high-profile physicists who would likely suggest this solution. In his book *Life 3.0*, Max Tegmark — a physicist at MIT — includes a chapter on consciousness. In that chapter, Tegmark states: "I'd been arguing for decades that consciousness is the way information feels when being processed in certain complex ways."

So here is one example of a physicist suggesting that consciousness arises from information processing.

As another example, in a post on her popular blog *Backreaction* (in the post "Electrons Don't Think"), the outspoken physicist Sabine Hossenfelder is dismissive of any alternative explanation of consciousness: "Consciousness is an act of information processing. I don't understand why some people think there's something mysterious about it."

So, as I suggested, a survey of 100 physicists would probably result in the majority view that consciousness arises from information processing. The reason why they should come to this conclusion is described by the physicist Paul Davies in his book *The Demon in the Machine*: "One thing isn't contentious: the brain processes information. It is therefore tempting to seek 'the source of consciousness' in the patterns of information swirling inside our heads."

As Paul Davies says, the brain is an information processor, and our consciousness is certainly produced by the brain. It would therefore appear to be logical to imagine consciousness arising from the processing of information — maybe as a side effect.

In fact, that conclusion can seem to be so logical as to be almost beyond doubt. As James Stone says in his book *Principles of Neural Information Theory*: "Neurons communicate information, **and that is pretty much all they do.**"

On the basis of that quote, the proposed solution of the physicists can seem like the obvious conclusion:

- 1) There are 86 billion neurons in the brain.
- 2) All they do is process information.
- 3) Consciousness arises as a result.
- 4) Therefore, the logical conclusion is that consciousness arises from the processing of information in the brain.

Expressed in this way, it is clear why, I would suspect, this would be the most popular solution among physicists.

However, those physicists who suggest this solution would not necessarily know the details as to **how** consciousness arises from information processing. And that is the challenge for anyone with a physics background who is attempting to try to solve the mystery of consciousness. That is the challenge which we will attempt to solve in the remainder of this book.

And, as a first step towards that solution, we should take special notice of this idea that consciousness is a **side effect** of information processing. That would appear to be a crucial clue, as, in the previous chapter of this book, we have already encountered several side effects of information processing ...

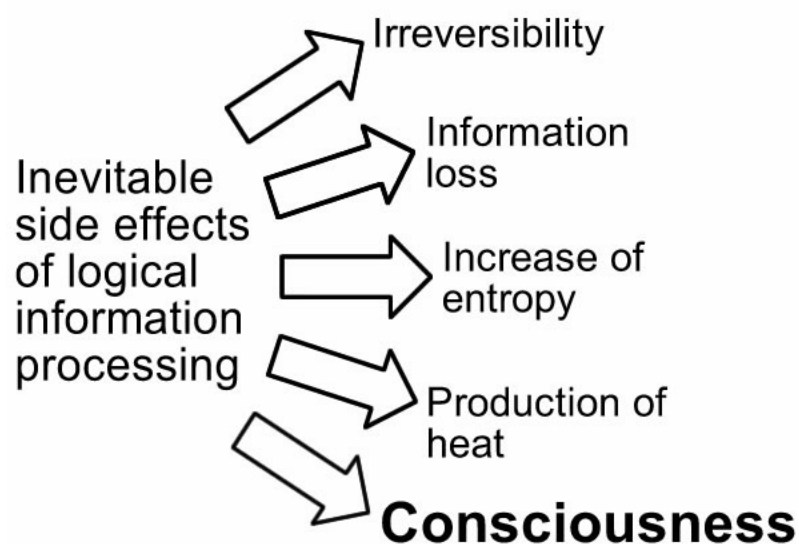

The fifth side effect

I would suggest that there is a very important point which must be appreciated in the attempt to understand the link between information processing and consciousness. The point is that the information processing which is performed in the brain is not of some arbitrary nature. It must be, as described in Chapter Seven, **logical** information processing.

Once it is realised that the brain must perform logical information processing, then I think that is the first step towards a solution to this mystery. This is because — as explained in the previous chapter — any logical information processing system necessarily introduces Landauer's principle. The system would inevitably lose information in its logic gates (or neurons) and so it would be necessary to use Landauer's principle to fully describe the behaviour of the system. In that case, it might be said that the system *invokes* Landauer's principle.

And, as described in the previous chapter, if a system invokes Landauer's principle then side effects will inevitably be introduced. Those side effects would include irreversibility and heat production (a diagram of the four side effects was included in the previous chapter). And the idea of side effects appearing in an information processing system should make our ears prick up and set alarm bells ringing, because — as has just been explained — **many physicists suggest that consciousness is also a side effect of information processing.**

On that basis, it is a relatively small leap to suggest that consciousness is a fifth inevitable side effect of logical information processing, as shown in the following diagram:

This idea forms the crux of the theory of consciousness described in this book. The idea is as follows:

Consciousness is an inevitable fifth side effect of logical information processing, as described by Landauer's principle.

Well, I told you it would be a simple theory!

Now, even though at the start of this chapter I stated that a theory should include an **explanation** of a phenomenon at a deep level, I am not going to include an explanation of the theory at this stage of this book. The proposed explanation will come later in this book. For now, this idea is being suggested as a tentative hypothesis which we will examine in the chapters to come.

In the following chapters, this idea will be used to test for the generation of consciousness in various systems.

DOES THE PRIMARY VISUAL CORTEX GENERATE CONSCIOUSNESS?

In 1952, the structure of the DNA molecule was discovered by Francis Crick and James Watson, who were working at the legendary Cavendish Laboratory in Cambridge, England. They were both awarded the Nobel Prize in 1962 for their discovery. However, it is not so well known that Francis Crick had an interest in solving another great mystery of biology. Crick was fascinated by the mystery of consciousness. And so it was that, in 1976, at the age of sixty, Francis Crick left Cambridge for California and started to pursue his interest in consciousness.

Crick started a collaboration with a young German-American neuroscientist named Christof Koch who was based at the California Institute of Technology (Caltech). It was to be a close and fruitful relationship which would continue until Crick's death in 2004. Together, Crick and Koch were determined to show the wider community that consciousness could be studied scientifically.

Crick and Koch wanted nothing to do with the endless philosophical discussions which had dogged the subject for centuries. Instead, they were only interested in developing **scientific** experiments which had the potential to shed light on consciousness. They chose to specialise on experiments which involved the human visual system.

One of the main reasons they chose to focus on vision was because it is easy to create optical illusions which provide insights into consciousness. In particular, it is possible to create optical illusions in which the consciously-perceived image can randomly switch between two different shapes.

As an example of this phenomenon, we might observe the following image of a vase, known as Rubin's vase:

As you stare at the vase, the image might suddenly switch so that you instead become consciously aware of the two faces staring at each other (the two faces on the side of the vase). Then, after a short period of time, the consciously-perceived image might switch so that you see the vase again.

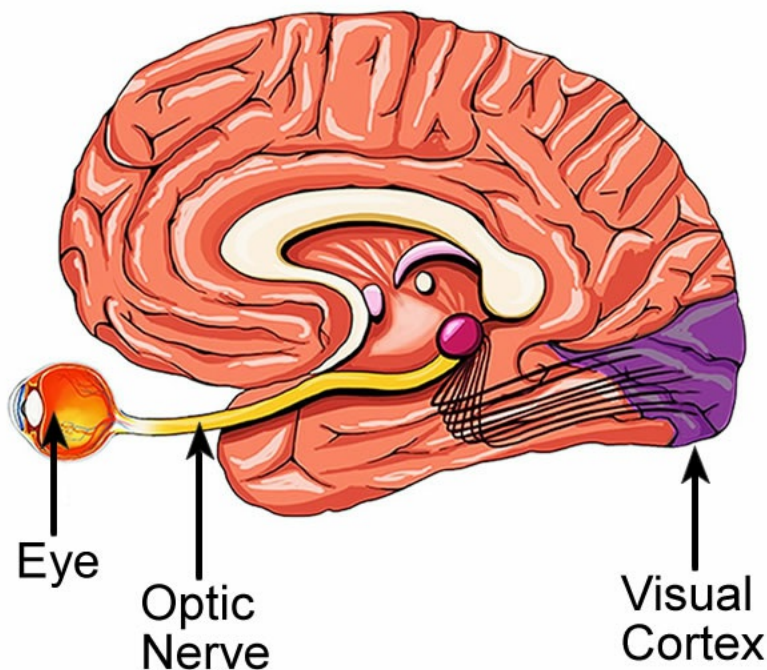

But throughout all of this switching process, **the raw data presented to your eyes does not vary**. So the

switching in your conscious perception must be entirely due to some switching in the activity of the neurons in your brain. Crick and Koch realised that if those switching neurons could be identified, then that would provide an insight into which parts of the brain were responsible for generating consciousness.

Francis Crick describes this approach in his 1995 book about consciousness titled *The Astonishing Hypothesis* (in the following quote, the "percept" means the perceived image): "Can we find neurons whose behaviour always correlates with the relevant visual percept? One way to do this would be to set up situations in which the visual information coming into the eyes remains the same but the percept changes. Which neurons change their firing, or style of firing, when the percept changes?"

It would appear that this approach could be used to identify the regions of the brain which are responsible for consciousness. Conversely, any region of the brain in which the neurons were **not** switching could then be deduced to be **not** playing a role in generating consciousness. And that resulted in Crick and Koch paying particular attention to the *primary visual cortex*.

The primary visual cortex is located at the back of the brain, and it is the first region of the brain to receive the raw visual data from the retina of the eye. The following diagram shows how the data is copied from the retina, along the optic nerve, to the primary visual cortex:

If we consider the Rubin's vase experiment again, we can see that the neurons in the retina contain the raw visual data from the image. Therefore, the activity of those neurons would not be switching as your conscious perception of the vase is switching.

The data in the primary visual cortex is just a copy of that data in the retinal neurons (copied along the optic nerve). Therefore, the activity of those neurons in the primary visual cortex would also not be switching as your conscious perception is switching. It would therefore appear logical to conclude that the primary visual cortex of the brain is not responsible for generating consciousness.

This conclusion of Crick and Koch is described by the physicist Max Tegmark in his book *Life 3.0*: "This same research controversially suggests that the primary visual cortex at the very back of the head is as unconscious as your eyeballs and your retinas."

Therefore, according to the reasoning of Crick and Koch, the primary visual cortex is a region of the brain that does not generate consciousness. Let us now apply the simple theory of consciousness described in the previous chapter to see if it comes to the same conclusion.

A simple test for consciousness

Allow me to remind you of the theory of consciousness described in the previous chapter. The theory says that consciousness is an inevitable side effect of logical information processing — as long as that information processing invokes Landauer's principle.

So the central question we need to answer is: "Is Landauer's principle invoked by the information processing?" One way to answer that question is by examining the inputs and outputs of the system which are captured in the form of a truth table. The truth table is then examined to determine whether or not it is irreversible. As was described in Chapter Eight, irreversibility in a truth table is a sure sign of information loss — which leads to an increase of entropy, the production of heat, and the invocation of Landauer's principle.

The following rule is then applied:

- If the truth table is **reversible**, then the system is declared to be **NOT** consciousness-generating.
- If the truth table is **irreversible**, then the system **IS** declared to be consciousness-generating.

It is hard to imagine a simpler test for the generation of consciousness!

The whole of Chapter Three (and a song!) was devoted to this subject of irreversibility. Hopefully it is now becoming clearer how irreversibility could potentially play a central role in detecting the generation of consciousness.

Let us now apply this simple consciousness test to see if it predicts that the primary visual cortex is conscious or not conscious.

Applying the test

As we are initially stating that the retina and eyeball are not conscious (this is not controversial), the question we need to consider is whether the information processing which occurs when the information is copied from the retina to the primary visual cortex is the type of information processing which will generate consciousness. As has just been explained, we will answer this question by describing the inputs and outputs of the information processing operation in the form of a truth table.

A simple information copying operation applied to, say, one bit of information would have one bit of input and one bit of output. It turns out that there are two Boolean logic operations which have one bit of input and one bit of output, and they are the NOT gate and the Buffer gate. The NOT gate was considered in Chapter Seven. To remind you, the NOT operator simply acts to invert the input value, as shown in the following truth table:

A	NOT A
0	1
1	0

As you can see from the previous truth table, the result of a NOT operation will be 1 if the input is 0, and it will be 0 if the input is 1. Crucially, this truth table is **reversible**, meaning that if we know the value of the output then we know what the value of the input was. This is described in an entry in the online *Stanford Encyclopedia of Philosophy* by Owen Maroney (in an article which considers reversibility and irreversibility in logic gates): "The NOT operation, for example, is a logically reversible operation. If the output is logical state one, then the input must have been logical state zero, and vice versa." [3]

The other logic gate which has a single input and a single output is the Buffer gate. The Buffer gate simply takes the input value and copies it to the output, as described by the following truth table:

A	B
0	0
1	1

As you can see from the previous truth table, the result of the Buffer gate will be 0 if the input is 0, and 1 if the input is 1. So, as is the case with the NOT gate, this truth table is also reversible because if we know the value of the output then we immediately know what the value of the input was. So both the NOT gate and the Buffer gate are reversible.

The following diagram shows the symbols for both the NOT gate and the Buffer gate:

The NOT gate

The Buffer gate

As you can see, the symbols are the same except that the Buffer gate does not have the small circle on the output of the gate (the small circle means that the output is inverted).

Let us now return to consider the primary visual cortex.

It has been explained that the information from the unconscious retina is copied to the primary visual cortex. A simple information copying operation would be represented by a Buffer logic gate. According to the consciousness test described earlier in this chapter, if the truth table describing a system is reversible, then the system is declared to be **not** consciousness-generating. As we have just seen that the truth table for the Buffer logic gate is reversible, we therefore declare that the information copying operation (from the retina to the primary visual cortex) has not generated consciousness. As a result, the primary visual cortex is declared to be unconscious — in agreement with the theory of Crick and Koch.

Copying information does not generate consciousness

As a general principle, this example has shown that the theory presented in this book predicts that simple copying of information from one point in space to another point in space (down a wire, for example) does not generate consciousness.^[4] Clearly, as long as the information copying is error-free then the process is completely reversible: the output data could be sent back to the input, thereby perfectly restoring the initial input data. And, according to

the theory, reversible operations do not generate consciousness.

Put simply, according to the theory, copying information does not generate consciousness.

IS A THERMOSTAT CONSCIOUS?

I suspect the thermostat has been responsible for more arguments at home and at work than any other device ever invented. Certainly, that was my experience of office work. Just when everyone is feeling too hot, the thermostat decides to turn the heating on, and when everyone is feeling too cold, the thermostat decides to turn the heating off. It is as if a thermostat has a mind of its own.

And this idea — that a thermostat has a "mind of its own" — was given serious consideration by John McCarthy, a professor at Stanford University. McCarthy was one of the pioneers of artificial intelligence (AI). In 1959, McCarthy invented the LISP programming language for developing AI applications (the language is still widely used today). McCarthy was even responsible for coining the term "artificial intelligence" in 1956.

In 1979, McCarthy wrote a paper titled *Ascribing Mental Qualities to Machines*. In that paper, he wrote: "Machines as simple as thermostats can be said to have beliefs, and having beliefs seems to be a characteristic of most machines capable of problem-solving performance."

In his paper, McCarthy presented a real example from his house which had two thermostats: an upstairs thermostat and a downstairs thermostat. McCarthy imagined that his thermostats had "beliefs" as to the temperature of the house. In the example, it is clear that McCarthy had been having the usual thermostat-related problems: "Recently, it was too hot upstairs, and the question arose as to whether the upstairs thermostat mistakenly **believed** it was too cold upstairs."

The idea that a thermostat has beliefs and, therefore, consciousness has also been taken seriously by the leading consciousness philosopher David Chalmers. Chalmers considered the thermostat in Chapter Eight of his 1997 book *The Conscious Mind*. In that chapter, Chalmers followed a similar line of reasoning to McCarthy, suggesting that — because a thermostat can be considered as being an information-processing device (a device which can make decisions) — then it is not unreasonable to suggest it has consciousness. To justify his view, Chalmers considered moving down the animal kingdom, starting from humans: "To make the view seem less crazy, we can think about what might happen to experience as we move down the scale of complexity. We start with the familiar cases of humans, in which very complex information processing gives rise to our familiar complex experiences. Moving to less complex systems, there does not seem much reason to doubt that dogs are conscious, or even that mice are. Moving down the scale through lizards and fish to slugs, similar considerations apply. As we move along the scale from fish and slugs through simple neural networks all the way to thermostats, where should consciousness wink out?"

I believe the theory of consciousness presented in this book can provide an answer to David Chalmers' question. In fact, I believe a simple thermostat is a perfect example for revealing the point at which consciousness "winks out", as Chalmers describes it. In this chapter we will see how the application of the simple consciousness test can provide a clear-cut decision as to whether or not a thermostat is different from a slug.

So let us apply the simple test and see whether or not a thermostat possesses that vital property essential for consciousness.

Applying the test

Let us now apply the simple truth-table based test for the generation of consciousness which was described in the previous chapter. Firstly, let us consider the behaviour of a thermostat.

A thermostat is a device capable of controlling the heating of a room. If the room is too cold, the thermostat turns the heating on, and if the room is too warm, the thermostat turns the heating off. A thermostat is therefore a device with a single input: the temperature of the room, and the thermostat has two possible output values: ON or OFF.^[5] On the basis of the room temperature, the thermostat has to make a simple decision: "Should the heating be on, or should it be off?"

So let us construct the truth table which captures the behaviour of the thermostat. We can then apply the simple test described in the previous chapter to analyse the truth table to determine if the thermostat is consciousness-generating or not.

For the purpose of capturing the functionality of the thermostat in a truth table, first let us consider the input values. Let us assign the value 0 with the room being cold, and the value 1 with the room being hot (we could assign these values the other way round as it would make no difference to the eventual conclusion — as will be explained in the final paragraph of this section). Then, considering the output of the truth table, let us assign the value 0 with the heating being OFF, and the value 1 with the heating being ON (again, these values could be the other way round). The truth table then becomes:

Room temp. (input)	Thermostat output
Cold 0	1 ON
Hot 1	0 OFF

We can see that what we have here is a logical NOT gate. When the input is 0 the output is 1, and when the input is 1 the output is 0. So the output is the inverse of the input. As explained in the previous chapter, a NOT operation is reversible because it is possible to "wind back" a NOT gate from the output to the input because if you know the

output value then you instantly know the input value (it will be the inverse of the output value). So a NOT gate is reversible.

Finally, according to the simple test, a reversible truth-table implies that a thermostat is **not** consciousness-generating.

In other words, a thermostat is not conscious.

Note that if we had assigned the truth values the other way round when forming the truth table, then we would have been left with a Buffer gate rather than a NOT gate. As explained in the previous chapter, both of these types of logical operation are reversible, so the consciousness test would still have declared the thermostat to be unconscious.

A solid lump of metal

Perhaps this result can be best understood when it is realised that the job of a thermostat can be performed by a solid lump of metal. A thermostat can be constructed from two strips of different types of metal which have different expansion coefficients (a *bimetallic strip*). As the strip becomes warmer, the difference in the expansions of the two metals will result in the strip bending. If the strip is used in an electrical circuit, this can break the circuit and turn the heating off — as shown in the following diagram:

While we cannot be certain that a lump of solid metal is not conscious, this result certainly ties in with our intuition about consciousness: we don't generally believe that a lump of solid metal is conscious.

Another way of realising that this is a prediction of the theory is to appreciate that a lump of metal produces no internal heat. Heat production is one of the four side effects of Landauer's principle, and so, according to the theory, a system which is producing no heat from internal information processing is not consciousness-generating. This would eliminate all systems made of cold, solid material — such as statues and rocks — from being conscious. Again, this agrees with our intuition: we don't generally imagine that statues and rocks are conscious.

The test for consciousness described in this book therefore concludes that a thermostat — which might well be nothing more than a solid lump of metal — is not conscious.

The human thermostat

I would like to end this chapter with a rather technical — though important — point.

In this book, a simple test for the generation of consciousness has been presented. As we have seen, the test is based on the analysis of truth tables. However, we have to be careful of a potential pitfall when applying the test. Allow me to explain.

A truth table has several columns which represent the inputs to a system, and one column representing the output of a system. So when we analyse a truth table we are analysing the inputs and outputs of a system. In effect, we are treating the system like a "black box", with no regard for its internal functioning. Can it really be possible to detect consciousness purely on that basis?

It was the English mathematician Alan Turing who, in 1950, first considered the possibility of examining an information processing system purely on the basis of its inputs and outputs. He devised a famous test which we now call the *Turing test*.

In the Turing test, your task is to ask questions to two different information processing systems: a computer and a human. The computer and the human are hidden behind a screen so you do not know which responses are coming from the computer and which responses are coming from the human. The task of the computer is to imitate a human in its responses, and to fool you into thinking that it is a human.

At the end of the question-and-answer session, you are asked which is the human and which is the computer. So you have to make a decision purely on the basis of the answers you have received. If you mistakenly reply that the computer is actually the human, then the computer has achieved its goal of fooling you, and the computer is said to have passed the Turing test. According to Alan Turing, the computer could then be said to possess intelligence.

So, clearly, what we have here is an attempt to analyse an information processing system purely on the basis of the inputs and outputs of that system.

Now, we could surely imagine a highly-advanced computer which is capable of fooling you by producing identical responses to the human. In that case, the responses could have come from the computer, or they could have come from the human — we would have absolutely no way of distinguishing between the two different systems. This results in an important conclusion: **it is clearly not possible to uniquely define a complex information processing system purely on the basis of its inputs and outputs.**

Does this pose a serious problem for the simple consciousness test we have been using in this book? After all, that test is based on the analysis of truth tables, and truth tables just show the relationships between the inputs and outputs of a system. If the same truth table can describe two wildly different systems, then how can the method ever be used to reliably detect consciousness?

Fortunately, this is a problem we can overcome. The secret is that we have an advantage over a "black box" test such as the Turing test. Our advantage is that **we can open the black box and look inside.** In other words, we have the ability to examine the internal information processing of the system — something we are prohibited from doing in the Turing test because we are not allowed to look behind the screen.

Our task then is to ensure that the truth table accurately represents the information processing which is being performed by the system. In particular, we have to be careful that the system is not a complex, conscious system which is just pretending to be a dumb, unconscious system.

As an extreme example of this, we might consider the hypothetical example of a "human thermostat". The human thermostat is a human who sits inside a big black box in your living room. The human has the simple job of turning the heating on and off when the room gets too hot or too cold (I would imagine job satisfaction would be rather low).

Purely on the basis of the inputs and outputs of that human-based system, we might construct the truth table for that system. The truth table would be the usual truth table for a thermostat which — as we have just seen — would be reversible. On that basis, the consciousness test would conclude that the system is not conscious, effectively deducing that the box contains nothing more than a lump of solid metal (a bimetallic strip) and is therefore not conscious. However, that would be an incorrect conclusion as the "human thermostat" is most certainly a conscious system!

So, as in the Turing test, we have to be careful when applying the consciousness test to check we are not being deceived. We have to "look inside the box" to ensure that the truth table is an accurate representation of the system.

That brings us to the end of this chapter.

In the last two chapters, we have applied the consciousness test to two very different information processing systems — the primary visual cortex, and a thermostat — and the test has returned a negative result in both cases. Before we consider the next example (which will provide us with our first positive result), there is something I must do.

At the start of Chapter Nine, it was explained how a scientific theory needs to do more than just make accurate predictions. The theory should also provide an *explanation*, it should explain **why** a particular phenomena occurs. Ideally, a scientific explanation should explain the phenomena in terms of low-level fundamental entities, such as particles, or fields, or space or time.

So, what is the explanation for the theory of consciousness which has been presented in this book? What is the connection between logical information processing and consciousness? Why is irreversibility so important?

I did not provide you with an explanation earlier, stating that an explanation would be provided later in the book. So I owe you an explanation, and — in the next two chapters — I will present an explanation.

Let me start by presenting what I feel is a very strong argument which provides a valuable insight into the nature and cause of consciousness ...

THE SUSPENDED ANIMATION ARGUMENT

I am a huge fan of classic science fiction movies. I can remember going to the local cinema in the 1970s with my father — another sci-fi aficionado — to watch a stream of classic movies from *Planet of the Apes* to *Close Encounters of the Third Kind*. It was a golden age for intelligent sci-fi.

But there is always a problem with presenting science fiction in a movie in a way which is scientifically accurate, certainly a problem if you want to portray space travel. The problem arises simply because everywhere interesting in space is such a long distance away — and you cannot travel faster than light. If you have read my third book then you will appreciate that if there is one law of physics which we will almost certainly never be able to break it is our inability to travel faster than light.

As an example of the great distances involved in space travel, the star which is nearest to the Sun is Proxima Centauri. Proxima Centauri is orbited by two exoplanets which have the potential to support life (see my seventh book for details), so this would certainly be an interesting place to visit. Unfortunately, Proxima Centauri — the nearest interesting place outside our Solar System — is 4.2 light years away from us. So even if we could make a spaceship which travelled at the speed of light, it would still take a minimum of 4.2 years to get there. Considering more realistic speeds of travel, it would take longer than a human lifetime to get there.

So this raises a problem for any science fiction movie attempting to present a realistic portrayal of space travel. Put simply, it would take too long to get anywhere interesting in the galaxy. Film makers then have two choices. Firstly, they could ignore the speed of light limitation and employ fictional faster-than-light travel as in movies such as *Star Wars* ("hyperdrive") or *Star Trek* ("warp drive").

Or, alternatively, they could use the realistic solution ...

Suspended animation

In February 2015, in the Pennsylvania town of Tresckow, 25-year-old Justin Smith went out for the night drinking with some friends. The temperature was twenty degrees Celsius below freezing, and there was snow on the ground.

At 9:30, Justin left the bar to walk home. At some point, it appears Justin blacked out and fell head first into a snowdrift. His body was not discovered until twelve hours later, frozen solid. There was no sign of a heartbeat. The paramedic on the scene reported back in a phone call and was recorded as saying "All signs lead us to believe that he has been dead for a considerable amount of time".

The state police arrived to investigate the death, and the body was transported to the local hospital. The team there were unable to pronounce Justin to be dead at that stage as the body was completely frozen.

However, almost working on a hunch, the hospital decided to try giving Justin a blood transfusion using warmed blood. After receiving the transfusion, early in the evening Justin's heart started to beat again.

Doctors were amazed to discover that Justin had suffered no brain damage, though some fingers and toes had to be amputated. To all intents and purposes, Justin Smith had come back from the dead.

The important factor in surviving being frozen appears to be the speed at which the body is frozen: not too fast (so that tissue is not damaged), and not too slow (so that the patient does not die from exposure before being frozen). If the speed of freezing is just right, then being frozen solid can actually save your life as it protects the body from the other harmful effects of exposure.

It is vital that the heart keeps beating — supplying the brain with oxygen — until the brain freezes. The brain is easily damaged by lack of oxygen, but if the brain is placed in suspended animation without being starved of oxygen at any stage of the process, then the brain will be undamaged. The patient can then be defrosted at a later stage without brain damage.

Fortunately, this is precisely what happened to Anna Bagenholm in Norway in 1999 when she was out skiing with friends. I can remember Anna's story making the international news reports at the time. Anna fell while skiing and plummeted head first through the ice covering a lake. Anna was trapped under the ice in the freezing water for a total of eighty minutes. Apparently her heart stopped beating after forty minutes, but that forty minutes in which the heart was supplying oxygen to the brain as it froze was crucial.

When Anna was eventually pulled out of the ice, she had no pulse, no breathing, and her pupils were dilated and unresponsive. She was clinically dead.

However, the Norwegians have a saying: "Nobody is dead until they are warm and dead". So Anna's blood was removed, warmed, and returned to her body. At 10pm that evening, Anna's heart started beating again. She has since made a full recovery.

These extraordinary stories provide a solution as to how to achieve long space journeys within the lifetime of an astronaut. The astronaut could be placed in a state of suspended animation at the start of the journey, and be revived many decades later when the destination is reached. This technique has been featured in many sci-fi movies including *Planet of the Apes*, *Alien*, and *Interstellar*. (Incidentally, *Interstellar* is the third Christopher Nolan movie to be mentioned in this book. Nolan certainly likes to get his science right.)

The following image is from the 1960s television series *Lost in Space* showing the Robinson Family being placed in suspended animation before a space flight:

NASA is seriously considering the possibility of using suspended animation for long space journeys. As part of its Innovative Advanced Concepts Program, research is being conducted to determine if astronauts could be successfully placed in a state of suspended animation for a journey to Mars.

Motion at the atomic scale

So, what are we actually doing when we place someone in a state of suspended animation? The real-life examples of Justin Smith and Anna Bagenholm which we have just considered have both involved extremely low temperatures. So what is it about low temperature that causes a subject to enter a state of suspended animation?

The physics behind heat and temperature was considered in Chapter Four. It was described how Rudolf Clausius, in 1857, was the first to realise that heat is nothing more than the motion of atoms in an object. If you rub your hands together, you cause the atoms in your hands to move, and your hands get warm as a result. Heat is nothing more than motion at the atomic scale.

So what we are actually doing when we freeze someone to place that person into suspended animation is to remove all motion from the atoms in their body — including their brain. So try not to think about hot and cold — this argument at its core is all about motion.

Now, here is an interesting question. When a person is in a state of suspended animation, with all of the atoms in their body motionless, do you think the person would be conscious? Surely not — it would be like the deepest sleep possible. So there appears to be a deep connection between motion at the atomic scale and consciousness: if motion is removed from atoms, consciousness is lost.

A similar argument was presented in 2017 by Romain Brette, a research director in theoretical and computational neuroscience at the Vision Institute in Paris.^[6] Brette used the 1960s TV series *Bewitched* to illustrate the point. Brette considered a stoppage in the flow of time rather than a stoppage of the motion of atoms: "In the TV series *Bewitched*, Samantha the housewife twitches her nose and everyone freezes except her. Then she twitches her nose and everyone unfreezes, without noticing that anything happened. For them, time has effectively stopped. The question is: was anyone experiencing anything during that time? To me, it is clear that no one can experience anything if time is frozen."

So, if motion is removed from atoms, it seems clear that consciousness is lost. The only possible counter-argument I can see would be the argument that a person whose atoms in their brain are stationary can still be conscious. In other words, a person with no brain activity can be conscious. Well, that's simply not the case, is it.

Let us perform a thought experiment to reveal the implication of this result.

Let us start by considering a conscious person. We are going to make a **single change** to this person, keeping all other variables unchanged. All we are going to do is use some advanced technology to render every atom in that person stationary (remember, this is a thought experiment so we can consider hypothetical situations even if we do not yet possess the suitable technology). No other change is made: the positions of the atoms are not altered, so no physical damage is caused to the person. Only the velocity of all the atoms which make up the person is stopped. At that point, according to the argument which has just been presented, the subject would no longer be conscious. So removal of motion at the atomic scale has resulted in a loss of consciousness.

We then make the second, single change. We restore the original motion to the atoms in the person. Again, no other change whatsoever is made — only atomic motion is added. As the state of the person has been restored to his or her original state, the person is now conscious again.

Logically, I can see only one conclusion. If you disagree with the following conclusion then you have to find a fault in the argument, and I can find no fault in the argument.

We have seen an unconscious, inert, unfeeling object become conscious when absolutely no other change is made apart from the addition of motion at the atomic scale. In other words, the addition of atomic motion has endowed inert, unfeeling matter with the gift of consciousness.

Therefore, it would appear that there can be only one logical conclusion:

Consciousness is caused by the motion of atoms.

I believe this is a hugely important result. I can see no logical weakness in this argument. I think it is watertight. Insights into the nature of consciousness which are fairly indisputable are few and far between.

It would appear that no arrangement of static, unmoving atoms can ever be used to create a conscious object. Consciousness is only generated when atomic motion is added to that object.

The result suggests that atomic motion is the essential ingredient for consciousness. It also suggests that if we want to discover the "stuff" of consciousness then we should look for a substance whose atoms are in continuous motion ...

IS CONSCIOUSNESS A FORM OF HEAT?

As research for this series of books, I have been reading various books on the philosophy of consciousness. One common theme in those books is the suggestion by some philosophers that physics is unable to describe consciousness. After all, say the philosophers, there seems to be nothing in our knowledge of physics which resembles consciousness. As an example, David Chalmers devotes the third chapter of his book *The Conscious Mind* to "arguing that consciousness is not entailed by the physics of our world".

It would appear that these philosophers have a point. For example, if we look at the Standard Model of particle physics — our best model of fundamental reality — consciousness does not feature as a particle, or a property of any particle. As another example, we might imagine the construction of an enormous textbook containing our entire knowledge of physics. This hypothetical book might be called "The Big Book of Physics". The following image shows a copy of the Big Book:

If you then did a search for the word "consciousness" in the Big Book of Physics you would find nothing. So, on that basis, the philosophers would appear to be correct.

But what if there was another possibility. What if consciousness **was** included in the Big Book, but it simply did

not appear in our word search.

Because it was called something else ...

A proposed unification

In physics, progress in our knowledge has frequently been made by achieving *unifications*. A unification occurs when two phenomena — which previously were considered to be completely unrelated — are shown to be two different aspects of the same phenomena.

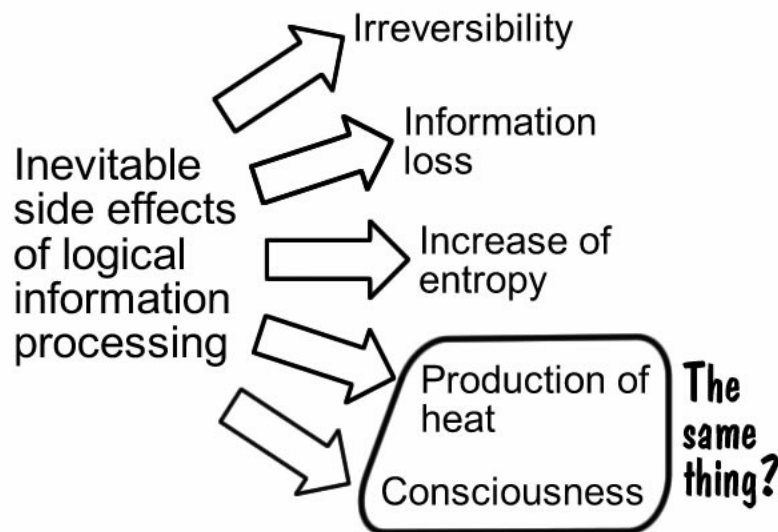

In Chapter Three, one of the first unifications in physics was described. It was Newton who had shown that the force which holds the planets in their orbits is the same force which pulls an apple down from a tree. These two phenomena had previously been considered to be completely unrelated. Hence, by showing that they were two different applications of the force of gravity, Newton had achieved a unification. Another unification — briefly described in Chapter Six — was James Clerk Maxwell's unification of electricity and magnetism, showing that they were two aspects of the single electromagnetic force.

Unifications greatly advance our knowledge, while also simplifying our view of the universe. In a unification, two different theories are combined into a single, unified theory, which is usually simpler and clearer than the two theories which it replaced. Also, the unified theory describes reality at a deeper, more fundamental level than the previous two theories, and that can clarify our understanding of the universe.

Not all proposed unifications turn out to be correct. In his book *The Trouble With Physics*, Lee Smolin presented a history of unifications in physics. One of the proposed unifications involved the proposal for phlogiston in 1678, which was considered in Chapter Two of his book. As Lee Smolin describes: "Not all proposals for unification turn out to be true. At one time, chemists proposed that heat was a substance, like matter. It was called phlogiston. This concept unified heat and matter. But it was wrong. The right proposal for the unification of heat and matter is that heat is the energy in random motion of atoms."

Let us now return to consider the four inevitable side effects of logical information processing, as predicted by Landauer's principle (as was described in Chapter Eight). If you remember, those four side effects were irreversibility, information loss, increase of entropy, and the production of heat. Then, in Chapter Nine, a theory of consciousness was presented which proposed that consciousness was a fifth side effect of logical information processing.

So let us redraw the diagram showing the five side effects of information processing — but this time you will notice an addition to the diagram:

You will notice on the previous diagram that a loop has been drawn around two items: the "Production of heat" and "Consciousness". The reason for this is because I am suggesting a unification, a unification between heat and consciousness. Even though the production of heat appears to be a totally different phenomena from consciousness, I am suggesting that they are two different aspects of the same phenomena. In other words, they are the same thing.

This is a bold step which requires justification. Five reasons will now be presented why consciousness and heat are the same thing. I believe the last two reasons are particularly important.

Firstly, there are several qualitative similarities between our consciousness and heat. Our conscious experience feels complex, random, chaotic, ever-changing and unceasing — which is what you would expect if consciousness was the result of the complex, random, chaotic, ever-changing and unceasing interactions of trillions of atoms (which forms heat).

Secondly, as was explained at the end of Chapter Four, consciousness is a *macroscopic* property, meaning it is large, a part of the human experience, a part of the human world. Somehow, this macroscopic property emerges from the motion of *microscopic* particles in our brains. So, if we want to try to find consciousness in the "Big Book of Physics" — with the understanding that it might well be called something else — we should filter our search by only looking for macroscopic properties.

When we do that, we find that there are several macroscopic properties described in the Big Book. For example, if we have a sample of gas in a container, then that gas will have a certain pressure, temperature and volume. Each of those three properties is a macroscopic quantity. That is because each of those properties is a part of our human-scale world (we can measure the value of those quantities using our human-scale thermometers and pressure gauges). But each of those macroscopic properties would depend on the behaviour of the microscopic atoms which make up the sample of gas. So macroscopic quantities depend on the behaviour of their microscopic constituents.

These macroscopic properties are said to be "emergent" in that they only appear when a large number of particles are considered together. Individually, for example, it makes no sense to talk about the temperature or entropy of a single particle. Temperature and entropy are examples of properties which only appear when a vast number of particles are involved. The physicist Carlo Rovelli makes this point in his book *Reality Is Not What it Seems*. As Rovelli explains, 'hot' and 'cold' are macroscopic concepts which only emerge when a large number of particles are considered: "There are no 'hot' or 'cold' things at a microscopic level but, when we put together a large number of microscopic constituents and describe them in terms of averages, then the notion of 'heat' appears."

So heat is a macroscopic property — just like consciousness. So at this early stage of our search, heat has passed our filter test as it is one of the macroscopic properties described in the Big Book of Physics. Heat has become a contender to be the "stuff" of our consciousness.

The third reason why consciousness might be a form of heat is because consciousness is an **irreversible** phenomenon. In Chapter Three it was explained how the fundamental laws of physics — and certainly the laws of Newton — are reversible in time. That means if we made a movie of the phenomenon, and then played that movie in reverse, the phenomenon would still appear to be correct. However, that is not the case for heat. Heat only ever flows in one direction, from hot to cold, so a movie of heat flow would not look correct if it was played in reverse. Similarly, our conscious experience has directionality in time: we feel as though we are moving from the past into the future, never vice versa. Also, we can remember the past but we cannot remember the future. If we somehow made a movie of our conscious experience, and played that movie in reverse, it would not appear to be correct (as the movie would show us remembering the future).

So heat and consciousness are both irreversible phenomena. This is surprising in a universe in which the fundamental laws of physics are reversible.

In a YouTube video, Carlo Rovelli has emphasized the irreversibility of consciousness:

<http://tinyurl.com/rovellivideo>

According to Carlo Rovelli: "Consciousness is a process — it is something that happens. It definitely happens in time, and in a time-oriented way. It's an extremely **irreversible** process. Where does this time orientation come from? The ability to make decisions about the future, but not to make decisions about the past? Why do we have memories about the past and not the future? The only answer is because of entropy."

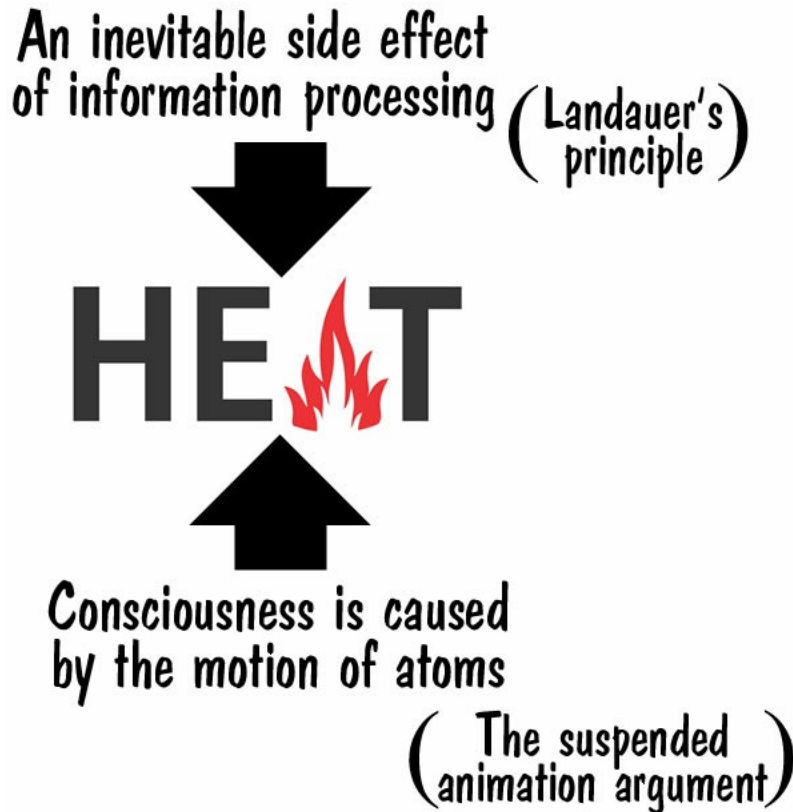

Let us now consider the fourth reason why consciousness might be a form of heat. As described in Chapter Eight, Landauer's principle reveals that heat is an inevitable side effect of logical information processing. If it is true that heat is consciousness, then that would provide a wonderfully simple explanation as to why consciousness emerges in our brains. Consciousness would be an inevitable side effect of thinking, because heat is an inevitable side effect of thinking. It would provide an elegant solution to the question of why consciousness is produced by the information processing in our brains.

Now let us move on to the fifth reason why heat might be consciousness, and that reason is provided by the suspended animation argument presented in the previous chapter. As I described, I feel it is a very strong argument, possibly watertight. If you remember, the conclusion of the argument was simple and impactful: consciousness is caused by the movement of atoms. And what is the movement of atoms? Well, of course, as described in Chapter Four, heat is nothing more than the movement of atoms. For example, if you rub your hands together then you will make the atoms in your hands move, and your hands will get warm as a result. So the idea of consciousness being a

form of heat ties in very nicely with the conclusion of the suspended animation argument.

So these last two reasons have provided two entirely separate arguments coming to the conclusion that consciousness is a form of heat. We have an argument based on Landauer's principle, and we have the suspended animation argument.

The following diagram shows the two arguments both pointing to the same conclusion:

I would suggest that having two entirely independent paths leading to the same conclusion means that this theory of consciousness as a form of heat is a compelling theory. It suggests that the word "consciousness" **IS** included in the Big Book of Physics ...

... but it is spelt "H-E-A-T".

Chaos and complexity at the nanoscale

To be clear, the type of "heat" being considered here is not truly heat at all — not in the generally-accepted meaning of the word. Heat, as defined in physics, is the truly random motion of atoms. The randomness is a crucial element. I am certainly not suggesting that truly random heat is a form of consciousness. No, the random heat we feel from the Sun or a campfire, for example, is surely not conscious.

However, the "heat" which is being considered in this chapter is the product of a very particular process: logical information processing. As such, the motion of the atoms would not be truly random. The particle motions would still retain correlations of the original information processing. Once the heat leaves the brain and interacts with the random motion of air particles, then those delicate correlations would be lost and at that stage it would truly become random disordered heat leaving our brains.

But while that heat is protected in our brains, the motion of the atoms would retain traces of the information processing which originally produced that heat. In other words, **it would retain traces of our thoughts**. It would be a special type of heat.

In Chapter Four, it was revealed how the atomic level is an extraordinarily fast-moving and violent environment. It was explained that one molecule of oxygen in a room full of oxygen gas will be moving on average at the speed of

461 metres per second, with molecular collisions occurring 6.8 billion times per second. All of this chaos is hidden from our eyes. It is easy to see how we might well overlook this churning, constant activity as being a potential cause of consciousness.

Perhaps we might speculate that microscopic transient structures might appear: order out of chaos. Maybe these structures might be formed by turbulence in the same way that tornadoes and hurricanes appear in the atmosphere. There is some interesting research in this area.

For example, in 2012, the physicist Peter Hoffman wrote a book titled *Life's Ratchet* which explores how biological systems exploit what Hoffman calls the "molecular storm" at the atomic scale. The use of the term "storm" seems to imply the possibility of the emergence of miniature "weather-related" structures such as microscopic tornadoes and hurricanes. Interestingly, Hoffman notes that the ancient Greek philosopher Democritus associated the human soul (consciousness?) with turbulence at the atomic level: "Democritus imagined the soul as a fire consisting of myriads of jostling particles, which Democritus called atoms."

The similarity between Democritus' view and the theory described in this book is quite remarkable. Democritus' description of a "fire" as describing the soul is also interesting, making an early connection between consciousness and heat.

George Ellis, a professor of complex systems at Cape Town University, is also exploring the importance of molecular chaos in our thought processes. According to Ellis, the randomness of molecular chaos in neurons might lead to a way in which the apparent free will of our consciousness can be accommodated in physics. The concept of free will is notoriously difficult to explain using physics which describes the universe in a predictable, deterministic way. Maybe the chaos of swirling molecules provides an answer? George Ellis has described his theory in an online essay titled *From Chaos to Free Will*. [\[7\]](#)

Whatever is the case, according to the theory of consciousness described in this book, it appears that "messiness" at the atomic and molecular scale is required for consciousness: smoothness and order simply will not do the trick. This idea of the importance of atomic "messiness" will be explored in the example in the final chapter of this book.

But now, before we leave this chapter, it is interesting to note that this proposed close connection between consciousness and heat provides an instant, simple answer to one of the great scientific mysteries about consciousness ...

Quantum mechanics and consciousness

When Erwin Schrödinger and Werner Heisenberg developed the theory of quantum mechanics in the mid 1920s, it launched one of the greatest revolutions in the history of physics. Applications of quantum mechanics include transistors, computers, and smartphones. It is the theory which has made our modern world.

However, when the theory was discovered, it quickly became clear that the role of the observer was particularly important. In 1927, the *Heisenberg uncertainty principle* revealed that the observer should not be regarded as being completely isolated from the system being observed. Instead, the act of observing inevitably affects the system. As an analogy from classical physics, when the air pressure in a tyre is measured, it is impossible to perform the measurement without extracting a small amount of air from the tyre. Therefore, the act of observation inevitably affects the system being observed.

In quantum mechanics, before a system is observed, that system can be in a remarkable state called a *superposition* state. For example, while it is in a superposition state, a particle can appear to be in two places at once (as revealed in the famous *double-slit experiment*).

It might sound bizarre, but this ability for a particle to be in two states at the same time is currently being used to make quantum computers. Quantum computers use particles in superposition states to perform multiple mathematical operations at the same time (for more details on quantum computing, see my tenth book).

So before a particle is observed, it can be in a superposition state. This superposition state can only be represented by a purely mathematical description called the *wavefunction*. However, the moment the system is observed, the system will no longer be in a superposition state. As an example, once it is observed, a particle will only ever be found at one particular point in space — not in two places at once. As a result, after observation there is said to be a *collapse of the wavefunction*.

This peculiar phenomenon forms the basis for the famous Schrödinger's Cat thought experiment. In the experiment, Schrödinger's cat is placed inside a sealed box. There is also a sealed glass jar of poison gas in the box, together with a small piece of radioactive material. If an atom of the radioactive material decays, the glass jar is broken, the poison is released, and the cat dies. Conversely, if an atom does not decay, the cat lives.

However, according to quantum mechanics, before the atom is observed we must consider the atom to be in a

superposition state of both "decayed" and "not decayed". It appears we must therefore treat the cat as being both dead and alive at the same time!

It is certainly true that if a human opens the box to observe the cat, the cat will be found to be either alive or dead — not in a strange mixture of both states. So there has been a "collapse of the wavefunction" caused by observation. The question was therefore raised, is there something special about observation by a conscious human being? Why do conscious beings never observe systems in superposition states? Why do conscious beings never observe cats which are both dead and alive? This has been one of the great scientific mysteries about consciousness.

Schrödinger's Cat remained a mystery for many years after it was first proposed. However, over the last fifty years, we have obtained a much greater understanding of the physical processes which occur during the so-called "collapse of the wavefunction". It is no longer so much of a mystery.

It appears that a particle which is in a superposition state is very rapidly reduced to a single, well-defined state when that particle interacts with a noisy, messy, random environment, full of fast-moving particles. This process is called *decoherence*. And what do we call the state when particles are moving in a random, fast-moving manner? That is heat. Heat is the random motion of particles. So a warm environment acts to collapse the wavefunction.

This is the reason why a quantum computer must operate at an incredibly low temperature. The temperature of the interior of a quantum computer is the lowest temperature in the entire universe, lower than the temperature of deep space. A quantum computer has to be kept at this low temperature to avoid the collapse of the wavefunction, which would take its particles out of their superposition state — ending the calculation.

And so this reveals why the theory presented in this book provides a simple solution of how consciousness will always act to collapse the quantum wavefunction. As has been explained in this chapter, the theory suggests a very close connection between consciousness and heat — even suggesting that heat is the "stuff" from which consciousness is made. That heat would therefore act to take any system out of its superposition state, very rapidly collapsing the wavefunction of that system.

In fact, according to the theory, it would be literally impossible for a conscious system to **not** collapse the wavefunction of a system it was observing. According to the theory, no conscious system could ever see a cat alive and dead at the same time.

The theory therefore provides a very simple solution as to how a conscious system will always collapse the quantum wavefunction.

That brings us to the end of this chapter. The next chapter is the final chapter of this book, and it contains another example of the simple consciousness test in action. It is also an important chapter.

Because the next chapter examines the big question ...

DOES A NEURON GENERATE CONSCIOUSNESS?

The human brain is composed of approximately 86 billion neurons. Somehow, by connecting a large number of these relatively simple devices together, consciousness is created. On that basis, surely it would appear that the answer to the mystery of consciousness must be found in a neuron.

Why are neurons capable of generating consciousness? Why, for example, does Nature not make a brain out of 86 billion miniature solid metal cubes? What property does a neuron have that a solid metal cube does not have? If you can answer that question, I would suggest you would have solved the mystery of consciousness.

In this final chapter, an attempt will be made to answer that question.

We will discover some truly remarkable conclusions ...

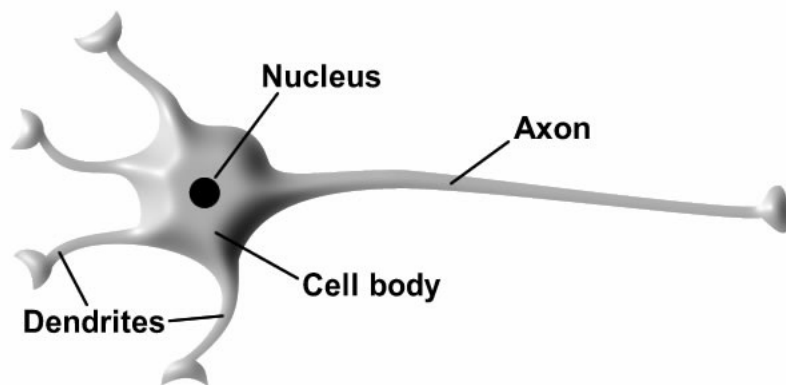

Applying the test

Let us start by applying the simple consciousness test to a neuron to see if it is predicted to be "consciousness-generating".

Of course, we already know what the outcome of this analysis should be. A neuron is certainly consciousness-generating. We know this because we know that if you have 86 billion neurons then you can make a brain (I am using this as the definition of what it means to be "consciousness-generating"). So let us apply the test and see if it comes to the correct conclusion.

Let me first remind you of the structure of a neuron.

A simplified diagram of a neuron was presented at the end of Chapter Seven, but it is presented again here. As you will remember, information enters the neuron via multiple *dendrites*. However, a neuron only ever has a single output, which is called an *axon*. Here is the simplified diagram of a neuron, showing the dendrites and the axon:

A neuron therefore operates like a logic gate, with the usual multiple inputs and single output of a logic gate (just as a truth table has multiple input columns and a single output column). This similarity between the functioning of neurons and logic gates has been noted by the physicist Paul Davies in his recent book *The Demon in the Machine*: "Because converging incoming signals from many neurons can be amalgamated, **the system acts rather like a logic circuit**, with the neuron being either on (firing) or off (quiescent), according to the state of combination of the incoming signals."

As a neuron acts like a logic gate, we can create a truth table of its inputs and outputs and apply the simple test for consciousness-generation described in this book. We might, for example, consider a multiple-input neuron which is performing an AND logical operation:

A	B	A AND B
0	0	0
0	1	0
1	0	0
1	1	1

}

Same
outputs

As described in Chapter Eight, we can see from the previous truth table that this is an irreversible operation. As you can see from the truth table, if the output of the gate is 0, then we cannot be certain if the input pairing had been 0 and 0, or 0 and 1, or 1 and 0. So this logic gate could not be operated in reverse as it is impossible to know what the input values had been if you only know the output value.

The consciousness test predicts that an irreversible truth table is a sign of consciousness-generation. Therefore, the test correctly predicts that a neuron is consciousness-generating.

If the consciousness test had predicted a negative result — that a neuron cannot generate consciousness — then the theory could have been rejected as being wrong. That is the advantage of a scientific theory of consciousness which makes clear, testable predictions.

Information loss in neurons

The irreversibility of the information processing in a neuron inevitably leads to the loss of information. Another simple way of realising that information must be lost in a neuron is due to the fact that a neuron has multiple inputs but only a single output. This point was made by Francis Crick in a quotation which was presented in Chapter Eight: "One characteristic of a neuron is already fairly clear. A single neuron can fire at different rates and, to some extent, in different styles. Even so, in any period of time it can only send out limited information. Yet during that time the potential information coming into it, through its many synapses, is very large. In this process — going from its input to its output — **there must be a loss of information.**"

Each "bit" of information lost in a neuron would produce an amount of heat equal to $kT \ln 2$ joules of heat, according to Landauer's principle. The suggestion is that it is that heat which would be the "stuff" of consciousness.

You will note that Boltzmann's constant, k , is included in the value. At the end of Chapter Four, it was explained that Boltzmann's constant is "the bridge between the microscopic and macroscopic world". For this reason, it was suggested that any final theory of consciousness would likely include Boltzmann's constant as a means of explaining how the macroscopic experience of consciousness can emerge from the microscopic movement of particles. So the presence of Boltzmann's constant here is an encouraging sign for the theory of consciousness described in this book.

In the previous chapter it was suggested that this production of heat — this "molecular chaos" — is the essential ingredient of consciousness. In contrast, a system which is sterile and cold, and which lacks that "messiness" at the atomic level, can never be conscious.

So let us now leave neurons behind and consider a solid metal cube instead. When we consider a cold, sterile object — such as a solid metal cube — we find none of that essential molecular chaos. We have already considered a solid lump of metal back in Chapter Eleven when we considered the question of whether or not a thermostat is conscious. It was explained that the function of a thermostat can be performed by a strip of solid metal (a bimetallic strip). It was also explained how the resultant truth table for that thermostat would be reversible — and therefore predicted to be **not** consciousness-generating.

So lumps of solid metal do not produce consciousness — they are simply too cold and sterile, with none of the essential "messiness" at the atomic level. Whereas the information processing in a neuron is irreversible and therefore inevitably produces heat — that essential atomic "messiness". And this is how the theory provides an explanation as to why Nature can make a conscious system out of 86 billion neurons — but not out of 86 billion solid metal cubes.

The neuron and the steam engine

At this point, I could quite happily finish this chapter. The consciousness test applied to a neuron has made the correct prediction, and the associated explanation appears credible. However, when we start to dig deeper into the functioning of a neuron, we discover some truly remarkable conclusions.

So let us dig a bit deeper.

Let us start by considering the steps which result in the so-called "firing" of a neuron, in which a neuron transmits its electrical signal to the next neuron in the network.

Earlier in this chapter, it was explained that the input signals enter a neuron through the neuron's dendrites. The voltages from the various inputs are then summed inside the neuron. If the total voltage exceeds a certain threshold (the *threshold potential*), the neuron is said to *fire*. At that point, the neuron sends a burst of electrical voltage down its single output (axon).

After the neuron has fired, the voltage inside the neuron body is reset to its initial value (the *resting potential*). The process then starts again, with voltage building inside the neuron. As a result, firing is a rapid and repetitive process.

The following diagram shows this sequence of steps during the firing of a neuron:

In the previous diagram, Step One shows the neuron in its initial state, with its internal voltage at its resting potential. Step Two shows the increase of internal voltage as electrical signals are received on the neuron's dendrites. Step Three shows the neuron firing, with a series of rapid voltage "spikes" being sent down the neuron's axon. Then the final stage is the reset operation which restores the neuron to its original state.

Because the sequence of steps ends in a reset operation, it is possible for the sequence to quickly repeat, and this is, indeed, what happens. A neuron will typically fire fifty times a second, with spikes of voltage being sent down the axon of a neuron like bullets from a machine gun.

So what we have here is a **cycle**. If you remember, we have already encountered cycles back at the start of Chapter One when we considered steam engines. A cycle was defined to be a sequence of linked steps ending with a reset operation. The reset operation is crucial as it allows the cycle to be rapidly repeated.

This definition of a cycle is described in the *Thermodynamics* textbook by Cengel and Boles: "A system is said to have undergone a **cycle** if it returns to its initial state at the end of the process. That is, for a cycle the initial and final states are identical."

In particular, I would suggest that there is a remarkable similarity between the cycle of a neuron firing and the cycle which occurs during the jumping of the lid on young James Watt's cooking pot boiling on his mother's fire. To remind you, here again is the diagram of the jumping lid of James Watt's cooking pot:

Initially, the pressure of the steam in the cooking pot is the same as the atmospheric pressure outside the pot. But as more heat energy enters the pot, the pressure of the steam in the pot increases (just as the voltage in a neuron increases). When the pressure of the steam in the pot exceeds a certain threshold value, it blows the lid of the pot up (just as the voltage inside a neuron has to exceed a certain threshold to initiate the spike). The whole process ends with a reset operation in which the pressure in the pot is equalised with the atmospheric pressure outside the pot (just as the voltage in a neuron is reset to its resting potential). Because of this reset operation, the lid of the pot drops back down again, and the cycle can rapidly repeat (just as a neuron firing can repeat fifty times a second).

In his recent book *Until the End of Time*, The physicist Brian Greene describes the importance of the reset operation in a steam engine: "The steam engine relies on a cyclical process: a piston is thrust forward by expanding steam and is then **reset** to its original position, where it awaits the next thrust. The steam, too, reverts to its original volume, temperature, and pressure, as must all of the engine's vital parts, readying the engine to heat back up and thrust the piston once again."

So it appears that there are clear similarities between the firing of a neuron and the operation of a steam engine. And I would suggest that these similarities raise some interesting questions about neurons and consciousness.

Firstly, a steam engine does not produce a constant motive force throughout its entire cycle. Considering James Watt's cooking pot, we could only extract power from the movement of the lid at the point where the steam pushes the lid upwards. No force is generated as the lid drops down again. This is typical of all single-acting steam engines. This explains why, in a steam engine, it is essential that the cycle is rapidly repeated. As the thermodynamics textbook, *Concepts in Thermal Physics*, explains: "It has to be cyclic so that it can be continuously operated, producing a steady power."

As a steam engine does not produce continuous power during its cycle, we might feel justified in asking a similar question about neurons: does a neuron generate consciousness continually? Or does a neuron only generate consciousness during a particular part of its cycle?

To answer that question, we must remember the reason why the consciousness test predicts that a neuron is consciousness-generating. The reason is because there is inevitable information loss in a neuron (not all of the multiple inputs can be passed to the single output). The point at which a neuron loses information is the point at which it fires. It is at that point that the voltage in the neuron is reset to its resting potential, with all internal information being erased. The spike of electric voltage down the axon would be matched by a burst of heat output (according to Landauer's Principle) and, according to the theory, a burst of consciousness.

Therefore, it is proposed that a neuron only generates consciousness at the point at which it fires.

Because consciousness is only generated at the point of firing, it would then be necessary for a neuron to fire repeatedly and rapidly in order to produce a continual experience of consciousness — just as a steam engine needs to cycle repeatedly and rapidly to produce continual motion. With neurons firing fifty times a second, the successive bursts of consciousness would generate a continuous impression of consciousness — just as frames in a movie played at fifty frames per second generate an impression of continuous motion.

The "reset" operation

There is another way to realise the potential importance of the firing process in generating consciousness.

When a neuron fires, its internal voltage is always reset to exactly the same original resting potential. This, therefore, acts as a "reset" operation. Rolf Landauer refers to a "reset" (or "restore") operation many times in his

original 1961 paper, the paper which first introduced what we now call Landauer's principle.

In that paper, Landauer describes the reset operation as follows: "We start with each bit in one of two states and end up with a well-defined state."

So, as Landauer explains, we have to create a truth table in which the inputs are in "one of two states" — 0 or 1 — but both inputs lead to the same single, "well-defined" output state. As an example, in the case of the following truth table for a reset function, both input values lead to a 0 output value (both inputs are reset to the same output value):

Input	Output
0	0
1	0

Applying the usual consciousness test, we now examine the truth table to see if it is reversible or irreversible. It can be seen that the truth table is irreversible (if we know the output is 0, we cannot be sure of the value of the input). The test predicts that an irreversible truth table is a sign of consciousness-generation. This is, therefore, another indicator that a neuron generates consciousness during its reset operation — the point at which it fires.

In his book about molecular biology, *Life's Ratchet*, the physicist Peter Hoffman considers several examples of "molecular machines". These incredible microscopic devices — only a few molecules in size — operate within the cells in our body. They are constantly in action, carrying nutrients around our cells, expelling waste, and repairing damage. But what is particularly interesting is that in Chapter Six of his book, it is explained how these molecular machines use cycles and reset operations to achieve their motion. In other words, this is conclusive evidence that the cells in our body — including our neurons — do, indeed, use the physics of James Watt's cooking pot.

Another example considered by Hoffman is the Maxwell's Demon thought experiment. Hoffman considers the situation in which the demon wants to process billions of particles — opening and shutting the trapdoor each time. As Hoffman explains, that represents a repeated operation: a cycle. In that case, there must be a reset operation in the demon's mind. As Hoffman explains: "In the case of the demon, erasing information restores or 'resets' the system to its original state, allowing a new measurement cycle to begin. The same applies to machines. To make a small machine perform repeated motions, a reset step is needed, as the machine needs to be returned to its original state before it can begin a new cycle. **And it is this reset step that leads to an inevitable increase in entropy.**"

Hoffman identifies the reset step as the point of increasing entropy — and therefore the point at which heat is produced. It is therefore the reset step that is potentially the point at which consciousness is generated in a neuron.

Neurons vs. electronic logic gates

Several times in this book, it has been stated that a neuron is a form of logic gate, performing the same function as an electronic logic gate in a computer. This is a well-accepted view, and it is largely correct. However, when we look more closely at the functioning of neurons and logic gates, we find there is one very big difference between them. And, based on the discussion in this chapter, it is a difference which might very well hold the key as to whether or not an electronic logic gate is capable of generating consciousness.

Let us first consider a neuron.

The firing mechanism of a neuron was considered earlier in this chapter. It was explained how the voltage in a neuron will keep increasing until the neuron fires — with the voltage inside the neuron being reset to the resting potential at that point. It is important to realise that this process in which the voltage continually builds will continue even if the inputs to the neuron are held steady and unchanging.

This important point is described in the textbook *Neuroscience: Exploring the Brain*.^[8] In that book, a wonderful analogy to the process is presented. The firing mechanism of a neuron is compared to the motorised drive of a fashion photographer's expensive camera: "We likened the generation of an action potential to taking a photograph by pressing the shutter button on a camera. But what if the camera is one of those fancy motor-driven models that fashion and sports photographers use? In that case, continued pressure on the shutter button beyond threshold would cause the camera to shoot frame after frame. The same thing is true for a neuron. If, for example, we pass continuous

current into a neuron through a microelectrode, we will generate not one, but many action potentials in succession."

So, if the photographer keeps his or her finger depressed on the button, the camera will take a stream of rapid photographs. Similarly, if the inputs to a neuron are kept constant and unchanging, the neuron will still be an extremely active and dynamic object, continuing to send a stream of spikes down its axon at a rate of around fifty spikes per second (50 Hz).

In this sense, we see a neuron is more than just a logic gate. Instead, a neuron is a logic gate ... **with an additional rapid firing mechanism attached.**

However, when we consider an electronic logic gate, we discover a very different situation. A typical circuit diagram of an electronic logic gate was presented in Chapter Seven:

It can be seen from the diagram that this AND gate consists of just five electronic components: two transistors and three resistors. It is a very simple device, and this is typically the case for all electronic logic gates. Crucially, then, **an electronic logic gate does not possess the in-built rapid firing mechanism which a neuron possesses.**

As has been explained, if the inputs to a neuron are held at constant values, the neuron will continue its 50 Hz firing mechanism. In contrast, if the inputs to an electronic logic gate are held constant, then the output of the logic gate will be a continuous constant value.

This difference in behaviour between neurons and electronic logic gates is shown in the following diagram. In the neuron, it can be seen that the output will "pop" fifty times a second when the neuron fires: "pop, pop, pop, ..." (I have used the terms "pop, pop" rather than "fire" to emphasize that this is a quick, repetitive action). Each of those "pops" will be accompanied by a loss of information, a burst of heat, and — according to the theory — a burst of consciousness. In contrast, the output of the electronic logic gate can be seen to be a constant value — with no "pops" of consciousness and heat:

A neuron is simply a far more dynamic device than an electronic logic gate. As the suspended animation argument (in Chapter Twelve) suggests, movement is essential for consciousness. It would appear that dynamism is essential for consciousness.

Neurons are constantly dynamic, continuously losing information in rapid bursts. According to the theory, that results in a continuous experience of consciousness. In contrast, information is not lost in an electronic logic gate with static inputs: it would not generate consciousness.

In fact, it appears that neurons are the optimal consciousness-generating devices, almost as if they have been specifically selected for their ability to generate a continuous experience of consciousness. Why should that be the case? Is consciousness important? I have no answer to that question.

But I find that to be an absolutely fascinating conclusion.

[4] I found a *Physics Today* webpage which makes it clear that the copying of information does not invoke Landauer's Principle: "Gaining, or writing, information is akin to copying information from one place to another. Such one-to-one mapping can be realized, in principle, without dissipating any heat.", *Information: From Maxwell's Demon to Landauer's Eraser*, <http://tinyurl.com/copyinginformation>

[5] In his book, David Chalmers considers a thermostat with three possible states corresponding to the room being too hot, the room being too cold, or the room temperature being OK. This implies that it is a more complex thermostat which is able to control the air conditioning to cool the room, as well as turn the heating on or off. This would require the setting of two temperatures to form an acceptable range. This would require two truth-tables: one to control the heating, and one to control the air-conditioning. But each individual truth-table would still be reversible.

Well, friend.... this is not how I wanted for us to meet again. I thought we had more time but things are moving quickly now. As we descend into chaos I'm going to try and turn these 'reports' out as often as possible...as often as justified. Please look for me on Facebook, I've got two pages going now as I'm bounced in and out of Facebook jail because I'm trying to wake people up and keep them updated. These are largely NWO-themed meme and news pages but I post links for pertinent other stuff also.

Search for 'Samaritan Sentinel' and 'Rise of the New World Order: The Culling of Man's Meme Machine'. If I'm not actively posting there that means I'm in FB jail...or worse.

I just feel like I needed to say something about the current events to the people who read my books and woke up. This is the best way to reach a ton of people as hopefully Amazon will alert you to my update here. I put this out on Amazon's Kindle for as cheap as they would let me = 2.99. Hopefully Amazon will contact you about this update, you've got to prepare for the financial implosion that will be blamed on this 'pandemic', but it's really a 'plannedemic'.

I'll also try to put this out on my Facebook pages, but it's pretty long for a FB post. I'll definitely try though.

I certainly do appreciate people purchasing my books and spreading them around to support me and my family right now as always. Thank you in advance for your continued support!!!! There is no other book I know of that covers all the bases of the NWO like my first one.

The following should be taken under advisement **as my opinion only** and it is up to you to do your own due diligence in looking into and tracking everything I'm going to say.

I don't know for sure what's going to happen, but we just took a financial gut-shot from the alleged "pandemic" and effectively bankrupted the entire United States and even global travel industries of airlines, hotels, restaurants, etc.

These businesses might never come back. Why would they? To go broke next year over the next plannedemic? This is a gaping hole in our economy with millions now immediately on the unemployment ranks with not much future getting back into the same line of work because all those businesses are folding as you read this. You are witnessing the controlled demolition of our economy, and our country, the United States, right now, right before your eyes while we are all detained in 'soft' martial law for our own good against a virus that will kill less people than the flu. No, you don't want to catch this virus, I've heard nothing good about the illness, but what has been foisted upon the world is a false flag of epic proportions.

I will repeat this as I did for my first two books: Don't ever believe what I say without doing your own research and then coming to your own conclusions.

I am speaking on the authority of the amount of research I've done and continue to do, tips from others, and of course praying my heart out that I will know what to say when the time comes for people to look to me for guidance. I've woke up many thousands or more with my books and I'm not done yet speaking about what has happened and what I can see happening.

So...with all that said....

We've had the NWO/Illuminati/Deep Staters boxed in a corner now for a little while. All their pedophilia was uncontrollably spilling out in the public arena. Pizzagate, Jeffrey Epstein, Jimmy Seville, the Royal Family and tons more are horrible monsters to the point and degree it cannot be hidden any more.

All the names on Epstein's 'Lolita Express' flight manifests read like a who's-who of Hollywood elite, politicians, and European royalty. The cat was out of the bag and they were forced to act and act now or we would be coming for them with torches and pitchforks.

The globalist proponents of the Great Plan and their agenda for global enslavement were being threatened by a ton of people who are now awake thanks to you, me and others spilling the truth about the Federal Reserve, 9/11, Bilderberg, and the like.

We are on to them and they had to act and act fast as they were losing the information war and badly. I have literally spent tens of thousands of hours at this point researching and passing on information to others in my books and on

Facebook...I live and breathe this stuff because that is what I was put here to do. When I woke up in 2007, I jumped right in the fight.

Unfortunately for us, they now use Artificial Intelligence to map out the NWO agenda these days, and apparently it called for releasing an engineered bioweapon against humanity to keep the Great Plan from being derailed.

They are probably going to pull it off with this plannedemic. There is the highest probability that this is the beginning of the End Game I'm afraid. It was always my intention to slow it down but it is moving full steam ahead.

You probably haven't heard this as this type of info is highly suppressed by the NWO-owned-and-controlled mainstream media, but the author of the U.S. Biowarfare Act has gone public stating he believes COVID-19 to be a BIOWEAPON that either escaped or was intentionally released. I believe the latter to be the truth. Watch this video interview on YouTube...as long as it is still up: https://youtu.be/F_TPjbu4FAE

They are not going to run us through this false flag and have millions more people wake up to the NWO, start looking for the truth about what is happening, start prepping, awakening others, etc. They are moving to quash the United States and humanity right now with this false flag called COVID-19.

We are in a bad way in terms of losing our country, and things are going to get way worse fast. This is a **'Red Alert'** status update, we've got a very rough road ahead of us. We've got an intentionally-released manmade bioweapon on one side and the empowered FEMA to "deal" with it, and the diabolical proponents of the New World Order who released the bioweapon on the other side and there is no where to run unless you have a rocket ship to Mars so buckle up.

Throw in an already-collapsed oil market, a soon-to-collapse stock market, and a dollar crisis not far behind and this is going to make for a truly interesting year. Oh yeah, we're supposed to hold an election or something also.... almost the entire Federal Government is up for grabs this November.

Now it came out that some of the Congressmen and women sold their stock in hotels, etc. because they had beforehand knowledge of exactly what was going to happen. This whole thing is a gigantic false flag to protect the Deep State/Illuminati/New World Order crowd.

Why didn't they warn the hotels/restaurants/hair dressers/etc. that this financial storm was coming when they clearly knew it? Because they didn't want to cause panic. They are still doing this right now with Trump saying that he can't wait to get back to business in America. You can tell he is quite uncomfortable jerking us off like this because he too knows what's coming: FEMA martial law and the end of the USA.

So now we've got all the **MILLIONS** of hotel workers, restaurant workers, airlines people, etc. all unemployed and largely going on the government payroll via unemployment...they are now dependent on the state to survive going forward because those jobs aren't needed in the New World Order. That type of excess is coming to an end, slaves.

This is not good at all, we are headed straight into tyrannical fascism. The definition of fascism is when the state takes over all corporations. It also works the other way and this is why we are falling: the corporations have already taken over the government via lobbyists. Term limits and anti-lobbying laws could have prevented this but you know...everyone has their price. The entire federal government is bought and paid for by the Federal Reserve crowd!!!!

I don't believe that we will pull out of the current financial nosedive we are in right now. This is probably going to be the big crash I talk about in my first book. This is why the Federal Reserve and Trump/Congress are all over this thing...throwing \$2 Trillion dollars at it just to start with. Mortgage companies letting people slide for a year on their mortgages, SBA emergency loans available, etc. They know the shitstorm is right on the horizon. You can expect a roller coaster ride on Wall Street going forward...it will be one step forward, two steps back all the way down...possibly to ZERO.

I knew that the next crash after the 2008 one was going to be the big one, they just barely staved it off last time but this time it will be too big of an issue.

After what they did to stop the big crash in 2008 by using all their silver-bullets of interest rate reductions, this Greatest Depression is going to hit HARD.

They already ran the interest rates so low they can't really go lower without them paying you to borrow money...

negative interest rates. Trump has publicly called for them himself!

The Fed right now is injecting money into the economy by buying “mortgage-backed securities”. This is a fancy way of saying they are entering numbers on a computer screen to create hundreds of billions of dollars out of thin air and purchasing the rights to your house when they foreclose on it after this Greatest Depression gets rolling. Your house. Your neighbor’s house. Your grandma’s house. My house. All by printing money out of thin air for a small handful of globalist, satanic pedophiles.

Getting mad yet? I am....I am PISSED, pardon my French!!!

Some people were barely making it before this happened...I’m one of them! I’m not sure what I’m going to do but if enough people pass this report around, I’d move a few books and get some kind of plan together for my family’s financial situation. I spent way too much time over the years working on waking people up instead of looking for work...my bad.

The lumber store down the street from my house is only open for ‘takeout’....?????. Look I’m a construction worker. You just don’t have a takeout/curbside lumber store...it just doesn’t work like that. I’m a lifelong carpenter, I’m going to be hand-selecting the best lumber there is to make my work look as good as possible!!!

This isn’t going to last long before everyone goes under like dominos and the whole thing crashes right to the ground....the whole pyramid scheme under the Federal Reserve is to thank for the coming financial woes.

Funny, that’s why it was expressly stated in the Constitution to NOT EVER ALLOW AN ENTITY LIKE THE PRIVATELY-OWNED, FOR-PROFIT FEDERAL RESERVE TO EVER EXIST. And we let it in and gave the country’s control to the evilest people on the planet: the Satanic pedophile murderous Illuminati banking families. You know exactly who they are from my first book!!!

You already know everything I’m talking about I hope...if you read my first book, I’m preaching to the choir here. It’s just unfolding now before our eyes and it’s like watching a horrific train wreck happen in slow motion, in real time.

And then when people are wondering what to do with the ‘cash’ they have in the bank after they barely sold their stock for pennies on the dollar...their ‘cash’ being literally numbers on a computer screen and not gold in their pocket...you know...real money? They are going to implode the dollar either during or after the stock market meltdown and the dollar will then be worthless also.

The 2020 coronavirus plannedemic will be the scapegoat for the illegal, not-so-Federal Reserve’s economy coming apart at the seams. This is an intentional, controlled demolition of our economy, just like the WTC on 9/11.

You know what’s funny? The goberment ran drills for this exact scenario last Fall!! The stock market will go to zero, then the dollar crisis will wipe out what is left. I wouldn’t be surprised to see UN troops on the ground here before the end of the year. This is about a right time to get right with God if you haven’t lately, because you might be going to see Him soon.

I fully am expecting riots to begin in the cities this year, either from people getting cabin fever or if the food starts to run out in the next few weeks/months, or whatever. People are broke right now, imagine not working at all for weeks or even months. This thing could drag on as long as they need it to in order to finish us off.

I also expect that we will be kicked when we’re down. I’m fully anticipating a major earthquake in the United States and soon, I would say this year. With the HAARP technology available to the NWO they could easily trigger the Cascadia Subduction Zone earthquake right in my backyard in Seattle!!!

This would essentially destroy about every city up and down the West coast, coast of Japan, etc. This will be a HUGE quake with massive damage and massive loss of life. They were just running drills about it out here a couple years ago so that should tell you all you need to get your guard up!!

Now, going forward from today, Trump will eventually be blamed for the economic meltdown and the handling of the COVID-19 ‘plannedemic’. All voting this Fall will probably be electronic/mail-in and there will be no exit polls to police this election because I believe we may still be in quarantine later this year!

This elimination of exit polls will open the door to the proponents of the Great Plan to rig the election and install

good ol' Hillary Clinton. Yes, I believe Hillary is going to be Biden's running mate, he will bow out or be removed, and Hillary will be in the driver's seat. Have you seen Hillary lately? She just got a bunch of plastic surgery in anticipation of her big day in the limelight as the "savior" of the U.S.....*gag*. She would love to be the one to put the knife right the heart of the good ol' USA.

The Illuminati need their Jezebel in the driver's seat to put out the flames of all the pedophilia and general corruption we all know that they're up to.

Forced vaccinations are probably coming later this year and will be accompanied by attempted gun confiscation in the USA. I don't know if this will ignite a Civil War, but the death from the force-injected bioweapon they will label a 'vaccine' will arguably be worse than being shot with a gun so take your pick when the time comes. You will know what to do.

Going forward after this plannedemic blows over, 'Pandemic' will be the new invisible boogeyman to terrorize humanity. It was terrorism but that wasn't good enough. You can expect a mandatory annual 'pandemic' shot against whatever it is they cook up that year to go along with your flu shots, etc. No. Thank. You.

I doubt I'll be around that long anyways to be quite honest, I'm not very popular with what I've already done in the infowar against the NWO. I won't be taking any vaccine either. Nope.

They will introduce the new digital global currency, which of course they will issue and control....and legally mandate you use. The mainstream media is already quacking about the paper money and coin transmitting the virus. They want to go to a cashless society so they can track everything and it is unfolding right this second!!

The same people who set up the central bank pyramid scheme are the same ones who are setting up the global currency system. We're going digital people. RFID chipping of the population is right around the corner and actually has been practiced for many years at this point already. Soon it will be mandatory...arguably the Mark of the Beast.

I see Bitcoin being outlawed for the 'good of humanity' after the dust settles. Can't have any rogue currencies running around competing with the Satanists for control of the money supply and therefore humanity.

I also see gold confiscation coming, again, just like during the Great Depression. They want it all. Every last bit of it. For a dozen or so Satanic families pulling the strings of our reality.

Hey, it's Satan's world, says so right in the Bible. That's what my second book is all about, how we are in the clutches of Satan and his minions and always have been, that's how it was designed. They just do his bidding and have for thousands of years...and reap the rewards.

Now the game is coming to an end. Just as the Baby Boomers start checking out in large numbers, possible thanks to this coming plague called COVID-19, Gen X, the Millennials, Gen Z and beyond are all going to be left here to go through a literal Hell on Earth.

Even though we are staring down the oncoming crisis, it is still our duty to tell people what is really going on. To educate them with the truth of everything in my first book. What I learned by researching and writing my first book transformed me from an unbelieving atheist to a born-again Christian. The entire New World Order conspiracy is in the Bible if you have eyes to see and ears to hear the truth, this cannot be disputed if you've read my books.

I do believe I was always a saved man...I just didn't know it. Something had to trigger it and that something was knowing what was really going on in our world. There are still thousands and millions to wake up to this truth so they can claim their rightful place in the Book of Life. If they are saved, their names are in the Book of Life from the beginning of the world. I think that's somewhere in Revelation lol. They just need to be triggered...in a good way!

So many people have no idea what is happening that there almost needs to be a 'group awakening' or something. Unfortunately, only a very small percentage of people listen to what I'm saying and a HUGE percentage of people listen to useless talking heads on mainstream media...literally paid actors! None of them investigate ANYTHING or I wouldn't be writing these books!

I will tell you this, if I only were to wake up one person with my first book it would have been worth it, but I've woke up many more simply because I jumped in the batter's box and swung for the fence for humanity.

You yourself can get just as active and fast. Throw together a blog. Start doing videos. Start posting on message boards. These are what I was doing at the start before I had the motivation to go full throttle and write a book outlining all the pertinent stuff going on.

And that reminds me....the third book...*big sigh*

I'm so sorry it has taken this long....it's going to take a little while longer now. I was on track to get it done and out by the end of this year but I don't know what's going to happen now that we are heading into dire straits...hence this 'report'. This may be the last you hear from me! I'll sure try and get it done and out though.

I can let you know that the third book is way more like the first book in that I'm giving out a bunch of different topics and showing how they tie to the first book and the Great Plan for global enslavement.

The second book of the series, the Awakening, was more of a one-off but is super-pertinent information. I wish I would have had the second book as a separate, stand-alone book but what are you gonna do? That's what I get for doing everything myself right? Right. Author. Editor. Publisher. Advertiser. Promoter. I don't really know what I'm doing, I'm just making it up as I go!

Obviously, I'm getting help from above with all of this, because if you knew me personally, I'm a lifelong construction worker to the core. I'm pretty rough around the edges in other words. I'm still a beer-drinking, cussing, gun-totin' rock-and-rollin' patriotic guy and nobody, and I mean NOBODY needed to be woken up more than me back in 2007.

That spun my head right off when I woke up to the NWO and I went crashing to the ground as an unwashed atheist with no hope knowing about the NWO and that it was real.

Only a couple years into my research and Jesus spun my head back on straight, picked me up and dusted me off, and sent me off to write that first book.

And here we are now 7 years after releasing my first book and it's all coming true. I would be lying if I told you I wasn't a little scared, but I'm also a little excited. I really can't wait to shed this worn, physical body and get a one-way ticket outta Satan's world and into the loving arms of Jesus. We've all gotta die sometime, that's a fact, so no reason to be scared of it knowing your place is secure after the fact.

Never in our history...since the days of Nimrod's Babylon, has the world been so gripped by evil. Think about it. We have the most decadent society in the history of mankind. With the technology came great evil. Online porn. Tinder for random sexual hookups. Gay marriage. Trans kids...? WTH is that? We are in BIG TROUBLE.

So...I haven't worked on the third book for about three or four weeks now, just too much going on to get my head into it. But this mini-book you are reading now suddenly came together in just the last few days...I was suddenly moved to get something out there.

I just went and read the preface to the third book and got sick to my stomach as to how drastically things can change in life, and quickly.

Here is the preface for the third book as it was intended to be released later this year:

Preface of “Rise of the New World Order 3:Resonance”

Well I can hardly believe I've reached another milestone in my crazy life and managed to get my third book out but here we are. The world still hasn't ended and I'm still working my construction jobs and working on these books as I've got time available.

I've been doing a lot of 'memelording' since getting onto social media at the start of 2013 and I HIGHLY encourage you to join me and millions of others globally in this very effective campaign against the NWO. A picture says a thousand words. If you combine a powerful, thought-provoking picture or image, coupled with witty, biting, factual smarm, you have created a powerful propaganda tool and the NWO knows this.

*You would be amazed at how many people are awake around the world to the Great Plan. It doesn't matter if you are black, white, Latino, Asian, gay, straight, Christian, Hindu or whatever, the people running the planet want to cull the global population way down for easier control and **EVERYONE** is on the chopping block.*

There is an old saying, the enemy of my enemy is my friend. The enemy to humanity are the proponents of the New World Order, this makes all of humanity to be friends against the foe, the NWO. I don't care who you are, if you are awake and against the NWO agenda for global enslavement I've got your back, friend.

If you're already awake and have been doing research of your own, you may know some or all and even more than what I'm going to talk about here. Great. Awesome. Love it. Thank you from the bottom of my heart for taking a keen interest in our future. But if you are just waking up and recently coming off my last two books, you will find this a continuation in your crash-course about how the NWO operates.

In fact, part of the reason for this book 3 is if someone were to sit down and wake up for the first time, they would be able to read all three of my books straight through and have a better understanding of the NWO than 99.99% of the rest of the population. Another part of the reason for this book is hopefully I am bringing to even seasoned researchers some new information. And lastly, part of the reason for this book is to put into writing the facts of what is going on before they are censored from the internet by Google, Bing, YouTube, and the rest whose owners and controllers have been sucked into the Illuminati and now regularly attend Bilderberg meetings, Bohemian Grove campouts, attend CFR meetings and are on the Trilateral Commission, etc.

As with all of my books, as a whole they should be considered to be my opinion. Don't believe what I write as Gospel, research about what I write, but don't disbelieve out of hand as you read it either. I make my books as fact-based as possible to stand up to the naysayers.

Again, as with my first book, each chapter and subchapter in this book could have multiple books written about it and have been. I'm just bringing to your attention everything I think you should be made aware of at this point in time, just like my first book. I put everything in that book that I thought you needed to know to get at least a basic understanding of the New World Order. Now I have many new topics for you to look into and add to your arsenal of knowledge about what's really going on in our world.

People have no idea how good we have it today compared to 100 years ago in terms of creature comforts. At the same time, we also have it worse today because all of those things can be instantly taken away by our advanced technology.

For example, a single nuclear device detonated 250 miles above Kansas would cause an EMP that would knock out the national power grid and anything that needs electrical components to operate...which is about everything. This would instantly send us back to the 1800s. The cities' sewers would shut down and immediately begin to spill into the streets, rampant disease would immediately follow. Rape, robbery and murder would immediately commence upon those in the cities, especially if the guns are managed to be taken from the law-abiding.

This is a fact and there have even been Congressional hearings and public warnings generated about this so it's not a matter of if but when stuff like this is going to happen. They even tell you to have two weeks of survival supplies on

hand. If you've read and followed my first book, you should actually have way more!

Look at how far we've fallen since the publication of my first book in January of 2013. Full-blown socialists occupying seats of our government at all levels. You should know by now that the New World Order is a socialist, anti-God/Jesus and pro-Satanic agenda run by the 'do as we say, not as we do' global elites.

"Bad men cannot make good citizens. It is impossible that a nation of infidels or idolaters should be a nation of freemen. It is when a people forget God that tyrants forge their chains. A vitiated state of morals, a corrupted public conscience, is incompatible with freedom"

-Patrick Henry, one of the Founding Fathers

The United States in particular is on the NWO's chopping block. A strong United States that the UN has no power over cannot be for much longer if things are to progress according to plan. We are the modern-day Babylon and we are slated to crash and burn...one way or another.

On June 26, 2015 the US Supreme Court legalized gay marriage nationwide. Gay marriage was just the beginning down the road to good ol' Sodom and Gomorrah. Now we've got 'trans kids' running around and we are expected to accept that that is the new societal norm. Now they are pushing for kids who aren't even old enough to decide their bedtime to decide if they want to undergo gender reassignment surgery...complete madness.

As an active member of the Truth Community I am pushing back against the lies and propaganda with everything I've got on social media as are others...and have paid the price being censored heavily, even banned for speaking my mind.

In particular, any opinion against the radical LGBT agenda is censored as 'hate speech'. If you are against pedophile drag queens hanging out in public libraries with unassuming parents with young, impressionable kids then you are a homophobe and not welcome on the liberal platforms of Facebook, Twitter, etc. We have fallen quite a way since I first woke up in 2007.

Since the publication of my last book in 2015 the banks and other major globalist corporations have installed RFID chips in all their debit/credit cards. These chips constantly track your location, buying habits, etc. and this information is collected and sold among the globalist entities. The next step from this is human implants, something that has already been happening for years now and is only increasing in usage.

Cancer rates are 100x what they were 100 years ago. As you know, we are under attack by land, sea and air.

Our GMO food is laced with biotoxins, pesticides and cancerous chemicals. It's not even food, it's a science experiment.

Fluoridated water is still the norm in the USSA, while being outlawed in about every other country on Earth.

The chemtrails/geoengineering are ramping up filling the air we breath with aluminum, barium, and who-knows-what-else.

We are exposed to millions of times more electromagnetic radiation than our grandparents were thanks to the proliferation of personal wireless devices: phones, tablets and laptops. The generally safe 'wired' desktop computer's numbers are declining as rapidly as the unsafe, radiation-spewing wireless devices are expanding. We're literally bathed in radiation these days and the closer you get to the city the worse it gets...another good reason to get out if you can.

The globalist drums are beating loudly for gun confiscation here in the United States thanks to a series of sloppy false flags that were picked apart by the Truthers.

Forced childhood vaccinations are now making their way through various local governments, again, largely pushed by government-worshipping statist.

Keep in mind that I'm not a Republican, a member of the 'alt right' or any kind of ridiculousness like that. I am a Libertarian believing in less government and more freedom, something neither the left or right is behind. No matter who is the President, the globalist, one-world agenda marches forward.

Remember from my first book about the global warming hoax/scare? The United Nations propaganda machine has been rolling tough as of late to scare everyone into thinking that 'Climate Change' is going to doom us all if we don't turn over all aspects of human society to UN control. Just look where we're at with 'climate change' being shoved down our throats at every mainstream media propagandized moment. Greta Thunberg anyone?

This engineered storm of 'climate change' is purely to stampede humanity into the UN's waiting clutches. This physically involves using Tesla's various amazing technologies to affect the global weather and cause events that the UN is pinning on 'Climate Change'.

Just about all the hurricanes, fires and floods that are going on these days are not necessarily all caused by Tesla technology, but all can either be created, made worse or alleviated completely with said technology and I'm going to show you how in this book.

Not only can they affect the weather through 'geoengineering', they can affect us personally using Tesla's technology via radio frequency (rf) waves...including being able to literally insert voices in our heads! This is a fact that I will prove using the various patents on file stating they can do exactly this!

There are pressing things for you to be aware of and/or watch out for going forward. A lot of people are sensing the dangers around them but less are actually 'waking up' to the Great Plan for global enslavement.

If you are awake and know others that aren't you need to step up your game in sounding the alarm that things aren't right. I talk to people constantly about what's going on in the world I come into contact with when I'm out and about.

Pretty much everyone I personally know I've impressed upon them the information about the Federal Reserve being privately owned and controlling our economy and by default our country. Everyone is interested and concerned about money so this is always a good 'in' to get a conversation going about how the Fed, 9/11, the CFR, etc. are all connected through the ancient money powers headed by the Rothschild Banking Dynasty and buttressed by the Rockefellers and others to maintain a death grip over humanity.

So...This is arguably the true sequel to the first book...this is largely information I didn't know about at the time of the publication of my first book, and it took a few years of researching and just living as an awake soul to take it all in and see what else was out there that needed to be put into writing so the facts may live after information like this is struck from the internet like a hatchet against 'domestic terrorism'.

You mark my words because it's coming. Only the paper copies of my books will withstand the test of time. Files and notes on computers will easily one day be able to be remotely scrubbed of information. If you don't think the FBI, NSA, CIA and the rest aren't intimately involved with the development side of companies like Microsoft, Google, Amazon, etc. you haven't been paying attention.

People like Bill Gates and the founders of Google are all-in for the NWO, attending Bilderberg meetings, etc. Remember, money is power. Gates and Bezos have billions. The families who run the Great Plan are worth in the hundreds of trillions.

The people who run the Great Plan have been drawing interest on monopoly money for hundreds of years at this point. They constantly add to the amount of money in circulation (inflation) which they own to start with by printing out of thin air, then they loan it out to governments AT INTEREST remember. They are stacking coin left and right and we pay for it all!

"Compound interest is the eighth wonder of the world. He who understands it, earns it; he who doesn't, pays it."

-Albert Einstein

If you've made it this far and have read my first two books, I commend you for wanting to know as much as me. I want to know exactly, factually what is happening no matter how ugly the truth is.

I've never said that I know it all when it comes to the New World Order, but I want to. I want to know everything about what's happened with the Great Plan and what's going to happen.... most don't. Most can't handle knowing what we've learned so far and we're not done yet.

Now, my second book was and is extremely important information that I felt at the time was needed to lay the ground work for going forward. I'm not so sure now (lol). That book is vastly ahead of its time, even now, as there were no books on Saturn worship to be found on Amazon or the whole of the internet when I wrote that book and believe you me I looked because I am a voracious reader and wanted to know everything about ancient Saturn worship.

It is still largely the only book putting all the pieces together of ancient history and how Satan navigated his way through it collecting worship and adoration the whole way. Now that that's out of the way, off my plate, off my back, whatever you want to call it, we're back on track getting into the nuts and bolts operations of the Great Plan....the forward march to totalitarian world government and eventual (re)appearance of King Nimrod, aka the Antichrist.

*A lot of people didn't like my last book, the Awakening, because they felt I gave too much attention to Satan. There is a **BIG** difference between attention and adoration. Hopefully they won't have a problem with me giving too much "attention" to Jesus and our Heavenly Father in this book 3, all entities need to be understood the best we can.*

It's important to me personally since coming around and getting born-again during the research for my first book to try and figure out what He wants from us and why we're even here. I'm always asking myself questions and then trying to figure out the answer.

So what does He want? Adoration. It's actually very simple. Adoration is love, fear and respect all wrapped into one word. And what's Satan's #1 job right now in this world? To block that adoration by misleading us from all angles in order to transfer adoration to himself or his 'son' King Nimrod.
